#### Abstract

A graph $G$ is a $\left(K_{q}, k\right)$ vertex stable graph $(q \geq 3)$ if it contains a $K_{q}$ after deleting any subset of $k$ vertices $(k \geq 0)$. We are interested by the $\left(K_{q}, \kappa(q)\right)$ vertex stable graphs of minimum size where $\kappa(q)$ is the maximum value for which for every nonnegative integer $k<\kappa(q)$ the only ( $K_{q}, k$ ) vertex stable graph of minimum size is $K_{q+k}$.

## 1. Introduction

In [6] Horwárth and Katona consider the notion of $(H, k)$ stable graph: given a simple graph $H$, an integer $k$ and a graph $G$ containing $H$ as subgraph, $G$ is a $a$ $(H, k)$ stable graph whenever the deletion of any set of $k$ edges does not lead to a $H$-free graph. These authors consider $\left(P_{n}, k\right)$ stable graphs and prove a conjecture stated in [5] on the minimum size of a $\left(P_{4}, k\right)$ stable graph. In [2], Dudek, Szymański and Zwonek are interested in a vertex version of this notion and introduce the ( $H, k$ ) vertex stable graphs. In [4] we have characterized $\left(K_{q}, k\right)$ vertex stable graphs with minimum size for $q=3,4,5$ (where $K_{q}$ denotes the clique on $q$ vertices).

Definition 1.1. [2] Given an integer $k \geq 0$ and a graph $H$, a graph $G$ containing a subgraph isomorphic to $H$ is said to be $a(H, k)$ vertex stable graph if, for every subset $S$ of $k$ vertices, $G-S$ contains (a subgraph isomorphic to) $H$.

In this paper, we are only interested by $(H, k)$ vertex stable graphs and, since no confusion will be possible, a ( $H, k$ ) vertex stable graph shall be simply called a $(H, k)$ stable graph.

Definition 1.2. A $(H, k)$ stable graph with minimum size (i.e. with minimum number of edges) is called minimum $(H, k)$ stable graph. The minimum size of a $(H, k)$ stable graph shall be denoted by $\operatorname{stab}(H, k)$.

It is clear that if $G$ is a $(H, k)$ stable graph with minimum size then the graph obtained from $G$ by addition or deletion of some isolated vertices is also minimum $(H, k)$ stable. Hence we shall asume that all the graphs considered in the paper have no isolated vertices.
Here we consider ( $K_{q}, k$ ) stable graphs. We have proved in [4] that $\operatorname{stab}\left(K_{q}, k\right)=$ $\binom{q+k}{2}$ for $q \geq 3$ and $k=1,2$. Moreover $K_{q}$ is the only minimum $\left(K_{q}, 0\right)$ stable graph for $q \geq 2$ and $K_{q+1}$ is the unique ( $K_{q}, 1$ ) stable graph for $q \geq 4$. Dudek, Szymański and Zwonek have proved the following result.

[^0]Theorem 1.3. [2] For every $q \geq 4$, there exists an integer $k(q)$ such that stab $\left(K_{q}, k\right) \leq$ $(2 q-3)(k+1)$ for $k \geq k(q)$.
As a consequence of this last result, for every $k \geq k(q)$ the graph $K_{q+k}$ is not minimum $\left(K_{q}, k\right)$ stable.

Definition 1.4. For every integer $q \geq 4$, we denote by $\kappa(q)$ the greatest integer such that for $1 \leq k<\kappa(q)$ the only minimum $\left(K_{q}, k\right)$ stable graph is $K_{q+k}$.
In two previous papers we have proved the following.
Theorem 1.5. $[3,4] \kappa(3)=1, \kappa(4)=3, \kappa(5)=4$ and for $q \geq 6 \quad \kappa(q)>\frac{q}{2}+1$.
In this paper we give an upper bound for the value of $\kappa(q)$.
Theorem 1.6. For every $q \geq 4$, if $\kappa(q)$ is even then $\kappa(q)<\sqrt{2(q-1)(q-2)}$ and if $\kappa(q)$ is odd then $\kappa(q)<\sqrt{1+2(q-1)(q-2)}$

We prove that these upper bounds are reached for values of $q$ such that there exists a minimum $\left(K_{q}, \kappa(q)\right)$ stable disconnected graph (note that it is the case for $q=4$ and $q=5$ ).
Theorem 1.7. Let $q \geq 4$ and suppose that there exists a disconnected minimum $\left(K_{q}, \kappa(q)\right)$ stable graph. Set $\rho(q)=\left\lceil\sqrt{\frac{1}{2}(q-1)(q-2)}\right\rceil-1$.
If $\frac{1}{2}(q-1)(q-2)>\rho(q)^{2}+\rho(q)$ then $\kappa(q)=2 \rho(q)+1$.
If $\frac{1}{2}(q-1)(q-2) \leq \rho(q)^{2}+\rho(q)$ then $\kappa(q)=2 \rho(q)$.
Proofs of Theorems 1.6 and 1.7 shall be given in subsection 3.2.
If there is no minimum disconnected $\left(K_{q}, \kappa(q)\right)$ stable graph then, by definition of $\kappa(q)$, there exists a connected minimum $\left(K_{q}, \kappa(q)\right)$ stable graph $G_{q}$ which is not complete. We think that it never happens, so we propose the following conjecture.

Conjecture 1.8. If $G$ is a minimum $\left(K_{q}, k\right)$ stable graph then every component of $G$ is complete.

If this last conjecture is true then Theorem 1.7 gives the exact value of $\kappa(q)$ for every $q \geq 4$.

## 2. Notations and general Results

For terms not defined here we refer to [1]. As usually, the order of a graph $G$ is the number of its vertices and the size of $G$ is the number of its edges (it is denoted by $e(G)$ ). The disjoint union of two graphs $G_{1}$ and $G_{2}$ is denoted by $G_{1}+G_{2}$. The union of $p$ mutually disjoint copies of a graph $G$ is denoted by $p G$. For any set $A$ of vertices, we denote by $G[A]$ the subgraph induced by $A$ and by $G-A$ the subgraph induced by $V(G)-A$. If $A=\{v\}$ we write $G-v$ for $G-\{v\}$. For any set $F$ of edges, we denote by $G-F$ the spanning subgraph $(V(G), E(G)-F)$. If $F=\{e\}$ we write $G-e$ instead of $G-\{e\}$. A complete subgraph of order $q$ of $G$ is called a $q$-clique of $G$. The complete graph of order $q$ is denoted by $K_{q}$. When a graph $G$ contains a $q$-clique as subgraph, we say " $G$ contains a $K_{q}$ ".

Lemma 2.1. [2] Let $G$ be $a(H, k)$ stable graph with $k \geq 1$. Then, for every vertex $v, G-v$ is $(H, k-1)$ stable.

A set of vertices of $G$ that intersects every subgraph of $G$ isomorphic to $H$ is called a transversal of all the subgraphs isomorphic to $H$ or simply a $H$-transversal of $G$. A $H$-transversal of $G$ having the minimum number of vertices is said to be a minimum $H$-transversal of $G$. The number of vertices of a minimum $H$-transversal is denoted by $\tau_{H}(G)$. Remark that $G$ is $(H, k)$ stable if and only if $\tau_{H}(G) \geq k+1$
Definition 2.2. Let $G$ be a $(H, k)$ stable graph. If $G$ has a minimum $H$-transversal having exactly $k+1$ vertices, $G$ is said to be exactly $(H, k)$ stable.
Remark 2.3. $H$ is the unique $(H, 0)$ stable graph with minimum size.
Lemma 2.4. [2] Let $G$ be $a(H, k)$ stable graph with $k \geq 1$ and $e \in E(G)$ such that $G-e$ is not $(H, k)$ stable. Then $G$ is exactly $(H, k)$ stable and $G-e$ is exactly ( $H, k-1$ ) stable.
Definition 2.5. [2] Let $G$ be a $(H, k)$ stable graph. If $G-e$ is not $(H, k)$ stable for every edge $e \in E(G), G$ is said to be minimal $(H, k)$ stable.
Remark 2.6. In [2] "minimal ( $H, k$ ) stable graphs" are called "strong ( $H, k$ ) stable graphs" by the authors. Note that a $(H, k)$ stable graph $G$ is minimal $(H, k)$ stable if and only if for every $e \in E(G)$ the graph $G-e$ is exactly $(H, k-1)$ stable. Moreover, a minimal $(H, k)$ stable graph is exactly $(H, k)$ stable.
If there exists an edge $e$ of an $(H, k)$ stable graph $G$ such that there are no subgraph isomorphic to $H$ containing $e$ then $G-e$ is a $(H, k)$ stable graph. Hence, we have the following.

Lemma 2.7. [2] Every edge of a minimal $(H, k)$ stable graph is contained in a subgraph isomorphic to $H$. Consequently, every vertex of a minimal $(H, k)$ stable graph is also contained in a subgraph isomorphic to $H$.
Remark 2.8. Clearly, every minimum $(H, k)$ stable graph is minimal $(H, k)$ stable.
One may ask what happens for components of a $(H, k)$ stable graph. The following theorem gives us an answer.
Theorem 2.9. Let $G$ be an exactly $(H, k)$ stable graph, and let $G_{1}, G_{2}, \ldots, G_{r}$, with $r \geq 1$, be its components. Then, there exist integers $k_{1}, k_{2}, \ldots, k_{r}$, with $0 \leq k_{i} \leq k$, sucht that
i) for every $i$, with $1 \leq i \leq r, G_{i}$ is exactly $\left(H, k_{i}\right)$ stable,
ii)

$$
\sum_{i=1}^{r} k_{i}+(r-1)=k
$$

$G$ is minimal $(H, k)$ stable if and only if for every $i, 1 \leq i \leq r, G_{i}$ is minimal $\left(H, k_{i}\right)$ stable. Moreover, if $G$ is minimum $(H, k)$ stable then for every $i, 1 \leq i \leq r$, $G_{i}$ is minimum $\left(H, k_{i}\right)$ stable.
Proof For each $i, 1 \leq i \leq r$, let us consider a minimum $H$-transversal of $G_{i}$, say $T_{i}$, and set $k_{i}=\left|T_{i}\right|-1$. Clearly, for each $i$ the graph $G_{i}$ is exactly $\left(H, k_{i}\right)$ stable and the set $T=\bigcup_{1 \leq i \leq r} T_{i}$ is a minimum $H$-transversal of $G$. Note that the number of elements of $T$ is $|T|=\sum_{i=1}^{r} k_{i}+l$ and we have $|T|>k$. Let $S$ be any set of vertices of $G$ such that $|S| \leq|T|-1$ and for every $i$ denote by $S_{i}$ the set $S \cap V\left(G_{i}\right)$. Clearly, there exists $i_{0} \in\{1, \cdots r\}$ such that $\left|S_{i_{0}}\right| \leq k_{i_{0}}=\left|T_{i_{0}}\right|-1$. Then, $G_{i_{0}}-S_{i_{0}}$
contains a subgraph isomorphic to $H$, that is, $G$ is exactly $(H,|T|-1)$ stable, and we have $\sum_{i=1}^{r} k_{i}+(r-1)=k$.
Let $e$ be an edge of $G$ and let $G_{i}$ be the component containing $e$.
Claim . $G-e$ is $(H, k)$ stable if and only if $G_{i}-e$ is $\left(H, k_{i}\right)$ stable.
Proof Suppose that $G_{i}-e$ is $\left(H, k_{i}\right)$ stable. Let $U$ be a $H$-transversal of $G-e$. Set $U_{i}=U \cap V\left(G_{i}-e\right)=U \cap V\left(G_{i}\right)$ and for every $j \neq i, U_{j}=U \cap V\left(G_{j}\right)$. Since $\left(G_{i}-e\right)-U_{i}$ and each $G_{j}-U_{j}, j \neq i$, contain no subgraphs of $G-e$ isomorphic to $H$, we have for every $j, 1 \leq j \leq r,\left|U_{j}\right| \geq k_{j}+1$. Then, $|U|=\sum_{j=1}^{r}\left|U_{j}\right| \geq k+1$. Hence, for every set $S$ of $k$ vertices $(G-e)-S$ contains a subgraph isomorphic to $H$, that is, $G-e$ is $(H, k)$ stable.
Conversely, suppose that $G_{i}-e$ is not $\left(H, k_{i}\right)$ stable. Let $T_{i}$ be a $H$-transversal of $\left(G_{i}-e\right)-T_{i}$ having $k_{i}$ vertices. For every $j \neq i$ let $T_{j}$ be a $H$-transversal of $G_{j}$ having $k_{j}+1$ vertices. The set $T=\cup_{j=1}^{r} T_{j}$ has $k$ vertices and is a $H$-transversal of $G-e$, that is, $G-e$ is not $(H, k)$ stable.

Thus, $G$ is minimal $(H, k)$ stable if and only if for every $i, 1 \leq i \leq r, G_{i}$ is minimal $\left(H, k_{i}\right)$ stable.
Note that, by replacing a minimal $\left(H, k_{i}\right)$ stable component $G_{i}$ by any minimal ( $H, k_{i}$ ) stable graph $G_{i}^{\prime}$ (connected or not), we obtain again a minimal $(H, k)$ stable graph. Thus, if $G$ is minimum $(H, k)$ stable then for every $i, 1 \leq i \leq r, G_{i}$ is minimum $\left(H, k_{i}\right)$ stable.

Remark 2.10. Let $r$ be an integer $\geq 2, k_{1}, \cdots, k_{r}$ be $r$ non negative integers and $k=\sum_{i=1}^{r} k_{i}+(r-1)$. If for every $i, 1 \leq i \leq r, G_{i}$ is a minimum $\left(H, k_{i}\right)$ stable graph then the disjoint union $G_{1}+G_{2}+\cdots+G_{r}$ may not be a minimum $(H, k)$ stable graph. For example, $K_{q}$ is minimum $\left(K_{q}, 0\right)$ stable, $2 K_{q}$ and $K_{q+1}$ are minimal $\left(K_{q}, 1\right)$ stable, but since $e\left(2 K_{q}\right)>e\left(K_{q+1}\right)$, for $q \geq 4$ the graph $2 K_{q}$ is not minimum $\left(K_{q}, 1\right)$ stable.

## 3. Minimum $\left(K_{q}, k\right)$ Stable GRaphs

In this section we are interested by $\left(K_{q}, k\right)$ stable graphs with minimum size $(q \geq 3)$. Recall that $\operatorname{stab}\left(K_{q}, k\right)=\operatorname{Min}\left\{e(G) \mid G\right.$ is $\left(\mathrm{K}_{\mathrm{q}}, \mathrm{k}\right)$ stable $\}$.
3.1. Some known results. We give here some known results about this topic. By Remark 2.6 and Lemma 2.7 we have:

Properties 3.1. [2] A minimal $\left(K_{q}, k\right)$ stable graphs $G$ has the following properties:
$\left.\mathrm{P}_{1}\right) G$ is exactly $\left(K_{q}, k\right)$ stable.
$\mathrm{P}_{2}$ ) For every edge $e, G-e$ is exactly $\left(K_{q}, k-1\right)$ stable.
$\left.\mathrm{P}_{3}\right)$ For every vertex $v, G-v$ is exactly $\left(K_{q}, k-1\right)$ stable.
$\mathrm{P}_{4}$ ) Every vertex of $G$ belongs to some $q$-clique of $G$.
$\mathrm{P}_{5}$ ) Every edge of $G$ belongs to some $q$-clique of $G$.
Remark 3.2. For any two integers $q \geq 3$ and $k \geq 1, K_{q+k}$ is minimal $\left(K_{q}, k\right)$ stable.
Proposition 3.3. [4] For every integer $q \geq 4, K_{q+1}$ is the unique minimum ( $K_{q}, 1$ ) stable graph.

Proposition 3.4. [4] For every integer $q \geq 4, K_{q+2}$ is the unique minimum $\left(K_{q}, 2\right)$ stable graph.
Proposition 3.5. [4] For every integer $q \geq 5, K_{q+3}$ is the unique minimum $\left(K_{q}, 3\right)$ stable graph.

Theorem 3.6. [2] For every $k \geq 1$, $\operatorname{stab}\left(K_{3}, k\right)=3 k+3$ and $\operatorname{stab}\left(K_{4}, k\right)=5 k+5$.
Theorem 3.7. [4] Let $G$ be a minimum $\left(K_{3}, k\right)$ stable graph, with $k \geq 0$. Then $G$ is isomorphic to $s K_{4}+t K_{3}$, for any choice of $s$ and $t$ such that $2 s+t=k+1$.
Theorem 3.8. [4] Let $G$ be a minimum $\left(K_{4}, k\right)$ stable graph, with $k \geq 1$. Then $G$ is isomorphic to $s K_{6}+t K_{5}$, for any choice of $s$ and $t$ such that $3 s+2 t=k+1$

Theorem 3.9. [4] For every $k \geq 5, \operatorname{stab}\left(K_{5}, k\right)=7 k+7$.
Theorem 3.10. [4] Let $G$ be a minimum $\left(K_{5}, k\right)$ stable graph, with $k \geq 5$. Then $G$ is isomorphic to $s K_{8}+t K_{7}$, for any choice of $s$ and $t$ such that $4 s+3 t=k+1$

Dudek et al. [2] defined the family $\mathcal{A}_{r}^{\left(K_{q}, k\right)}$ with $k \geq 0, q \geq 3,1 \leq r \leq k+1$ as the family of graphs consisting of $r$ complete graphs $K_{i_{j}}$ with $i_{1} \geq \cdots \geq i_{r} \geq q$ satisfying the condition $\sum_{i=1}^{r}\left(i_{j}-q\right)+(r-1)=k$ and they prove that every graph in $\mathcal{A}_{r}^{\left(K_{q}, k\right)}$ is minimal $\left(K_{q}, k\right)$ stable. We observe that if $G$ is a $\left(K_{q}, k\right)$ stable graph disjoint union of $r \geq 1$ cliques $K_{i_{j}}, 1 \leq j \leq r$, then by Theorem 2.9, $G \in \mathcal{A}_{r}^{\left(K_{q}, k\right)}$. They defined a graph $G \in \mathcal{A}_{r}^{\left(K_{q}, k\right)}$ as a balanced union if $\left|i_{j}-i_{l}\right| \in\{0,1\}$ for every $j$ and $l$ in $\{1,2, \cdots, r\}$ and they proved that given $q, k$ and $r$ there is exactly one balanced union $\mathcal{B}_{r}^{\left(K_{q}, k\right)}$ in $\mathcal{A}_{r}^{\left(K_{q}, k\right)}$, and that $\mathcal{B}_{r}^{\left(K_{q}, k\right)}$ has the minimum number of edges among the graphs in $\mathcal{A}_{r}^{\left(K_{q}, k\right)}$.
In [2] the following lemma has been given. We give its proof for completeness.
Lemma 3.11. [2] Let $G_{0}$ be a $\left(K_{q}, k_{0}\right)$ stable graph ( $k_{0} \geq 0$ ) which has the minimum size among all graphs beeing a disjoint union of $r$ cliques ( $r \geq 1$ ) $G_{i} \equiv K_{q+k_{j}}$ with $1 \leq j \leq r, k_{j} \geq 0$. There exists a positive integer $s$ and a nonnegative integer $k$ such that

$$
\begin{aligned}
k \geq 0, s \leq r, G_{0} & =s K_{q+k}+(r-s) K_{q+k-1} \text { with } r k+s=k_{0}+1 \text { and } \\
e\left(G_{0}\right) & =\frac{\left.\left(r(q-1)+k_{0}+1-s\right)\left(r(q-2)+k_{0}+1+s\right)\right)}{2 r}
\end{aligned}
$$

Proof Suppose, without loss of generality, that $k_{1} \geq k_{2} \geq \cdots \geq k_{r}$ and that there exist two components $G_{i}$ and $G_{j}$ with $i<j$ such that $k_{i}-k_{j} \geq 2$. By substituting $G_{i}^{\prime} \equiv K_{q+k_{i}-1}$ for $G_{i}$ and $G_{j}^{\prime} \equiv K_{q+k_{j}+1}$ for $G_{j}$, we obtain a new ( $K_{q}, k$ ) stable graph $G_{0}^{\prime}$ such that $e\left(G_{0}^{\prime}\right)=e\left(G_{0}\right)-\left(k_{i}-k_{j}-1\right)<e\left(G_{0}\right)$, which is a contradiction. Thus, for any $i$ and any $j, 0 \leq\left|k_{i}-k_{j}\right| \leq 1$. Hence, either for any $i$ and any $j$ $k_{i}$ and $k_{j}$ have the same value $k$ and we have $G_{0}=r K_{q+k}$ with $k \geq 0$, or there exist distinct $k_{i}$ and $k_{j}$ and we have $G_{0}=s K_{q+k}+(r-s) K_{q+k-1}$ with $k \geq 1$ and $1 \leq s \leq r-1$.

If $G_{0}=s K_{q+k}+(r-s) K_{q+k-1}$ then a minimum $K_{q}$-transversal of $G_{0}$ has $k_{0}+1=s(k+1)+(r-s) k=s+r k$ vertices. Note that $r$ divides $k_{0}+1-s$. We have $2 e\left(G_{0}\right)=s(q+k)(q+k-1)+(r-s)(q+k-1)(q+k-2)$. Since $k=\frac{k_{0}+1-s}{r}$, we obtain $e\left(G_{0}\right)=\frac{\left.\left(r(q-1)+k_{0}+1-s\right)\left(r(q-2)+k_{0}+1+s\right)\right)}{2 r}$.
3.2. Minimum $\left(K_{q}, k\right)$ stable graph for small $k$. Recall that for every integer $q \geq 2, K_{q}$ is the unique minimum $\left(K_{q}, 0\right)$ stable graph.
Remark 3.12. By Propositions 3.3 and $3.4, K_{5}$ is the unique minimum $\left(K_{4}, 1\right)$ stable graph, $K_{6}$ is the unique minimum $\left(K_{4}, 2\right)$ stable graph and, by Theorem $3.8,2 K_{5}$ is the unique minimum $\left(K_{4}, 3\right)$ stable graph.
Remark 3.13. By Propositions 3.3, 3.4 and 3.5, for every $k \in\{1,2,3\}$ the graph $K_{5+k}$ is the unique minimum $\left(K_{5}, k\right)$ stable graph.

Lemma 3.14. [3] $K_{9}$ and $K_{6}+K_{7}$ are the only minimum $\left(K_{5}, 4\right)$ stable graphs.
Theorem 3.15. [3] Let $G$ be a minimum $\left(K_{q}, k\right)$ stable graph, where $q \geq 6$ and $k \leq \frac{q}{2}+1$. Then $G$ is isomorphic to $K_{q+k}$.
Recall that for every integer $q \geq 4, \kappa(q)$ is the greatest integer such that for $1 \leq k<$ $\kappa(q)$ the only minimum $\left(K_{q}, k\right)$ stable graph is $K_{q+k}$. Then, either $e\left(K_{q+\kappa(q)}\right)>$ $\operatorname{stab}\left(K_{q}, \kappa(q)\right)$ or $e\left(K_{q+\kappa(q)}\right)=\operatorname{stab}\left(K_{q}, \kappa(q)\right)$ but there is a minimum $\left(K_{q}, \kappa(q)\right)$ stable graph $G$ such that $K_{k+\kappa(q)} \not \equiv G$.

Lemma 3.16. $\kappa(4)=3$ and $\kappa(5)=4$.
Proof By Remark 3.12, $\kappa(4)=3$ (and $2 K_{5}$ is the unique minimum $\left(K_{4}, 3\right)$ stable graph). By Remark 3.13 and by Lemma $3.14, \kappa(5)=4$ (and $K_{9}$ and $K_{6}+K_{7}$ are the minimum $\left(K_{5}, 4\right)$ stable graphs).

In the following, if no confusion is possible, we simply denote the integer $\kappa(q)$ by $\kappa$.
Lemma 3.17. Suppose that $q \geq 4$. If $\kappa$ is even then $\operatorname{stab}\left(K_{q}, \kappa-1\right)<e\left(2 K_{q+\frac{\kappa}{2}-1}\right)$ and $\operatorname{stab}\left(K_{q}, \kappa\right) \leq e\left(K_{q+\frac{\kappa}{2}}+K_{q+\frac{\kappa}{2}-1}\right)$.
If $\kappa$ is odd then $\operatorname{stab}\left(K_{q}, \kappa-1\right)<e\left(K_{q+\frac{\kappa-1}{2}}+K_{q+\frac{\kappa-3}{2}}\right)$ and $\operatorname{stab}\left(K_{q}, \kappa\right) \leq e\left(2 K_{q+\frac{\kappa-1}{2}}\right)$.
Proof Recall that, by definition of $\kappa, K_{q+\kappa-1}$ is the only one minimum $\left(K_{q}, \kappa-1\right)$ stable. If $\kappa$ is even then $2 K_{q+\frac{\kappa}{2}-1}$ is exactly $\left(K_{q}, \kappa-1\right)$ stable and $K_{q+\frac{\kappa}{2}}+K_{q+\frac{\kappa}{2}-1}$ is exactly $\left(K_{q}, \kappa\right)$ stable. If $\kappa$ is odd then $K_{q+\frac{\kappa-1}{2}}+K_{q+\frac{\kappa-3}{2}}$ is exactly $\left(K_{q}, \kappa-1\right)$ stable and $2 K_{q+\frac{\kappa-1}{2}}$ is exactly $\left(K_{q}, \kappa\right)$ stable.

Lemma 3.18. Let $q \geq 3$ and $p \geq 0$ be two integers. Then, $e\left(K_{q+2 p}\right)<e\left(K_{q+p}+K_{q+p-1}\right)$ if and only if $p^{2}+p<\frac{1}{2}(q-1)(q-2)$ and $e\left(K_{q+2 p}\right)=e\left(K_{q+p}+K_{q+p-1}\right)$ if and only if $p_{0}=\frac{1}{2}(\sqrt{1+2(q-1)(q-2)}-1)$ is an integer and $p=p_{0}$.
$e\left(K_{q+2 p+1}\right)<e\left(2 K_{q+p}\right)$ if and only if $(p+1)^{2}<\frac{1}{2}(q-1)(q-2)$ and
$e\left(K_{q+2 p+1}\right)=e\left(2 K_{q+p}\right)$ if and only if $p_{1}=\frac{1}{2}(\sqrt{2(q-1)(q-2)}-1)$ is an integer and $p=p_{1}$.
Proof It is easy to check that $e\left(K_{q+2 p}\right)-e\left(K_{q+p}+K_{q+p-1}\right)=p^{2}+p-\frac{1}{2}(q-1)(q-2)$ and $e\left(K_{q+2 p+1}\right)-e\left(2 K_{q+p}\right)=(p+1)^{2}-\frac{1}{2}(q-1)(q-2)$. These polynomials of degree 2 in $p$ have respectively $p_{0}=\frac{1}{2}(\sqrt{1+2(q-1)(q-2)}-1)$ and $p_{1}=$ $\frac{1}{2}(\sqrt{2(q-1)(q-2)}-1)$ as positive roots.

Proof of Theorem 1.6. If $\kappa=2 p$ then, by Lemma 3.17, $\operatorname{stab}\left(K_{q}, \kappa-1\right)<$ $e\left(2 K_{q+\frac{\kappa}{2}-1}\right)$. Since $\kappa-1=2(p-1)+1$, by Lemma 3.18, $p^{2}<\frac{1}{2}(q-1)(q-2)$, that is, $\kappa<\sqrt{2(q-1)(q-2)}$.

If $\kappa=2 p+1$ then by Lemma $3.17, \operatorname{stab}\left(K_{q}, \kappa-1\right)<e\left(K_{q+\frac{\kappa-1}{2}}+K_{q+\frac{\kappa-3}{2}}\right)$. Since $\kappa-1=2 p$, by Lemma 3.18, $p<\frac{1}{2}(\sqrt{1+2(q-1)(q-2)}-1)$, that is, $\kappa<\sqrt{1+2(q-1)(q-2)}$.

Lemma 3.19. For every integer $q \geq 4$ and $\kappa=\kappa(q)$ we have $e\left((\kappa+1) K_{q}\right)>$ $e\left(K_{q+\kappa}\right)$
Proof We have $2\left(e\left((\kappa+1) K_{q}\right)-e\left(K_{q+\kappa}\right)\right)=\kappa\left(q^{2}-3 q-\kappa+1\right)$. By Theorem 1.6, $\kappa<\sqrt{1+2(q-1)(q-2)}<\frac{3 q}{2}$, and hence $\kappa\left(q^{2}-3 q-\kappa+1\right)>0$.

Theorem 3.20. Let $q \geq 4$ and suppose that there exists a minimum $\left(K_{q}, \kappa\right)$ stable graph $G_{0}$ which is disconnected. Then $G_{0}$ is isomorphic to $K_{q+\left\lfloor\frac{\kappa}{2}\right\rfloor}+K_{q+\left\lfloor\frac{\kappa-1}{2}\right\rfloor}$.

Proof Let $G_{0}$ be a minimum $\left(K_{q}, \kappa\right)$ stable disconnected graph having $r \geq 2$ connected components $G_{1}, G_{2}, \cdots, G_{r}$. By Theorem 2.9, there are integers $k_{1} \geq$ $k_{2} \geq \cdots \geq k_{r}$ with $\sum_{i=1}^{r} k_{i}+(r-1)=\kappa$ such that for $1 \leq i \leq r, G_{i}$ is minimum $\left(K_{q}, k_{i}\right)$ stable. For every $i$, since $k_{i}<\kappa$, we have $G_{i} \equiv K_{q+k_{i}}$.
We shall prove first that $r=2$. In fact, it is clear that $r \geq 2$. Let us suppose that $r \geq 3$. We have $k_{r}+k_{r-1}=\kappa-\left(k_{r-2}+k_{r-3}+\ldots+k_{1}\right)-(r-$ 1) $\leq \kappa-2$. Hence, $e\left(K_{q+k_{r}+k_{r-1}+1}\right)<e\left(K_{q+k_{r}}\right)+e\left(K_{q+k_{r-1}}\right)$ and the graph $K_{q+k_{1}}+K_{q+k_{2}}+\cdots+K_{q+k_{r-2}}+K_{q+k_{r-1}+k_{r}+1}$ is $\left(K_{q}, \kappa\right)$ stable with strictly smaller size than $K_{k_{1}}+K_{k_{2}}+\cdots+K_{k_{r}}$, a contradiction. So, $G_{0} \in \mathcal{B}_{2}^{\left(K_{q}, \kappa\right)}$ and the proof follows.

Note that Theorem 3.20 implies that there exists at most one disconnected $\left(K_{q}, \kappa\right)$ stable graph and this graph, if it exists, is

- either isomorphic to $K_{q+\frac{\kappa}{2}}+K_{q+\frac{\kappa}{2}-1}$ (if $\kappa$ is even)
- or else isomorphic to $2 K_{q+\frac{\kappa-1}{2}}$ (if $\kappa$ is odd).

Proof of Theorem 1.7 By Lemma 3.17 and Theorem 3.20, if $\kappa$ is odd then

$$
e\left(K_{q+\kappa-1}\right)<e\left(K_{q+\frac{\kappa-1}{2}}+K_{q+\frac{\kappa-3}{2}}\right)<\operatorname{stab}\left(K_{q}, \kappa\right)=e\left(2 K_{q+\frac{\kappa-1}{2}}\right) \leq e\left(K_{q+\kappa}\right)
$$

(note that, by Lemma 3.18, it may be possible that $e\left(2 K_{q+\frac{\kappa-1}{2}}\right)=e\left(K_{q+\kappa}\right)$ for some values of $q$ ),
if $\kappa$ is even then

$$
e\left(K_{q+\kappa-1}\right)<e\left(2 K_{q+\frac{\kappa}{2}-1}\right)<\operatorname{stab}\left(K_{q}, \kappa\right)=e\left(K_{q+\frac{\kappa}{2}}+K_{q+\frac{\kappa}{2}-1}\right) \leq e\left(K_{q+\kappa}\right)
$$

(note that, by Lemma 3.18, it may be possible that $e\left(K_{q+\frac{\kappa}{2}}+K_{q+\frac{\kappa}{2}-1}\right)=e\left(K_{q+\kappa}\right)$ for some values of $q$ ).
For $\kappa=2 p+1$ we have
$\frac{1}{2}(q+2 p)(q+2 p-1)<(q+p-1)^{2}<(q+p)(q+p-1) \leq \frac{1}{2}(q+2 p+1)(q+2 p)$.
This implies that

$$
\text { (A) } p^{2}+p<\frac{1}{2}(q-1)(q-2) \leq(p+1)^{2}
$$

For $\kappa=2 p$ we have
$\frac{1}{2}(q+2 p-1)(q+2 p-2)<(q+p-1)(q+p-2)<(q+p-1)^{2} \leq \frac{1}{2}(q+2 p)(q+2 p-1)$.
This implies that

$$
\text { (B) } 2 p^{2}<\frac{1}{2}(q-1)(q-2) \leq p^{2}+p \text {. }
$$

Combining $(A)$ and $(B)$ yields

$$
p^{2}<\frac{1}{2}(q-1)(q-2) \leq(p+1)^{2}
$$

This implies that

$$
\sqrt{\frac{1}{2}(q-1)(q-2)}-1 \leq p<\sqrt{\frac{1}{2}(q-1)(q-2)} .
$$

Hence, $p=\rho(q)=\left\lceil\sqrt{\frac{1}{2}(q-1)(q-2)}\right\rceil-1$.
By inequalities $(A)$ and $(B)$, position of $\frac{1}{2}(q-1)(q-2)$ in comparison to $\rho(q)^{2}+\rho(q)$ determines the parity of $\kappa$. Hence, if $\frac{1}{2}(q-1)(q-2)>\rho(q)^{2}+\rho(q)$ then $\kappa=$ $2 \rho(q)+1=2\left\lceil\sqrt{\frac{1}{2}(q-1)(q-2)}\right\rceil-1$ else $\kappa=2 \rho(q)=2\left\lceil\sqrt{\frac{1}{2}(q-1)(q-2)}\right\rceil-2$

If there is no minimum disconnected $\left(K_{q}, \kappa(q)\right)$ stable graph then, by definition of $\kappa(q)$, there exists a connected minimum $\left(K_{q}, \kappa(q)\right)$ stable graph $G_{q}$ distinct from a clique. Note that if such a graph exists then

$$
e\left(G_{q}\right) \leq \operatorname{Min}\left\{e\left(K_{q+\kappa(q)}\right), e\left(K_{q+\frac{\kappa}{2}}+K_{q+\frac{\kappa}{2}-1}\right)\right\} \text { if } \kappa(q) \text { is even }
$$

or

$$
e\left(G_{q}\right) \leq \operatorname{Min}\left\{e\left(K_{q+\kappa(q)}\right), e\left(2 K_{q+\frac{\kappa-1}{2}}\right)\right\} \text { if } \kappa(q) \text { is odd }
$$

Conjecture 1.8 states that there is no such graph $G_{q}$.
