## ABSTRACT

We consider the problem of deciding whether the persistent homology group of a simplicial pair  $(K, L)$  can be realized as the homology  $H_*(X)$  of some complex  $X$  with  $L \subset X \subset K$ . We show that this problem is NP-complete even if  $K$  is embedded in  $\mathbb{R}^3$ .

As a consequence, we show that it is NP-hard to simplify level and sublevel sets of scalar functions on  $\mathbb{S}^3$  within a given tolerance constraint. This problem has relevance to the visualization of medical images by isosurfaces. We also show an implication to the theory of well groups of scalar functions: not every well group can be realized by some level set, and deciding whether a well group can be realized is NP-hard.

## 1. INTRODUCTION

In this paper, we establish NP-completeness of a variety of related problems that ask for an object in  $\mathbb{R}^3$  with a prescribed homology.

In the most basic setting, we have a point cloud in  $\mathbb{R}^d$  that samples a shape and want to retrieve information on the sampled shape. There exists a whole spectrum of possibilities regarding the type of sought information. At the coarsest level, we can content ourselves with the homology groups which record the “holes” of a given dimension, hereafter referred to as *homological features* (connected components, cycles, cavities and so on). At a finer level, we may be interested in building an approximation of the shape, reflecting as accurately as possible both its geometry and topology. The standard way is to construct a *simplicial complex* using the data points as vertices, such as for instance the  $\alpha$ -complex, the Rips complex or

the Čech complex [12, 11]. All three constructions have in common to depend upon a scale parameter  $\alpha$  and to get bigger as  $\alpha$  increases. In the ideal case, we expect the complex to have the right homology for some suitable value of  $\alpha$  [19, 6, 7, 2]. Unfortunately, depending on the sampling, it may happen that such a value of  $\alpha$  does not exist. Nonetheless, we might still be able to infer the true homology of the shape hidden in the noisy data using persistent homology [14, 9, 8]. Given two scale parameters  $\alpha_1$  and  $\alpha_2$ , the *persistent homology groups* record the homological features that persist from  $\alpha_1$  to  $\alpha_2$ . Under very weak hypotheses, we know that the persistent homology is precisely that of the sampled shape [9]. The persistent homology can be computed efficiently (i.e., in polynomial time).

A natural question is then to ask for a complex that carries the persistent homology: given a complex  $K$  and a subcomplex  $L$ , can we find a subcomplex of  $K$  that contains  $L$  and whose homological features are precisely those common to  $L$  and  $K$ ? Our answer is that sometimes we cannot, and deciding whether we can is NP-complete. This answer was first given in the general case by Attali and Lieutier [1], who posed the restriction to complexes embedded in  $\mathbb{R}^3$  as an open problem. We resolve this problem by proving NP-completeness even for complexes embedded in  $\mathbb{R}^3$ . Note that in  $\mathbb{R}^2$  a solution always exists and can be computed in polynomial time. The above problem concentrates on building a complex whose homology matches perfectly the persistent homology of  $L$  into  $K$ : all the homological noise has been removed. We call such an object a *homological reconstruction*. However, when it does not exist, it is still relevant to look for a complex nested between  $L$  and  $K$  and whose homology is as close as possible to the persistent homology of  $L$  into  $K$ : as much noise as possible has been removed. We call such a complex a *homological simplification* and prove that finding one is also an NP-hard problem.

In the field of visualization and image analysis, another common setting consists in describing a shape through a continuous function  $f : \mathbb{R}^d \rightarrow \mathbb{R}$  instead of a point cloud in  $\mathbb{R}^d$ . For instance, a medical image may be a collection of density measurements over a grid of 3D points and is best modeled as a continuous map over a certain domain of  $\mathbb{R}^3$ . In the ideal case, the shape is a sublevel set of the function,  $f^{-1}(-\infty, t]$ . Unfortunately, noise can plague the data. As the parameter  $t$  increases, sublevel sets inflate and we can track the evolution of their homology. Features that appear and disappear quickly are considered topological noise, and we can consider the common features of two sublevel sets as those of a denoised sublevel set. The question now becomes: can we find another cleaner function, close enough to the original one, whose sublevel set has

**Figure 1: Example of a simplicial pair  $(K, L)$  having no homological reconstruction. The simplices of  $L$  are colored red.**

the denoised homology, i.e., a *sublevel set reconstruction*? Again, in  $\mathbb{R}^2$  such a denoised function always exists and can be found in polynomial time [3], while in  $\mathbb{R}^3$  the problem does not always have a solution. The corresponding optimization problem asks for a *sublevel set simplification*, i.e., a function close to the original one that minimizes the number of homological features of the sublevel set. We show that these two problems are the equivalents in the functional setting to the homological reconstruction and simplification of simplicial pairs described above.

Often, one is also interested in the homology of a level set,  $f^{-1}(t)$ . We show how it can be related to the (persistent) homology of sublevel sets, and consider the corresponding *level set reconstruction/simplification* problems.

Further in this direction, Edelsbrunner et al. introduced the well group [15, 4] as a denoised version of the homology group of a level set. Again, we can ask whether one can find a *realization* of the well group, i.e., a cleaner function whose level set has the same homology as the well group?

We shall see in this paper that all of these related problems are NP-hard, as a consequence of the NP-completeness of the homological reconstruction problem.

## 1.1 Background and notations

We are only concerned with topological spaces that are triangulable by a finite simplicial complex, so simplicial and singular homology are isomorphic and we make no distinction between the two. In particular, we use the simplicial versions of the Excision and Mayer-Vietoris sequence theorems, which have less restrictive assumptions than their singular counterparts. If  $K$  is an abstract simplicial complex, we denote by  $|K|$  its geometric realization. Throughout this article, we consider homology with coefficients in an arbitrary field  $\mathbb{F}$ , so the homology groups are finite-dimensional  $\mathbb{F}$ -vector spaces and there is no torsion. Note that for simplicial complexes  $K$  embedded in  $\mathbb{R}^3$ , this is in fact not a restriction, since due to the absence of torsion in  $\mathbb{R}^3$  the Betti numbers are independent of the choice of coefficients [16, §3.3].

Given a topological space  $\mathcal{K}$ , we write  $H_*(\mathcal{K}) = \bigoplus_i H_i(\mathcal{K})$  for the direct sum of homology groups in all dimensions, and  $\beta(\mathcal{K}) = \sum_{i \geq 0} \beta_i(\mathcal{K})$  for the *total Betti number*. If  $(\mathcal{K}, \mathcal{L})$  is a pair of topological spaces  $\mathcal{L} \subset \mathcal{K}$ , the inclusion  $\mathcal{L} \hookrightarrow \mathcal{K}$  induces a homomorphism  $H_*(\mathcal{L}) \rightarrow H_*(\mathcal{K})$ , which is denoted by  $H_*(\mathcal{L} \hookrightarrow \mathcal{K})$ . The rank of this map is the *persistent Betti number* of the inclusion  $\mathcal{L} \hookrightarrow \mathcal{K}$  and is denoted by  $\beta(\mathcal{L} \hookrightarrow \mathcal{K}) = \text{rank } H_*(\mathcal{L} \hookrightarrow \mathcal{K})$ ; the image  $\text{im } H_*(\mathcal{L} \hookrightarrow \mathcal{K})$  is a *persistent homology group*. If  $(K, L)$  is a *simplicial pair*, that is, a pair of simplicial complexes such that  $L \subset K$ , then the persistent Betti number  $\beta(|L| \hookrightarrow |K|)$  can be computed in time cubic in the number of simplices in  $K$  [14].

A *piecewise linear function* on a topological space  $\mathcal{K}$  is a continuous function  $f : \mathcal{K} \rightarrow \mathbb{R}$  such that there exists a finite triangulation of  $\mathcal{K}$  on which  $f$  is simplexwise linear. Note that a *simplexwise*

**Figure 2: Example of a simplicial pair (left) having a homological reconstruction as a subspace (right), but not as a subcomplex. The simplicial complex on the left contains three tetrahedra which share the inner blue edge and whose union forms a triangular bipyramid.**

*linear function* must be linear on each simplex of the *given* triangulation, while a *piecewise linear function* is linear on each simplex of *some* arbitrary triangulation.

## 2. RECONSTRUCTION AND SIMPLIFICATION OF SIMPLICIAL PAIRS

In this section, we consider a simplicial pair and define the homological reconstruction problem and the homological simplification problem. We prove that both problems are NP-hard when the simplicial pair is embedded in  $\mathbb{R}^3$ . We start with a simple lemma:

**LEMMA 1.** *Consider a triple of topological spaces  $\mathcal{L} \subset \mathcal{X} \subset \mathcal{K}$  with finite Betti numbers. Then*

$$\beta(\mathcal{X}) \geq \beta(\mathcal{L} \hookrightarrow \mathcal{K}).$$

**PROOF.** This is a consequence of the fact that whenever we consider two linear maps  $j : U \rightarrow V$  and  $i : V \rightarrow W$  between finite dimensional vector spaces, then  $\dim V \geq \text{rank } j \geq \text{rank } i \circ j$ .  $\square$

This property suggests the following definition:

**Definition 1.** Consider a triple of topological spaces  $\mathcal{L} \subset \mathcal{X} \subset \mathcal{K}$  with finite Betti numbers. Then  $\mathcal{X}$  is called a *homological reconstruction* of the pair  $(\mathcal{K}, \mathcal{L})$  if  $\beta(\mathcal{X}) = \beta(\mathcal{L} \hookrightarrow \mathcal{K})$ .

We will often omit “homological” since there is no ambiguity in this paper. An equivalent condition for  $\mathcal{X}$  being a reconstruction is that  $H_*(\mathcal{L} \hookrightarrow \mathcal{X})$  is surjective and  $H_*(\mathcal{X} \hookrightarrow \mathcal{K})$  is injective, as defined in [1]. Not every pair  $(\mathcal{K}, \mathcal{L})$  admits a reconstruction; a simple counterexample is shown in Fig. 1. The use of topological spaces in the definition (as opposed to simplicial complexes) is motivated by the following observation. Let  $(K, L)$  be a simplicial pair. Then there might be a reconstruction of  $(|K|, |L|)$ , but not as a subcomplex of  $K$ . An example is shown in Fig. 2.

### 2.1 Homological reconstruction is NP-hard

We now focus our attention on spaces that are geometric realizations of finite simplicial complexes embedded in  $\mathbb{R}^3$ .

**THEOREM 1.** *The homological reconstruction problem is NP-hard: Given as input a simplicial pair  $(K, L)$  embedded in  $\mathbb{R}^3$ , decide whether there exists a reconstruction  $\mathcal{X}$  of  $(|K|, |L|)$ . The problem is NP-complete if  $\mathcal{X}$  is required to be a subcomplex of  $K$ .*

This section is devoted to the proof of Theorem 1 by reduction from 3-SAT. Recall that a Boolean formula  $\Phi$  is in 3-CNF if it is

**Figure 3: Variable (top) and clause (bottom) gadgets for the reduction of homological reconstruction to 3-SAT.**

a conjunction of several clauses, each of which is a disjunction of three literals, a literal being either a variable or its negation. Given a 3-CNF formula  $\Phi$ , we construct a simplicial pair  $(K_\Phi, L_\Phi)$  embedded in  $\mathbb{R}^3$  and prove that  $(|K_\Phi|, |L_\Phi|)$  has a reconstruction (as a subcomplex of  $K_\Phi$ ) if and only if  $\Phi$  has a satisfying assignment (see Lemmas 2 and 3 below).

For this, we associate to the 3-CNF formula  $\Phi$  a simplicial pair  $(K_\Phi, L_\Phi)$  with trivial persistent homology. Equivalently, any reconstruction  $X$  of  $(|K_\Phi|, |L_\Phi|)$  has trivial homology, i.e.,

$$\beta_d(X) = \beta_d(|L_\Phi| \hookrightarrow |K_\Phi|) = \begin{cases} 1 & \text{if } d = 0, \\ 0 & \text{otherwise.} \end{cases}$$

This means that  $X$  has a single connected component, no loops, and no cavities.  $X$  has to fill all loops or cavities in  $L_\Phi$  and has to connect the different connected components of  $L_\Phi$  by adding to  $L_\Phi$  portions of  $K_\Phi$  without creating any new loops or cavities. In the figures, red represents the subcomplex  $L_\Phi$ .

### The variable gadget.

The variable gadget is a simplicial pair  $(V_i, W_i)$  as depicted in Fig. 3, top. The simplicial complex  $V_i$  contains 4 edges forming a cycle. The two red edges belong to  $W_i$ , but not the two blue ones. One of the blue edges will be called  $\text{True}_i$  and the other one will be called  $\text{False}_i$ . The key property of this construction is that any reconstruction of the pair  $(|V_i|, |W_i|)$  cannot contain both edges  $\text{True}_i$  and  $\text{False}_i$ , for otherwise they would create a 1-cycle together with the red ones. This property will allow us to match the presence of the edge  $\text{True}_i$  to a *true* assignment of the variable  $v_i$ .

### The clause gadget.

The clause gadget is a simplicial pair  $(C_j, D_j)$  as depicted in Fig. 3, bottom. The simplicial complex  $D_j$  contains a cycle ABCDE. The cycle is closed with two surfaces in  $C_j$  (thereafter referred to as the lower hemisphere and the disk) thereby creating a cavity. Furthermore, the complex  $D_j$  contains an arc that ends inside the disk. Whenever we fill the cycle ABCDE with the disk, this connects the two endpoints of the arc, thus creating a new cycle, which we close twice in  $C_j$  by a left hemisphere and a right hemisphere. Consider one bold edge in the interior of each hemisphere, which is

where the clause gadget will connect to the variable gadgets.

The key property of this clause gadget is that at least one of the 3 bold edges must be present in any reconstruction  $X$  of the pair  $(|C_j|, |D_j|)$ . Indeed, the cycle ABCDE in  $X$  must be filled up. If it is filled by the lower hemisphere, we are done. If it is filled by the disk, we have a new cycle EFGH in  $X$  which in turn must be killed either by the left or by the right hemisphere. In any case,  $X$  contains at least one of the hemispheres and thus one of the three bold edges.

### Correspondence with a formula.

Given a 3-CNF formula  $\Phi$  with  $n$  clauses  $c_1, \dots, c_n$  and  $m$  variables  $v_1, \dots, v_m$ , we construct a 2-dimensional pair  $(K_\Phi, L_\Phi)$  as follows. For each variable  $v_i$  we take a copy  $(V_i, W_i)$  of the variable gadget. For each clause  $c_j$ , we take a copy  $(C_j, D_j)$  of the clause gadget; for each literal  $ev_i$  of  $c_j$ , we identify one of the bold edges of  $C_j$  to  $\text{False}_i$  if  $e$  is a negation and  $\text{True}_i$  otherwise. See Fig. 4 for an example.

First notice that  $\beta_2(L_\Phi) = 0$  (i.e.,  $L_\Phi$  has no cavities). Second, we can assume that  $\beta_0(K_\Phi) = 1$  (i.e.,  $K_\Phi$  is connected). Indeed, if  $K_\Phi$  is disconnected, it means that the 3-SAT problem (and the reconstruction problem) can be decomposed into 2 independent subproblems with disjoint sets of variables, which can be solved separately. Last,  $\beta_1(L_\Phi \hookrightarrow K_\Phi) = 0$  (i.e., the cycles in  $L_\Phi$  are boundaries in  $K_\Phi$ ). Indeed, the only 1-cycles in  $L_\Phi$  are the 1-cycles ABCDE in each  $D_j$ , and they are filled in  $K_\Phi$ . This means that we are looking for a reconstruction with trivial homology.

### From a reconstruction to a satisfying assignment.

Let  $X$  be a homological reconstruction of the pair  $(|K_\Phi|, |L_\Phi|)$ . We do not assume that  $X$  is the geometric realization of some subcomplex of  $K_\Phi$ . Assign to each variable  $v_i$  the value *true* if the edge  $\text{True}_i$  is entirely contained in  $X$ , and *false* otherwise. For each clause gadget  $(C_j, D_j)$ , at least one bold edge is contained in  $X$ . If this edge corresponds to a positive literal  $v_i$ , this means that  $\text{True}_i$  is in  $X$ ,  $v_i$  is *true* and the clause is satisfied. If the edge corresponds to a negative literal  $\neg v_i$ , this implies that  $\text{False}_i$  is in  $X$ .  $\text{True}_i$  is thus not in  $X$ , so  $v_i$  was assigned *false* and the clause is satisfied. We have thus shown that the assignment of the variables makes the formula evaluate to *true*:

**LEMMA 2.** *If  $(|K_\Phi|, |L_\Phi|)$  has a homological reconstruction, then  $\Phi$  has a satisfying assignment.*

### From a satisfying assignment to a reconstruction.

Given a satisfying assignment for the formula  $\Phi$ , we construct a subcomplex  $X \subset K_\Phi$  such that  $|X|$  is a reconstruction of  $(|K_\Phi|, |L_\Phi|)$ . We start with  $X = L_\Phi$  and add to  $X$  a selected set of simplices from  $K_\Phi$ . For each clause  $c_j$ , we pick one literal that evaluates to *true* and close the cycle in the clause gadget complex  $D_j$  correspondingly. If the literal corresponds to the bold edge of the lower hemisphere, we add this hemisphere. Otherwise, we add the disk and the hemisphere that contains the bold edge corresponding to the selected literal.

The only 2-cycles in  $K_\Phi$  are in the clause gadgets. As we did not create any 2-cycle in  $X$ , it follows that  $\beta_2(X) = 0$ . By construction, filling the clause gadgets never introduced both  $\text{True}_i$  and  $\text{False}_i$  in  $X$ . Indeed, it could only introduce  $\text{True}_i$  if  $v_i$  was assigned the value *true* and  $\text{False}_i$  if it was assigned the value *false*. Therefore, the 1-cycle in the variable gadgets do not appear in  $X$ . Also, for each clause gadget, we filled the ABCDE 1-cycle, and whenever we created an extra EFGH 1-cycle by adding the disk, we immediately filled it with the left or right hemisphere. Now we only need to check that the construction did not create any “non-local” 1-cycles.

**Figure 4: Embedding of the clause gadget with aligned hemispheres (top), and the simplicial pair  $(K_\Phi, L_\Phi)$  generated in the reduction from the 3-SAT instance  $(\neg t \wedge u \wedge v) \vee (t \wedge \neg v \wedge \neg w) \vee (\neg u \wedge \neg v \wedge w)$  (bottom left), with parallel projection (bottom right) orthogonal to the alignment axis of the variable gadgets.**

Since for each clause we have only used one of the literals which evaluate to *true*, the only contact a clause gadget in  $X$  has with the rest of  $X$  is through a single bold edge, and the clause gadget can be collapsed to that edge. After collapsing all clause gadgets, all that remains are disconnected variable gadgets with at most 3 edges each, and so  $\beta_1(X) = 0$ . We finally add to  $X$  just enough edges from  $K_\Phi$  so that it becomes connected, without creating any extra cycles in the process. This is possible since we assumed that  $K_\Phi$  is connected. Thus we have  $\beta_0(X) = 1$ . We conclude:

**LEMMA 3.** *If  $\Phi$  has a satisfying assignment, then there is a subcomplex  $X$  of  $K_\Phi$  such that  $|X|$  is a homological reconstruction of  $(|K_\Phi|, |L_\Phi|)$ .*

We are now in a position to prove Theorem 1.

**PROOF OF THEOREM 1.** First we show that the homological reconstruction problem is NP-hard. We proceed by reduction from 3-SAT. Let  $(K, L) = (K_\Phi, L_\Phi)$  be a simplicial pair defined by a 3-SAT instance  $\Phi$ . We show that the following propositions are equivalent:

- (a)  $(|K|, |L|)$  has a reconstruction;
- (b)  $\Phi$  has a satisfying assignment;

- (c) there exists a subcomplex  $X \subset K$  such that  $|X|$  is a reconstruction of  $(|K|, |L|)$ .

The implication (a)  $\implies$  (b) is shown in Lemma 2; (b)  $\implies$  (c) is shown in Lemma 3. Finally, (c)  $\implies$  (a) is trivial.

The pair  $(K, L)$  can be constructed from  $\Phi$  in time polynomial in the size of  $\Phi$ . Together with the equivalence (a)  $\iff$  (b), this establishes NP-hardness of the homological reconstruction problem.

The equivalence (b)  $\iff$  (c) also yields NP-hardness of the homological reconstruction problem restricted to subcomplexes  $X \subset K$ . Moreover, given a subcomplex  $X$  as a polynomial size certificate, we can decide in polynomial time whether  $|X|$  is a reconstruction of  $(|K|, |L|)$ . Thus the problem is also in NP and hence NP-complete.  $\square$

### Embedding.

Later, we have to consider not only an embedding of  $K_\Phi$ , but also a triangulation of its complement. The following fact will be useful:

**LEMMA 4.** *There is a triangulation of  $\mathbb{S}^3$  with size polynomial in the size of  $K_\Phi$  and having  $K_\Phi$  as a subcomplex.*

PROOF. First, referring to Fig. 4, it is clear that  $K_\Phi$  can be embedded in  $\mathbb{R}^3$ . Indeed, we can align the clause gadgets and the variable gadgets along two lines parallel to the coordinate axes and make each clause gadget look like a small body with three long tentacles (colored green in Fig. 4) that connect to the variable gadgets. Due to the way the variable and clause gadgets are aligned in the construction along skew axes, the tentacles do not intersect in their interior.

We can subdivide the space by first projecting  $K_\Phi$  onto a plane orthogonal to the line carrying the variable gadgets. We get a polygonal region whose complement can easily be triangulated inside a bounding box without adding any new vertex and thus adding a linear number of edges. Extending each triangle in the direction of the projection, we get a collection of tubes, one for each triangle. The tubes can easily be triangulated while respecting  $K_\Phi$  to obtain a polynomial size triangulation of a bounding box of the construction, which can trivially be extended to a polynomial size triangulation of  $\mathbb{S}^3$ .  $\square$

We want to remark that a similar construction can be realized even if we restrict edges and faces of  $L$  and  $K$  to be edges and faces of a 3D grid (see Fig. 5). This means that a variant of Theorem 1 can also be shown for cubical complexes arising from 3D image data.

**COROLLARY 1.** *The homological simplification problem is NP-hard: Given as input a simplicial pair  $(K, L)$  embedded in  $\mathbb{R}^3$ , find a complex  $X$  minimizing  $\beta(X)$  subject to  $L \subset X \subset K$ .*

PROOF. We use a reduction from the homological reconstruction problem. To determine if a reconstruction exists, we can first find a complex  $X$  minimizing  $\beta(X)$  subject to  $L \subset X \subset K$ . We then only need to check if its Betti number matches the lower bound  $\beta(L \hookrightarrow K)$ .  $\square$

### 3. RECONSTRUCTION AND SIMPLIFICATION OF LEVEL AND SUBLEVEL SETS

In this section, we consider a real-valued simplexwise linear function defined on a simplicial complex embedded in  $\mathbb{R}^3$  and establish the NP-hardness of problems that ask for a nearby function with a simplified sublevel set (Section 3.1) and a simplified level set (Section 3.3).

Given a real-valued function  $f$ , we write  $F_t$  for the  $t$ -level set  $f^{-1}(t)$ ,  $F_{\leq t}$  for the (closed)  $t$ -sublevel set  $f^{-1}((-\infty, t])$ , and  $F_{< t}$  for the open  $t$ -sublevel set  $f^{-1}((-\infty, t))$ . In this paper we shall only consider real-valued piecewise linear functions. Note that level and sublevel sets of a simplexwise linear function on a simplicial complex  $K$  are not necessarily subcomplexes of  $K$ , but subcomplexes of an appropriate subdivision of  $K$ . Moreover, we have the following property:

**PROPOSITION 1** (KÜHNEL [17], MOROZOV [18]). *Let  $f$  be a simplexwise linear function on a simplicial complex  $K$ . Let  $K(t)$  be the induced subcomplex of  $K$  on  $\{v \in \text{vert } K : f(v) \leq t\}$ . Then  $K(t)$  is homotopy equivalent to the sublevel set  $F_{\leq t}$ . If  $t \neq f(v)$  for all  $v \in \text{vert } K$ , then  $K(t)$  is also homotopy equivalent to the open sublevel set  $F_{< t}$ .*

**Definition 2.** Let  $f, g$  be piecewise linear functions and consider real parameters  $t$  and  $\delta$ . The function  $g$  is called a *sublevel set  $(t, \delta)$ -reconstruction* of  $f$  if  $\|g - f\|_\infty \leq \delta$  and  $G_{\leq t}$  is a reconstruction of the pair  $(F_{\leq t+\delta}, F_{\leq t-\delta})$ , i.e.,

$$\beta(G_{\leq t}) = \beta(F_{\leq t-\delta} \hookrightarrow F_{\leq t+\delta}).$$

**Figure 6: Top: A simplicial pair  $(K, L)$  and a homological reconstruction of  $(K, L)$  as a subcomplex. Bottom: values of  $f$  (left) and  $g$  (right) at the vertices of the barycentric subdivision  $\text{sd } K$ , as used in the proof of Theorem 2.**

Note that

$$F_{\leq t-\delta} \subseteq G_{\leq t} \subseteq F_{\leq t+\delta},$$

so that

$$\beta(G_{\leq t}) \geq \beta(F_{\leq t-\delta} \hookrightarrow F_{\leq t+\delta}).$$

A sublevel set  $(t, \delta)$ -reconstruction is thus also a minimizer of  $\beta(G_{\leq t})$  subject to  $\|g - f\|_\infty \leq \delta$ .

#### 3.1 Sublevel set reconstruction is NP-hard

**THEOREM 2.** *The sublevel set reconstruction problem is NP-hard: Given as input a simplexwise linear function  $f$  on a simplicial complex embedded in  $\mathbb{R}^3$  and parameters  $t$  and  $\delta$ , decide whether there exists a sublevel set  $(t, \delta)$ -reconstruction  $g$  of  $f$ . The problem is NP-complete if  $g$  is required to be simplexwise linear on the same complex.*

PROOF. It suffices to establish the theorem for  $t = 0$  and  $\delta = 1$ . We proceed by reduction from 3-SAT using the results of the previous section. Let  $(K, L) = (K_\Phi, L_\Phi)$  be a simplicial pair defined by a 3-SAT instance  $\Phi$ . We construct an instance of the level set simplification problem by defining a simplexwise linear function  $f : |\text{sd } K| \rightarrow \mathbb{R}$  on the barycentric subdivision of  $K$ ; see Figure 6. Recall that the *barycentric subdivision* (or *derived subdivision*) of a simplicial complex  $K$  is the *order complex* of the face relation, i.e., the abstract simplicial complex  $\text{sd } K$  whose vertices are the simplices of  $K$  and whose simplices are the totally ordered subsets of  $K$  with regard to the face relation. We define  $f$  via its values on the vertices of  $\text{sd } K$ . Using the fact that a vertex  $\sigma$  of  $\text{sd } K$  is a simplex of  $K$ , we let

$$f : \sigma \mapsto \begin{cases} -2 & \text{if } \sigma \in L, \\ 0 & \text{otherwise.} \end{cases} \quad (1)$$

Note that for every function  $g$  with  $\|g - f\|_\infty \leq 1$ , the 0-sublevel set  $G_{\leq 0}$  contains  $L$  and is contained in  $K$ . We show that the following propositions are equivalent to propositions (a)–(c) in the proof of Theorem 1:

- (d)  $f$  has a simplexwise linear sublevel set  $(0, 1)$ -reconstruction  $g$ .
- (e)  $f$  has a sublevel set  $(0, 1)$ -reconstruction  $g$ .

Figure 5: Example of 3-SAT reduction using a 3D grid embedding.

To show (c)  $\implies$  (d), we define a simplexwise linear function  $g$  on  $|\text{sd } K|$  by its values on the vertices of  $\text{sd } K$  (the simplices of  $K$ ); see Figure 6:

$$g : \sigma \mapsto \begin{cases} -2 & \text{if } \sigma \in L, \\ -1 & \text{if } \sigma \in X \setminus L, \\ 1 & \text{if } \sigma \in K \setminus X. \end{cases} \quad (2)$$

We have  $\|g - f\|_\infty = 1$ . By Proposition 1, the sublevel set  $G_{\leq 0}$  is homotopy equivalent to  $|X|$  and hence is a reconstruction of the pair

$$(|K|, |L|) \simeq (F_{\leq 1}, F_{\leq -1}).$$

Finally, (d)  $\implies$  (e) is trivial and (e)  $\implies$  (a) follows directly with  $G_{\leq 0}$  as a reconstruction of  $(F_{\leq 1}, F_{\leq -1}) \simeq (|K|, |L|)$ .

The function  $f$  can be constructed from  $\Phi$  in polynomial time. Together with the equivalence (b)  $\iff$  (e), this establishes NP-hardness of the sublevel set reconstruction problem.

The equivalence (b)  $\iff$  (d) also yields NP-hardness of the sublevel set reconstruction problem restricted to simplexwise linear functions  $|\text{sd } K| \rightarrow \mathbb{R}$ . Moreover given a simplexwise linear function  $g$  as a polynomial size certificate, by computing and comparing  $\beta(G_{\leq 0})$  and  $\beta(F_{\leq -1} \hookrightarrow F_{\leq 1})$  we can decide in polynomial time whether  $g$  is a sublevel set  $(0, 1)$ -reconstruction of  $f$ . Thus the problem is also in NP and hence NP-complete.  $\square$

**COROLLARY 2.** *The sublevel set simplification problem is NP-hard: Given as input a simplexwise linear function  $f$  on a simplicial complex embedded in  $\mathbb{R}^3$  and parameters  $t$  and  $\delta$ , find a simplexwise linear function  $g$  minimizing  $\beta(G_{\leq t})$  subject to  $\|g - f\|_\infty \leq \delta$ .*

**PROOF.** We use a reduction from the sublevel set reconstruction problem. To determine if  $f$  has a sublevel set  $(t, \delta)$ -reconstruction, we can first find a simplexwise linear minimizer of  $\beta(G_{\leq t})$ . We then only need to check if  $\beta(G_{\leq t})$  matches the lower bound

$$\beta(F_{\leq t-\delta} \hookrightarrow F_{\leq t+\delta}),$$

which can be done in time polynomial in the size of  $K$ .  $\square$

### 3.2 Betti numbers of level and sublevel sets

The Betti numbers of level and sublevel sets are related by the following formula:

**LEMMA 5.** *Let  $f$  be a piecewise linear function on  $\mathbb{S}^n$ ,  $n > 1$ , and let  $t$  be in the interior of the image of  $f$ ,  $t \in \text{int}(\text{im } f)$ . Then*

$$\beta_d(F_t) = \beta_d(F_{\leq t}) + \beta_{n-d-1}(F_{< t}).$$

**PROOF.** First recall that  $F_{\leq t}$ ,  $F_{\geq t}$ , and  $F_{\geq t}$  are subcomplexes of an appropriate triangulation of  $\mathbb{S}^n$ , so we can apply the simplicial version of the Mayer-Vietoris theorem [20, §4.6]. By exactness of the Mayer-Vietoris sequence for  $\mathbb{S}^n$ ,  $F_{\leq t}$ , and  $F_{\geq t}$ , we have [13]

$$\beta_d(F_t) = \beta_d(F_{\leq t}) + \beta_d(F_{\geq t}) + \begin{cases} -1 & \text{if } d = 0, \\ 1 & \text{if } d = n - 1, \\ 0 & \text{otherwise.} \end{cases} \quad (3)$$

By Alexander duality [16, §3.3], the duality of homology and cohomology with field coefficients resulting from the universal coefficient theorem [16, §3.1], and isomorphism of dual finite-dimensional vector spaces, we have

$$\widetilde{H}_d(F_{\geq t}) \cong \widetilde{H}^{n-d-1}(F_{< t}) \cong \text{Hom}(\widetilde{H}_{n-d-1}(F_{< t}), \mathbb{F}) \cong \widetilde{H}_{n-d-1}(F_{< t}),$$

where  $\widetilde{H}_d$  denotes the  $d$ th reduced homology group and  $\text{Hom}(\widetilde{H}_{n-d-1}(F_{< t}), \mathbb{F})$  is the dual vector space of  $H_{n-d-1}(F_{< t})$ , i.e., the linear maps to  $\mathbb{F}$ . Recall that

$$\beta_d(X) = \text{rank}(\widetilde{H}_d(X)) + \begin{cases} 1 & \text{if } d = 0, \\ 0 & \text{otherwise.} \end{cases}$$

We thus have

$$\beta_d(F_{\geq t}) = \beta_{n-d-1}(F_{< t}) + \begin{cases} 1 & \text{if } d = 0, \\ -1 & \text{if } d = n - 1, \\ 0 & \text{otherwise.} \end{cases} \quad (4)$$

By combining Eqs. (3) and (4), we obtain the stated equality.  $\square$

For all piecewise linear functions  $f, g$  on  $\mathbb{S}^n$  with  $\|g - f\|_\infty \leq \delta$  and  $t \pm \delta \in \text{int}(\text{im } f)$ , we have  $t \in \text{int}(\text{im } g)$  and thus by Lemmas 1 and 5,

$$\beta(G_t) \geq \beta(F_{\leq t-\delta} \hookrightarrow F_{\leq t+\delta}) + \beta(F_{< t-\delta} \hookrightarrow F_{< t+\delta}).$$

This motivates the following definition:

**Definition 3.** Let  $f, g$  be piecewise linear functions on  $\mathbb{S}^n$  and consider real parameters  $t$  and  $\delta$  with  $t \pm \delta \in \text{int}(\text{im } f)$ . The function  $g$  is called a *level set  $(t, \delta)$ -reconstruction* of  $f$  if  $\|g - f\|_\infty \leq \delta$  and

$$\beta(G_t) = \beta(F_{\leq t-\delta} \hookrightarrow F_{\leq t+\delta}) + \beta(F_{< t-\delta} \hookrightarrow F_{< t+\delta}).$$

A level set  $(t, \delta)$ -reconstruction is thus also a minimizer of  $\beta(G_t)$  subject to  $\|g - f\|_\infty \leq \delta$ .

Since the above equality can only be achieved if both inequalities

$$\begin{aligned}\beta(G_{\leq t}) &\geq \beta(F_{\leq t-\delta} \hookrightarrow F_{\leq t+\delta}) \quad \text{and} \\ \beta(G_{< t}) &\geq \beta(F_{< t-\delta} \hookrightarrow F_{< t+\delta})\end{aligned}$$

derived from Lemma 1 hold with equality, we conclude:

LEMMA 6. *Let  $f, g$  be piecewise linear functions on  $\mathbb{S}^n$ . If  $g$  is a level set  $(t, \delta)$ -reconstruction of  $f$ , then*

$$\begin{aligned}\beta(G_{\leq t}) &= \beta(F_{\leq t-\delta} \hookrightarrow F_{\leq t+\delta}) \\ \beta(G_{< t}) &= \beta(F_{< t-\delta} \hookrightarrow F_{< t+\delta})\end{aligned}$$

and in particular  $g$  is also a sublevel set  $(t, \delta)$ -reconstruction of  $f$ .

We will show in the following that sublevel set reconstructions are also level set reconstructions, under some additional hypotheses.

### 3.3 Level set reconstruction is NP-hard

Definition 4. Let  $f$  be a piecewise linear function. A homological regular value of  $f$  is a number  $t \in \mathbb{R}$  such that  $H_*(F_{< t} \hookrightarrow F_{\leq t})$  is an isomorphism.

We remark that there exist several other notions of regularity in the literature, which do not match our definition when extended to general functions [9, 5]. For piecewise linear functions however, all these definitions are equivalent. Note also that regularity should be understood with respect to sublevel sets;  $t$  can be a regular value even though  $H_*(F_{> t} \hookrightarrow F_{\geq t})$  might not be an isomorphism.

LEMMA 7. *Let  $f$  be a piecewise linear function on  $\mathbb{S}^n$ ,  $n > 1$ . If  $t \pm \delta \in \text{int}(\text{im } f)$  are regular values of  $f$  and  $g$  is a level set  $(t, \delta)$ -reconstruction of  $f$ , then  $t$  is a regular value of  $g$ .*

PROOF. By hypothesis  $t \pm \delta$  are regular values of  $f$ , so

$$H_*(F_{< t-\delta} \hookrightarrow F_{\leq t-\delta}) \quad \text{and} \quad H_*(F_{< t+\delta} \hookrightarrow F_{\leq t+\delta})$$

are isomorphisms and

$$\beta(F_{< t-\delta} \hookrightarrow F_{< t+\delta}) = \beta(F_{< t-\delta} \hookrightarrow F_{\leq t+\delta}) = \beta(F_{\leq t-\delta} \hookrightarrow F_{\leq t+\delta}).$$

Since  $g$  is a level set  $(t, \delta)$ -reconstruction of  $f$ , by Lemma 6 we have

$$\begin{aligned}\beta(G_{\leq t}) &= \beta(F_{\leq t-\delta} \hookrightarrow F_{\leq t+\delta}) \quad \text{and} \\ \beta(G_{< t}) &= \beta(F_{< t-\delta} \hookrightarrow F_{< t+\delta})\end{aligned}$$

and hence

$$\beta(G_{\leq t}) = \beta(G_{< t}) = \beta(F_{< t-\delta} \hookrightarrow F_{\leq t+\delta}).$$

Observing that

$$F_{< t-\delta} \subset G_{< t} \subset G_{\leq t} \subset G_{\leq t+\delta}$$

and using the fact that whenever we have three linear maps

$$U \rightarrow V \rightarrow W \rightarrow X$$

between finite-dimensional vector spaces, then

$$\text{rank}(U \rightarrow X) \leq \text{rank}(V \rightarrow W),$$

we get

$$\beta(F_{< t-\delta} \hookrightarrow F_{\leq t+\delta}) \leq \beta(G_{< t} \hookrightarrow G_{\leq t}) \leq \beta(G_{\leq t}).$$

Combining all these relations, we deduce that

$$\beta(G_{\leq t}) = \beta(G_{< t}) = \beta(G_{< t} \hookrightarrow G_{\leq t}) = \beta(G_{\leq t}).$$

and conclude that  $H_*(G_{< t} \hookrightarrow G_{\leq t})$  is an isomorphism.  $\square$

LEMMA 8. *Let  $f$  and  $g$  be piecewise linear functions on  $\mathbb{S}^n$ ,  $n > 1$ . Assume that  $t \pm \delta \in \text{int}(\text{im } f)$  are regular values of  $f$  and  $t \in \text{int}(\text{im } g)$  is a regular value of  $g$ . Then  $g$  is a sublevel set  $(t, \delta)$ -reconstruction of  $f$  if and only if  $g$  is a level set  $(t, \delta)$ -reconstruction of  $f$ .*

PROOF. By hypothesis,  $t$  is a regular value of  $g$ . Substituting into Lemma 5, we obtain the first equation below; the second equation comes from the fact that  $t \pm \delta$  are regular values of  $f$ :

$$\begin{aligned}2\beta(G_{\leq t}) &= \beta(G_t), \\ 2\beta(F_{\leq t-\delta} \hookrightarrow F_{\leq t+\delta}) &= \beta(F_{\leq t-\delta} \hookrightarrow F_{\leq t+\delta}) + \beta(F_{< t-\delta} \hookrightarrow F_{< t+\delta}).\end{aligned}$$

By definition,  $g$  is a sublevel set  $(t, \delta)$ -reconstruction of  $f$  if and only if the left hand sides of the two equations above are equal. Similarly,  $g$  is a level set  $(t, \delta)$ -reconstruction if and only if the right hand sides of the two equations above are equal. The result follows immediately.  $\square$

THEOREM 3. *The level set reconstruction problem is NP-hard: Given as input a simplexwise linear function on a triangulation of  $\mathbb{S}^3$  and parameters  $t$  and  $\delta$ , decide whether there exists a level set  $(t, \delta)$ -reconstruction  $g$  of  $f$ . The problem is NP-complete if  $g$  is required to be simplexwise linear on this triangulation.*

PROOF. We reuse the same reduction as in Theorem 2. Since we need functions defined on the sphere, we triangulate the complement of  $K$  to obtain a triangulation  $S$  of the sphere with size polynomial in the size of  $K$  and  $K \subset S$  as in Lemma 4. We extend  $f$  from Eq. (1) to a simplexwise linear function  $\tilde{f}$  on  $|\text{sd } S|$ :

$$\tilde{f} : \sigma \mapsto \begin{cases} f(\sigma) & \text{if } \sigma \in K, \\ 2 & \text{otherwise.} \end{cases}$$

We then prove that propositions (a)–(e) in the proofs of Theorems 1 and 2 and (f), (g) below are equivalent.

(f)  $\tilde{f}$  has a simplexwise linear level set  $(0, 1)$ -reconstruction  $\tilde{g}$ .

(g)  $\tilde{f}$  has a level set  $(0, 1)$ -reconstruction  $\tilde{g}$ .

We trivially have (f)  $\implies$  (g). Now we prove that (g)  $\implies$  (d). Proposition 1 implies that the values  $\pm 1$  are regular values of  $\tilde{f}$ . By Lemma 7, the value 0 is a regular value of  $\tilde{g}$ . Lemma 8 then proves that  $\tilde{g}$  is a sublevel set reconstruction of  $\tilde{f}$ . Now let  $g$  be the restriction of  $\tilde{g}$  to  $K$ . Since the sublevel sets  $F_{\leq t}$  and  $\bar{F}_{\leq t}$  are homotopy equivalent for  $t \leq 1$ , and the sublevel sets  $G_{\leq t}$  and  $\bar{G}_{\leq t}$  are homotopy equivalent for  $t \leq 0$ , it follows that  $g$  is a sublevel set reconstruction of  $f$ .

Next we prove that (c)  $\implies$  (f). Given a subcomplex  $X \subset K$  such that  $|X|$  is a reconstruction of  $(|K|, |L|)$ , we define  $g$  using Eq. (2) and extend it to  $\tilde{g} : |\text{sd } S| \rightarrow \mathbb{R}$  as above for  $\tilde{f}$ . Since 0 is a regular value of  $\tilde{g}$ , Lemma 8 implies that  $\tilde{g}$  is a level set reconstruction.

In analogy to the proof of Theorem 2, we obtain NP-hardness of the level set reconstruction problem and NP-completeness of the problem restricted to simplexwise linear functions.  $\square$

COROLLARY 3. *The level set simplification problem is NP-hard: Given a piecewise linear function  $f$  on  $\mathbb{S}^3$  and parameters  $t$  and  $\delta$ , find a simplexwise linear function  $g$  minimizing  $\beta(G_t)$  subject to  $\|g - f\|_\infty \leq \delta$ .*

PROOF. To determine if  $f$  has a level set  $(t, \delta)$ -reconstruction, we can first find a minimizer of  $\beta(G_t)$ . We then only need to check if  $\beta(G_t)$  matches the lower bound

$$\beta(F_{\leq t-\delta} \hookrightarrow F_{\leq t+\delta}) + \beta(F_{< t-\delta} \hookrightarrow F_{< t+\delta}),$$

which can be done in time polynomial in the size of the underlying triangulation.  $\square$

## 4. REALIZATIONS OF WELL GROUPS

We now discuss how the previous results relate to the concept of well groups, which were introduced in [15] as a robust version of the homology group of a level set.

Let  $f : \mathcal{K} \rightarrow \mathbb{R}$  be a piecewise linear function. For  $\delta \geq 0$  and  $t \in \mathbb{R}$ , the  $(t, \delta)$ -well group of  $f$  is defined as

$$W_*(f, t, \delta) = \bigcap_{g: \|g-f\|_\infty \leq \delta} \text{im } H_*(G_t \hookrightarrow F_{[t-\delta, t+\delta]}),$$

where  $F_{[a,b]} = f^{-1}([a,b])$ . Intuitively, it captures the homology common to all perturbed level sets.

Clearly, the rank of the well group provides a lower bound on the Betti number of the  $t$ -level set of any  $g$  with  $\|g-f\|_\infty \leq \delta$ :

$$\beta(G_t) \geq \beta(G_t \hookrightarrow F_{[t-\delta, t+\delta]}) \geq \text{rank } W_*(f, t, \delta).$$

We say that the well group is *realized* by such a function  $g$  if

$$\beta(G_t) = \text{rank } W_*(f, t, \delta),$$

or equivalently, if  $H_*(G_t \hookrightarrow F_{[t-\delta, t+\delta]})$  maps  $H_*(G_t)$  bijectively to  $W_*(f, t, \delta)$ .

As we will show in Theorem 5, the lower bound cannot always be achieved, and hence not every well group is realizable.

More generally, for an interval  $[a, b]$  we have

$$W_*(f, [a, b], \delta) = \bigcap_{g: \|g-f\|_\infty \leq \delta} \text{im } H_*(G_{[a,b]} \hookrightarrow F_{[a-\delta, b+\delta]}).$$

In fact, as shown in [4], the well group is already given by the intersection of just two persistent homology groups:

$$W_*(f, [a, b], \delta) = \text{im } H_*(F_{[a-\delta, b-\delta]} \hookrightarrow F_{[a-\delta, b+\delta]}) \cap \text{im } H_*(F_{[a+\delta, b+\delta]} \hookrightarrow F_{[a-\delta, b+\delta]}). \quad (5)$$

The following formula expresses the rank of the well group in terms of persistent Betti numbers using relative homology.

**THEOREM 4** (BENDICH ET AL. [4]). *Let  $f : \mathcal{K} \rightarrow \mathbb{R}$  be a piecewise linear function and let  $a \leq b$  and  $\delta \in \mathbb{R}$  be such that  $a \pm \delta, b \pm \delta$  are regular values of  $f$ . Then*

$$\begin{aligned} \text{rank } W_*(f, [a, b], \delta) &= \beta(F_{\leq b-\delta} \hookrightarrow F_{\leq b+\delta}) \\ &\quad - \beta((F_{\leq b-\delta}, \emptyset) \hookrightarrow (\mathcal{K}, F_{\geq a+\delta})) \\ &\quad + \beta((\mathcal{K}, F_{\geq a+\delta}) \hookrightarrow (\mathcal{K}, F_{\geq a-\delta})) \\ &\quad - \beta((F_{\leq b+\delta}, \emptyset) \hookrightarrow (\mathcal{K}, F_{\geq a-\delta})). \end{aligned}$$

### 4.1 Realizability of well groups is NP-hard

We now show that a realization of a well group is the same as a level set reconstruction:

**THEOREM 5.** *Let  $f$  be a piecewise linear function on  $\mathbb{S}^n$  with  $t \pm \delta \in \text{int}(\text{im } f)$ . A piecewise linear function  $g$  realizes the well group  $W_*(f, t, \delta)$  if and only if it is a level set  $(t, \delta)$ -reconstruction of  $f$ .*

**PROOF.** The number of critical values of  $f$  is finite, and so for every  $s \in \mathbb{R}$ , there is  $\epsilon > 0$  such that all values in  $[s - \epsilon, s]$  and in  $[s, s + \epsilon]$  are regular, and hence

$$H_*(F_{\leq s-\epsilon} \hookrightarrow F_{< s}) \quad \text{and} \quad H_*(F_{\leq s} \hookrightarrow F_{\leq s+\epsilon})$$

are isomorphisms. Choose  $\epsilon$  such that the above holds for  $s = t \pm \delta$ . Let  $a = t - \epsilon$  and  $b = t + \epsilon$ . Now  $a \pm \delta, b \pm \delta$  are regular values and we can apply Theorem 4.

The second and forth terms in the formula of Theorem 4 vanish. To see this, note that  $t \pm \delta \in \text{int}(\text{im } f)$  implies

$$F_{\leq b \pm \delta} = F_{\leq t + \epsilon \pm \delta} \subsetneq \mathbb{S}^n$$

for  $\epsilon$  small enough, and thus  $\beta_n(F_{\leq b \pm \delta}) = 0$ . Similarly,

$$F_{\geq a \pm \delta} = F_{\geq t - \epsilon \pm \delta} \neq \emptyset$$

and thus  $\beta_0(\mathbb{S}^n, F_{\geq a \pm \delta}) = 0$ . Moreover,  $\beta_d(\mathbb{S}^n) = 0$  for  $d \notin \{0, n\}$ . Since the induced homomorphisms

$$H_*((F_{\leq b \pm \delta}, \emptyset) \hookrightarrow (\mathbb{S}^n, F_{\geq a \pm \delta}))$$

factor as

$$H_*(F_{\leq b \pm \delta}) \rightarrow H_*(\mathbb{S}^n) \rightarrow H_*(\mathbb{S}^n, F_{\geq a \pm \delta}),$$

we have

$$\beta((F_{\leq b \pm \delta}, \emptyset) \hookrightarrow (\mathbb{S}^n, F_{\geq a \pm \delta})) = 0.$$

Moreover, by the duality theorem of extended persistence on manifolds [10], we can rewrite the third term in Theorem 4 as

$$\beta_d((\mathbb{S}^n, F_{\geq a+\delta}) \hookrightarrow (\mathbb{S}^n, F_{\geq a-\delta})) = \beta_{n-d}(F_{\leq a-\delta} \hookrightarrow F_{\leq a+\delta}).$$

Finally, by regularity of the values  $[a \pm \delta, t \pm \delta]$  and  $(t \pm \delta, b \pm \delta)$  we have isomorphisms

$$H_*(F_{t \pm \delta} \hookrightarrow F_{[a \pm \delta, b \pm \delta]}) \quad \text{and} \quad H_*(F_{[t-\delta, t+\delta]} \hookrightarrow F_{[a-\delta, b+\delta]})$$

and thus by Eq. (5)

$$W_*(f, t, \delta) \cong W_*(f, [a, b], \delta).$$

Altogether, this yields

$$\text{rank } W_*(f, t, \delta) = \beta(F_{\leq t-\delta} \hookrightarrow F_{\leq t+\delta}) + \beta(F_{< t-\delta} \hookrightarrow F_{< t+\delta}).$$

The statement now follows directly from the definitions.  $\square$

Together with Theorem 3, we have:

**COROLLARY 4.** *The well group realization problem is NP-hard: Given a piecewise linear function  $f : |K| \subseteq \mathbb{S}^3 \rightarrow \mathbb{R}$  and parameters  $t$  and  $\delta$ , decide whether the well group  $W_*(f, t, \delta)$  can be realized. The problem is NP-complete if the realization is required to be simplexwise linear on  $K$ .*

## 5. CONCLUSION

The homological reconstruction problem of simplicial pairs embedded in  $\mathbb{R}^3$  is NP-hard. It is also NP-hard to decide whether a real-valued simplexwise linear function in  $\mathbb{R}^3$  has a level set or a sublevel set reconstruction. We deduce that simplifying the homology of a simplicial pair embedded in  $\mathbb{R}^3$  is also NP-hard and so is the homological simplification of level and sublevel sets of real-valued simplexwise linear functions in  $\mathbb{R}^3$ . This raises the question of whether such problems can be solved in polynomial time if we restrict ourselves to particular classes of three-dimensional simplicial pairs or functions. For instance, what can be said for pairs of  $\alpha$ -complexes in  $\mathbb{R}^3$ ?
