#### Abstract

Our aim is to validate the effectiveness of a matched asymptotic expansion method introduced in [1], [2]. A simplified model for the influence of small identical heterogeneities periodically distributed on an internal surface is obtained and applied to the overall response of a linearly elastic body. A careful numerical study compares the solution obtained by a standard method on a fine mesh to the one obtained by asymptotic expansion. We compute both the zero th and first order terms in the expansion. To efficiently compute the first order term we introduce a domain decomposition method.

Keywords: finite element method, linear elasticity, matched asymptotic expansions, domain decomposition

## 1. Introduction

For various research applications in fields spanning the mathematical, physical and engineering communities, there is great interest in a rigorous and efficient numerical approximation of the solution of boundary value problems where the domain and/or the coefficients have a large number of heterogeneities When the characteristic size of the heterogeneitis is much smaller than the whole structure and the heterogeneities are periodically distibuted in all the volume a now classical approach is to use an homogenization method [3], [4], [5], [6]. Simplified models for multi-materials consider two elastic bodies connected by a strong thin material layer whose stiffness grows [7],
[8] or by a thin adhesive layer [9]. The situation is different when the heterogeneities are periodically distributed on an internal surface $\omega$. In this case an alternative approach is mandatory. The analysis of the behaviour of a structure made of a material with a large number of heterogeneities distributed on a surface using a standard finite element method becomes very expensive when the characteristic size of the heterogeneity is much smaller than the whole structure. In this case an alternative approach is to use a multi-scale method such as those proposed in [10], [11] in the framework of matched asymptotic expansions and more recently developed in [12], [13], [14], [15]. The first objective of this paper is to numerically validate a recently proposed new method [1], [2] and the second one is to introduce a numerical algorithm which accurately implements the method. Basically the matched asymptotic expansions allow to replace the initial problem by a set of new ones: the layer of heterogeneities is replaced by a surface (in 3D) or a line in (2D) on which particular jumping conditions are defined. These are the macroscopic problems. The definition of these problems requires several quantities which are computed via the solution of cell problems at the microscopic level. The paper is organized as follows: in Section 2 we set the problem and briefly recall the asymptotic analysis of this problem based on the matched asymptotic expansion method. Specifically we assume that the displacement and stress fields admit two asymptotic expansions, one far from the heterogeneities (the outer one) another one close (the inner one). The construction of the outer and inner problem allows to define the transmission coefficients across the surface. We show that the order 0 outer problem is independent of the heterogeneities. For the first order outer problem the transmission coefficients are given by several elementary inner problems posed on a representative cell. These problems depend on the nature of the heterogeneities (holes, highly contrasted materials). In Section 3 we introduce a domain decomposition type algorithm to numerically solve the first order problem (the problem with jumps on an internal boundary). Finally in Section 4 we validate the whole procedure by comparing, on a test problem, the solution obtained using standard finite elements on a large mesh to the solution obtained by the asymptotic approach.

## 2. Asymptotic model

### 2.1. The problem

Let us consider a three dimensional structure $\Omega$ (an open domain of $\mathbb{R}^{3}$ with smooth boundary $\partial \Omega$ ) containing small identical heterogeneities periodically distributed along a surface $\omega$ that we assume for simplicity contained in the plane $x_{1}=0$ (see Fig. 1). We assume that $\omega$ is contained in the union of

Figure 1: The structure with the layer of heterogeneities
$\mathcal{N}(\varepsilon) \approx \frac{\operatorname{aire}(\omega)}{\operatorname{aire}(\hat{Y})} \varepsilon^{-2}$ sets $\varepsilon \hat{Y}$, where $\hat{Y} \subset \mathbb{R}^{2}$ is the basis of a periodic planar net (we take for simplicity $\hat{Y}=]-\frac{1}{2}, \frac{1}{2}[\times]-\frac{1}{2}, \frac{1}{2}[$ ). Let $I$ be a non-empty $3 D$ domain contained in $\mathbb{R} \times \hat{Y}$ with smooth boundary $\partial I$, with diameter $d$ satisfying $0<\frac{d}{\operatorname{diam}(\Omega)}<+\infty$ and such that $I \cap\left\{x_{1}=0\right\}$ is strictly contained in $\hat{Y}$ (hence $d<\sqrt{2}$ ). We also assume that the heterogeneities have a diameter $\varepsilon d$ and fill every domain $\varepsilon I$. We denote by $\varepsilon \partial I$ the boundary of $\varepsilon I$ and by $\mathcal{I}^{\varepsilon}$, resp. $\partial \mathcal{I}^{\varepsilon}$, the union of all the heterogeneities, resp. of all their boundaries.

Hence from a geometrical point of view there are two natural length scales: the first is a global one (the $3 D$-diameter of $\Omega$ or the $2 D$-diameter of $\omega$ ) the other one is a local one connected with the heterogeneities (e.g. the diameter of each heterogeneity). The ratio between these two scales will be denoted by $\varepsilon$. More precisely, the parameter $\varepsilon$ is a non-dimensional parameter characterizing the geometrical distribution of the heterogeneities in the structure
since, at the same time, it characterizes the ratio between the diameter of any heterogeneity $(\varepsilon d)$ and the diameter of $\Omega$ and the ratio between the diameter of the period $(\varepsilon \hat{Y})$ of the planar net and the diameter of the planar set $\omega$ supporting the heterogeneities.

In this work we consider two types of inclusions: holes and soft elastic inclusions with stiffness dependent on $\varepsilon$. In the case of elastic inclusions, transmission conditions must be verified on $\partial \mathcal{I}^{\varepsilon}$, while free boundary conditions must be taken into account on $\partial \mathcal{I}^{\varepsilon}$ in the case of the holes. The boundary of $\Omega$ is composed of two parts $\Gamma_{0}$ and $\Gamma_{F}$ with $\partial \Omega=\overline{\Gamma_{0}} \cup \overline{\Gamma_{F}}$ and $\Gamma_{0} \cap \Gamma_{F}=\emptyset$. The structure is clamped on $\Gamma_{0}$ and a density $\boldsymbol{F}$ of surface forces is applied on the complementary part $\Gamma_{F}$. Let $\boldsymbol{u}^{\varepsilon}$ and $\boldsymbol{\sigma}^{\varepsilon}$ be the displacement and the stress field at equilibrium. These fields verify the following equations:

$$
\begin{cases}\boldsymbol{d i v} \boldsymbol{\sigma}^{\varepsilon}=\mathbf{0} & \text { in } \Omega^{\varepsilon}  \tag{1}\\ \boldsymbol{\sigma}^{\varepsilon}=\boldsymbol{A} \boldsymbol{\gamma}\left(\boldsymbol{u}^{\varepsilon}\right) & \text { in } \Omega^{\varepsilon} \\ \boldsymbol{\sigma}^{\varepsilon} \boldsymbol{n}=\boldsymbol{F} & \text { on } \Gamma_{F} \\ \boldsymbol{u}^{\varepsilon}=\mathbf{0} & \text { on } \Gamma_{0}\end{cases}
$$

where

$$
\Omega^{\varepsilon}= \begin{cases}\Omega \backslash \mathcal{I}^{\varepsilon} & \text { in the holes case } \\ \Omega & \text { in the elastic inclusions case }\end{cases}
$$

$$
\boldsymbol{A}= \begin{cases}\boldsymbol{A}^{S} & \text { in } \Omega \backslash \mathcal{I}^{\varepsilon}  \tag{2}\\ \varepsilon^{p} \boldsymbol{A}^{I}, p \in \mathbb{N} & \text { in } \mathcal{I}^{\varepsilon} \text { (in the case of elastic inclusions) }\end{cases}
$$

with $A^{S}$ and $A^{I}$ of same order.
Let us stress that in the case of elastic inclusions as shown in (2) the parameter $\varepsilon$ is a non-dimensional parameter characterizing at the same time the geometrical distribution of the heterogeneities in the structure and the ratio between the rigidity of the heterogeneities and the rigidity of the structure.

The inner-outer matched asymptotic method approximates the initial problem with a set of new ones defined in $\Omega$ where the layer of heterogeneities is replaced by the surface $\omega$ (see Fig. 2) where suitable transmission conditions are defined.

Figure 2: The structure without the layer of heterogeneities

### 2.2. The inner-outer matched asymptotic method

The presence of the heterogeneities involves a boundary layer effect, i.e. a significant variation of the solution near $\omega$. The matched asymptotic expansion method applied to the present problem has the following steps:

- Decomposition of the domain $\Omega$ into two overlapping subdomains (see Fig. 3 and Fig. 4):
$\star$ the domain $\Omega^{\text {out }, \varepsilon}=\left\{\boldsymbol{x}=\left(x_{1}, x_{2}, x_{3}\right) \in \Omega ;\left|x_{1}\right|>\frac{\varepsilon}{2}\right\}$,
$\star$ the domain $\Omega^{i n, \varepsilon}=\left\{\boldsymbol{x}=\left(x_{1}, x_{2}, x_{3}\right) \in \Omega^{\varepsilon} ;\left|x_{1}\right|<\frac{\eta(\varepsilon)}{2}\right\}$ where $\eta(\varepsilon)$ is a function satisfying the following conditions:

$$
\left\{\begin{array}{l}
\lim _{\varepsilon \rightarrow 0} \eta(\varepsilon)=0  \tag{3}\\
\lim _{\varepsilon \rightarrow 0} \frac{\eta(\varepsilon)}{\varepsilon}=+\infty
\end{array}\right.
$$

- Introduction of the normalized coordinate systems:

Figure 3: $\Omega^{o u t, \varepsilon}=\Omega^{+, \varepsilon} \cup \Omega^{-, \varepsilon}$

Figure 4: $\Omega^{i n, \varepsilon}$
$\star$ When $\varepsilon \rightarrow 0$, the domain $\Omega^{\text {out }, \varepsilon}$ tends to a fixed domain $\Omega^{-} \cup \Omega^{+}=$ $\Omega \backslash \omega=\left\{\boldsymbol{x} \in \Omega ;\left|x_{1}\right|>0\right\}$ which is also called the outer domain. The outer system of coordinates is $\boldsymbol{x}:=\left(x_{1}, x_{2}, x_{3}\right) \in \Omega \backslash \omega$.
$\star$ Since $\omega$ is contained in the union of $\mathcal{N}(\varepsilon)$ sets $\varepsilon \hat{Y}$, as in the periodic homogenisation procedure the position $\boldsymbol{z}:=\left(z_{1}, z_{2}, z_{3}\right)$ of a point $M$ in the domain $\Omega^{i n, \varepsilon}$ can be given by two independent data:
i) the macroscopic position $(0, \hat{\boldsymbol{x}}):=\left(0, x_{2}, x_{3}\right) \in \omega$ of the center of the period $\varepsilon \hat{Y}$ containing the projection of $M$ on $\omega$
ii) the microscopic position defined as the position of the point $M$ with respect to this center. To obtain a domain and a coordinate system independent from $\varepsilon$, one applies a dilatation of the variables $\varepsilon y_{i}$ of a factor $\frac{1}{\varepsilon}$. Using (3) and the periodicity assumption on the heterogeneities, the inner domain is $\omega \times Y$ where $Y:=\mathbb{R} \times \hat{Y}$ is called the basic cell (see Fig.5) and the relation between the
coordinates $\boldsymbol{z}$ of the point $M$ and the point $((0, \hat{\boldsymbol{x}}), \boldsymbol{y})$ of the inner domain is given by:

$$
\begin{equation*}
\boldsymbol{z}=(0, \hat{\boldsymbol{x}})+\varepsilon \boldsymbol{y} . \tag{4}
\end{equation*}
$$

Figure 5: The basic cell $Y$
This correspondence implies that the operators divergence (div) and symmetric gradient $(\gamma)$ must be reformulated in terms of the macroscopic $\hat{\boldsymbol{x}}$ and the microscopic $\boldsymbol{y}=\left(y_{1}, \hat{\boldsymbol{y}}\right)$ coordinates in the following way:

$$
\begin{array}{r}
\operatorname{div} \boldsymbol{\tau}(\hat{\boldsymbol{x}}, \boldsymbol{y})=\operatorname{div}_{x} \boldsymbol{\tau}(\hat{\boldsymbol{x}}, \boldsymbol{y})+\frac{1}{\varepsilon} \boldsymbol{d i v}_{y} \boldsymbol{\tau}(\hat{\boldsymbol{x}}, \boldsymbol{y}) \\
\gamma(\boldsymbol{v}(\hat{\boldsymbol{x}}, \boldsymbol{y}))=\gamma_{x}(\boldsymbol{v}(\hat{\boldsymbol{x}}, \boldsymbol{y}))+\frac{1}{\varepsilon} \gamma_{y}(\boldsymbol{v}(\hat{\boldsymbol{x}}, \boldsymbol{y})) \tag{5}
\end{array}
$$

with:

$$
\begin{cases}\boldsymbol{d i v}_{x} \boldsymbol{\tau}=\frac{\partial \tau_{i j}}{\partial x_{j}} \boldsymbol{e}_{i} & , \quad \boldsymbol{d i v}_{y} \boldsymbol{\tau}=\frac{\partial \tau_{i j}}{\partial y_{j}} \boldsymbol{e}_{i}  \tag{6}\\ \left(\gamma_{x}(\boldsymbol{v})\right)_{i j}=\frac{1}{2}\left(\frac{\partial v_{j}}{\partial x_{i}}+\frac{\partial v_{i}}{\partial x_{j}}\right) & , \quad\left(\boldsymbol{\gamma}_{y}(\boldsymbol{v})\right)_{i j}=\frac{1}{2}\left(\frac{\partial v_{j}}{\partial y_{i}}+\frac{\partial v_{i}}{\partial y_{j}}\right)\end{cases}
$$

- Ansatz:

Introduction of the two a priori asymptotic expansions of $\boldsymbol{u}^{\varepsilon}$ :

* the outer expansion

$$
\begin{equation*}
\boldsymbol{u}^{\varepsilon}\left(x_{1}, x_{2}, x_{3}\right)=\sum_{i=0}^{\infty} \varepsilon^{i} \boldsymbol{u}^{i}\left(x_{1}, x_{2}, x_{3}\right) \tag{7}
\end{equation*}
$$

* the inner expansion

$$
\begin{equation*}
\boldsymbol{u}^{\varepsilon}\left(x_{1}, x_{2}, x_{3}\right)=\sum_{i=0}^{\infty} \varepsilon^{i} \boldsymbol{v}^{i}\left(\hat{\boldsymbol{x}}, y_{1}, \hat{\boldsymbol{y}}\right) \tag{8}
\end{equation*}
$$

where the $\boldsymbol{v}^{i}$ are $\hat{Y}$-periodic, i.e. such that:

$$
\begin{equation*}
\boldsymbol{v}^{i}\left(\hat{\boldsymbol{x}}, y_{1}, \hat{\boldsymbol{y}}+p \boldsymbol{e}_{2}+q \boldsymbol{e}_{3}\right)=\boldsymbol{v}^{i}\left(\hat{\boldsymbol{x}}, y_{1}, \hat{\boldsymbol{y}}\right) \quad \forall(p, q) \in \mathbb{Z}^{2} \tag{9}
\end{equation*}
$$

and $\hat{\boldsymbol{x}} \in \omega$ has to be considered as a parameter.

- Deduction of the outer and inner expansion of $\boldsymbol{\sigma}^{\varepsilon}$ :

We use the constitutive equations and the inner and outer expansion of $\boldsymbol{u}^{\varepsilon}$ to determinate the outer and the inner expansion of $\boldsymbol{\sigma}^{\varepsilon}$. One has a priori to distinguish between the case of holes and the case of hyper-elastic inclusions characterized by the hyper-elastic fourth-order tensor $\boldsymbol{A}^{\varepsilon, I}=\varepsilon^{p} \boldsymbol{A}^{I}$ with $\boldsymbol{A}^{I} \simeq \boldsymbol{A}$ and $p \in \mathbb{N}$.

* Outer expansion. Outside the heterogeneities the structure is constituted by a linearly hyper-elastic material whose rigidity tensor is $\boldsymbol{A}$, and hence:

$$
\begin{equation*}
\boldsymbol{\sigma}^{\varepsilon}(\boldsymbol{x})=\sum_{i=0}^{\infty} \varepsilon^{i} \boldsymbol{\sigma}^{i}(\boldsymbol{x}) \tag{10}
\end{equation*}
$$

with

$$
\begin{equation*}
\boldsymbol{\sigma}^{i}=\boldsymbol{A} \boldsymbol{\gamma}_{x}\left(\boldsymbol{u}^{i}\right) \tag{11}
\end{equation*}
$$

* Inner expansion. The distinction between the holes and the elastic inclusions is significant:
* in $Y \backslash I$ (for holes or elastic inclusions):

$$
\begin{equation*}
\boldsymbol{\sigma}^{\varepsilon}(\boldsymbol{x})=\sum_{i=-1}^{\infty} \varepsilon^{i} \boldsymbol{\tau}^{i}(\hat{\boldsymbol{x}}, \boldsymbol{y}) \tag{12}
\end{equation*}
$$

with

$$
\left\{\begin{array}{l}
\boldsymbol{\tau}^{-1}=\boldsymbol{A} \boldsymbol{\gamma}_{y}\left(\boldsymbol{v}^{0}\right)  \tag{13}\\
\boldsymbol{\tau}^{i}=\boldsymbol{A} \boldsymbol{\gamma}_{x}\left(\boldsymbol{v}^{i}\right)+\boldsymbol{A} \boldsymbol{\gamma}_{y}\left(\boldsymbol{v}^{i+1}\right) \text { for } \quad i \geq 0
\end{array}\right.
$$

* in $I$ (only for elastic inclusions):

$$
\begin{equation*}
\boldsymbol{\sigma}^{\varepsilon}(\boldsymbol{x})=\sum_{i=p-1}^{\infty} \varepsilon^{i} \boldsymbol{\tau}^{i}(\hat{\boldsymbol{x}}, \boldsymbol{y}) \tag{14}
\end{equation*}
$$

with

$$
\left\{\begin{array}{l}
\boldsymbol{\tau}^{p-1}=\boldsymbol{A}^{I} \boldsymbol{\gamma}_{y}\left(\boldsymbol{v}^{0}\right)  \tag{15}\\
\boldsymbol{\tau}^{i}=\boldsymbol{A}^{I} \boldsymbol{\gamma}_{x}\left(\boldsymbol{v}^{i-p}\right)+\boldsymbol{A}^{I} \boldsymbol{\gamma}_{y}\left(\boldsymbol{v}^{i-p+1}\right) \text { for } \quad i \geq p
\end{array}\right.
$$

The fields $\boldsymbol{\tau}^{i}$ are $\hat{Y}$-periodic, with respect to $\hat{\boldsymbol{y}}$ and $\hat{\boldsymbol{x}} \in \omega$ has to be considered as a parameter.

- Deduce the boundary value problems verified by the different terms of the inner and outer expansion. In general the boundary value problems for the terms of the outer expansion need transmission conditions on $\omega$ that are not directly determined and the boundary value problems for the terms of the inner expansion may have a non unique solution.
- Provide matching conditions between the inner and the outer expansion in order to complete the statement of the transmission conditions on $\omega$ and to completely determine the inner solution.

Following these steps one can compute the terms of each asymptotic expansion; in our situation only the first two deserve attention. Let us explicitly remark that in the inner expansion the development of $\boldsymbol{\sigma}^{\varepsilon}$ begins with the term $\boldsymbol{\tau}^{-1}$ in $Y \backslash I$ and the term $\boldsymbol{\tau}^{p-1}$ in $I$.

### 2.2.1. Theoretical results for the asymptotic study

This section is a reminder without any proofs of the main results of the asymptotic study (see [1] for details ).

## Zeroth-order approximation: .

- inner approximation: the solution $\boldsymbol{v}^{0}$ verify

$$
\begin{equation*}
\boldsymbol{v}^{0}(\boldsymbol{x}, \boldsymbol{y})=\boldsymbol{v}^{0}(\boldsymbol{x})=\boldsymbol{u}^{0}(0, \hat{\boldsymbol{x}}) \tag{16}
\end{equation*}
$$

where $\boldsymbol{u}^{0}$ is the solution of the outer approximation

- outer approximation: $\boldsymbol{u}^{0}$ is solution of

$$
\begin{cases}\boldsymbol{d i v} \boldsymbol{\sigma}^{0}\left(\boldsymbol{u}^{0}\right)=\mathbf{0} & \text { in } \Omega_{0}  \tag{17}\\ \boldsymbol{\sigma}^{0}=\boldsymbol{A} \boldsymbol{\gamma}\left(\boldsymbol{u}^{0}\right) & \text { in } \Omega_{0} \\ \boldsymbol{\sigma}^{0} \boldsymbol{n}=\boldsymbol{F} & \text { on } \Gamma_{F} \\ \boldsymbol{u}^{0}=\mathbf{0} & \text { on } \Gamma_{0}\end{cases}
$$

Remark 1: Notice that there are no jumps on $\omega$ for the outer approximation. In other words, at the zero order the outer approximation does not take into account the heterogeneities. Thus this problem can be solved using a standard finite element procedure.

Remark 2: Since $\boldsymbol{A}$ is constant (or regular), the classical regularity results for linear elasticity imply that the solution $\boldsymbol{u}^{0}$ is regular in $\bar{\Omega} \backslash\left(\overline{\Gamma_{0}} \cap \overline{\Gamma_{F}}\right)$ and hence on $\bar{\omega}$ when $\partial \omega \cap\left(\overline{\Gamma_{0}} \cap \overline{\Gamma_{F}}\right)=\emptyset$.

First-order approximation: .

- inner approximation:
$\star$ The definition of $\boldsymbol{v}^{1}(\hat{\boldsymbol{x}}, \boldsymbol{y})$ is similar in the case of holes and in the case of elastic inclusions

$$
\begin{equation*}
\boldsymbol{v}^{1}(\hat{\boldsymbol{x}}, \boldsymbol{y})=f\left(y_{1} ; a, b\right) \frac{\partial \boldsymbol{u}^{0}}{\partial x_{1}}(0, \hat{\boldsymbol{x}})+\frac{\partial u_{i}^{0}}{\partial x_{j}}(0, \hat{\boldsymbol{x}}) \boldsymbol{V}^{i j}(\boldsymbol{y})+\check{\boldsymbol{v}}(\hat{\boldsymbol{x}}) \tag{18}
\end{equation*}
$$

where: $f\left(y_{1} ; a, b\right)$ is an odd function of class $\mathcal{C}^{2}(\mathbb{R})$ such that

$$
f\left(y_{1} ; a, b\right)= \begin{cases}0 & \text { if } 0<\left|y_{1}\right| \leq a  \tag{19}\\ y_{1} & \text { if }\left|y_{1}\right| \geq b\end{cases}
$$

with $d<2 a<2 b$ (in the sequel, except when we wish to stress the dependence on $a, b$, we will simply write $\left.f\left(y_{1}\right)\right)$. Let us only stress that in the case of holes $\boldsymbol{y} \in Y \backslash I$ and in the case of elastic inclusions $\boldsymbol{y} \in Y$.
$\star$ When $\boldsymbol{y} \in Y \backslash I$ the definition of $\boldsymbol{\tau}^{0}$ is the same for holes and for elastic inclusions and follows from (13) :

$$
\begin{equation*}
\boldsymbol{\tau}^{0}(\hat{\boldsymbol{x}}, \boldsymbol{y})=\boldsymbol{G}\left(y_{1}, \boldsymbol{u}^{0}\right)+\frac{\partial u_{i}^{0}}{\partial x_{j}}(0, \hat{\boldsymbol{x}}) \boldsymbol{A} \boldsymbol{\gamma}_{y}\left(\boldsymbol{V}^{i j}\right)(\boldsymbol{y}) \tag{20}
\end{equation*}
$$

where the tensor $\boldsymbol{G}$ is defined by

$$
\begin{equation*}
\boldsymbol{G}\left(y_{1}, \boldsymbol{u}^{0}\right)=\boldsymbol{A}\left(\gamma_{x}\left(\boldsymbol{u}^{0}(0, \hat{\boldsymbol{x}})\right)+f^{\prime}\left(y_{1}\right) \frac{\partial \boldsymbol{u}^{0}}{\partial x_{1}}(0, \hat{\boldsymbol{x}}) \otimes_{S} \boldsymbol{e}_{1}\right) \tag{21}
\end{equation*}
$$

$\star$ When $\boldsymbol{y} \in I$ then (14) and (15) imply that the definition of $\boldsymbol{\tau}^{0}$ depends on $p$. More precisely when $p \geq 1$ one has $\boldsymbol{\tau}^{0}=0$ and when $p=0$ one has:

$$
\begin{equation*}
\boldsymbol{\tau}^{0}(\hat{\boldsymbol{x}}, \boldsymbol{y})=\boldsymbol{G}\left(y_{1}, \boldsymbol{u}^{0}\right)+\frac{\partial u_{i}^{0}}{\partial x_{j}}(0, \hat{\boldsymbol{x}}) \boldsymbol{A} \boldsymbol{\gamma}_{y}\left(\boldsymbol{V}^{i j}\right)(\boldsymbol{y}) \tag{22}
\end{equation*}
$$

where the tensor $\boldsymbol{G}$ is defined by

$$
\begin{equation*}
\boldsymbol{G}\left(y_{1}, \boldsymbol{u}^{0}\right)=\boldsymbol{A}^{I}\left(\gamma_{x}\left(\boldsymbol{u}^{0}(0, \hat{\boldsymbol{x}})\right)+f^{\prime}\left(y_{1}\right) \frac{\partial \boldsymbol{u}^{0}}{\partial x_{1}}(0, \hat{\boldsymbol{x}}) \otimes_{S} \boldsymbol{e}_{1}\right) \tag{23}
\end{equation*}
$$

$\star$ The fields $\boldsymbol{V}^{i j}$ are solution of the following cell problems for $p=0$, resp. for $p \geq 1$ (or for the case of holes since the two situations give rise to the same equations):
i) for $(1,1), l=1,2,3$ :

$$
\begin{cases}\boldsymbol{d i v}_{y} \boldsymbol{T}^{l 1}=-f^{\prime \prime}\left(y_{1}\right) A_{i 111} \boldsymbol{e}_{i} & \text { in } Y(\text { resp. in } Y \backslash I)  \tag{24}\\ \boldsymbol{T}^{l 1}=\boldsymbol{A} \boldsymbol{\gamma}_{y}\left(\boldsymbol{V}^{l 1}\right) & \text { in } Y(\text { resp. in } Y \backslash I) \\ \boldsymbol{T}^{l 1}\left(\hat{\boldsymbol{x}}, y_{1}, \frac{1}{2}, y_{3}\right) \boldsymbol{e}_{2}=\boldsymbol{T}^{l 1}\left(\hat{\boldsymbol{x}}, y_{1},-\frac{1}{2}, y_{3}\right) \boldsymbol{e}_{2} & \text { on } \mathbb{R} \times \partial \hat{Y} \\ \boldsymbol{T}^{l 1}\left(\hat{\boldsymbol{x}}, y_{1}, y_{2}, \frac{1}{2}\right) \boldsymbol{e}_{3}=\boldsymbol{T}^{l 1}\left(\hat{\boldsymbol{x}}, y_{1}, y_{2},-\frac{1}{2}\right) \boldsymbol{e}_{3} & \text { on } \mathbb{R} \times \partial \hat{Y} \\ \boldsymbol{V}^{l 1}\left(\hat{\boldsymbol{x}}, y_{1}, \frac{1}{2}, y_{3}\right)=\boldsymbol{V}^{l 1}\left(\hat{\boldsymbol{x}}, y_{1},-\frac{1}{2}, y_{3}\right) & \text { on } \mathbb{R} \times \partial \hat{Y} \\ \boldsymbol{V}^{l 1}\left(\hat{\boldsymbol{x}}, y_{1}, y_{2}, \frac{1}{2}\right)=\boldsymbol{V}^{l 1}\left(\hat{\boldsymbol{x}}, y_{1}, y_{2},-\frac{1}{2}\right) & \text { on } \mathbb{R} \times \partial \hat{Y} \\ \lim _{y_{1} \rightarrow \pm \infty} \boldsymbol{T}^{l 1}\left(y_{1}, \hat{\boldsymbol{y}}\right) \boldsymbol{e}_{1}=\mathbf{0} & \text { for } \hat{\boldsymbol{y}} \in \hat{Y}\end{cases}
$$

with the transmission or boundary conditions on $\partial I$ :

| elastic inclusions $(p=0)$ | elastic inclusion $(p>0)$ <br> holes |
| :---: | :---: |
| $\left[\boldsymbol{V}^{l 1}\right]=\left[\boldsymbol{T}^{l 1} \boldsymbol{n}\right]=\mathbf{0}$ | $\boldsymbol{T}^{l 1} \boldsymbol{n}=\mathbf{0}$ |

ii) for $(\mathrm{l}, \mathrm{k})=(1,2) ;(2,2) ;(3,2) ;(1,3) ;(2,3) ;(3,3)$,

$$
\begin{cases}\boldsymbol{d i v}_{y} \boldsymbol{T}^{l k}=\mathbf{0} & \text { in } Y(\text { resp. in } Y \backslash I)  \tag{26}\\ \boldsymbol{T}^{l k}=\boldsymbol{A} \boldsymbol{\gamma}_{y}\left(\boldsymbol{V}^{l k}\right) & \text { in } Y(\text { resp. in } Y \backslash I) \\ \boldsymbol{T}^{l k}\left(\hat{\boldsymbol{x}}, y_{1}, \frac{1}{2}, y_{3}\right) \boldsymbol{e}_{2}=\boldsymbol{T}^{l k}\left(\hat{\boldsymbol{x}}, y_{1},-\frac{1}{2}, y_{3}\right) \boldsymbol{e}_{2} & \text { on } \mathbb{R} \times \partial \hat{Y} \\ \boldsymbol{T}^{l k}\left(\hat{\boldsymbol{x}}, y_{1}, y_{2}, \frac{1}{2}\right) \boldsymbol{e}_{3}=\boldsymbol{T}^{l k}\left(\hat{\boldsymbol{x}}, y_{1}, y_{2},-\frac{1}{2}\right) \boldsymbol{e}_{3} & \text { on } \mathbb{R} \times \partial \hat{Y} \\ \boldsymbol{V}^{l k}\left(\hat{\boldsymbol{x}}, y_{1}, \frac{1}{2}, y_{3}\right)=\boldsymbol{V}^{l k}\left(\hat{\boldsymbol{x}}, y_{1},-\frac{1}{2}, y_{3}\right) & \text { on } \mathbb{R} \times \partial \hat{Y} \\ \boldsymbol{V}^{l k}\left(\hat{\boldsymbol{x}}, y_{1}, y_{2}, \frac{1}{2}\right)=\boldsymbol{V}^{l k}\left(\hat{\boldsymbol{x}}, y_{1}, y_{2},-\frac{1}{2}\right) & \text { on } \mathbb{R} \times \partial \hat{Y} \\ \lim _{y_{1} \rightarrow \pm \infty} \boldsymbol{T}^{l k}\left(y_{1}, \hat{\boldsymbol{y}}\right) \boldsymbol{e}_{1}=\mathbf{0} & \text { for } \hat{\boldsymbol{y}} \in \hat{Y}\end{cases}
$$

with the transmission or boundary conditions on $\partial I$ :

| elastic inclusions $(p=0)$ | elastic inclusion $(p>0)$ <br> holes |
| :---: | :---: |
| $\left[\boldsymbol{V}^{l k}\right]=\mathbf{0}$ | $\boldsymbol{T}^{l k} \boldsymbol{n}=-\left(A_{i j l k} n_{j}\right) \boldsymbol{e}_{i}$ |
| $\left[\boldsymbol{T}^{l k} \boldsymbol{n}\right]=\left(\left(\boldsymbol{A}^{I}-\boldsymbol{A}\right)\left(\boldsymbol{e}_{l} \otimes_{S} \boldsymbol{e}_{k}\right)\right) \boldsymbol{n}$ |  |

Remark 3: For the problems (24) and (26), the following asymptotic behavior holds:

$$
\begin{equation*}
\lim _{y_{1} \rightarrow \pm \infty} \boldsymbol{V}^{i j}\left(y_{1}, \hat{\boldsymbol{y}}\right)=\boldsymbol{V}^{i j \pm} \tag{28}
\end{equation*}
$$

Furthermore, the solutions of the cell problems are only defined up to a translation. The uniqueness of $\boldsymbol{V}^{i j}$ can be recovered by adding the following condition:

$$
\begin{equation*}
\boldsymbol{V}^{i j+}+\boldsymbol{V}^{i j-}=\mathbf{0} \tag{29}
\end{equation*}
$$

Remark 4: The inner term $\boldsymbol{\tau}^{0}$ is completely determined by the computation of the cell problems while (18) implies that $\boldsymbol{v}^{1}$ requires the calculation of the constant $\check{\boldsymbol{v}}$. This constant will be determined once $\boldsymbol{u}^{1}$ is known by the following relation:

$$
\begin{equation*}
\check{\boldsymbol{v}}(\hat{\boldsymbol{x}})=\frac{1}{2}\left(\boldsymbol{u}^{1}\left(0^{+}, \hat{\boldsymbol{x}}\right)+\boldsymbol{u}^{1}\left(0^{-}, \hat{\boldsymbol{x}}\right)\right) \tag{30}
\end{equation*}
$$

Let us also remark that in the case $p=1(24),(26)$ and (30) allow to compute $\boldsymbol{v}^{1}\left(\hat{\boldsymbol{x}}, y_{1}, \hat{\boldsymbol{y}}\right)$ only in $Y \backslash I$. In order to find the displacement
field $\boldsymbol{v}^{1}$ in all $Y$ we remark that in $I$ it is the unique solution of the elasticity problem with Dirichlet boundary conditions:

$$
\begin{cases}\boldsymbol{d i v}_{y} \boldsymbol{A}^{I} \boldsymbol{\gamma}_{y}\left(\boldsymbol{v}^{1}\right)=0 & \text { in } I  \tag{31}\\ \boldsymbol{v}^{1}=\frac{\partial u_{l}^{0}}{\partial x_{k}}(0, \hat{\boldsymbol{x}}) \boldsymbol{V}^{l k}(\boldsymbol{y})+\check{\boldsymbol{v}}(\hat{\boldsymbol{x}}) & \text { on } \partial I\end{cases}
$$

- outer approximation:

The outer term $\boldsymbol{u}^{1}$ is the solution of the following boundary value problem:

$$
\begin{cases}\boldsymbol{d i v} \boldsymbol{\sigma}^{1}=\mathbf{0} & \text { in } \Omega_{0} \backslash \omega  \tag{32}\\ \boldsymbol{\sigma}^{1}=\boldsymbol{A} \gamma\left(\boldsymbol{u}^{1}\right) & \text { in } \Omega_{0} \backslash \omega \\ \boldsymbol{\sigma}^{1} \boldsymbol{n}=\mathbf{0} & \text { on } \Gamma_{F} \\ \boldsymbol{u}^{1}=\mathbf{0} & \text { on } \Gamma_{0}\end{cases}
$$

and the transmissions conditions on $\omega$ :

$$
\left\{\begin{array}{l}
{\left[\boldsymbol{u}^{1}\right](\hat{\boldsymbol{x}})=\mathcal{G}_{\boldsymbol{d}}\left(\boldsymbol{u}^{0}(0, \hat{\boldsymbol{x}}) ;\left[\boldsymbol{V}^{i j}\right]^{\infty}\right)} \\
{\left[\boldsymbol{\sigma}^{1} \boldsymbol{e}_{1}\right](\hat{\boldsymbol{x}})=\boldsymbol{\mathcal { G }}_{n S}\left(\boldsymbol{u}^{0}(0, \hat{\boldsymbol{x}}) ; \int_{Y} \boldsymbol{T}^{i j}(\boldsymbol{y}) d \boldsymbol{y}\right)}
\end{array}\right.
$$

where

$$
\left[\boldsymbol{V}^{i j}\right]^{\infty}=\boldsymbol{V}^{i j+}-\boldsymbol{V}^{i j-}
$$

For the different types of inclusions considered, one has:

$$
\begin{equation*}
\mathcal{G}_{\boldsymbol{d}}=\frac{\partial u_{i}^{0}}{\partial x_{j}}(0, \hat{\boldsymbol{x}})\left[\boldsymbol{V}^{i j}\right]^{\infty} \tag{33}
\end{equation*}
$$

The expression of $\boldsymbol{\mathcal { G }}_{\boldsymbol{n} \boldsymbol{S}}$ depends on the inclusion:
i) in the elastic inclusions case one has:

$$
\begin{equation*}
\mathcal{G}_{n S}=\operatorname{div}_{x}\left(|I|\left(\boldsymbol{A}-\boldsymbol{A}^{I}\right) \gamma_{x}\left(\boldsymbol{u}^{0}(0, \hat{\boldsymbol{x}})\right)-\frac{\partial u_{i}^{0}}{\partial x_{j}}(0, \hat{\boldsymbol{x}}) \int_{Y} \boldsymbol{T}^{i j}(\boldsymbol{y}) d \boldsymbol{y}\right) \tag{34}
\end{equation*}
$$

ii) in the holes case one has:

$$
\begin{equation*}
\mathcal{G}_{n S}=\boldsymbol{d i v}_{x}\left(|I| \boldsymbol{A} \boldsymbol{\gamma}_{x}\left(\boldsymbol{u}^{0}(0, \hat{\boldsymbol{x}})\right)-\frac{\partial u_{i}^{0}}{\partial x_{j}}(0, \hat{\boldsymbol{x}}) \int_{Y} \boldsymbol{T}^{i j}(\boldsymbol{y}) d \boldsymbol{y}\right) \tag{35}
\end{equation*}
$$

Remark 5: In practice, an efficient way to implement the jumping conditions in problem (32) is to solve this problem by a domain decomposition type algorithm. The actual procedure will be detailed in section 3 .

### 2.3. Definition of the outer and inner approximations

Once determined the different terms $\mathbf{u}^{i}$ and $\mathbf{v}^{i}$ one can define an outer and an inner approximation of order $m$ :

$$
\begin{align*}
& \mathbf{u}_{m}^{\text {out }}:=\sum_{i=0}^{i=m} \varepsilon^{i} \mathbf{u}^{i}  \tag{36}\\
& \mathbf{u}_{m}^{i n n}:=\sum_{i=0}^{i=m} \varepsilon^{i} \mathbf{v}^{i} \tag{37}
\end{align*}
$$

The quality of these approximations increases with $m$; in our situation we only consider the cases $m=0$ and $m=1$.

## 3. Solution of the first order problem by domain decomposition

The first order problem (32) will be solved by a domain decomposition type algorithm. In order to describe this method we first recall (see e.g. [16]) the starting point for solving a standard linear elasticity problem by domain decomposition and then we adapt the solution procedure to this particular problem.

### 3.1. A linear elasticity model problem

As it is well known, under the usual symmetry and coercivity assumptions on $\boldsymbol{A}$, the following linear elasticity problem has a unique solution $\boldsymbol{u} \in$ $\boldsymbol{H}^{1}(\Omega)$ :

$$
\left\{\begin{array}{lll}
-\boldsymbol{d i v} \boldsymbol{\sigma} & =\mathbf{f}^{\Omega} &  \tag{38}\\
\text { in } \Omega \\
\boldsymbol{\sigma} & =\boldsymbol{A} \gamma(\boldsymbol{u}) & \text { in } \Omega \\
\boldsymbol{\sigma} \boldsymbol{n} & =\mathbf{F} & \\
\boldsymbol{o n} \Gamma_{F} \\
\boldsymbol{u} & =\mathbf{u}^{d} & \\
\text { on } \Gamma_{0}
\end{array}\right.
$$

Let the domain $\Omega$ be decomposed in two non overlapping subdomains $\Omega_{1}$ and $\Omega_{2}$ and let $\omega$ be the interface between the subdomains. The objective of the domain decomposition method is to replace the problem on the whole domain by a problem formulated on the interface. The two following conditions hold on the interface:

- continuity of the solution $\boldsymbol{u}$
- continuity of the normal stress

We'll impose one condition and verify the second. In the following to underline the (linear) dependence on $\boldsymbol{u}$ we set $\boldsymbol{\sigma}(\boldsymbol{u}):=\boldsymbol{A} \gamma(\boldsymbol{u})$. Let's define $\boldsymbol{\lambda}=\operatorname{Tr}(\boldsymbol{u})$ on the interface $\omega$ where $\boldsymbol{u}$ denotes the solution of problem (38). Solve the problem (38) is equivalent to solve, on each subdomain, the following problems

$$
\left\{\begin{array}{lll}
\operatorname{div} \boldsymbol{\sigma}\left(\boldsymbol{u}^{i}\right) & =\mathbf{f}^{\Omega} &  \tag{39}\\
\boldsymbol{\text { in }} \Omega_{i} \\
\boldsymbol{\sigma}\left(\boldsymbol{u}^{i}\right) & =\boldsymbol{A} \gamma\left(\boldsymbol{u}^{i}\right) & \\
\text { in } \Omega_{i} \\
\boldsymbol{\sigma}\left(\boldsymbol{u}^{i}\right) \boldsymbol{n} & =\mathbf{F} & \\
\mathbf{u}^{i} & =\mathbf{u}^{d} & \\
\mathbf{o n ~}_{F} \cap \Omega_{i} \\
\mathbf{u}^{i} & =\boldsymbol{\lambda} & \\
\text { on } \Gamma_{0} \cap \Omega_{i}
\end{array}\right.
$$

where $\boldsymbol{\lambda}$ is an additional unknown that must be determined in such a way that the normal stresses be continuous on the interface $\omega$, i. e. since $\boldsymbol{n}^{1}=-\boldsymbol{n}^{2}$ :

$$
\begin{equation*}
\boldsymbol{\sigma}\left(\boldsymbol{u}^{1}\right) \boldsymbol{n}^{1}+\boldsymbol{\sigma}\left(\boldsymbol{u}^{2}\right) \boldsymbol{n}^{2}=0 \tag{40}
\end{equation*}
$$

On each subdomain $\Omega_{i}$ we define the Steklov-Poincaré operator $S_{i}$ as follows: for $\boldsymbol{\lambda}$ given $\mathbf{u}_{\lambda}^{i}$ is the solution of

$$
\left\{\begin{array}{llll}
\boldsymbol{\operatorname { d i v } \boldsymbol { v }}\left(\mathbf{u}_{\lambda}^{i}\right) & =0 & & \text { in } \Omega_{i}  \tag{41}\\
\boldsymbol{\sigma}\left(\mathbf{u}_{\lambda}^{i}\right) & =\boldsymbol{A} \gamma\left(\mathbf{u}_{\lambda}^{i}\right) & & \text { in } \Omega \\
\boldsymbol{\sigma}\left(\mathbf{u}_{\lambda}^{i}\right) \boldsymbol{n}^{i} & =0 & & \text { on } \Gamma_{F} \cap \Omega_{i} \\
\mathbf{u}_{\lambda}^{i} & =\mathbf{u}^{d} & & \text { on } \Gamma_{0} \cap \Omega_{i} \\
\mathbf{u}_{\lambda}^{i} & =\boldsymbol{\lambda} & & \text { on } \omega
\end{array}\right.
$$

and $S_{i}$ is defined by:

$$
S_{i} \boldsymbol{\lambda}=\boldsymbol{\sigma}\left(\mathbf{u}_{\lambda}^{i}\right) \boldsymbol{n}^{i}
$$

where $\boldsymbol{n}^{i}$ denotes the outer normal to $\Omega_{i}$ on $\omega$.
Notice that using the linearity of (39) one has $\boldsymbol{u}^{i}=\boldsymbol{u}_{0}^{i}+\boldsymbol{u}_{\lambda}^{i}$ where $\boldsymbol{u}_{0}^{i}$ is solution of (39) with $\boldsymbol{u}_{0}^{i}=0$ on $\omega$. The continuity of the normal stress (40) gives

$$
\boldsymbol{\sigma}\left(\mathbf{u}_{\lambda}^{1}\right) \boldsymbol{n}^{1}+\boldsymbol{\sigma}\left(\boldsymbol{u}_{0}^{1}\right) \boldsymbol{n}^{1}+\boldsymbol{\sigma}\left(\mathbf{u}_{\lambda}^{2}\right) \boldsymbol{n}^{2}+\boldsymbol{\sigma}\left(\boldsymbol{u}_{0}^{2}\right) \boldsymbol{n}^{2}=0
$$

After introducing the Steklov-Poincaré operators we have

$$
S_{1} \boldsymbol{\lambda}+S_{2} \boldsymbol{\lambda}=-\boldsymbol{\sigma}\left(\mathbf{u}_{0}^{1}\right) \boldsymbol{n}^{1}-\boldsymbol{\sigma}\left(\mathbf{u}_{0}^{2}\right) \boldsymbol{n}^{2}
$$

and finally, setting $S=S_{1}+S_{2}$ the system on the interface becomes

$$
\begin{equation*}
S \boldsymbol{\lambda}=-\boldsymbol{\sigma}\left(\mathbf{u}_{0}^{1}\right) \boldsymbol{n}^{1}-\boldsymbol{\sigma}\left(\mathbf{u}_{0}^{2}\right) \boldsymbol{n}^{2} \tag{42}
\end{equation*}
$$

Remark 1: The operators $S_{i}$ are linear and continuous from $\boldsymbol{V}(\omega)$ into its dual $\boldsymbol{V}^{\prime}(\omega)$. The definition of these spaces depends on the geometry of $\omega$. When $\omega$ is a closed Lipschitz surface with no intersection with $\partial \Omega$ then $\boldsymbol{V}(\omega)=\boldsymbol{H}^{1 / 2}(\omega)$. Since $\boldsymbol{H}^{1 / 2}(\omega) \subset \boldsymbol{L}^{2}(\omega):=\boldsymbol{H}$ with continuous and dense imbedding one can take $\boldsymbol{H} \simeq \boldsymbol{H}^{\prime}$ as pivot space and then $\boldsymbol{V}^{\prime}(\omega)=\boldsymbol{H}^{-1 / 2}(\omega)$. When $\omega \cap \partial \Omega \neq \varnothing$ then an analogous construction is also possible but presents some technical difficulties.

Remark 2: $S$ is a symmetric positive defined operator which, after discretization, gives the Schur complement. This operator is not known directly and is rather difficult to construct but the product $S \boldsymbol{\lambda}$ is easy to compute as it requires the solution of one problem by subdomain. It is thus convenient to solve the linear system by an iterative method as conjugate gradient or GMRES. GMRES is preferred for its robustness. In addition we'll note that even when CG is used a re-orthogonalisation is mandatory for such problems [17].

Remark 3: What was described in this section is only the starting point for a primal domain decomposition method. Several choices of preconditioners are available and the efficiency of the algorithm is indeed strongly depending on this choice. There is a vast literature on the subject, see e.g. [16]. We will use the Neumann-Neumann algorithm which was intensively studied and proved to be robust, [16], [18]. An alternative is to use a dual method of FETI type [19].

### 3.2. Solution of the first order problem

The script 1 which indicates the first order problem is omitted hereafter. The generic form of the first order problem (32) is given by:

$$
\left\{\begin{array}{lll}
-\boldsymbol{\operatorname { d i v } \boldsymbol { v } ( \boldsymbol { u } )} & =\mathbf{0} & \text { in } \Omega  \tag{43}\\
\boldsymbol{\sigma}(\boldsymbol{u}) & =\boldsymbol{A} \gamma(\boldsymbol{u}) & \text { in } \Omega \\
\boldsymbol{\sigma}(\boldsymbol{u}) \boldsymbol{n} & =\mathbf{0} & \text { on } \partial \Omega_{F} \\
\boldsymbol{u} & =\mathbf{0} & \text { on } \partial \Omega_{u} \\
{[\boldsymbol{u}]} & =\mathcal{G}_{d} & \text { on } \omega \\
{[\boldsymbol{\sigma}(\boldsymbol{u}) \boldsymbol{n}]} & =\mathcal{G}_{\boldsymbol{n} \boldsymbol{S}} & \text { on } \omega
\end{array}\right.
$$

where $\mathcal{G}_{\boldsymbol{d}}$ and $\mathcal{G}_{n \boldsymbol{S}}$ denote the gap in displacements, respectively normal stresses on $\omega$. These data are known and can be computed once the zero order problem is solved. It should noted that the solution $\boldsymbol{u}$ of (43) does not belong to $\boldsymbol{H}^{1}(\Omega)$. More precisely, let be $\Omega_{1}:=\Omega^{+}, \Omega_{2}:=\Omega^{-}$and :

$$
\begin{equation*}
\boldsymbol{Z}_{0}:=\left\{\boldsymbol{z} \in \boldsymbol{L}^{2}(\Omega) ; \boldsymbol{\operatorname { d i v }} \boldsymbol{A} \boldsymbol{\gamma}\left(\left.\boldsymbol{z}\right|_{\Omega_{i}}\right)=0 ;\right\} ; \tag{44}
\end{equation*}
$$

then $\boldsymbol{u} \in \boldsymbol{Z}_{0}$. Hence the transmission conditions $[\boldsymbol{u}]=\mathcal{G}_{\boldsymbol{d}}$ and $[\boldsymbol{\sigma}(\boldsymbol{u}) \boldsymbol{n}]=$ $\mathcal{G}_{n \boldsymbol{S}}$ on $\omega$ have to be taken in a weak sense adapting the methods of LionsMagenes [20] In the Appendix we briefly recall how this can be done.

The actual computation of $\boldsymbol{\mathcal { G }}_{\boldsymbol{d}}$ and $\boldsymbol{\mathcal { G }}_{\boldsymbol{n} \boldsymbol{S}}$ will be described later on, see 3.3; the objective here is to transform the problem in order to obtain a domain decomposition as in (39).

The scripts in the following formulae indicates the subdomain number. Let $\boldsymbol{z}^{i}$ be the solution of the following problem:

$$
\left\{\begin{array}{lll}
-\boldsymbol{d i v} \boldsymbol{\sigma}\left(\boldsymbol{z}^{i}\right) & =\mathbf{0} & \text { in } \Omega_{i}  \tag{45}\\
\boldsymbol{\sigma}\left(\boldsymbol{z}^{i}\right) & =\boldsymbol{A} \gamma\left(\boldsymbol{z}^{i}\right) & \text { in } \Omega_{i} \\
\boldsymbol{\sigma}\left(\boldsymbol{z}^{i}\right) \boldsymbol{n} & =\mathbf{0} & \\
\boldsymbol{z}^{i} & =\mathbf{0} & \text { on } \partial \Omega_{F} \cap \Omega_{i} \\
\boldsymbol{z}^{i} & =\mathcal{G}_{\boldsymbol{d}} & \\
\text { on } \partial \Omega_{u} \cap \Omega_{i} \\
& \text { on } \omega
\end{array}\right.
$$

Note that these are two independent problems. Thereafter, on each subdomain, we will look for a solution $\boldsymbol{u}^{i}$ which takes the following form:

$$
\boldsymbol{u}^{i}=\boldsymbol{w}^{i}+\beta_{i} \boldsymbol{z}^{i}
$$

with $\beta_{i}$ two real numbers conveniently chosen. This can be done because the operator considered is linear. With these notations the new unknown of the problem is $\boldsymbol{w}^{i}$. Notice that $-\operatorname{div} \boldsymbol{\sigma}\left(\boldsymbol{w}^{i}\right)=0$ and that the transmission conditions on $\omega$ for $\boldsymbol{w}^{i}$ are given by:

$$
\left\{\begin{array}{l}
{[\boldsymbol{w}]=[\boldsymbol{u}]-\beta_{1} \mathcal{G}_{\boldsymbol{d}}+\beta_{2} \mathcal{G}_{\boldsymbol{d}}=\left(1-\beta_{1}+\beta_{2}\right) \mathcal{G}_{\boldsymbol{d}}} \\
{[\boldsymbol{\sigma}(\boldsymbol{w}) \boldsymbol{n}]=[\boldsymbol{\sigma}(\boldsymbol{u}) \boldsymbol{n}]+\beta_{1} \boldsymbol{\sigma}\left(\boldsymbol{z}^{1}\right) \boldsymbol{n}-\beta_{2} \boldsymbol{\sigma}\left(\boldsymbol{z}^{2}\right) \boldsymbol{n}=\boldsymbol{\mathcal { G }}_{n \boldsymbol{S}}+\beta_{1} \boldsymbol{\sigma}\left(\boldsymbol{z}^{1}\right) \boldsymbol{n}-\beta_{2} \boldsymbol{\sigma}\left(\boldsymbol{z}^{2}\right) \boldsymbol{n}}
\end{array}\right.
$$

If we choose $1-\beta_{1}+\beta_{2}=0$ then $\boldsymbol{w}$ is continuous on the interface $\omega$ but the normal stress is not and it is the unique non-homogeneous data. As in section 3.1 using the Steklov-Poincaré operator the problem to solve on the interface is

$$
S \boldsymbol{\lambda}=\mathcal{G}_{n S}+\beta_{1} \boldsymbol{\sigma}\left(\boldsymbol{z}^{1}\right) \boldsymbol{n}^{1}-\beta_{2} \boldsymbol{\sigma}\left(\boldsymbol{z}^{2}\right) \boldsymbol{n}^{2}
$$

which can also be written as:

$$
\begin{equation*}
S \lambda=-\boldsymbol{\sigma}\left(\boldsymbol{w}_{0}^{1}\right) \boldsymbol{n}^{1}-\boldsymbol{\sigma}\left(\boldsymbol{w}_{0}^{2}\right) \boldsymbol{n}^{2}+\mathcal{G}_{\boldsymbol{n} \boldsymbol{S}}+\beta_{1} S_{1} \mathcal{G}_{\boldsymbol{d}}-\beta_{2} S_{2} \mathcal{G}_{\boldsymbol{d}} \tag{46}
\end{equation*}
$$

Notice that equations (42) and (46) differ only on the right hand side. Thus as the operator does not change, the same algorithms may be used to solve the problem with the same performance and no additional analysis is required to prove efficiency.

### 3.3. Implementation issues

In the framework of domain decomposition algorithms, the implementation of the problem (43) is straightforward as it only requires the solution of an additional problem by subdomain. This problem is of the same type as the standard ones solved by the algorithm.

If we come back to the original equation into consideration (32) the only remaining problem is to compute the input data for the domain decomposition algorithm, that is the right hand sides for the jumps.

$$
\left\{\begin{align*}
\mathcal{G}_{\boldsymbol{d}} & =\mathcal{G}_{\boldsymbol{d}}\left(\frac{\partial u_{i}}{\partial x_{j}}(0, \hat{\boldsymbol{x}}) ;\left[\boldsymbol{V}^{i j}\right]^{\infty}\right)  \tag{47}\\
\mathcal{G}_{n S} & =\mathcal{G}_{n S}\left(\frac{\partial^{2} u_{i}}{\partial x_{\alpha} \partial x_{j}}(0, \hat{\boldsymbol{x}}) ; \int_{Y} \boldsymbol{T}^{i j}(\boldsymbol{y}) d \boldsymbol{y}\right)
\end{align*}\right.
$$

From a mathematical point of view these quantities are data as they depend on the solution of the zero order problem. From a computational point of view this task is rather delicate. Indeed the solution of the zero order problem was obtained by a standard finite element method. So the solution $\boldsymbol{u}^{0}$ is $\mathcal{C}^{0}$ that means no continuity of the derivatives. The actual computations require first order derivatives for stresses that means second order derivatives for displacements. As it is well known, see e.g [21] Chap. 4, Sec 4.2, the calculation of derivatives numerically is a hazardous operation since it is inherently sensitive, as small perturbations in data can cause large changes in result (in other words numerical differentiation is ill-conditioned). For this reason, to approximate derivative of a function whose values are known only at discrete set of points, a good approach is to fit some smooth function to given data and then differentiate the approximating function. If the given data are sufficiently smooth, then interpolation may be appropriate; here $\boldsymbol{u}^{0} \in \mathcal{C}^{0}$ and hence it is worth regularizing before computing
derivatives. Let us remark, with [21], Chap 6, Sect 6.7 that the choice of the better approximation "is in the realm of the art rather than in the science of numerical analysis. Intuition - meaning experience, really - and general physical knowledge of the problem must be used."

## - computation of $\mathcal{G}_{d}$

In practice the value of the displacement derivative at a node is a weighted average of the values of the different elements containing the node.

## - computation of $\mathcal{G}_{n S}$

Let's first notice that, for the sake of simplicity, all equations appear as partial differential equations, instead of in variational form. What is needed in practice, once the variational form is introduced, is $\int_{\Gamma} \mathcal{G}_{n S} v d v$. As the integral is computed element by element at a first glance it is not mandatory to regularize before integrating. Nevertheless our choice was to use the same regularization as for the computation of $\mathcal{G}_{\boldsymbol{d}}$.

## 4. Validation

The objective of the validation is to study, in an appropriate norm, the error between the exact solution and the solution obtained by asymptotic expansions (zero order and first order). This error depends both on $\boldsymbol{u}_{h}^{\varepsilon}$ and $h$ the discretisation step. Our interest is to focus on the dependence of the error of $\varepsilon$ and $h$. So for all the computations the approximation error (which depends on $h$ ) has to be negligible, in other words $h$ has to be much smaller then $\varepsilon$. Hence there are several difficulties in the validation process:
i) The domain depends on the value of $\varepsilon$. For the test problem and for decreasing values of $\varepsilon$ the number of heterogeneities increases, thus the domain changes and it is impossible to obtain an uniform refinement of the mesh with respect to $\varepsilon$.
ii) The analytical solution of the original test problem is not known. We use instead a reference solution $\boldsymbol{u}_{h}^{\varepsilon}$ obtained with standard $P 2$ finite elements on a suitable mesh $\Omega_{h}^{\varepsilon}$, fine enough so that the error between the exact solution and the computed one is negligible in comparison
with the error due to the use of asymptotic expansions. Let us recall that when the solution $\boldsymbol{u}^{\varepsilon}$ has enough regularity the $H^{1}$ norm is used to measure the error and one has, for a fixed $\varepsilon$ and for a regular mesh with discretization step $h:\left\|\boldsymbol{u}^{\varepsilon}-\boldsymbol{u}_{h}^{\varepsilon}\right\|_{H^{1}\left(\Omega^{\varepsilon}\right)} \leq C h^{2}$. The solution of our target problem is not regular enough, this is why an $L^{2}$ norm will be preferred as detailed here in Sect. 4.3
iii) The definition of $\Omega^{i n, \varepsilon}$ depends on $\eta(\varepsilon)$. The function $\eta(\varepsilon)$ is not given, it must only verify (3) and it has a crucial importance on the overlap.
iv) The boundary of the domain $\Omega$ has corners: the numerical solution of the different problems has boundary layers whose effects can perturb the quality of the results.

Taking into account these difficulties the validation is achieved trough the following steps:

1. Description of the test problem
2. Numerical solution of the cell problem
3. Validation at the macroscopic scale
4. Validation at the microscopic scale

### 4.1. Description of the test problem

Let $\Omega=(-L, L) \times(-H, H)$ be a plane domain containing $\mathcal{N}(\varepsilon)=2 H \varepsilon^{-1}$ identical discs of radius $\varepsilon R$, arranged periodically (with period $\varepsilon$ ), along the line $\omega$ of equation $x_{1}=0$; let us remark that hence $d=2 R$. Outside the heterogeneities the structure is constituted of an elastic homogeneous isotropic material, characterized by its Young modulus $E$ and Poisson coefficient $\nu$. The boundary $\Gamma_{0}$ of the structure is clamped and a density $\boldsymbol{F}$ of linear force is applied on the complementary part $\Gamma_{F}$. There are no body forces (see Fig. 6 ). We will consider a 2D plane stress problem. The heterogeneities can be holes or elastic inclusions; in this case the elastic homogeneous isotropic material forming the heterogeneities is characterized by the Young modulus $E^{\varepsilon, I}=\varepsilon^{p} E^{I}$ and the Poisson coefficient $\nu^{\varepsilon, I}=\nu$. In all cases the problem is solved by a standard $P 2$ finite element method and we take $L=1$ and $H=0.5$.

Figure 6: Test Problem

### 4.2. Numerical solution of the cell problems

The transmission conditions of the first-order outer problem (32) depend on the function $f\left(y_{1}\right)$ and on the solution of the cell problems posed on the unbounded domain $Y$. In practice we will use a bounded domain $Y_{L^{\infty}}=$ $] \frac{-L^{\infty}}{2}, \frac{L^{\infty}}{2}[\times] \frac{-1}{2}, \frac{1}{2}\left[\right.$ with a $L^{\infty}>0$ big enough. The domain $Y_{L^{\infty}}$ contains a circular heterogeneity of radius $R$ and centred at the origin. At first we numerically study, in the case of elastic inclusions with $p=0$ and in the case of holes (or of elastic inclusions with $p>1$ ), the robustness of the coefficients $\left[\boldsymbol{V}^{i j}\right]$ and $\int_{Y} \boldsymbol{T}^{i j} d \boldsymbol{y}$ with respect to:
i) the size $L^{\infty}$ needed to approximate $Y$ for the computation of $\boldsymbol{V}^{i j}$,
ii) the choice of the function $f\left(y_{1}\right)$,
iii) the choice of the radius $R$,
iv) In the case of elastic inclusions with $p=0$ the dependence on $E^{I} / E$.

The cell problems (24)-(27) are solved by a standard P2 finite elements method.

### 4.2.1. Dependence on $L^{\infty}$

The cell problems are solved by gradually increasing the length value $L^{\infty}$. As odd function of class $\mathcal{C}^{2}(\mathbb{R})$ satisfying (19) a polynomial of order 5 for $a \leq\left|y_{1}\right| \leq b$ is choosed. The results are obtained with $R=0.30, a=1.5$, $b=3 a, E=1, \nu=0.25$ (and also with $E^{I}=0.5, \nu^{I}=0.25$ in the case $p=0$ ). They show that for $L^{\infty} \geq 2.01 b$ the coefficients $\left[\boldsymbol{V}^{i j}\right]$ and $\int_{Y} \boldsymbol{T}^{i j} d \boldsymbol{y}$ are stable (see Tables 1, 2, 3 and 4 below where only non-zero coefficients are given).

Table 4: Variation of $\int_{Y} T_{k l}^{i j} d \boldsymbol{y}$ with $L^{\infty}$ : holes case

### 4.2.2. Dependence on $f$

We consider two functions $f_{1}\left(y_{1} ; a, b\right)$ et $f_{2}\left(y_{2} ; a, b\right)$ which satisfy the condition (19) (we give their definition only for $y_{1}>0$ ):

|  | for $a \leq y_{1} \leq b$ |
| :---: | :---: |
| $f_{1}\left(y_{1} ; a, b\right)$ | $\left(y_{1}-a\right)^{3}\left(A y_{1}^{2}+B y_{1}+C\right)$ |
| $f_{2}\left(y_{1} ; a, b\right)$ | $\left(y_{1}-a\right)^{3}\left(\alpha y_{1}^{3}+\beta y_{1}^{2}+\gamma y_{1}+\delta\right)$ |

The comparison of $\left[\boldsymbol{V}^{i j, f_{1}}\right]$ with $\left[\boldsymbol{V}^{i j, f_{2}}\right]$ and of $\int_{Y} \boldsymbol{T}^{i j, f_{1}} d \boldsymbol{y}$ with $\int_{Y} \boldsymbol{T}^{i j, f_{2}} d \boldsymbol{y}$ confirms the independence of these coefficients from the choice of $f$. The values of the coefficients calculated for both $f_{1}$ and $f_{2}$ are given in the case of elastic inclusions with $p=0$ in Tab. 5 (only non-zero coefficients are given) where $a=0.5, b=4 a, E=1, E^{I}=0.5, \nu=\nu^{I}=0.25, R=0.30$ and $L^{\infty}=10$. The analogous situation for the holes is given in Tab. 6 where : $a=0.5, b=4 a, E=1, \nu=0.25, R=0.30$ and $L^{\infty}=10$.

Note that condition (19) implies that the function $f$ is involved in the loading in problems $P^{11}$ and $P^{21}$. For both problems, the influence of the function $f$ on this loading is shown in figures (7), (8), (9) and (10).

| $\left[V_{1}^{11}\right]^{\infty}$ |  | $\left[V_{2}^{21}\right]^{\infty}$ |  | $\int_{Y} T_{22}^{11}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $f_{1}$ | $f_{2}$ | $f_{1}$ | $f_{2}$ | $f_{1}$ | $f_{2}$ |

Table 6: Result of the coefficient calculation: holes case

### 4.2.3. Dependence on $R$

It is also interesting to study the dependence of $\left[\boldsymbol{V}^{i j}\right]^{\infty}$ and of $\int_{Y} \boldsymbol{T}^{i j} d \boldsymbol{y}$ on the radius $R$. In the case of holes (or equivalently of elastic inclusions with $p>0$ ) the influence can be very important when the radius become almost of the same order as the period or becomes very small as one can see in Tables 7 and 8.

| $R$ | $\left[V_{1}^{11}\right]^{\infty}$ | $\left[V_{2}^{12}\right]^{\infty}$ | $\left[V_{2}^{21}\right]^{\infty}$ | $\left[V_{1}^{22}\right]^{\infty}$ |

Figure 7: loading for $P^{11}: f=f_{1}$

Figure 8: loading for $P^{11}: f=f_{2}$

For these comparisons we have chosen $a=1.5, b=3 a, E=1, \nu=0.25$ and $L^{\infty}=10$. The corresponding results obtained for elastic inclusion with $p=0$ when $a=1.5, b=3 a, E=1, \nu=0.25, E^{I}=0.5, \nu^{I}=0.25$ and $L^{\infty}=10$ are given in Table 9 and Table 10.

### 4.2.4. Dependence on $E^{I} / E$ in the case of elastic inclusions with $p=0$

In the case of elastic inclusions with $p=0$ it is also interesting to study the dependence of $\left[\boldsymbol{V}^{i j}\right]^{\infty}$ and of $\int_{Y} \boldsymbol{T}^{i j} d \boldsymbol{y}$ on $E^{I} / E$. We have considered the case where $\mathrm{a}=1.5, \mathrm{~b}=3^{*} \mathrm{a}, R=0.30, \mathrm{E}=1, \nu=0.25, \nu^{I}=0.25, L^{\infty}=10$. It is interesting to remark the difference of situations when $E^{I} / E$ decreases or increases, see Tables 11, 12. When $E^{I} / E>1$ (i.e. the material of the inclusion is more rigid than the surrounding material) then the coefficients $\left[\boldsymbol{V}^{i j}\right]^{\infty}$ become all negative and, in absolute value, monotonically increasing. In all other situations these coefficients are positive.

### 4.3. Validation at the macroscopic scale

The validation at the macroscopic scale should be performed by comparing $\boldsymbol{u}_{0}^{\text {out }}:=\boldsymbol{u}^{0}$ and $\boldsymbol{u}_{1}^{\text {out }}:=\boldsymbol{u}^{0}+\varepsilon \boldsymbol{u}^{1}$ with $\boldsymbol{u}^{\varepsilon}$; however we can only compute $\boldsymbol{u}_{h}^{\varepsilon}, \boldsymbol{u}_{h}^{0}$ and $\boldsymbol{u}_{h}^{1}$. Since $\boldsymbol{u}^{1}$ does not belong to $\boldsymbol{H}^{1}(\Omega)$ but only to $\boldsymbol{Z}_{0} \subset \boldsymbol{L}^{2}(\Omega)$ (as it has been observed in Sect. 3.2) the relative norm errors $\left\|\boldsymbol{u}_{h}^{\varepsilon}-\boldsymbol{u}_{0, h}^{\text {out }}\right\| /$ $\left\|\boldsymbol{u}_{h}^{\varepsilon}\right\|$ and $\left\|\boldsymbol{u}_{h}^{\varepsilon}-\boldsymbol{u}_{1, h}^{\text {out }}\right\| /\left\|\boldsymbol{u}_{h}^{\varepsilon}\right\|$ are computed using the norm of $\boldsymbol{L}^{2}\left(\Omega^{\varepsilon}\right)$. The

Table 12: Dependence on $E^{I} / E$ for $\int_{Y} \boldsymbol{T}^{i j} d \boldsymbol{y}$

Figure 9: loading for $P^{21}: f=f_{1}$

Figure 10: loading for $P^{21}: f=f_{2}$
numerical reference solution $\boldsymbol{u}_{h}^{\varepsilon}$ is computed on a mesh $\Omega_{h}^{\varepsilon}$ and the numerical asymptotic solutions $\boldsymbol{u}_{0, h}^{\text {out }}:=\boldsymbol{u}_{h}^{0}$ and $\boldsymbol{u}_{1, h}^{\text {out }}:=\boldsymbol{u}_{h}^{0}+\varepsilon \boldsymbol{u}_{h}^{1}$ are computed on a coarse mesh $\Omega_{h}$. Hence in order to compare these numerical approximations one has at first to determine by interpolation the nodal values of $\boldsymbol{u}_{0, h}^{\text {out }}$ and of $\boldsymbol{u}_{1, h}^{\text {out }}$ on $\Omega_{h}^{\varepsilon}$. We have the following obvious estimate for $i=0,1$ :

$$
\begin{equation*}
\left\|\boldsymbol{u}^{\varepsilon}-\boldsymbol{u}_{i}^{\text {out }}\right\| \leq\left\|\boldsymbol{u}^{\varepsilon}-\boldsymbol{u}_{h}^{\varepsilon}\right\|+\left\|\boldsymbol{u}_{h}^{\varepsilon}-\boldsymbol{u}_{i h}^{\text {out }}\right\|+\left\|\boldsymbol{u}_{i h}^{\text {out }}-\boldsymbol{u}_{i}^{\text {out }}\right\| \tag{48}
\end{equation*}
$$

Since we compute just the term $\left\|\boldsymbol{u}_{h}^{\varepsilon}-\boldsymbol{u}_{i}^{\text {out }}\right\|$ we should choose a discretization step $h$ so that the approximation errors $\left\|\boldsymbol{u}^{\varepsilon}-\boldsymbol{u}_{h}^{\varepsilon}\right\|$ and $\left\|\boldsymbol{u}_{i}^{\text {out }}-\boldsymbol{u}_{i}^{\text {out }}\right\|$ be negligible with respect to $\varepsilon$. This is a priori a difficult task: the abstract error estimates results on FEM approximations depend on the regularity of the solution (see [22]). For instance, since we use P2 finite elements, the regularity of $\boldsymbol{u}^{0}$ implies that for the norms in $L^{2}(\Omega)$ we have the estimate:

$$
\begin{equation*}
\left\|\boldsymbol{u}_{0}^{\text {out }}-\boldsymbol{u}_{0}^{\text {out }}\right\|=\left\|\boldsymbol{u}_{h}^{0}-\boldsymbol{u}^{0}\right\| \leq C h^{3} \tag{49}
\end{equation*}
$$

However $\boldsymbol{u}^{\varepsilon}$ and $\boldsymbol{u}^{1}$ are not so regular that an analogous of (49) be valid. In any case it must be pointed out that for small values of $\varepsilon$ it is too expensive to choose discretization steps such that the approximation errors be negligible with respect to $\varepsilon$. For this reasons a judicious choice of feasible and reasonable meshes is required. In most of the computations we take
a regular triangulation $\Omega_{h}$ of $\Omega$ with mesh-size $h=1 / 120$ (and 57600 elements P2-Lagrange) and a varying mesh for $\Omega_{h}^{\varepsilon}$ where the largest mesh-size is $h_{\varepsilon}=1 / 80$. In the case of holes, we get 32240 elements P2-Lagrange when $\varepsilon=0.05,54240$ when $\varepsilon=0.025$ and 78240 when $\varepsilon=0.0125$. In the case of elastic inclusions, we get 35440 elements P2-Lagrange when $\varepsilon=0.05$, 59200 when $\varepsilon=0.025$ and 88480 when $\varepsilon=0.0125$.

The numerical results for the different situations (holes, elastic inclusions with $p=0$ and $p=1$ ) are given in tables 13,14 and 15 . It appears immediately that in all situations $\left\|\boldsymbol{u}_{h}^{\varepsilon}-\boldsymbol{u}_{0, h}^{o u t}\right\| /\left\|\boldsymbol{u}_{h}^{\varepsilon}\right\| \approx \varepsilon$ and $\left\|\boldsymbol{u}_{h}^{\varepsilon}-\boldsymbol{u}_{1, h}^{\text {out }}\right\| /$ $\left\|\boldsymbol{u}_{h}^{\varepsilon}\right\| \approx \varepsilon^{m}$ with $m \gtrsim 1.5$.

Table 15: Relative errors : elastic inclusions with $p=1$ and $E^{I}=0.5 E$

Another peculiarity of the matched asymptotic expansion method is that the quality of the outer approximation increases far from the surface $\omega$ where the heterogeneities are concentrated. In order to test that $\boldsymbol{u}_{1, h}^{\text {out }}$ gives indeed a better approximation of $\boldsymbol{u}_{h}^{\varepsilon}$ far from the heterogeneities (and obviously far from the singularities of $\boldsymbol{u}_{h}^{\varepsilon}$ induced by the geometry of $\Omega$ or by the loading) we introduce for $\delta \geq 0$ the domains $\hat{\Omega}^{\text {out }}(\delta):=\left\{\boldsymbol{x}=\left(x_{1}, x_{2}\right) \in \Omega^{\varepsilon} ;\left|x_{1}\right| \geq \frac{\delta}{2}\right\}$. We then computed the relative errors norm in $\boldsymbol{L}^{2}\left(\hat{\Omega}^{\text {out }}(\delta)\right)$ for different values of $\varepsilon$ in the case of the holes and in the case of elastic inclusions with $p=0$ and $p=1$ (see tables 16,17 and 18 ). The numerical results not only agree with this property of the matched asymptotic expansion method but also prove that if one takes the same domain $\hat{\Omega}^{\text {out }}(\delta)$ then the error due to the approximation decreases with $\varepsilon$ with an order $\gtrsim 1.5$ : see e.g. the values of $\delta / \varepsilon=1$, resp. $=2$, resp. $=4$ when $\varepsilon=0.05$, resp. $=0.025$, resp. $=0.0125$ or analogous triplet of values.

The correction of $\boldsymbol{u}^{0}$ by $\varepsilon \boldsymbol{u}^{1}$ is of order $\varepsilon$. One might then say that

the need to calculate $\boldsymbol{u}^{1}$ depends on the precision with which one wishes to estimate $\boldsymbol{u}^{\varepsilon}$. However it is important to remember that $\boldsymbol{u}_{0}^{\text {out }}$ and $\boldsymbol{u}_{1}^{\text {out }}$ do not provide any information about inclusions and the approximation of the behaviour of $\boldsymbol{u}^{\varepsilon}$ in the layer $\Omega^{i n, \varepsilon}$ by the inner term $\boldsymbol{v}^{0}+\varepsilon \boldsymbol{v}^{1}$ requires the calculation of $\boldsymbol{u}^{1}$ to recover the uniqueness of $\boldsymbol{v}^{1}$ (see remark 2.2.1). Therefore the implementation and validation of the computation of $\boldsymbol{u}_{h}^{1}$ is necessary.

### 4.4. Validation at the microscopic scale

Let us remark at first that as shown in (16) $\boldsymbol{u}_{0, h}^{i n n}:=\boldsymbol{u}_{h}^{0}$ is independent from the inclusions. Hence this validation will be realized studying the relative error norms for $\boldsymbol{u}_{1, h}^{i n n}$ in a suitably defined domain $\Omega_{h}^{i n}(\varepsilon)$ whose thickness is given by the function $\eta(\varepsilon)$ which is not explicitly defined. As has been previously remarked at the beginning of sect. 4.3 , in order to compute these relative error norms one must determine the nodal values of $\boldsymbol{u}_{1, h}^{i n n}:=\boldsymbol{v}_{h}^{0}+\varepsilon \boldsymbol{v}_{h}^{1}$ on the mesh $\Omega_{h}^{\varepsilon}$ where the numerical reference solution $\boldsymbol{u}_{h}^{\varepsilon}$ is defined. We use the same meshes as for the macroscopic scale validation. In order to evaluate $\eta(\varepsilon)$ at first we compute for increasing values of $\eta>0$ the relative errors $\frac{\left\|\boldsymbol{u}_{h}^{\varepsilon}-\boldsymbol{u}_{1 h}^{i n n}\right\|_{L^{2}}}{\left\|\boldsymbol{u}_{h}^{\varepsilon}\right\|_{L^{2}}}$ in the domain $\Omega^{\eta, \varepsilon}=\left\{\boldsymbol{x}=\left(x_{1}, x_{2}\right) \in \Omega^{\varepsilon}:\left|x_{1}\right|<\frac{\eta}{2}\right\}$. Then $\eta(\varepsilon)$ will be in the interval between the value of $\eta$ such that this relative errors is minimum and the next value of $\eta$. In the case of holes the results are given in table 19. We also give in table 20 the estimated value of $\eta(\varepsilon)$ and of $\eta(\varepsilon) / \varepsilon$. For elastic inclusions with $p=0$ and $E^{I}=0.5 E$ the analogous results are given in tables 21 and 22. All these results are in agreement with the asymptotic assumptions, in particular with (3).

Figure 18: Comparison of $\boldsymbol{\sigma}_{h}^{\varepsilon, V M}$ (left) and $\boldsymbol{\tau}_{h}^{0, V M}$ (right) in $\mathcal{U}_{4}^{\varepsilon}$, elastic inclusion with $E^{I} / E=4$

Important informations on the behaviour of the structure are given by the stress field, in particular near the inclusions. In order to validate our asymptotic model it is therefore important to compare $\boldsymbol{\sigma}_{h}^{\varepsilon}$ and $\boldsymbol{\tau}_{\boldsymbol{h}}{ }^{0}$ near the inclusions. In the following this comparison is done for $\varepsilon=0.0125$, for both holes and elastic inclusions with $p=0$. We consider 4 inclusions $\mathcal{I}_{k}^{\varepsilon}$, $k=1,2,3$ and 4 , located in $\Omega^{\varepsilon}$ by their center of coordinates $\left(x_{1}=0, x_{2}^{k}\right)$ with $x_{2}^{k}=-20 \varepsilon,-\varepsilon, 10 \varepsilon$ and $30 \varepsilon$. Let $\boldsymbol{\sigma}_{h}^{\varepsilon, V M}$ (resp. $\boldsymbol{\tau}_{h}^{0, V M}$ ), denote the equivalent Von Mises stress of $\boldsymbol{\sigma}_{h}^{\varepsilon}$ (resp. $\boldsymbol{\tau}_{\boldsymbol{h}}{ }^{0}$ ). We plot the isovalues of $\boldsymbol{\sigma}_{h}^{\varepsilon, V M}$ in a suitable neighbourhood $\mathcal{U}_{k}^{\varepsilon}$ of each inclusion and we compare them to the isovalues of $\boldsymbol{\tau}_{h}^{0, V M}$. The results in the case of holes are given in fig. 11, 12,13 and 14 ; in the case of elastic inclusions with $p=0$ and $E^{I} / E=4$ in fig. $15,16,17$ and 18.

## 5. Concluding remarks

The numerical algorithm which combines matched asymptotic expansions and domain decomposition is an efficient tool to effectively solve multi-scale problems with a large number of heterogeneities. The zero order problems do not consider the heterogeneities and hence give no information on the microscopic behaviour near the heterogeneities. However the first order problems allow to obtain the necessary informations in order to reconstruct displacement and stress fields around the heterogeneities.

As in the classical homogenization [3], [4], [5], [6] the coefficients useful for the first order problems can be easily computed once for all as solutions
of cell problems. Indeed these cell problems do not depend on the forces and displacements imposed on the whole structure, but only on the geometry of the heterogeneities and on the material properties. Many computations have been done in order to stress the dependence of these coefficients on the geometric and materials parameters: for instance the diameter in the case of the holes and the relative strength for elastic inclusions.

The zeroth and the first order approximations are computed on a structure without the heterogeneities using a coarse mesh simple to obtain. The numerical validation proves that the informations so obtained are as good as the informations obtained on the real structure on a very fine and difficult to realize mesh.

At last let us emphasize that the numerical experiments agree with the assumptions of the ansatz at the basis of the matched asymptotic expansion method.

## Appendix

In order to avoid inessential technicalities we consider the following simplified form of the first order problem (32) where we assume that $\omega$ is at least of class $\mathcal{C}^{2}$, that $\omega \cap \partial \Omega=\emptyset$ and that $\partial \Omega_{u}=\partial \Omega$ :

$$
\left\{\begin{array}{lll}
-\boldsymbol{\operatorname { d i v } \boldsymbol { v } ( \boldsymbol { u } )} & =\boldsymbol{f} & \text { in } \Omega  \tag{50}\\
\boldsymbol{\sigma}(\boldsymbol{u}) & =\boldsymbol{A} \gamma(\boldsymbol{u}) & \\
\text { in } \Omega \\
\boldsymbol{u} & =0 & \\
{[\boldsymbol{\text { on }} \partial \Omega} \\
{[\boldsymbol{u}]} & =\boldsymbol{g} & \text { on } \omega \\
{[\boldsymbol{\sigma}(\boldsymbol{u}) \boldsymbol{n}]} & =\boldsymbol{h} & \\
\text { on } \omega
\end{array}\right.
$$

where $\boldsymbol{f} \in \boldsymbol{L}^{2}(\Omega), \boldsymbol{g} \in \boldsymbol{H}^{-1 / 2}(\omega)$ and $\boldsymbol{h} \in \boldsymbol{H}^{-3 / 2}(\omega)$ denote the gap in displacements and in normal stresses on $\omega$. These data are known and can be computed once the zero order problem is solved. Let us remark at first that the solution $\boldsymbol{u}$ of (43) does not belong to $\boldsymbol{H}^{1}(\Omega)$. More precisely, let be $\Omega_{1}:=\Omega^{+}, \Omega_{2}:=\Omega^{-}$and :

$$
\begin{equation*}
\boldsymbol{Z}:=\left\{\boldsymbol{z} \in \boldsymbol{L}^{2}(\Omega) ; \boldsymbol{\operatorname { d i v }}\left(\boldsymbol{A} \boldsymbol{\gamma}\left(\left.\boldsymbol{z}\right|_{\Omega_{i}}\right) \in \boldsymbol{L}^{2}\left(\Omega_{i}\right)\right\} ;\right. \tag{51}
\end{equation*}
$$

equipped with the natural graph norm. Then $\boldsymbol{u} \in \boldsymbol{Z}$. Since $\left.\left(\left.\boldsymbol{z}\right|_{\Omega_{i}}\right)\right|_{\omega}$ and $\left(\left.\left(\boldsymbol{A} \boldsymbol{\gamma}\left(\left.\boldsymbol{z}\right|_{\Omega_{i}}\right) \boldsymbol{n}\right)\right|_{\omega}\right.$ cannot have a classical meaning for $\boldsymbol{u} \in \boldsymbol{Z}$ the transmission conditions $[\boldsymbol{u}]=\mathcal{G}_{\boldsymbol{d}}$ and $[\boldsymbol{\sigma}(\boldsymbol{u}) \boldsymbol{n}]=\mathcal{G}_{\boldsymbol{n} \boldsymbol{S}}$ on $\omega$ have to be taken in a weak sense adapting the methods of Lions-Magenes [20]. Let us consider separately
$\Omega_{1}$ and $\Omega_{2}$ and with an obvious notation $\boldsymbol{Z}\left(\Omega_{i}\right)$ and let us assume that the elasticity tensor $\mathbf{A}$ is constant on each $\Omega_{i}$. We drop the index $i$ since the reasoning is the same for both cases. As in distribution theory $\left.\boldsymbol{z}\right|_{\omega}$ and $\left.(\boldsymbol{A} \gamma(\boldsymbol{z}) \boldsymbol{n})\right|_{\omega}$ will be defined by duality.

Theorem 1. The space $\mathcal{C}^{\infty}\left(\bar{\Omega} ; \mathbf{R}^{3}\right)$ is dense in $\boldsymbol{Z}(\Omega)$.
Proof. Let be $\mathbf{u} \longrightarrow \mathbf{L}(\mathbf{u})$ a linear and continuous form on $\boldsymbol{Z}(\Omega)$; since $\boldsymbol{L}^{2}(\Omega)$ is an Hilbert space there exist $\Psi, \Phi \in \boldsymbol{L}^{2}(\Omega)$ such that:

$$
\begin{equation*}
\mathbf{L}(\mathbf{u})=\int_{\Omega} \Psi \mathbf{u} d x+\int_{\Omega} \Phi \operatorname{div} \boldsymbol{A} \boldsymbol{\gamma}(\boldsymbol{u}) d x \tag{52}
\end{equation*}
$$

To conclude it is enough to prove that if

$$
\begin{equation*}
\mathbf{L}(\theta)=0 \text { for all } \theta \in \mathcal{C}^{\infty}\left(\bar{\Omega} ; \mathbf{R}^{3}\right) \tag{53}
\end{equation*}
$$

then $\mathbf{L}(\mathbf{u})=0$ for all $\mathbf{u} \in \boldsymbol{Z}(\Omega)$. Since every $\theta \in \mathcal{C}^{\infty}\left(\bar{\Omega} ; \mathbf{R}^{3}\right)$ is the restriction to $\Omega$ of (at least) one $\Theta \in \mathcal{D}\left(\mathbf{R}^{3} ; \mathbf{R}^{3}\right)$ then we can write (53) a s:

$$
\begin{equation*}
\mathbf{L}(\theta)=\int_{\mathbf{R}^{3}} \tilde{\Psi} \Theta d x+\int_{\mathbf{R}^{3}} \tilde{\Phi} \boldsymbol{\operatorname { d i v }} \boldsymbol{A} \boldsymbol{\gamma}(\Theta) d x=0 \tag{54}
\end{equation*}
$$

where $\tilde{\Psi}, \tilde{\Phi} \in \boldsymbol{L}^{2}\left(\mathbf{R}^{3}\right)$ are the extensions with 0 outside $\Omega$ of $\Psi, \Phi \in \boldsymbol{L}^{2}(\Omega)$. Equation (54) means that in the distributions sense on $\mathbf{R}^{3}$ one has

$$
\begin{equation*}
\operatorname{div} \boldsymbol{A} \gamma(\tilde{\Phi})=-\tilde{\Psi} \tag{55}
\end{equation*}
$$

and hence (local regularity of elliptic systems) that $\tilde{\Phi} \in \boldsymbol{H}^{2}(\tilde{\Omega})$ for any bounded $\tilde{\Omega} \supset \bar{\Omega}$. This means that indeed $\Phi \in \boldsymbol{H}_{0}^{2}(\Omega)$ and so integrating by parts (52) we get thanks to (54) $\mathbf{L}(\mathbf{u})=\int_{\Omega}(\operatorname{div} \boldsymbol{A} \boldsymbol{\gamma}(\Phi)+\Psi) \mathbf{u} d x=0$.

Before to state and prove the fundamental result we recall the following lemma.

Lemma 1. The map $\mathfrak{t r}:=\mathbf{v} \longrightarrow\left(\left.\mathbf{v}\right|_{\omega},\left.(\boldsymbol{A} \boldsymbol{\gamma}(\boldsymbol{v}) \boldsymbol{n})\right|_{\omega}\right)$ is linear, continuous and onto from $\boldsymbol{H}^{2}(\Omega)$ onto $\boldsymbol{H}^{3 / 2}(\omega) \times \boldsymbol{H}^{1 / 2}(\omega)$ and admits a non-unique linear right-inverse $\mathfrak{R}$; moreover $\operatorname{ker}(\mathfrak{t r})=\boldsymbol{H}_{0}^{2}(\Omega)$

The lemma is a particular case of a more general result on the so-called Cauchy data proved by Grubb, see e.g. [23] and the bibliography therein.

Theorem 2. The trace map $\mathfrak{t r}: \mathbf{u} \longrightarrow \mathfrak{t r}(\mathbf{u}):=\left(\left.\mathbf{u}\right|_{\omega},\left.(\boldsymbol{A} \boldsymbol{\gamma}(\boldsymbol{u}) \boldsymbol{n})\right|_{\omega}\right)$ defined on $\mathcal{C}^{\infty}\left(\bar{\Omega} ; \mathbf{R}^{3}\right)$ can be extended by continuity to a linear and continuous map, denoted $\mathfrak{T} \mathfrak{R}$, from $\boldsymbol{Z}(\Omega)$ into $\boldsymbol{H}^{-1 / 2}(\omega) \times \boldsymbol{H}^{-3 / 2}(\omega)$.

Proof. Let be given $(\eta, \varrho) \in \boldsymbol{H}^{3 / 2}(\omega) \times \boldsymbol{H}^{1 / 2}(\omega)$ and let be $\mathbf{v}(\eta, \varrho):=$ $\mathfrak{R}(-\eta, \varrho)$ where $\mathfrak{R}$ is one linear right inverse. Let now define on $\boldsymbol{Z}(\Omega) \times$ $\left(\boldsymbol{H}^{3 / 2}(\omega) \times \boldsymbol{H}^{1 / 2}(\omega)\right)$ the bilinear and bi-continuous form:

$$
\begin{equation*}
L(\mathbf{u},(\eta, \varrho))=\int_{\Omega} \mathbf{u d i v} \boldsymbol{A} \boldsymbol{\gamma}(\mathbf{v}) d x-\int_{\Omega} \operatorname{div} \boldsymbol{A} \gamma(\mathbf{u}) \mathbf{v} d x \tag{56}
\end{equation*}
$$

Let us at first remark that $L(\mathbf{u},(\eta, \varrho))$ is well defined since it does not depend on the particular right inverse $\mathfrak{R}$ chosen. Indeed if $\mathbf{v}(\eta, \varrho)$ and $\mathbf{v}_{1}(\eta, \varrho)$ correspond to two different right inverses then $\left(\mathbf{v}(\eta, \varrho)-\mathbf{v}_{1}(\eta, \varrho)\right) \in \boldsymbol{H}_{0}^{2}(\Omega)$. The density of $\mathcal{D}\left(\mathbf{R}^{3} ; \mathbf{R}^{3}\right)$ in $\boldsymbol{H}_{0}^{2}(\Omega)$ and (56) imply the result. It is also obvious that $L(\mathbf{u},(\eta, \varrho))$ is bi-continuous and hence there exists a linear and continuous map $\mathfrak{T} \mathfrak{R}$, from $\boldsymbol{Z}(\Omega)$ to $\boldsymbol{H}^{-1 / 2}(\omega) \times \boldsymbol{H}^{-3 / 2}(\omega)$ such that

$$
\begin{equation*}
L(\mathbf{u},(\eta, \varrho))=<\mathfrak{T} \mathfrak{R} \mathbf{u},(\eta, \varrho)> \tag{57}
\end{equation*}
$$

where $<\bullet, \bullet>$ denotes the duality between $\boldsymbol{H}^{-1 / 2}(\omega) \times \boldsymbol{H}^{-3 / 2}(\omega)$ and $\boldsymbol{H}^{1 / 2}(\omega) \times \boldsymbol{H}^{3 / 2}(\omega)$. When $\mathbf{u} \in \mathcal{C}^{\infty}\left(\bar{\Omega} ; \mathbf{R}^{3}\right)$ then the Green formula, (56) and (57) imply that $\mathfrak{T R u}=\left(\left.\mathbf{u}\right|_{\omega},\left.(\boldsymbol{A} \boldsymbol{\gamma}(\boldsymbol{u}) \boldsymbol{n})\right|_{\omega}\right)$. Hence Theorem 1 implies the result.

Remark 1:Let us explicitly remark that the generic form of the first order problem (32) implies that $\mathbf{u} \in \boldsymbol{Z}_{0}:=\left\{\boldsymbol{z} \in \boldsymbol{L}^{2}(\Omega) ; \operatorname{div}\left(\boldsymbol{A} \boldsymbol{\gamma}\left(\left.\boldsymbol{z}\right|_{\Omega_{i}}\right)=0\right)\right\}$;
