Virtual Organizations in Arigatoni

Michel Cosnard [a] Luigi Liquori [a] Raphael Chand [a]

[a] *INRIA, France*

Abstract

Arigatoni is a lightweight communication model that deploys the *Global Computing Paradigm* over the Internet. Communications over the behavioral units of the model are performed by a simple *Global Internet Protocol* (GIP) on top of TCP or UDP protocol. Basic Global Computers Units (GCU) can communicate by first registering to a brokering service and then by mutually asking and offering services.

Colonies and Communities are the main entities in the model. A Colony is a simple virtual organization composed by exactly one leader and some set (possibly empty) of individuals. A Community is a raw set of colonies and global computers (think it as a *soup* of colonies and global computer without a leader).

We present an operational semantics via a labeled transition system, that describes the main operations necessary in the Arigatoni model to perform leader negotiation, joining/leaving a colony, linking two colonies and moving one GCU from one colony to another. Our formalization results to be adequate w.r.t. the algorithm performing peer logging/delogging and colony aggregation.

1 Introduction

Effective use of computational grids via P2P systems requires *up-to-date* information about widely-distributed resources. This is a challenging problem for very large distributed systems particularly when taking into account the continuously changing state of resources. Discovering dynamic resources must be scalable in number of resources and users and hence, as much as possible, fully decentralized. It should tolerate intermittent participation and dynamically changing status/availability.

The Arigatoni Model is suitable to deploy, via the Internet the *Global Computing Communication Paradigm*, *i.e*. computation via a seamless, geographically distributed, open-ended network of bounded resources by agents acting with partial knowledge and no central coordination. The model can be deployed firstly in an intranet and further from intranet to intranet by overlapping an *Overlay Network* on the top of the *actual network*. An *Overlay Network* is an abstraction on top of a global network to yield another global network. Overlay examples are *resource*

Electronic Notes in Theoretical Computer Science
URL: www.elsevier.nl/locate/entcs

discovery services (notion of resource sharing in distributed networks), search engines (abstraction of information repository) or systems of trusted mobile agents (notion of autonomic, exploratory behavior) [5].

The Arigatoni model provides the necessary basic infrastructure necessary for a real deployment of the overlay network itself. Moreover, our work abstracts on *which kind of resource* the overlay network is playing with; pragmatically speaking, this work could be useful for Grid, or for distributed file/band sharing, or for more evolved scenarios like mobile and distributed object-oriented computation.

The Arigatoni communication model is organized in *colony* governed by a clear leader. Global Computers belong to only one colony, and requests for resources located in the same or in another colony traverse a broker-2-broker negotiation whose security is guaranteed via PKI mechanisms.

The model is suitable to fit with various global scenarios from classical P2P applications, like file or band sharing, to more sophisticated Grid applications, like remote and distributed big (and small) computations, until possible, futuristic *migration computations*, *i.e*. transfer of a non completed local run in another GCU, the latter scenario being useful in case of catastrophic scenarios, like fire, terrorist attack, earthquake etc., in the vein of Global Programming Languages *à la* Obliq or Telescript.

The Units in the Arigatoni model are one protocol, the *Global Internet Protocol*, GIP, and three main units:

- A *Global Computer Unit*, GCU, *i.e*. the basic peer of the Global Computer paradigm; it is typically a small device, like a PDA, a laptop or a PC, connected via IP, unrelated to the media used, wired or wireless, etc.
- A *Global Broker Unit*, GBU, is the basic unit devoted to register and unregister GCUs, to receive service queries from client GCUs, to contact potential servants GCUs, to negotiate with the latter the given services, to trust clients and servers and to send all the information necessary to allow the client GCU and the servants GCUs to communicate. Every GCU can register to only one GBU, so that every GBU controls a *colony* (denoted by COL) of collaborating Global Computers. Hence, communication intra-colony is initiated via only one GBU, while communication inter-colonies is initiated through a chain of GBU-2-GBU message exchanges. In both cases, when a client GCU receives an acknowledgment for a request service (with related trust certificate) from the proper GBU, then the client will enjoy the service directly from the servant(s) GCU, *i.e*. without a further mediation of the GBU itself.
- A *Global Router Unit*, GRU is a simple basic unit that is devoted to send and receive packets using a proper Global Internet Protocol and to forward the payload to the units which are connected with this router. Every GCU and every GBU has one personal GRU, with which it communicates via a suitable API. The connection between router and peer is ensured via a suitable API.

Colonies and Individuals are the main entities in the model. A Colony is a simple virtual organization composed by exactly one leader and some set (possibly

$\{\mathsf{GBU}\}$ is a (small) colony

$\{\mathsf{GBU}_1, \mathsf{GCU}_1 \ldots \mathsf{GCU}_m\}$ is a colony

$\{\mathsf{GBU}_1, \mathsf{GCU}_1 \ldots \mathsf{GCU}_m, \overbrace{\{\mathsf{GBU}_2, \mathsf{GCU}_{m+1} \ldots \mathsf{GCU}_{m+n}\}}^{subcolony}\}$

is a colony (it contains a subcolony)

$\{\mathsf{GBU}_1, \mathsf{GCU}_1 \ldots \mathsf{GCU}_m, \mathsf{GBU}_2, \mathsf{GCU}_{m+1} \ldots \mathsf{GCU}_{m+n}\}$

is not a colony (two GBUs)

$\{\mathsf{GBU}_3, \overbrace{\{\mathsf{GBU}_1, \mathsf{GCU}_1 \ldots \mathsf{GCU}_m\}}^{subcolony}, \overbrace{\{\mathsf{GBU}_2, \mathsf{GCU}_{m+1} \ldots \mathsf{GCU}_{m+n}\}}^{subcolony}\}$

is a colony (with two subcolonies)

$\{\overbrace{\{\mathsf{GBU}_1, \mathsf{GCU}_1 \ldots \mathsf{GCU}_m\}}^{subcolony}, \overbrace{\{\mathsf{GBU}_2, \mathsf{GCU}_{m+1} \ldots \mathsf{GCU}_{m+n}\}}^{subcolony}\}$

is not a colony (no leader in the toplevel colony) but it is a community

Figure 1. Some Colony's Examples

empty) of individuals. Individuals are Global Computers (think it as an *Amoeba*), or (sub)colonies (think it as a *Protozoa*). A formal definition of a colony is given using this simple BNF syntax:

$$\mathsf{COL} ::= \{\mathsf{GBU}\} \mid \mathsf{COL} \cup \{\mathsf{GCU}\} \mid \mathsf{COL} \cup \{\, \mathsf{COL} \,\}$$

The two main characteristics of a colony are:

(i) a colony has *exactly* one leader GBU and at least one individual (the GBU itself);

(ii) a colony contains individuals (some GCU's, or other colonies).

Some examples of colonies are shown in Figure 1.

A Community (denoted by COM) is a raw set of colonies and global computers (think it as a *soup* of colonies and GCU without a leader). A formal definition of community is given using the BNF syntax:

$$\mathsf{COM} ::= \emptyset \mid \mathsf{COM} \cup \{\mathsf{GCU}\} \mid \mathsf{COM} \cup \{\, \mathsf{COL} \,\}$$

A simple example of a community is shown in Figure 1. As one can see from the abstract syntax, a colony is a community but the reverse is not true.

Resource Discovery is one of the key issues in building overlay computer networks. Individuals (global computers) can register and unregister to a colony. The same holds true for the subcolonies that, in turn, can (un)register to another colony. The main difficulty in (un)registering is dealing with *Administrative Domains*; as well stated in the seminal Cardelli and Gordon paper on Mobile Ambients [2]:

> *"In the early days of the* Internet *one could rely on a flat name space given by* IP *addresses; knowing the* IP *address of a computer would very likely allow now to talk to that computer in some way. This is no longer the case: firewalls partition*

the Internet *into administrative domains that are isolated from each other except for rigidly controlled pathways. System administrators enforce policies about what can move through firewalls and how [...]"*

(Un)Registering Modalities. There are essentially two ways of registering to a GBU leader of a colony, the latter being not enforced by the Arigatoni model:

- registration of an individual (GCU or colony) to a GBU leader of a colony belonging to the same *current administrative domain*;
- registration via *remote tunnelling* of an individual (GCU or colony) to another GBU leader of a colony belonging to a *different administrative domain*. In this case, we say that the individuals *de facto* are working in local mode *in the current administrative domain* and in global mode *in another administrative domain*.

  In addition to this remote registration, the same individual can still register to the GBU leader of the colony belonging to the same administrative domain in which it resides. As such, in its global mode, it will belong to the colony of the current administrative domain, and, in its local mode (via remote tunnelling), it will belong to another colony in another administrative domain.

Counterwise, an individual can unregister according to the following simple rules *d'étiquette*:

- unregistration is possible only when there are no pending services demanded or requested to the leader GBU of the colony it belongs: it must wait for an answer of the leader GBU or for a direct connection of the GCU requesting the already offered service, or wait for a timeout. The colony accepts the unregistration only if the colony itself will not be *corrupted*;
- (as a corollary of the above) a GBU cannot unregister from its own colony, *i.e.* it cannot discharge itself. However, for fault tolerance purposes, a GBU can be faulty. In that case, the GCUs will unregister one after the other and the colony will "disappear";
- once a GCU (*e.g.* a laptop) has been disconnected from a colony belonging to any administrative domain, it can migrate in another colony belonging to any other administrative domain;

Summarizing, the original contributions of the paper are:

- a formalization of the Registration and of the Resource Discovery Mechanism in the Arigatoni model in terms of a labeled transition system;
- a *complete domain independence* of the model w.r.t. other models in the literature. In other words Arigatoni completely abstracts of its use, *i.e.* Grid, file/band sharing, web services, etc.
- some simulation results of the intermittent participation for a given network topology.

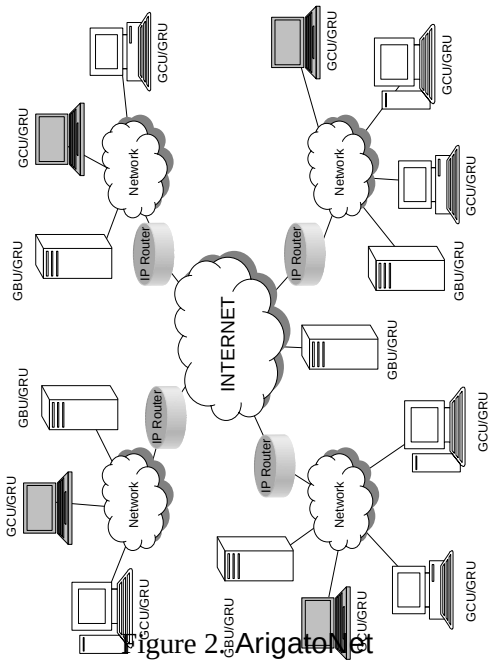

Figure 2. ArigatoNet

2 Units in a Nutshell

A complete description of all the functional units of the Arigatoni model is given in [1]; this section is an overview.

2.1 Global Computer Unit

In the Arigatoni model, a *Global Computer Unit (*GCU*)* is a cheap computer device. The computer should be able to work in *Standalone Local Mode* for all the tasks that it can do locally or in *Global Mode*, by first registering itself in the Arigatoni architecture, and then by making a global request to the Overlay Network induced by the architecture (that we call, ArigatoNet). Figure 2 shows the Arigatoni model. The GCU must be able to perform the following tasks:

- Discover, upon the physical arrival of the GCU in a new colony, the address of a GBU, representing the *leader* of the colony;
- Register/Unregister on the GBU which manages the colony;
- Request some services to its GBU, and respond to some requests from the GBU;
- Upon reception from a GBU of a positive response to a request, be able to connect directly with the servant(s) GCU in a P2P fashion, and offer/receive the service.

2.2 Global Broker Unit

The *Global Broker Unit (*GBU*)* performs the following tasks:

- Discover the address of another *super* GBU, representing the *superleader* of the *supercolony*, where the GBU's colony is embedded. We assume that every GBU comes with its proper PKI certificate.

- Register/Unregister the proper colony to the *leader* GBU which manages the supercolony;
- Register/Unregister clients and servants GCU in its local base of Global Computers. By definition every GCU can register to *at most* one GBU;
- Acknowledge the request of service of the client GCU;
- Discover the resource(s) that satisfies the GCU's request in its local base (local colony) of GCU;
- Delegate the request to another GBU governing another colony;
- Perform a combination of the above two actions;
- Deal with all PKI intra- and inter-colony policies;
- Notify the client GCU (or the delegating GBU) that some servant(s) GCUs have accepted to serve the request, or just notify a *failure* of the request.

Every GCU in the colony sends its request to the GBU which is the leader of the colony. There are different scenarios concerning the demanded resource for service discovery, namely:

(i) The broker finds all the resource(s) needed to satisfy the requested services of the GCU client locally in the intranet. Then it will send all the information necessary to make the GCU client able to communicate with the GCU servants. This notification will be encoded using the GIP protocol. Then, the GCU client will directly talk with GCU servant(s), and the latter will manage the request, as in classical P2P systems;

(ii) The broker did not find all the resource(s) in its local intranet. In this case it will forward and delegate the request to another broker. For that purpose, it must first register the whole colony to another supercolony;

(iii) A combination of steps 1 + 2 could be envisaged depending on the capability of the GBU to combine resources that it manages and resources that come from a delegate GBU;

(iv) After a fixed *timeout period*, or when all delegate GBUs have failed to satisfy the delegated request, the broker will notify the GCU client of the *refusal of service*.

2.3 Global Router Unit

The last unit in the Arigatoni model is the *Global Router Unit (*GRU*)*. The GRU implements all the low-level network routines, those which really have access to the IP network. It is the only unit which effectively runs the GIP protocol. The GRU can be implemented as a small daemon which runs on the same device as a GCU or a GBU, or as a shared library dynamically linked with a GCU or a GBU. The GRU is devoted to the following tasks:

- Upon the initial startup of a GCU it helps to register the unit to a GBU;
- It checks the well-formedness and forwards GIP packets across the ArigatoNet

toward their destinations. GIP packets encode the requests of a GCU or a GBU in the Arigatoni network;

- Upon the initial startup of a GBU it helps the unit with several other GBUs that it knows or discovers.

2.4 Unit Semantics

The formal semantics of the three formal units was first presented in [1]: Figures 3 and 4 show the pseudo code embedded inside a GCU and a GBU. We write in blue the code not essential to the semantics of peer discovery and the virtual (un)growth of colonies, and we highlight in red the code which is essential.

```

Figure 3. GCU pseudocode

3 Formal Semantics of the Virtual Organization

Let $\{\ldots\}$ denotes a colony and not necessarily an administrative domain (like in Cardelli-Gordon ambients), and let every individual come with its own IP address and security certificate. Let $\{\mathsf{GBU}, \ldots\}$ denotes a colony with its leader, *e.g.*

$$\{\mathsf{GBU}, \mathsf{COL}_1, \mathsf{COL}_2, \mathsf{GCU}_1, \mathsf{GCU}_2, \ldots\}$$

```
inparallel
while true do                          // Registration loop
 GBU = Discover(MyCard)
 case (GlobalMode,RegMode) is
  (true,false):
   ServiceReg(MyCard,GBU,LOGIN)
  (false,true):
   ServiceReg(MyCard,GBU,LOGOUT)
  otherwise:                           // Do nothing
 endcase
endwhile
with
 while true do                         // Shell loop
  Data     = ListenLocal()
  Response = LocalServe(Data)
  case (Response,GlobalMode,RegMode) is
   (login,_,_):                        // Open global mode
    GlobalMode = true
   (logout,_,_):                       // Close global mode
    GlobalMode = false
   (fail,true,true):                   // You ask for you
    MetaData = PackScenario(Data)
    ServiceRequest(MyCard,MyCard,MetaData)
   otherwise: LocalReply(Response)
  endcase
 endwhile
with
 while true do                         // Intra-colony listening
  MetaData = ListenPeer()
  PushHistory(MetaData)
  case MetaData.CMD.SERVICE is
   SREG:    // A Peer is asking for (un)registration
    Update(Colony,MetaData)
   SREQ:     // A Peer is asking for some request
    SubColony = SelectPeers(Colony,MetaData)
    if SubColony == {}                 // Broadcast inter
    then
      ServiceRequest(MyCard,GBU,MetaData)
    endif
     foreach Peer in SubColony do
                                       // Broadcast intra
      ServiceRequest(MyCard,Peer,MetaData)
     endforeach

    Sort&PushPeers4Id(MetaData)
    endcase
  endcase
 endwhile
endinparallel
```

Figure 4. GBU pseudocode

is a colony with two subcolonies and two GCUs highlighted. A colony is virtually addressed by the IP of its GBU leader. Let a community be denoted by $\{\ldots\}$, *e.g.*

$$\{\mathsf{COL}_1, \mathsf{COL}_2, \mathsf{GCU}_1, \mathsf{GCU}_2\}$$

is a community with two subcolonies and two GCU's.

We present an operational semantics via a reduction relation "$\rightarrow$", between communities, that describes the main operations necessary in the Arigatoni model to perform leader discovery and colony's service registration, namely joining/leaving a colony, linking two colonies and moving one GCU from one colony to another.

As usual in process algebras, the reduction is quotiented by a set theoretical equivalence between communities. As remarked by Michele Bugliesi during the workshop, we omit in the reduction rules all the imperative aspects related to the changing of *state* of Individuals; we focus only on the functional rules of the protocol describing the intermittent participation of Individuals. The reduction rules are listed below with a concise explication.

(i) A GCU joins a Colony *in the same Administrative Domain*

$$\frac{\begin{array}{c} discover(\mathsf{GCU}) = \mathsf{GBU} \\ samedom(\mathsf{GBU},\mathsf{GCU}) = \textit{true} \quad gmode(\mathsf{GCU}) = \textit{true} \\ accept(\mathsf{GBU},\mathsf{GCU}) = \textit{true}\ regmode(\mathsf{GCU}) = \textit{false} \end{array}}{\{\{\mathsf{GBU},\ldots\},\mathsf{GCU}\} \rightarrow \{\{\mathsf{GBU},\mathsf{GCU},\ldots\}\}}\ (\mathsf{JoinGCU})$$

- $discover(\mathsf{GCU}) = \mathsf{GBU}$ discovers the leader-GBU unit, upon physical/logical insertion of the GCU in the ArigatoNet network;
- $samedom(\mathsf{GBU},\mathsf{GCU}) = \textit{true}$: both the broker and the global computer reside in the same administrative domain;
- $accept(\mathsf{GBU},\mathsf{GCU}) = \textit{true}$: the broker accepts the global computer in its colony;
- $gmode(\mathsf{GCU}) = \textit{true}\ \&\ regmode(\mathsf{GCU}) = \textit{false}$: the global computer is in global mode but not yet registered. The side effect of this rule is to set the registration mode to *true*.

(ii) A GCU leaves a Colony *in the same Administrative Domain*

$$\frac{\begin{array}{c} pendingip(\mathsf{GCU}) = \textit{false} \\ samedom(\mathsf{GBU},\mathsf{GCU}) = \textit{true} \quad gmode(\mathsf{GCU}) = \textit{false} \\ accept(\mathsf{GBU},\mathsf{GCU}) = \textit{false}\ regmode(\mathsf{GCU}) = \textit{true} \end{array}}{\{\{\mathsf{GBU},\mathsf{GCU},\ldots\}\} \rightarrow \{\{\mathsf{GBU},\ldots\},\mathsf{GCU}\}}\ (\mathsf{LeaveGCU})$$

- $pendingip(\mathsf{GCU}) = \textit{false}$: the global computer has no pending service to give to its leader;
- $samedom(\mathsf{GBU},\mathsf{GCU}) = \textit{true}$: both the broker and the global computer reside in the same administrative domain;
- $accept(\mathsf{GBU},\mathsf{GCU}) = \textit{false}$: the broker accepts to delog the global computer in its colony;
- $gmode(\mathsf{GCU}) = \textit{false}\ \&\ regmode(\mathsf{GCU}) = \textit{true}$: the global computer is in local mode but still registered. The side effect of this rule is to set its registration mode to *false*.

(iii) A SubColony joins a Colony *in the same Administrative Domain*

$$\frac{\begin{array}{c} discover(\mathsf{GBU}_2) = \mathsf{GBU}_1 \\ samedom(\mathsf{GBU}_1,\mathsf{GBU}_2) = \textit{true} \quad gmode(\mathsf{GBU}_2) = \textit{true} \\ accept(\mathsf{GBU}_1,\mathsf{GBU}_2) = \textit{true} \quad regmode(\mathsf{GBU}_2) = \textit{false} \end{array}}{\{\{\mathsf{GBU}_1,\ldots\},\{\mathsf{GBU}_2,\ldots\}\} \rightarrow \{\{\mathsf{GBU}_1,\{\mathsf{GBU}_2,\ldots\},\ldots\}\}}\ (\mathsf{JoinCol})$$

- $discover(\mathsf{GBU}_2) = \mathsf{GBU}_1$: the broker GBU_2 discovers the broker GBU_1, upon physical/logical insertion in the ArigatoNet network;
- $samedom(\mathsf{GBU}_1,\mathsf{GBU}_2) = \textit{true}$: both reside in the same administrative domain;

- $accept(\mathsf{GBU}_1, \mathsf{GBU}_2) = \textit{true}$: the broker GBU_1 accepts the subcolony in its colony;
- $gmode(\mathsf{GBU}_2) = \textit{true}\ \&\ regmode(\mathsf{GBU}_2) = \textit{false}$: the broker GBU_2 is in global mode but not yet registered. The side effect of this rule is to set its registration mode to *true*.

(iv) A SubColony leaves a Colony *in the same Administrative Domain*

$$\frac{\begin{array}{rr} pendingip(\mathsf{GBU}_2) = \textit{false} & \\ samedom(\mathsf{GBU}_1, \mathsf{GBU}_2) = \textit{true} & gmode(\mathsf{GBU}_2) = \textit{false} \\ accept(\mathsf{GBU}_1, \mathsf{GBU}_2) = \textit{false} & regmode(\mathsf{GBU}_2) = \textit{true} \end{array}}{\{\{\mathsf{GBU}_1, \{\mathsf{GBU}_2, \ldots\}, \ldots\}\} \rightarrow \{\{\mathsf{GBU}_1, \ldots\}, \{\mathsf{GBU}_2, \ldots\}\}}\ (\mathsf{LeaveCol})$$

- $pendingip(\mathsf{GBU}_2) = \textit{false}$: the broker GBU_2 has no pending service to give to its leader GBU_1;
- $samedom(\mathsf{GBU}_1, \mathsf{GBU}_2) = \textit{true}$: both reside in the same administrative domain;
- $accept(\mathsf{GBU}_1, \mathsf{GBU}_2) = \textit{false}$: the broker GBU_1 does not accept the subcolony in its colony;
- $gmode(\mathsf{GBU}_2) = \textit{false}\ \&\ regmode(\mathsf{GBU}_2) = \textit{true}$: the broker GBU_2 is in local mode but still registered. The side effect of this rule is to set its registration mode to *false*.

(v) Linking two Colonies *in different Administrative Domains*

$$\frac{\begin{array}{rr} & gmode(\mathsf{GBU}_1) = \textit{true} \\ newgbu(\mathsf{GBU}_1, \mathsf{GBU}_2) = \mathsf{GBU}_3 & gmode(\mathsf{GBU}_2) = \textit{true} \\ samedom(\mathsf{GBU}_1, \mathsf{GBU}_2) = \textit{false} & regmode(\mathsf{GBU}_1) = \textit{false} \\ agree(\mathsf{GBU}_1, \mathsf{GBU}_2) = \textit{true} & regmode(\mathsf{GBU}_2) = \textit{false} \end{array}}{\{\{\mathsf{GBU}_1, \ldots\}, \{\mathsf{GBU}_2, \ldots\}\} \rightarrow \{\{\mathsf{GBU}_3, \{\mathsf{GBU}_1, \ldots\}, \{\mathsf{GBU}_2, \ldots\}\}\}}\ (\mathsf{LinkCol})$$

- $newgbu(\mathsf{GBU}_1, \mathsf{GBU}_2) = \mathsf{GBU}_3$: a new broker is created on behalf on GBU_1 and GBU_2;
- $samedom(\mathsf{GBU}_1, \mathsf{GBU}_2) = \textit{false}$: both reside in the same administrative domain;
- $agree(\mathsf{GBU}_1, \mathsf{GBU}_2) = \textit{true}$: an agreement between the two brokers is signed;
- $gmode(\mathsf{GBU}_1) = \textit{true}\ \&\ gmode(\mathsf{GBU}_2) = \textit{true}\ \&\ regmode(\mathsf{GBU}_1) = \textit{false}\ \&\ regmode(\mathsf{GBU}_2) = \textit{false}$: the brokers are in global mode but still not ,registered. The side effect of this rule is to set the registration mode of both brokers to *true*.

(vi) Unlinking two Colonies *in different Administrative Domains*

$$\frac{\begin{array}{rr} pendingip(\mathsf{GBU}_1) = \textit{false} & pendingip(\mathsf{GBU}_2) = \textit{false} \\ pendingip(\mathsf{GBU}_3) = \textit{false} & gmode(\mathsf{GBU}_1) = \textit{false} \\ newgbu(\mathsf{GBU}_1, \mathsf{GBU}_2) = \mathsf{GBU}_3 & gmode(\mathsf{GBU}_2) = \textit{false} \\ samedom(\mathsf{GBU}_1, \mathsf{GBU}_2) = \textit{false} & regmode(\mathsf{GBU}_1) = \textit{true} \\ agree(\mathsf{GBU}_1, \mathsf{GBU}_2) = \textit{false} & regmode(\mathsf{GBU}_2) = \textit{true} \end{array}}{\{\{\mathsf{GBU}_3, \{\mathsf{GBU}_1, \ldots\}, \{\mathsf{GBU}_2, \ldots\}\}\} \rightarrow \{\{\mathsf{GBU}_1, \ldots\}, \{\mathsf{GBU}_2, \ldots\}\}}\ (\mathsf{UnLinkCol})$$

- $newgbu(\mathsf{GBU}_1, \mathsf{GBU}_2) = \mathsf{GBU}_3$: a new broker is created on behalf of GBU_1 and GBU_2;
- $samedom(\mathsf{GBU}_1, \mathsf{GBU}_2) = \textit{true}$: both reside in the same administrative domain;
- $agree(\mathsf{GBU}_1, \mathsf{GBU}_2) = \textit{false}$: an agreement between the two brokers is withdrawn;
- $pendingip(\mathsf{GBU}_1) = \textit{false}$ & $pendingip(\mathsf{GBU}_2) = \textit{false}$ & $pendingip(\mathsf{GBU}_3) = \textit{false}$: the brokers $\mathsf{GBU}_{1,2,3}$ has no pending service;
- $gmode(\mathsf{GBU}_1) = \textit{false}$ & $gmode(\mathsf{GBU}_2) = \textit{false}$ & $regmode(\mathsf{GBU}_1) = \textit{true}$ & $regmode(\mathsf{GBU}_2) = \textit{true}$: the brokers are in local mode but still registered. The side effect of this rule is to set their registration mode to *false*.

(vii) Contextual Rules and Congruence

As usual in process algebras, we add the following congruence rules for set union and set minus, and Morris-style equivalence rules, where COM denotes communities, COL denotes colonies and $=$ denotes the set theoretical equality. All symbols can be indexed.

$$\frac{\mathsf{COM}_1 \rightarrow \mathsf{COM}_2}{\mathsf{COM}_1 \cup \mathsf{COM}_3 \rightarrow \mathsf{COM}_2 \cup \mathsf{COM}_3}\ (\mathsf{CommCup})$$

$$\frac{\mathsf{COM}_1 = \mathsf{COM}_3 \cup \mathsf{COM}_4 \quad \mathsf{COM}_3 \cap \mathsf{COM}_4 = \emptyset \quad \mathsf{COM}_3 \rightarrow \mathsf{COM}_2}{\mathsf{COM}_3 \rightarrow \mathsf{COM}_2 \setminus \mathsf{COM}_4}\ (\mathsf{CommMinus})$$

$$\frac{\mathsf{COM}_1 = \mathsf{COM}_3 \quad \mathsf{COM}_3 \rightarrow \mathsf{COM}_4 \quad \mathsf{COM}_4 = \mathsf{COM}_2}{\mathsf{COM}_1 \rightarrow \mathsf{COM}_2}\ (\mathsf{MorrisEq})$$

Rule (CommCup) is the usual Contextual closure of the reduction rules, while rule (CommMinus) states that a reduction can drop in its right-hand side some individuals that are not essential to the firing of the reduction itself. As usual let $\rightarrow^*$ be the reflexive and transitive closure of $\rightarrow$.

4 Join/Leave a Colony in a Different Administrative Domain

The acute reader has observed that the above labeled transition system *forbids* an individual to join/leave another colony whose leader resides *in a different Admin-*

istrative Domain. This is sound in order to guarantee the integrity and the security of the virtual organization induced by the Arigatoni model. Crossing safely administrative domains is an important security problem that the model must take into account. However, the situation where one individual does not receive enough help from the local colony or, worst, where it is even rejected as an individual, could be very common. In this case, it is highly desirable that the model permits a mechanism to cross boundaries of the administrative domain in order to make a service request to another colony which resides in another administrative domain. This can be done in two ways:

(i) the individual resident in an administrative domain IP_1 knows some "friends" inhabitant of the colony resident in another administrative domain IP_2 (think of the individual as a laptop connected in a hot spot of an airport, and think of the "friend" as the desktop in its own office). Then, via an explicit `ssh` the laptop can log into the desktop and send a global request to the "mother colony". As such, the laptop works in its *local mode* while the desktop works in *global mode*. The final result will be send, via `ssh-tunneling` to the laptop.

This mechanism of tunneling is well-known in common practice of nomadic behaviors and it does not require any *ad hoc* rewriting rules in the Arigatoni virtual organization since the connection individual-friend is done explicitly and privately;

(ii) the individual resident in an administrative domain IP_1 knows no inhabitant of the colony resident in another administrative domain IP_2, but it knows the IP address of the leader of the colony. If the leader agrees, it can arrange an `ssh-tunnel` by creating from scratch a *virtual clone* of the remote individual and by registering it in the colony on behalf of the leader of the colony. As in the previous case, the laptop can log into the desktop and send a global request to the "mother colony". As such, the laptop works in *local mode* while the clone works in *global mode*. The final result will be sent, via `ssh-tunneling` to the laptop.

This mechanism is well-known in common practice of nomadic behaviors and is reminiscent of the *Virtual Private Network* technology (VPN) [6]. To implement this VPN-like behavior, we must add four *ad hoc* rewriting rules in the labeled transition system showed in Figure 5. For obvious lack of space those rules are not commented but left as an easy exercise to the interested reader.

5 Firing Free Riders

Again, the acute reader has observed that the original labeled transition system allows *free riders* to become members of one colony.

"In economics and political science, free riders are actors who consume more than their fair share of a resource, or shoulder less than a fair share of the costs

$$\frac{\begin{array}{rr} discover(\mathsf{GCU}_1) = \mathsf{GBU} & agree(\mathsf{GBU}, \mathsf{GCU}_1) = \mathit{true} \\ samedom(\mathsf{GBU}, \mathsf{GCU}_1) = \mathit{false} & gmode(\mathsf{GCU}_1) = \mathit{true} \\ newgcu(\mathsf{GBU}, \mathsf{GCU}_1) = \mathsf{GCU}_2 & regmode(\mathsf{GCU}_1) = \mathit{true} \\ samedom(\mathsf{GBU}, \mathsf{GCU}_2) = \mathit{true} & gmode(\mathsf{GCU}_2) = \mathit{false} \\ accept(\mathsf{GBU}, \mathsf{GCU}_2) = \mathit{true} & regmode(\mathsf{GCU}_2) = \mathit{false} \end{array}}{\{\{\mathsf{GBU}, \ldots\}, \mathsf{GCU}_1\} \rightarrow \{\{\mathsf{GBU}, \mathsf{GCU}_2, \ldots\}, \mathsf{GCU}_1\}} \text{(JoinTunnelGCU)}$$

$$\frac{\begin{array}{rr} & agree(\mathsf{GBU}, \mathsf{GCU}_1) = \mathit{false} \\ samedom(\mathsf{GBU}, \mathsf{GCU}_1) = \mathit{false} & pendingip(\mathsf{GCU}_2) = \mathit{false} \\ newgcu(\mathsf{GBU}, \mathsf{GCU}_1) = \mathsf{GCU}_2 & gmode(\mathsf{GCU}_1, \mathsf{GCU}_2) = \mathit{false} \\ samedom(\mathsf{GBU}, \mathsf{GCU}_2) = \mathit{true} & regmode(\mathsf{GCU}_1) = \mathit{false} \\ accept(\mathsf{GBU}, \mathsf{GCU}_2) = \mathit{false} & regmode(\mathsf{GCU}_2) = \mathit{true} \end{array}}{\{\{\mathsf{GBU}, \mathsf{GCU}_2, \ldots\}, \mathsf{GCU}_1\} \rightarrow \{\{\mathsf{GBU}, \ldots\}, \mathsf{GCU}_1\}} \text{(LeaveTunnelGCU)}$$

$$\frac{\begin{array}{rr} discover(\mathsf{GBU}_2) = \mathsf{GBU}_1 & agree(\mathsf{GBU}_1, \mathsf{GBU}_2) = \mathit{true} \\ samedom(\mathsf{GBU}_1, \mathsf{GBU}_2) = \mathit{false} & gmode(\mathsf{GBU}_3) = \mathit{true} \\ newgbu(\mathsf{GBU}_1, \mathsf{GBU}_2) = \mathsf{GBU}_3 & regmode(\mathsf{GBU}_3) = \mathit{true} \\ samedom(\mathsf{GBU}_1, \mathsf{GBU}_3) = \mathit{true} & gmode(\mathsf{GBU}_2) = \mathit{false} \\ accept(\mathsf{GBU}_1, \mathsf{GBU}_3) = \mathit{true} & regmode(\mathsf{GBU}_2) = \mathit{false} \end{array}}{\{\{\mathsf{GBU}_1, \ldots\}, \{\mathsf{GBU}_2, \ldots\}\} \rightarrow \{\{\mathsf{GBU}_1, \{\mathsf{GBU}_3\}, \ldots\}, \{\mathsf{GBU}_2, \ldots\}\}} \text{(JoinTunnelCol)}$$

$$\frac{\begin{array}{rr} & agree(\mathsf{GBU}_1, \mathsf{GBU}_2) = \mathit{false} \\ samedom(\mathsf{GBU}, \mathsf{GBU}_2) = \mathit{false} & pendingip(\mathsf{GBU}_3) = \mathit{false} \\ newgbu(\mathsf{GBU}_1, \mathsf{GBU}_2) = \mathsf{GBU}_3 & gmode(\mathsf{GBU}_2, \mathsf{GBU}_3) = \mathit{false} \\ samedom(\mathsf{GBU}_1, \mathsf{GBU}_3) = \mathit{true} & regmode(\mathsf{GBU}_2) = \mathit{true} \\ accept(\mathsf{GBU}_1, \mathsf{GBU}_3) = \mathit{false} & regmode(\mathsf{GBU}_3) = \mathit{false} \end{array}}{\{\{\mathsf{GBU}_1, \{\mathsf{GBU}_3\}, \ldots\}, \{\mathsf{GBU}_2, \ldots\}\} \rightarrow \{\{\mathsf{GBU}_1, \ldots\}, \{\mathsf{GBU}_2, \ldots\}\}} \text{(LeaveTunnelCol)}$$

Figure 5. Extra Reduction Rules for Service Request via Tunnelling *à la* VPN

of its production. The free rider problem is the question of how to prevent free riding from taking place, or at least limit its negative effects. Because the notion of "fairness" is a subject of controversy, free riding is usually only considered to be an economic "problem" when it leads to the non-production or under-production of a public good, and thus to Pareto inefficiency, or when it leads to the excessive use of a common property resource" [From Wikipedia].

$$\frac{pendingip(\mathsf{GCU}) = \mathit{false} \quad gmode(\mathsf{GCU}) = \mathit{true} \quad samedom(\mathsf{GBU},\mathsf{GCU}) = \mathit{true} \quad regmode(\mathsf{GCU}) = \mathit{true} \quad fairness(\mathsf{GBU},\mathsf{GCU}) \leq \epsilon \; notifiring(\mathsf{GBU},\mathsf{GCU})}{\{\{\mathsf{GBU},\mathsf{GCU},\ldots\}\} \rightarrow \{\{\mathsf{GBU},\ldots\},\mathsf{GCU}\}}\ (\mathsf{FireGCU})$$

$$\frac{pendingip(\mathsf{GBU}_2) = \mathit{false} \quad gmode(\mathsf{GBU}_2) = \mathit{true} \quad samedom(\mathsf{GBU}_1,\mathsf{GBU}_2) = \mathit{true} \quad regmode(\mathsf{GBU}_2) = \mathit{true} \quad fairness(\mathsf{GBU}_1,\mathsf{GBU}_2) \leq \epsilon \; notifiring(\mathsf{GBU}_1,\mathsf{GBU}_2)}{\{\{\mathsf{GBU}_1,\{\mathsf{GBU}_2,\ldots\},\ldots\}\} \rightarrow \{\{\mathsf{GBU}_1,\ldots\},\{\mathsf{GBU}_2,\ldots\}\}}\ (\mathsf{FireCol})$$

Figure 6. Extra Reduction Rules for Firing *Free Riders*

The selfish nodes in P2P networks, called free riders, only utilize other peers resources without providing any contribution in return, have greatly jeopardized the fairness attribute of P2P networks. Figure 6 presents the two rules that take into account the ratio between the number of services offered and the number of services demanded by an individual. If the leader of a colony finds that an individual ratio of fairness is too small ($\leq \epsilon$ for a given ϵ), it can arbitrarily decide to fire that individual without notice. Here, the function *pendingip* also checks that the individual has no pending services to offer, or that the timeout of some promised services has expired, the latter case means that the free rider promised some services but finally did not provide any service at all (not trustful). The function *notifiring* sends a message to the free rider, notifying it that it was definitively fired from the colony.

6 Examples

In [1], a Grid scenario for Seismic Monitoring was presented. In this section we briefly recall the scenario and we present, by means of labeled transition system reductions, the evolution of the given virtual organization.

6.1 (Re)Setting the Scenario (from [1])

John, chief engineer of the SeismicDataCorp Company, Taiwan, on board of the seismic data collector ship, has to decide on the next data collect campaign. For this he would like to process the 100 TeraBytes of seismic data that have been recorded on the mass data recorder located in the offshore data repository of the company, to be processed and then analyzed.

He has written the processing program for modeling and visualizing the seismic cube using some *parallel library* like *e.g.* `MPI/PVM`: his program can be distributed over different machines that will compute a chunk of the whole calculus;

However, the amount of computation is so big that a supercomputer ($\mathsf{GCU}_{\mathrm{SCU}}$) and a cluster of PC ($\mathsf{GCU}_{\mathrm{CLU}}$) has to be *rented* by the SeismicDataCorp company.

John will also ask for *bandwidth* via an ISP located in Taiwan ($\mathsf{GCU}_{\mathrm{ISPTW}}$) in order to get rid of any bottleneck related to the big amount of data to be transferred.

Aftermath, the processed data should be analyzed using a *Virtual Reality Center*, VRC ($\mathsf{GCU}_{\mathrm{VCRCPU}}$) based in Houston, U.S.A. by a specialist team and the resulting recommendations for the next data ($\mathsf{GCU}_{\mathrm{VRCSPEC}}$) collect campaign have to be sent to John. Hence one would like the following scenario to happen:

- John logs with its laptop ($\mathsf{GCU}_{\mathrm{John}}$) to the Arigatoni overlay network in a given colony in Taiwan, and sends a quite complicated service request in order for the data to be processed using his own code. Usually the GBU leader of the colony will receive and process the request;
- If the resource discovery performed by the GBU succeeds, *i.e.* a supercomputer, a cluster and an ISP are found, then the data are transferred at a very high speed and processed;
- John will order to the $\mathsf{GCU}_{\mathrm{SDTW}}$ containing the seismic data to dispatch suitable chunks of data to the supercomputer and the cluster designated by the GBU to perform some pieces of computation;
- John will assign to the supercomputer unit the task of collecting all intermediate results in order to compute the final result (*i.e.* it will play the role of *Maestro di Orchestra*);
- The processed data are then sent from the supercomputer, via the high speed ISP to the Houston center for being visualized and analyzed;
- Finally, the specialist team's recommendations have to be sent to John's laptop.

This scenario is pictorially presented in Figure 7.

6.2 Formalizing the Scenario

The initial community (the primitive *Soup*) will be composed of the following elements:

$$\begin{aligned}\mathsf{COM}_{\mathrm{Soup}} \triangleq \{\{&\mathsf{GBU}_{\mathrm{SDTW}}\}, \mathsf{GCU}_{\mathrm{SDTW}}, \{\mathsf{GBU}_{\mathrm{ISPTW}}\}, \mathsf{GCU}_{\mathrm{ISPTW}}, \{\mathsf{GBU}_{\mathrm{CPU}}\},\\ &\mathsf{GCU}_{\mathrm{SCU}}, \mathsf{GCU}_{\mathrm{CLU}}, \{\mathsf{GBU}_{\mathrm{VRC}}\}, \mathsf{GCU}_{\mathrm{VRCPU}}, \mathsf{GCU}_{\mathrm{VRCSPEC}}\}\end{aligned}$$

By applying five times the reduction rule $(\mathsf{JoinGCU})$ we obtain the new community:

$$\begin{aligned}\mathsf{COM}_1 \triangleq \{\{&\mathsf{GBU}_{\mathrm{SDTW}}, \mathsf{GCU}_{\mathrm{SDTW}}\}, \{\mathsf{GBU}_{\mathrm{ISPTW}}, \mathsf{GCU}_{\mathrm{ISPTW}}\}, \{\mathsf{GBU}_{\mathrm{CPU}},\\ &\mathsf{GCU}_{\mathrm{SCU}}, \mathsf{GCU}_{\mathrm{CLU}}\}, \{\mathsf{GBU}_{\mathrm{VRC}}, \mathsf{GCU}_{\mathrm{VRCPU}}, \mathsf{GCU}_{\mathrm{VRCSPEC}}\}\}\end{aligned}$$

and $\mathsf{COM}_{\mathrm{Soup}} \rightarrow^5 \mathsf{COM}_1$. Then by applying the reduction rule $(\mathsf{CommCup})$ we see John's laptop appear in the new community, $\mathsf{COM}_2 \triangleq \mathsf{COM}_1 \cup \{\mathsf{GCU}_{\mathrm{John}}\}$:

$$\begin{aligned}\mathsf{COM}_2 \triangleq \{&\mathsf{GCU}_{\mathrm{John}}, \{\mathsf{GBU}_{\mathrm{SDTW}}, \mathsf{GCU}_{\mathrm{SDTW}}\}, \{\mathsf{GBU}_{\mathrm{ISPTW}}, \mathsf{GCU}_{\mathrm{ISPTW}}\},\\ &\{\mathsf{GBU}_{\mathrm{CPU}}, \mathsf{GCU}_{\mathrm{SCU}}, \mathsf{GCU}_{\mathrm{CLU}}\}, \{\mathsf{GBU}_{\mathrm{VRC}}, \mathsf{GCU}_{\mathrm{VRCPU}}, \mathsf{GCU}_{\mathrm{VRCSPEC}}\}\}\end{aligned}$$

Figure 7. A Grid Scenario for Seismic Monitoring

By applying again $(\mathsf{JoinGCU})$ we obtain the new community:

$$\mathsf{COM}_3 \triangleq \{\{\mathsf{GBU}_{\mathrm{SDTW}}, \mathsf{GCU}_{\mathrm{SDTW}}, \mathsf{GCU}_{\mathrm{John}}\}, \{\mathsf{GBU}_{\mathrm{ISPTW}}, \mathsf{GCU}_{\mathrm{ISPTW}}\},$$
$$\{\mathsf{GBU}_{\mathrm{CPU}}, \mathsf{GCU}_{\mathrm{SCU}}, \mathsf{GCU}_{\mathrm{CLU}}\}, \{\mathsf{GBU}_{\mathrm{VRC}}, \mathsf{GCU}_{\mathrm{VRCPU}}, \mathsf{GCU}_{\mathrm{VRCSPEC}}\}\}$$

Now, if the community whose leader is $\mathsf{GBU}_{\mathrm{SDTW}}$ agrees to join the colony whose leader is $\mathsf{GBU}_{\mathrm{ISPTW}}$ (both are supposed to live in the same administrative domain), by applying rule $(\mathsf{JoinCol})$, we obtain the new community:

$$\mathsf{COM}_4 \triangleq \{\{\mathsf{GBU}_{\mathrm{ISPTW}}, \mathsf{GCU}_{\mathrm{ISPTW}}, \{\mathsf{GBU}_{\mathrm{SDTW}}, \mathsf{GCU}_{\mathrm{SDTW}}, \mathsf{GCU}_{\mathrm{John}}\}\},$$
$$\{\mathsf{GBU}_{\mathrm{CPU}}, \mathsf{GCU}_{\mathrm{SCU}}, \mathsf{GCU}_{\mathrm{CLU}}\}, \{\mathsf{GBU}_{\mathrm{VRC}}, \mathsf{GCU}_{\mathrm{VRCPU}}, \mathsf{GCU}_{\mathrm{VRCSPEC}}\}\}$$

The colony in Taiwan and the colony whose leader is $\mathsf{GBU}_{\mathrm{CPU}}$ (they are supposed to live in different administrative domain) sign an "agreement", by applying rule $(\mathsf{LinkCol})$, so giving the new community:

$$\mathsf{COM}_5 \triangleq$$
$$\{\ \{\mathsf{GBU}_{\mathsf{ISP\&CPU}}, \{\mathsf{GBU}_{\mathrm{ISPTW}}, \mathsf{GCU}_{\mathrm{ISPTW}}, \{\mathsf{GBU}_{\mathrm{SDTW}}, \mathsf{GCU}_{\mathrm{SDTW}}, \mathsf{GCU}_{\mathrm{John}}\}\},$$
$$\{\mathsf{GBU}_{\mathrm{CPU}}, \mathsf{GCU}_{\mathrm{SCU}}, \mathsf{GCU}_{\mathrm{CLU}}\} \quad \},$$
$$\{\mathsf{GBU}_{\mathrm{VRC}}, \mathsf{GCU}_{\mathrm{VRCPU}}, \mathsf{GCU}_{\mathrm{VRCSPEC}}\}\}$$

Finally, the colony containing John's laptop is ready to receive *John's huge Service Request*, and, hopefully for John, the request will be accepted and performed ... It is now time for John to come back home and the community COM_5 could then (but this is not mandatory) disintegrate. By applying the "dual" reduction rules (LeaveGCU), (LeaveCol), and (UnLinkCol) plus the congruence rules (CommCup) and (CommMinus), we come back to the initial soup, *i.e.* $\mathsf{COL}_5 \rightarrow^* \mathsf{COM}_{\mathrm{Soup}}$.

7 Properties

In this section we prove that our process algebra is able to model the virtual organization induced by an Arigatoni overlay network. Morris-style contextual equivalence [4] is the standard way of saying that two communities have *the same behavior* (are equivalent) if and only if whenever they are merged inside an arbitrary community, they admit the same elementary observations. In our setting and as usual in process algebras, contextual equivalence is formulated in terms of observing the presence of top-level colonies, as in the next definition.

Definition 7.1 [Colony Exhibition and Contextual Equivalence]

(i) a community COM must exhibit a colony COL, write $\mathsf{COM} \downarrow_{must} \mathsf{COL}$, if COL is a community containing a top-level colony COL, *i.e.*

$$\mathsf{COM} \downarrow_{must} \mathsf{COL} \triangleq \mathsf{COM} = \{\ldots, \mathsf{COL}, \ldots\}$$

(ii) a community COM may exhibit a colony COL, write $\mathsf{COM} \downarrow_{may} \mathsf{COL}$, if after a number of reductions, COL is a community containing a top-level colony COL, *i.e.*

$$\mathsf{COM} \downarrow_{may} \mathsf{COL} \triangleq \mathsf{COM} \rightarrow^* \mathsf{COM}' \text{ and } \mathsf{COM}' = \{\ldots, \mathsf{COL}, \ldots\}$$

(iii) let the context $\mathsf{C}[\cdot]$ be a community containing zero or more holes, and for any community COM let $\mathsf{C}[\mathsf{COM}]$ be the community obtained by filling each hole in $\mathsf{C}[\cdot]$ with a copy of COM. The contextual equivalence between community, write $\mathsf{COM} \simeq \mathsf{COM}'$, is defined as

$$\mathsf{COM} \simeq \mathsf{COM}' \triangleq \text{ for all COL and } \mathsf{C}[\cdot] \text{ we have}$$
$$\mathsf{C}[\mathsf{COM}] \downarrow_{may} \mathsf{COL} \Leftrightarrow \mathsf{C}[\mathsf{COM}'] \downarrow_{may} \mathsf{COL}$$

(iv) let $\mathsf{COM} \rightarrow^* \simeq \mathsf{COM}'$ if there exists COM'' such that $\mathsf{COM} \rightarrow^* \mathsf{COM}''$ and $\mathsf{COM}'' \simeq \mathsf{COM}'$.

Let $\mathcal{COM}$ be the set of communities generated by the BNF syntax.

Theorem 7.2 (Closure Under Reduction)

(i) *If* $\mathsf{COM} \in \mathcal{COM}$, *and* $\mathsf{COM} \rightarrow^* \mathsf{COM}'$, *then* $\mathsf{COM} \in \mathcal{COM}$;

(ii) *If* $\mathsf{COM} \simeq \mathsf{COM}'$, *then* $\mathsf{COM}, \mathsf{COM}' \in \mathcal{COM}$;

(iii) *If* $\mathsf{COM} \rightarrow^{*} \simeq \mathsf{COM}'$, *then* $\mathsf{COM}, \mathsf{COM}' \in \mathcal{COM}$

Proof

1) By observing the reduction rules of the labeled transition system, one can verify that if the left-hand side belongs to $\mathcal{COM}$*, then it is also the case for the right-hand side. The final result can be obtained by induction on the number of reduction.*

2,3) By point 1) using Definition 7.1.

□

Theorem 7.3 (Inversion)

(i) *If* $\mathsf{COM} \rightarrow_{(\mathsf{JoinGCU/COL})} \mathsf{COM}'$ *on the individual (*GCU *or* COL*), and* $\mathsf{COM}' \rightarrow_{(\mathsf{LeaveGCU/COL})} \mathsf{COM}''$ *on the same individual, then* $\mathsf{COM} = \mathsf{COM}''$*;*

(ii) *If* $\mathsf{COM} \rightarrow_{(\mathsf{LinkCol})} \mathsf{COM}'$ *on two colonies, and* $\mathsf{COM}' \rightarrow_{(\mathsf{UnLinkCOL})} \mathsf{COM}''$ *on the same colonies, then* $\mathsf{COM} = \mathsf{COM}''$.

Proof *By observing the reduction rules, one can observe that the right-hand side of the reduction rules* (JoinGCU)*,* (JoinCOL)*, and* (LinkCOL) *corresponds to the left-hand side of the dual reduction rules* (LeaveGCU)*,* (LeaveCOL)*, and* (UnLinkCol)*, and conversely the left-hand side of the reduction rules* (JoinGCU)*,* (JoinCOL)*, and* (LinkCOL) *corresponds to the right-hand side of the dual reduction rules* (LeaveGCU)*,* (LeaveCOL)*, and* (UnLinkCol)*. Applying one rule after the other clearly corresponds to an identity operation.* □

Conjecture 7.4 (Adequacy of the labeled transition system w.r.t. the pseudocode) *The labeled reduction system is adequate with the pseudocode of the* GBU *and of the* GCU *shown in Figure 3 and 4.*

Proof *(Sketch) Observe that the red parts of the pseudocode of the* GCU *concerning the set and unset of the variables* $globalmode/regmode$ *leads to the firing of the two rules* (JoinGCU) *and* (LeaveGCU)*. Moreover, the red parts of the pseudocode of the* GBU *concerning the set and unset of the variables* $globalmode/regmode$ *leads to to the firing of the two rules* (JoinGCU) *and* (LeaveGCU)*. The last two rules of the transition systems, namely* (LinkCol) *and* (UnLinkCol) *are encapsulated (hence hidden) in the function calls* `Update(Colony,Metadata)`. □

8 Experimental Evaluation

In this section, we provide results from experimental evaluation. We have conducted simulations using large numbers of units and service requests. In this paper, we specifically focus on the effect of individuals disconnections on the average service acceptation ratio.

More precisely, we have implemented reduction rules (JoinGCU), (LeaveGCU), (JoinCol), and (LeaveCol), that represent the "core" rewriting set to simulate the

dynamic behavior in the Arigatoni overlay network. We expect to implement the full set of rewriting rules defining the operational semantics soon.

8.1 Simulation Setup

We have generated a network topology using the transit-stub model of the Georgia Tech Internetwork Topology Models package [7], on top of which we added the Arigatoni Overlay Network. The resulting network topology, shown in Figure 8, contains 103 GBUs. GBU_2 (highlighted with a square in Figure 8) was chosen as the root of the topology. We considered a finite set of resources $R_1 \cdots R_r$ of

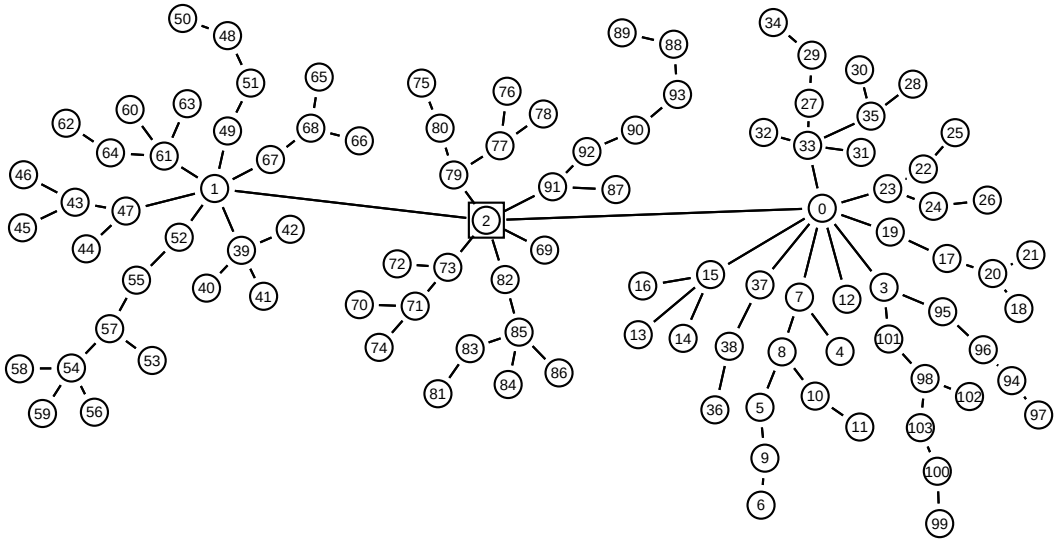

Figure 8. Simulated network topology with 103 GBUs

variable size r, and represented a service by a direct mapping to a resource. In other words, a service expresses the conditional presence of a single resource. We have a set of r services $\{S_1 \cdots S_r\}$, where service S_i expresses the conditional presence of resource R_i. A GCU declaring service S_i means that it can provide resource R_i. This model, while quite simple, is still generic enough, and is sufficient for the main purpose of our experiments, which is to study the impact of individuals disconnections on the average service acceptation ratio. Results are illustrated in Figure 9.

To simulate GCU load, we attached 50 GCUs to each GBU; we then randomly added each service S_i with probability ρ at each GCU and had it registered via the registration service of Arigatoni. The routing tables of the GBUs were updated starting at the initial GBU and ending at the root of the topology, GBU_2.

We then issued n service requests at GCUs chosen uniformly at random. Each request contained one service also chosen uniformly at random. Each service request was then handled by the Resource Discovery mechanism of Arigatoni (described in [3]). We used a service acceptation probability of $\alpha = 75\%$, which corresponds to the probability that a GCU that receives a service request *and* that

declared itself as a potential Individual for that service (*i.e*. that registered it), accepts to serve it.

Upon completion of the n requests, we computed the average service acceptation ratio as follows. For each GCU, we computed the local acceptation ratio as the number of service requests that yielded a positive response (*i.e*. the system found at least one Individual), over the number of service requests issued at that GCU. We then computed the average acceptation ratio as the average value over the number of GCUs (that issued at least one service request).

To study the impact of GBUs disconnections (*i.e*., rewriting rules $(\mathsf{JoinCol})$ and $(\mathsf{LeaveCol})$), we used a disconnection probability variable δ that indicates a fraction of disconnected individuals ($\delta = 0\%$ means all individuals are connected, while $\delta = 100\%$ means all individuals are disconnected). We then repeated the same experiment when δ of the GBUs population, chosen uniformly at random, have been disconnected from their leader. When a subcolony has been disconnected from its GBU leader, it continues to operate *in standalone* mode, *i.e*. with its local GBU leader as the current broker. Therefore, the services offered by the other colonies are unavailable inside, while services offered by the colony itself are not available outside. For each value of $\delta \in [0 \cdots 100]\%$, we repeated the same experiment 10 times, and measured the average value of the acceptation ratio. In each of the 10 runs, the disconnected GBUs were chosen uniformly at random, *independently* of the previous runs (*i.e*., with a different random seed). We then computed the standard deviation of the average service acceptation ratio (over the 10 values).

Starting from the fully connected topology COM_1 of Figure 8, the rationale of the simulation corresponds to applying a number of $(\mathsf{JoinCol})$ rewriting rules to have some subcolonies join the Colony, and then applying a number of $(\mathsf{LeaveCol})$ rewriting rules to have some other subcolonies leave the Colony, and then performing the experiment 10 times.

$$\mathsf{COM}_i \rightarrow^*_{(\mathsf{JoinCol})} \mathsf{COM}'_{i+1} \rightarrow^*_{(\mathsf{LeaveCol})} \mathsf{COM}_{i+1} \qquad i = 1 \ldots 10$$

We also studied the effect of GCUs disconnections (rewriting rules $(\mathsf{JoinGCU})$ and $(\mathsf{LeaveGCU})$), by repeating the same experiment when δ of the GCUs population have been disconnected from their leader. Also in this case, a disconnected GCU continues to work in standalone mode using only their own resources.

As for the GBU case, we have

$$\mathsf{COM}_i \rightarrow^*_{(\mathsf{JoinGCU})} \mathsf{COM}'_{i+1} \rightarrow^*_{(\mathsf{LeaveGCU})} \mathsf{COM}_{i+1} \qquad i = 1 \ldots 10$$

The Resource Discovery algorithm was implemented in C++ and compiled using GNU C++ version 2.95.3. Experiments were conducted on a 3.0 Ghz Intel Pentium machine with 2 GB of main memory running Linux 2.4.28. The different experimental parameters are summarized in Table 1. The service availability ratio, ρ, was fixed to a value of 0.12%, which yields an average service acceptation ratio of almost 100% with no subcolonies disconnections. Figure 9(a) shows that the average service acceptation ratio decreases exponentially with the number of

Parameter	Description	Value
K	Number of GBUs	103
r	Size of services pool	128
ρ	Service availability	0.12%
α	Service acceptation probability	75%
n	Number of service requests issued	50000
δ	Fraction of disconnected individuals	$[0 \cdots 100]\%$

Table 1
Parameters of the experiments

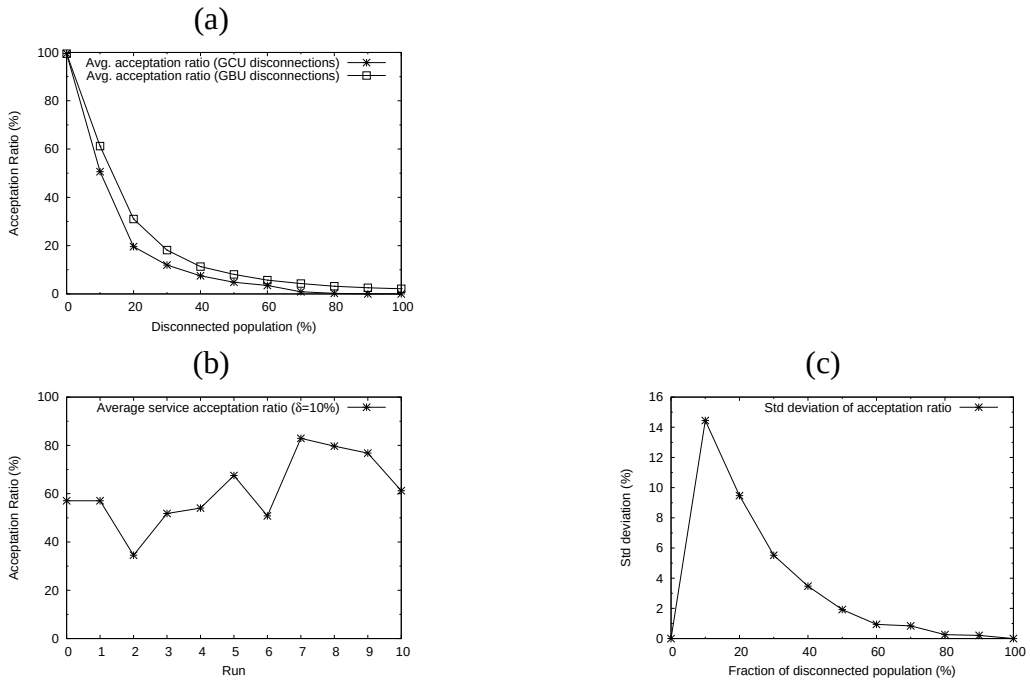

Figure 9. (a) Average service acceptation ratio w.r.t. fraction of disconnected population. (b) Average service acceptation ratio for the different runs of the value $\delta = 10\%$. (c) Standard deviation of the service acceptation ratio w.r.t. fraction of disconnected population.

subcolonies (*i.e.*, GBUs) disconnections. This is not surprising, since when a subcolony has been disconnected, all the services offered by the other colonies are unavailable. Conversely, all the services offered by the subcolony are unavailable for the other colonies. Note that when all subcolonies have been disconnected ($\delta = 100\%$), then the average service acceptation ratio is not null. Indeed, the local colony of a GBU (*i.e.*, the GCUs directly connected to the GBU) remains operational, *i.e.*, the services offered by a GCU are available for the other GCUs of the same colony.

We observe that GCU disconnections have more impact on the average service acceptation ratio than GBU disconnections. This is due to the fact that when a GCU is disconnected, all the services that it provided are unavailable for the entire system and, conversely, all the services provided by the system are unavailable for it. As expected, for a value of $\delta = 100\%$, the average acceptation ratio is 0, as no

service at all is unavailable.

Figure 9(a) shows the different values of the average service acceptation ratio obtained for a value of $\delta = 10\%$ of the fraction of disconnected population. As previously explained, for each run, we have chosen 10 GBUs ($\sim 10\%$ of 103) uniformly at random, and *independently* of the previous runs, *i.e.*, with a different random seed. In other words, the disconnected subcolonies are different in each run. Figure 9(b) shows that subcolonies disconnections can have a very different impact on the acceptation ratio. In fact, "low-level" subcolonies disconnections have a dramatic impact whereas "high-level" subcolonies disconnections have a very limited, local impact. Figure 9(c) shows that, unsurprisingly, the level of the disconnected subcolony has less impact on the service acceptation ratio for higher values of δ.
