HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Interval estimation for systems with time delays and algebraic constraints

Denis Efimov, Andrey Polyakov, Jean-Pierre Richard

Abstract—The problem of interval observer design is addressed for a class of descriptor linear systems with delays. Two sets of conditions are proposed. First, an interval observation for any input in the system is provided. Second, the control input is designed together with the observer gains in order to guarantee interval estimation and stabilization simultaneously. Efficiency of the proposed approach is illustrated by numerical experiments.

I. INTRODUCTION

The state estimation problem for uncertain models of industrial plants or biological systems has a great practical importance [1], [2], [3]. The model uncertainty can be presented by unknown (possibly time-varying) parameters, external disturbances and/or measurement noises. In such a way the designed estimator has to ensure a certain robustness of generated estimates with respect to perturbations. Another issue is that the observer design is structurally complicated in this case, since all uncertain terms should be either estimated simultaneously or avoided in the observer equations (*e.g.* substituted by some known bounds).

Then an important characteristic appears dealing with accuracy of the generated estimates of the state in the presence of all perturbations (unknown parameters, exogenous disturbances, measurement noise). The problem of accuracy evaluation is partially related with the problem of quantitative estimation of robustness. The difference is that usually for robustness quantification a gain should be computed between the maximal amplitude of a perturbation and the maximal amplitude of the response (the state estimation error in our case), while for accuracy evaluation the deviations from the real values have to be computed as tight as possible. It is strongly appreciated in applications to estimate this accuracy either off-line (during the design phase) or on-line using some numerical routines.

This work is supported in part by EU Interreg IV A 2 Mers Seas Zeeën Cross-border Cooperation Programme under SYSIASS project 06-020, by the Ministry of Higher Education and Research, Nord-Pas de Calais Regional Council and FEDER through the “Contrat de Projets Etat Region (CPER) CIA 2007-2013”, by the Government of Russian Federation (Grant 074-U01) and the Ministry of Education and Science of Russian Federation (Project 14.Z50.31.0031).

There exist many approaches to design state observers for uncertain systems [1], [2], [3], all of them are heavily related with the type of the plant model. A special class of models is composed by the so-called (linear) continuous-time descriptor systems, singular systems or differential-algebraic systems [4]. Descriptor systems have attracted much attention due to the numerous applications in economics (Leontief dynamic model) [5], in electrical engineering [6], mechanical systems with constraints [7] or flow optimal control [8]. Another important class of models is described by time-delay differential equations [9]. The problem of observer design for delayed systems is rather complex [10], as well as the stability conditions for analysis of functional differential equations are rather complicated [11], [12]. Especially the observer synthesis is problematical for the cases when the model of a delayed system contains parametric and signal uncertainties, or when the delay is time-varying or uncertain [13], [14], [15], [16], [17].

The present work deals with an intersection of these classes, with linear descriptor time-delay systems. An observer solution for this more complex situation may be demanded in many real-world applications (economics, electrical circuits, flow control systems, and so on). Inclusion in a descriptor model of (almost always presented) delay effects increases accuracy of modeling (among others, in the case of convection effects in a fluid flow). In addition, a delayed descriptor system is a combination of two dynamics: a differential equation with a difference equation (in the delay-free case, algebraic constraint is static), which enlarges the class of physical phenomenon that can be modeled by the approach.

The solution of estimation problem for these systems is based on the set-membership estimation approaches [18], [19], [20], and in particular a design of interval observers [21], [22], [18], [23], [24], [25] is presented in this work. Some results have been obtained recently on synthesis of interval observers for time-delay systems [16], [17], and the objective is to extend these design tools to the class of descriptor systems. The advantages of the interval observers are that they are well adapted for observer design for highly uncertain systems (if the intervals of admissible values for unknown terms are given) and that they are capable to provide asymptotically rather tight bounds on the estimation accuracy, since the interval of admissible values for the state at each instant of time is evaluated.

The outline of this work is as follows. Some preliminary

results are given in Section 2. Problem statement is presented in Section 3. Main results are formulated in Section 4. Numerical experiments and concluding remarks are presented in sections 5 and 6 respectively.

II. PRELIMINARIES

In the rest of the paper, the following definitions will be used:

- \mathbb{R} is the set of all real numbers ($\mathbb{R}_+ = \{\tau \in \mathbb{R} : \tau \geq 0\}$), $\mathcal{C}_\tau = C([- \tau, 0], \mathbb{R})$ is the set of continuous maps from $[- \tau, 0]$ into \mathbb{R} ; $\mathcal{C}_{\tau+} = \{y \in \mathcal{C}_\tau : y(s) \in \mathbb{R}_+, s \in [- \tau, 0]\}$;
- x_t is an element of \mathcal{C}_τ^n associated with a map $x_t : \mathbb{R} \rightarrow \mathbb{R}^n$ by $x_t(s) = x(t + s)$, for all $s \in [- \tau, 0]$;
- $|x|$ denotes the absolute value of $x \in \mathbb{R}$, $\|x\|$ is the Euclidean norm of a vector $x \in \mathbb{R}^n$, $\|\varphi\| = \sup_{t \in [- \tau, 0]} \|\varphi(t)\|$ for $\varphi \in \mathcal{C}_\tau^n$, $\|A\|$ corresponds to the Euclidean induced norm for a matrix $A \in \mathbb{R}^{n \times n}$;
- for a measurable and locally essentially bounded input $u : \mathbb{R}_+ \rightarrow \mathbb{R}^p$ the symbol $\|u\|_{[t_0, t_1]}$ denotes its L_∞ norm $\|u\|_{[t_0, t_1]} = \text{ess sup}\{|u(t)|, t \in [t_0, t_1]\}$, the set of all such inputs u with the property $\|u\|_{[0, +\infty)} < \infty$ will be denoted as \mathcal{L}_∞^p ;
- for a matrix $A \in \mathbb{R}^{n \times n}$ the vector of its eigenvalues is denoted as $\lambda(A)$;
- $1_n \in \mathbb{R}^n$ is stated for a vector with unit elements, I_n denotes the identity matrix of dimension $n \times n$;
- $a \mathcal{R} b$ corresponds to an elementwise relation \mathcal{R} (a and b are vectors or matrices): for example $a < b$ (vectors) means $\forall i : a_i < b_i$; for $\phi, \varphi \in \mathcal{C}_\tau^n$ the relation $\phi \mathcal{R} \varphi$ has to be understood elementwise for all domain of definition of the functions, i.e. $\phi(s) \mathcal{R} \varphi(s)$ for all $s \in [- \tau, 0]$;
- the relation $P \prec 0$ ($P \succ 0$) means that the matrix $P \in \mathbb{R}^{n \times n}$ is negative (positive) definite.

A. Descriptor linear systems

A descriptor system

$$E\dot{x}(t) = A_0x(t) + Bu(t),$$

where $x \in \mathbb{R}^n$ and $u(t) \in \mathcal{L}_\infty^m$ are the state and the input (the matrices $E \in \mathbb{R}^{n \times n}$, $A_0 \in \mathbb{R}^{n \times n}$ and $B \in \mathbb{R}^{n \times m}$), is called regular if the characteristic polynomial $\det(sE - A)$ does not vanish identically for all $s \in \mathbb{C}$ [26], [27]. In the regular case there exist matrices $P, Q \in \mathbb{R}^{n \times n}$ such that

$$QEP = \begin{bmatrix} I_{n_1} & 0 \\ 0 & N \end{bmatrix}, \quad QA_0P = \begin{bmatrix} J & 0 \\ 0 & I_{n_2} \end{bmatrix},$$

where $n_2 = n - n_1$ for some $1 \leq n_1 < n$, $N \in \mathbb{R}^{n_2 \times n_2}$ and $J \in \mathbb{R}^{n_1 \times n_1}$ are in the Jordan canonical form, the matrix N is nilpotent of index ν (i.e. $N^\nu = 0$ and $N^{\nu-1} \neq 0$). The descriptor system (or the pair (E, A_0)) has index that is the index of nilpotence ν of N . If a descriptor system has index $\nu > 1$, then it admits impulsive solutions.

B. Descriptor linear time-delay systems

A descriptor time-delay system

$$E\dot{x}(t) = A_0x(t) + A_1x(t - \tau) + Bu(t), \quad (1)$$

where $\tau > 0$ is the delay and $x(t) \in \mathbb{R}^n$ is the state, $x_0 \in \mathcal{C}_\tau^n$ is the initial condition, $u(t) \in \mathcal{L}_\infty^m$, has an index that is equal to the index of the pair (E, A_0) . If $\nu > 1$ then the descriptor time-delay system has impulsive solutions. If a regular descriptor system has index 1, then it can be presented in a canonical form (similar case has been considered in [26]), where

$$E = \begin{bmatrix} I_{n_1} & 0 \\ 0 & 0 \end{bmatrix}; \quad B = \begin{bmatrix} B_1 \\ B_2 \end{bmatrix}; \quad (2)$$

$$A_i = \begin{bmatrix} A_{i1} & A_{i2} \\ A_{i3} & A_{i4} \end{bmatrix}, \quad i = 0, 1.$$

Denote in this case $x = [x_1^T \ x_2^T]^T$, where $x_1 \in \mathbb{R}^{n_1}$ and $x_2 \in \mathbb{R}^{n_2}$.

Proposition 1. [26] Assume that $\det(A_{04}) \neq 0$ and $x_0 \in \mathcal{C}_\tau^n$, then for any $u(t) \in \mathcal{L}_\infty^m$ an absolute continuous solution of (1) exists for all $t \in \mathbb{R}_+$ and it is unique.

Proposition 2. [26] Assume that $\det(A_{04}) \neq 0$ and $\max_{1 \leq i \leq n_2} |\lambda_i(A_{04}^{-1}A_{14})| < 1$. If there exist $P \in \mathbb{R}^{n \times n}$,

$$P = \begin{bmatrix} P_1 & 0 \\ P_2 & P_3 \end{bmatrix}, \quad P_1 = P_1^T \succ 0, \quad (3)$$

$$P_1 \in \mathbb{R}^{n_1 \times n_1}, \quad P_3 \in \mathbb{R}^{n_2 \times n_2},$$

and $U = U^T \in \mathbb{R}^{n \times n}$ that satisfy the following LMI for some $\gamma > 0$:

$$\begin{bmatrix} \Psi & P^T B & P^T A_1 \\ B^T P & -\gamma^2 I_m & 0 \\ A_1^T P & 0 & -U \end{bmatrix} \prec 0,$$

$$\Psi = P^T A_0 + A_0^T P + U,$$

then the system (1), (2) is globally asymptotically stable for $u \equiv 0$ and any delay $\tau > 0$, in addition its H_∞ gain from the input u to the state x is less than γ .

C. Positive descriptor linear time-delay systems

Positive (nonnegative) or cooperative (monotone) models [28], [29], [30], [31] have a large area of applications for description the systems of different nature in biology, economics, chemistry etc.

Definition 1. A regular descriptor system (1) with index 1 is called positive if the restrictions $x_0 \in \mathcal{C}_{\tau+}^n$, $u(t) \in \mathbb{R}_+^m$ for all $t \geq 0$ imply that $x(t) \in \mathbb{R}_+^n$ for all $t \geq 0$.

The generic results on positivity of the descriptor linear systems (without time delays) and their stability results are presented in [27], [32]. In the regular case with index 1 they can be seriously simplified [32]. In the spirit of these results, for time delay systems the following extensions can be obtained. For this purpose recall that a matrix A is called

Metzler if all its off-diagonal elements are nonnegative, a matrix A is called nonnegative if $A \geq 0$ (elementwise).

Proposition 3. *A regular descriptor system (1) with index 1, written in the canonical form (2) with $\det(A_{04}) \neq 0$, is positive if and only if A_0 is Metzler and A_1, B are nonnegative.*

All proofs are omitted due to space limitations.

D. Interval arithmetic

The following lemmas have been proven in [22], [21]. Given a matrix $A \in \mathbb{R}^{m \times n}$, define $A^+ = \max\{0, A\}$, $A^- = A^+ - A$ (similarly for vectors) and denote the matrix of absolute values of all elements by $|A| = A^+ + A^-$.

Lemma 1. *Let $x \in \mathbb{R}^n$ be a vector variable, $\underline{x} \leq x \leq \bar{x}$ for some $\underline{x}, \bar{x} \in \mathbb{R}^n$, and $A \in \mathbb{R}^{m \times n}$ be a constant matrix, then*

$$A^+ \underline{x} - A^- \bar{x} \leq Ax \leq A^+ \bar{x} - A^- \underline{x}.$$

Lemma 2. *Let $\underline{A} \leq A \leq \bar{A}$ for some $\underline{A}, \bar{A}, A \in \mathbb{R}^{n \times n}$ and $\underline{x} \leq x \leq \bar{x}$ for some $\underline{x}, \bar{x}, x \in \mathbb{R}^n$, then*

$$\begin{aligned} \underline{A}^+ \underline{x}^+ - \bar{A}^+ \underline{x}^- - \underline{A}^- \bar{x}^+ + \bar{A}^- \bar{x}^- &\leq Ax \\ &\leq \bar{A}^+ \bar{x}^+ - \underline{A}^+ \bar{x}^- - \bar{A}^- \underline{x}^+ + \underline{A}^- \underline{x}^-. \end{aligned}$$

III. PROBLEM STATEMENT

In this work we will consider an extended version of the descriptor time-delay system (1)

$$\begin{aligned} E\dot{x}(t) &= A_0x(t) + A_1x(t-\tau) + Bu(t) + d(t), \\ y(t) &= Cx(t) + v(t), \end{aligned} \quad (4)$$

where as before $\tau > 0$ is the delay and $x(t) \in \mathbb{R}^n$ is the state (with initial conditions $x_0 \in \mathcal{C}_\tau^n$); $u(t) \in \mathcal{L}_\infty^m$ is the control signal; $d(t) \in \mathcal{L}_\infty^n$ is a disturbance; $y \in \mathbb{R}^p$ is the output signal available for measurements; $v(t) \in \mathcal{L}_\infty^p$ is the measurement noise. The constant matrices E, A_0, A_1, B and C have appropriate dimensions. The following restrictions are imposed on (4). The case of multiple delays can be incorporated using the results of [26].

Assumption 1. *The system (4) is regular with index 1, $\det(A_{04}) \neq 0$, presented in the canonical form (2).*

Assumption 2. *The state $x(t)$ is a bounded function of time (i.e. $x(t) \in \mathcal{L}_\infty^n$).*

Assumption 3. *There is a known constant $V > 0$ such that $\|v_i\|_{[0, \infty)} \leq V$ for all $1 \leq i \leq p$, and there exist two known functions $\underline{d}, \bar{d}: \mathbb{R}_+ \rightarrow \mathbb{R}^n$, $\underline{d}(t), \bar{d}(t) \in \mathcal{L}_\infty^n$ such that $\underline{d}(t) \leq d(t) \leq \bar{d}(t)$ for all $t \geq 0$.*

The first assumption claims that the system (4) is regular and it has no impulsive solutions. It is also indicated that (4) is transformed to the canonical representation (that is always possible for regular systems with index 1). In the second assumption, boundedness of the state is imposed, which is a typical restriction in the estimation theory. In the third

assumption it is assumed that the noise is bounded by V and the lower and upper bounds for $d(t)$ are given (an interval of admissible values for $d(t)$ at each instant of time $t \geq 0$).

The objective is to design an interval observer for (4), i.e. a dynamical system

$$\begin{aligned} \dot{z}(t) &= F(z_t, y_t, u(t), V, \underline{d}(t), \bar{d}(t)), \quad z_0 \in \mathcal{C}_\tau^k, \quad k > 0, \\ \underline{x}(t) &= \underline{H}(z_t, y_t, u(t), V, \underline{d}(t), \bar{d}(t)), \\ \bar{x}(t) &= \bar{H}(z_t, y_t, u(t), V, \underline{d}(t), \bar{d}(t)), \end{aligned}$$

such that $\underline{x}(t) \leq x(t) \leq \bar{x}(t)$ for all $t \geq 0$ provided that $\underline{x}_0 \leq x_0 \leq \bar{x}_0$. In addition, if $\lim_{t \rightarrow +\infty} |\underline{d}(t) - \bar{d}(t)| = \lim_{t \rightarrow +\infty} |v(t)| = 0$, then $\lim_{t \rightarrow +\infty} |\underline{x}(t) - \bar{x}(t)| = \lim_{t \rightarrow +\infty} |x(t) - \bar{x}(t)| = 0$.

IV. MAIN RESULTS

First of all note that for any $L_1, L_2 \in \mathbb{R}^{n \times p}$ the system (4) can be rewritten as follows:

$$\begin{aligned} E\dot{x}(t) &= A_0x(t) + A_1x(t-\tau) + Bu(t) + d(t) \\ &\quad + L_1(y(t) - Cx(t) - v(t)) \\ &\quad + L_2(y(t-\tau) - Cx(t-\tau) - v(t-\tau)) \\ &= (A_0 - L_1C)x(t) + (A_1 - L_2C)x(t-\tau) \\ &\quad + Bu(t) + \delta(t) + L_1y(t) + L_2y(t-\tau), \end{aligned} \quad (5)$$

where $\delta(t) = d(t) - L_1v(t) - L_2v(t-\tau)$, and using the result of Lemma 2, for all $t \geq 0$:

$$\begin{aligned} \underline{\delta}(t) &\leq \delta(t) \leq \bar{\delta}(t), \\ \underline{\delta}(t) &= \underline{d}(t) - (|L_1| + |L_2|)\mathbf{1}_pV, \\ \bar{\delta}(t) &= \bar{d}(t) + (|L_1| + |L_2|)\mathbf{1}_pV. \end{aligned}$$

Below, two sets of different conditions on L_1 and L_2 are considered with two different interval observers. Next, we will skip the requirement of Assumption 2 that the state $x(t)$ is bounded, and in addition to L_1, L_2 we will design a control $u(t)$ dependent on the interval estimates $\underline{x}(t), \bar{x}(t)$ providing the state $x(t)$ stabilization, as it has been done in [21], [33] for ordinary differential equations and time-delay systems (with the delay in the input channel only).

Further, denote

$$C = [C_1 \ C_2], \quad L_i = \begin{bmatrix} L_{i1} \\ L_{i2} \end{bmatrix}, \quad i = 1, 2,$$

where $C_1 \in \mathbb{R}^{p \times n_1}$, $C_2 \in \mathbb{R}^{p \times n_2}$, $L_{i1} \in \mathbb{R}^{n_1 \times p}$ and $L_{i2} \in \mathbb{R}^{n_2 \times p}$.

A. The case of a positive system

Actually we will not assume explicitly in this subsection that $x(t) \in \mathbb{R}_+^n$ and that (4) is positive, but the conditions imposed on L_1 and L_2 imply that the linear part in (5) is positive.

Consider the following interval observer:

$$\begin{aligned} E\dot{\underline{x}}(t) &= (A_0 - L_1C)\underline{x}(t) + (A_1 - L_2C)\underline{x}(t - \tau) \\ &\quad + Bu(t) + \underline{\delta}(t) + L_1y(t) + L_2y(t - \tau), \quad (6) \\ E\dot{\bar{x}}(t) &= (A_0 - L_1C)\bar{x}(t) + (A_1 - L_2C)\bar{x}(t - \tau) \\ &\quad + Bu(t) + \bar{\delta}(t) + L_1y(t) + L_2y(t - \tau). \end{aligned}$$

As we can conclude from (6), the dynamics of $\underline{x}(t)$ and $\bar{x}(t)$ are independent.

Theorem 1. *Let assumptions 1–3 be satisfied and $A_0 - L_1C$, $A_1 - L_2C$ be a Metzler and a nonnegative matrix respectively with $\det(A_{04} - L_{12}C_2) \neq 0$. Then in (4), (6), $\underline{x}(t) \leq x(t) \leq \bar{x}(t)$ for all $t \geq 0$ provided that $\underline{x}_0 \leq x_0 \leq \bar{x}_0$. If $\max_{1 \leq i \leq n_2} |\lambda_i([A_{04} - L_{12}C_2]^{-1}[A_{14} - L_{22}C_2])| < 1$ and there exist matrices $P \in \mathbb{R}^{n \times n}$ of the form (3) and $U = U^T \in \mathbb{R}^{n \times n}$ that satisfy the LMI*

$$\begin{bmatrix} \Psi & P^T & P^T(A_1 - L_2C) \\ P & -\gamma^2 I_n & 0 \\ (A_1 - L_2C)^T P & 0 & -U \end{bmatrix} \prec 0, \\ \Psi = P^T(A_0 - L_1C) + (A_0 - L_1C)^T P + U,$$

for some $\gamma > 0$, then $\underline{x}(t), \bar{x}(t) \in \mathcal{L}_\infty^n$ for any $\tau > 0$ and an H_∞ gain from the inputs $\delta - \underline{\delta}, \bar{\delta} - \delta$ to the state estimation errors $x - \underline{x}, \bar{x} - x$ respectively is less than γ .

Remark 1. Note that the result of Theorem 1 means that if $\delta(t) - \underline{\delta}(t) \rightarrow 0, \bar{\delta}(t) - \delta(t) \rightarrow 0$ with $t \rightarrow +\infty$, then $\underline{x}(t) \rightarrow x(t) \leftarrow \bar{x}(t)$ asymptotically.

B. The case of a positive delay-free system

In this part we would like to relax the restrictions introduced in the previous subsection for L_1 and L_2 . For this purpose consider another interval observer:

$$\begin{aligned} E\dot{\underline{x}}(t) &= (A_0 - L_1C)\underline{x}(t) + (A_1 - L_2C)^+ \underline{x}(t - \tau) \\ &\quad - (A_1 - L_2C)^- \bar{x}(t - \tau) \\ &\quad + Bu(t) + \underline{\delta}(t) + L_1y(t) + L_2y(t - \tau), \quad (7) \\ E\dot{\bar{x}}(t) &= (A_0 - L_1C)\bar{x}(t) + (A_1 - L_2C)^+ \bar{x}(t - \tau) \\ &\quad - (A_1 - L_2C)^- \underline{x}(t - \tau) \\ &\quad + Bu(t) + \bar{\delta}(t) + L_1y(t) + L_2y(t - \tau). \end{aligned}$$

In this case the dynamics of \underline{x}, \bar{x} are interrelated in (7).

Theorem 2. *Let assumptions 1–3 be satisfied and $A_0 - L_1C$ be a Metzler matrix with $\det(A_{04} - L_{12}C_2) \neq 0$. Then in (4), (7), $\underline{x}(t) \leq x(t) \leq \bar{x}(t)$ for all $t \geq 0$ provided that $\underline{x}_0 \leq x_0 \leq \bar{x}_0$. If $\max_{1 \leq i \leq 2n_2} |\lambda_i(\Lambda_{04}^{-1}\Lambda_{14})| < 1$ and there exist matrices $P \in \mathbb{R}^{2n \times 2n}$,*

$$P = \begin{bmatrix} P_1 & 0 \\ P_2 & P_3 \end{bmatrix}, \quad P_1 = P_1^T \succ 0, \quad (8) \\ P_1 \in \mathbb{R}^{2n_1 \times 2n_1}, \quad P_3 \in \mathbb{R}^{2n_2 \times 2n_2}$$

and $U = U^T \in \mathbb{R}^{2n \times 2n}$ that satisfy the LMI

$$\begin{bmatrix} \Psi & P^T & P^T \Lambda_1 \\ P & -\gamma^2 I_{2n} & 0 \\ \Lambda_1^T P & 0 & -U \end{bmatrix} \prec 0, \\ \Psi = P^T \Lambda_0 + \Lambda_0^T P + U, \\ \Lambda_i = \begin{bmatrix} \Lambda_{i1} & \Lambda_{i2} \\ \Lambda_{i3} & \Lambda_{i4} \end{bmatrix}, \quad i = 1, 2,$$

$$\Lambda_{01} = \begin{bmatrix} A_{01} - L_{11}C_1 & 0 \\ 0 & A_{01} - L_{11}C_1 \end{bmatrix},$$

$$\Lambda_{02} = \begin{bmatrix} A_{02} - L_{11}C_2 & 0 \\ 0 & A_{02} - L_{11}C_2 \end{bmatrix},$$

$$\Lambda_{03} = \begin{bmatrix} A_{03} - L_{12}C_1 & 0 \\ 0 & A_{03} - L_{12}C_1 \end{bmatrix},$$

$$\Lambda_{04} = \begin{bmatrix} A_{04} - L_{12}C_2 & 0 \\ 0 & A_{04} - L_{12}C_2 \end{bmatrix},$$

$$\Lambda_{11} = \begin{bmatrix} (A_{11} - L_{21}C_1)^+ & (A_{11} - L_{21}C_1)^- \\ (A_{11} - L_{21}C_2)^- & (A_{11} - L_{21}C_1)^+ \end{bmatrix},$$

$$\Lambda_{12} = \begin{bmatrix} (A_{12} - L_{21}C_2)^+ & (A_{12} - L_{21}C_2)^- \\ (A_{12} - L_{21}C_2)^- & (A_{12} - L_{21}C_2)^+ \end{bmatrix},$$

$$\Lambda_{13} = \begin{bmatrix} (A_{13} - L_{22}C_1)^+ & (A_{13} - L_{22}C_1)^- \\ (A_{13} - L_{22}C_1)^- & (A_{13} - L_{22}C_1)^+ \end{bmatrix},$$

$$\Lambda_{14} = \begin{bmatrix} (A_{14} - L_{22}C_2)^+ & (A_{14} - L_{22}C_2)^- \\ (A_{14} - L_{22}C_2)^- & (A_{14} - L_{22}C_2)^+ \end{bmatrix}$$

for some $\gamma > 0$, then $\underline{x}(t), \bar{x}(t) \in \mathcal{L}_\infty^n$ for any $\tau > 0$ and an H_∞ gain from the inputs $\delta - \underline{\delta}, \bar{\delta} - \delta$ to the state estimation errors $x - \underline{x}, \bar{x} - x$ respectively is less than γ .

Remark 2. Contrarily Theorem 1, the restriction $A_1 - L_2C \geq 0$ is not imposed in Theorem 2, the price for that is more complicated equations of interval observer (check (7) with respect to (6)) and more sophisticated matrix inequalities.

The conditions of Theorem 2 may be relaxed asking existence of a transformation matrix $S \in \mathbb{R}^{n_1 \times n_1}$ such that $S^{-1}(A_0 - L_1C)S$ is Metzler, the conditions of such a transformation matrix existence can be found in [25].

Remark 3. Finally note that a bounded function $d(\cdot)$ can be dependent on measured output y and input u in a nonlinear fashion, which does not change the applicability conditions of theorems 1 and 2 provided that $\underline{d}(t)$ and $\bar{d}(t)$ can be constructed. Thus the proposed interval observers (6) and (7) can be applied for estimation of uncertain nonlinear differential-algebraic systems. The delay τ can also be considered time-varying and uncertain under a mild modification of the structure of observers (6) and (7) in the way it has been proposed in [17].

C. Stabilization of descriptor time-delay systems using interval observer (6)

In this subsection we will try to skip Assumption 2 and, in order to simplify the presentation, we will consider the case

of interval observer (6) only (similar results can be obtained for (7), they are omitted for compactness).

In Theorem 1 the gains L_1 and L_2 have been used to guarantee the properties of positivity and stability for the dynamics of estimation errors $\underline{e}(t), \bar{e}(t)$. The positivity property has been obtained uniformly in $u(t)$. Thus the control design can be applied in order to ensure boundedness of the observer estimates $\underline{x}(t), \bar{x}(t)$, that in its turn ($\underline{x}(t) \leq x(t) \leq \bar{x}(t)$ for all $t \geq 0$) will provide boundedness of $x(t)$. An advantage of this approach is that the system (4) is uncertain and the state of that system is not measured, while the observer (6) is a completely known system with the accessible state $\underline{x}(t), \bar{x}(t)$ [21]. A drawback is that the dimension of the state for (6) is $2n$, while the dimension of the control is m , similarly to (4).

It is also necessary to take into account that for stabilization of $\underline{x}(t), \bar{x}(t)$ in (6), the signals $y(t)$ and $y(t - \tau)$ form a kind of functional perturbation, which is globally Lipschitz with respect to $\underline{x}(t), \bar{x}(t)$. Indeed, from the relation $\underline{x}(t) \leq x(t) \leq \bar{x}(t)$ we have

$$\begin{aligned} |x_i(t)| &\leq \max\{|\underline{x}_i(t)|, |\bar{x}_i(t)|\} \quad \forall 1 \leq i \leq n, \\ |x_i(t)|^2 &\leq |\underline{x}_i(t)|^2 + |\bar{x}_i(t)|^2 \quad \forall 1 \leq i \leq n, \\ \|x(t)\| &\leq \sqrt{\|\underline{x}(t)\|^2 + \|\bar{x}(t)\|^2} \\ &\leq \sqrt{2} \max\{\|\underline{x}(t)\|, \|\bar{x}(t)\|\}, \end{aligned}$$

then $\|y(t)\| \leq \|C\| \sqrt{2} \max\{\|\underline{x}(t)\|, \|\bar{x}(t)\|\}$.

Take

$$\begin{aligned} u(t) &= \underline{K}_1 \underline{x}(t) + \bar{K}_1 \bar{x}(t) + \underline{K}_2 \underline{x}(t - \tau) \\ &\quad + \bar{K}_2 \bar{x}(t - \tau) - R_1 y(t) - R_2 y(t - \tau) \end{aligned} \quad (9)$$

for some matrices $\underline{K}_i, \bar{K}_i \in \mathbb{R}^{m \times n}$, $R_i \in \mathbb{R}^{m \times p}$ with $i = 1, 2$. The idea of introduction of R_1 and R_2 is to minimize the influence of $y(t), y(t - \tau)$ on the dynamics of $\underline{x}(t), \bar{x}(t)$ in (6), i.e. to minimize the norm of $F_i = L_i - BR_i$. In a similar way, a term can be introduced in $u(t)$ in order to reduce the influence of $\underline{\delta}(t), \bar{\delta}(t)$.

Theorem 3. *Let assumptions 1,3 be satisfied and $A_0 - L_1 C$, $A_1 - L_2 C$ be a Metzler and a nonnegative matrix respectively with $\det(A_{04} - L_{12} C_2) \neq 0$. Then in (4), (6) with the control (9), $\underline{x}(t) \leq x(t) \leq \bar{x}(t)$ for all $t \geq 0$ provided that $\underline{x}_0 \leq x_0 \leq \bar{x}_0$. If $\max_{1 \leq i \leq n_2} |\lambda_i(\Delta_{04}^{-1} \Delta_{14})| < 1$ and there exist matrices $P \in \mathbb{R}^{2n \times 2n}$ of the form (8) and $U = U^T \in \mathbb{R}^{2n \times 2n}$ that satisfy the matrix inequalities*

$$\begin{aligned} \begin{bmatrix} \Psi & P^T & P^T \Delta_1 \\ P & -\gamma^2 I_n & 0 \\ \Delta_1^T P & 0 & -U \end{bmatrix} &< 0, \\ \Psi &= P^T \Delta_0 + \Delta_0^T P + U, \\ \Delta_i &= \begin{bmatrix} \Delta_{i1} & \Delta_{i2} \\ \Delta_{i3} & \Delta_{i4} \end{bmatrix}, \quad i = 1, 2, \end{aligned}$$

$$\begin{aligned} \Delta_{01} &= \begin{bmatrix} A_{01} - L_{11} C_1 + B_1 \underline{K}_{11} & B_1 \bar{K}_{11} \\ B_1 \underline{K}_{11} & A_{01} - L_{11} C_1 + B_1 \bar{K}_{11} \end{bmatrix}, \\ \Delta_{02} &= \begin{bmatrix} A_{02} - L_{11} C_2 + B_1 \underline{K}_{12} & B_1 \bar{K}_{12} \\ B_1 \underline{K}_{12} & A_{02} - L_{11} C_2 + B_1 \bar{K}_{12} \end{bmatrix}, \\ \Delta_{03} &= \begin{bmatrix} A_{03} - L_{12} C_1 + B_2 \underline{K}_{11} & B_2 \bar{K}_{11} \\ B_2 \underline{K}_{11} & A_{03} - L_{12} C_1 + B_2 \bar{K}_{11} \end{bmatrix}, \\ \Delta_{04} &= \begin{bmatrix} A_{04} - L_{12} C_2 + B_2 \underline{K}_{12} & B_2 \bar{K}_{12} \\ B_2 \underline{K}_{12} & A_{04} - L_{12} C_2 + B_2 \bar{K}_{12} \end{bmatrix}, \\ \Delta_{11} &= \begin{bmatrix} A_{11} - L_{21} C_1 + B_1 \underline{K}_{21} & B_1 \bar{K}_{21} \\ B_1 \underline{K}_{21} & A_{11} - L_{21} C_1 + B_1 \bar{K}_{21} \end{bmatrix}, \\ \Delta_{12} &= \begin{bmatrix} A_{12} - L_{21} C_2 + B_1 \underline{K}_{22} & B_1 \bar{K}_{22} \\ B_1 \underline{K}_{22} & A_{12} - L_{21} C_2 + B_1 \bar{K}_{22} \end{bmatrix}, \\ \Delta_{13} &= \begin{bmatrix} A_{13} - L_{22} C_1 + B_2 \underline{K}_{21} & B_2 \bar{K}_{21} \\ B_2 \underline{K}_{21} & A_{13} - L_{22} C_1 + B_2 \bar{K}_{21} \end{bmatrix}, \\ \Delta_{14} &= \begin{bmatrix} A_{14} - L_{22} C_2 + B_2 \underline{K}_{22} & B_2 \bar{K}_{22} \\ B_2 \underline{K}_{22} & A_{14} - L_{22} C_2 + B_2 \bar{K}_{22} \end{bmatrix}. \end{aligned}$$

for $\gamma < \left[\|C\| \sqrt{2} (\|F_1\| + \|F_2\|) \right]^{-1}$, then $x(t), \underline{x}(t), \bar{x}(t) \in \mathcal{L}_\infty^n$ for any $\tau > 0$ and an H_∞ gain from the inputs $\underline{\delta}, \bar{\delta}$ to the states \underline{x}, \bar{x} is less than γ and to the state x is less than $\sqrt{2}\gamma$.

In order to calculate $L_i, \underline{K}_i, \bar{K}_i, i = 1, 2$ the conditions of Theorem 3 can be decoupled. First, asking for L_i such that $A_0 - L_1 C$ is Metzler and Hurwitz and $A_1 - L_2 C$ is nonnegative and Schur stable. Second, looking for $\underline{K}_i, \bar{K}_i$ such that the LMI in the formulation of Theorem 3 is satisfied.

V. SIMULATIONS

Let us consider system (4) with

$$A_0 = \begin{bmatrix} -2 & 0 & 1 \\ -1 & -4 & 0 \\ -0.5 & 1 & -1 \end{bmatrix}, \quad A_1 = \begin{bmatrix} 0 & 0.5 & 0 \\ -1 & 0 & 0.25 \\ 0 & 1 & 0.25 \end{bmatrix},$$

$$E = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix}, \quad C = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}^T,$$

$$d(t) = \begin{bmatrix} \sin(x_1) + \delta \sin(x_2) \\ \sin(x_1) - \delta \cos(2t) \\ \sin(0.5x_1) + \delta \sin(x_2 t) \end{bmatrix}, \quad u(t) = \sin\left(\frac{t}{4}\right),$$

$$v(t) = V \sin(25t), \quad \delta = 1.5, \quad V = 0.2, \quad \tau = 0.1,$$

where the part of d proportional to δ is unknown (the model uncertainty). The system is nonlinear since d depends on x , however the known part of d depends on $x_1(t) = y(t) - v(t)$, then we can design $\underline{d}(t)$ and $\bar{d}(t)$ dependent on the measured signals only. Take

$$L_1 = \begin{bmatrix} 3 \\ -1 \\ -0.5 \end{bmatrix}, \quad L_2 = \begin{bmatrix} 0 \\ -1 \\ 0 \end{bmatrix},$$

then the LMI of Theorem 1 is satisfied for $\gamma = 1$, $P = \text{diag}[0.05 \ 1 \ 0.3]$ and $U = 0.3P$. All conditions of this theorem are valid and the results of interval observer (6) application are given in Fig. 1, for the coordinates x_2 and x_3 .

Figure 1. The results of simulation of the interval observer (6)

VI. CONCLUSION

For a class of regular descriptor linear systems of index 1 with delays two interval observers are proposed. Two sets of conditions are developed for these observers guaranteeing an interval estimation in the presence of any control input. Next, a control input is designed based on interval estimates providing interval estimation and stabilization simultaneously. Efficiency of the proposed approach is demonstrated in simulation.

As directions of future works, the development of computationally simple LMIs and the analysis of a time-varying delay can be considered.
