Abstract: An ejection mechanism consisting four reset springs, an electromagnet and a seed disk was designed for tray seeder. The motion conditions of seeds in the seed disk were theoretical analyzed and intensity and height of seed ejection were calculated. The motions of the seeds and seed disk were multi-body dynamic simulated using Cosmos modules plug-in SolidWorks software package. The simulation results showed the consistence with the theoretical analysis.

Key words: Tray seeders; ejection mechanism; numerical simulation; motion analysis;

1. INTRODUCTION

The Tray seeder is an essential component for modern cultivation techniques. Whether seeds are vibrated uniformly to suspension state by vibration device can affect the seeding capability. Now continual excited vibration by electromagnetic vibration device has been extensively employed to make the seeds “bouncing” and enable them being sucked. However, the uneven vibration intensity of seeds in different positions causes the seeds suspend in different height, so seeder has the poor air-suction effect for seeds. In recent years, the motion law of seeds based on continual excited vibration has been studied (cheng jin, 2002; Li Yaoming et al, 2009; Zhao Lixin et al, 2003). They reported that the seeds should obtain enough inertia force to get in appropriate suspension station for satisfaction of the air-suction requirements. But there is lack of information on how to make all seeds in different positions acquire same vibrating intensity. In this paper, an ejection mechanism consisting four reset springs, a electromagnet and a seed disk was designed. The motion conditions of seeders in the seed disk were theoretical analyzed and then ejection intensity and height were calculated. The motions of the seeds and seed disk were multi-body dynamic simulated using Cosmos modules plug-in SolidWorks software package. The simulation results showed the consistence with the theoretical analysis.

2. WORKING PRINCIPLE OF EJECTION MECHANISM

The ejection mechanism schematic diagram is shown in Fig.1. It mainly consists of four reset springs, a electromagnet and a seed disk. The disk and the armature of electromagnet are connected together by pin bolts. The reset springs are installed in the lug boss between the worktable and the seed disk. The armature overcomes friction, pulls the disk down when the electromagnet is charged, and conversely, the disk is ejected by the reset springs and the seeds are tossed into suspension. The hopping seeds can overcome the force among seeds, effectively improving the adsorption rate of all seeds.

Structural Design Parameters :

The weight of disk is 3kg, the stiffness of spring is 4N/mm, the voltage of electromagnet is 220v, the maximum traction force is 80N, and the maximum stroke is 25mm.

3. ANALYSIS OF MOTION REGULARITY OF EJECTION MECHANISM

3.1 Moving condition and calculation for hopping of seeds

The movements of monolayer seeds on the disk are studied. Gravity and force of inertia of the seeds are mainly considered (J. Theuerkauf P. Witt, 2006), air resistance is neglected. The critical condition for hopping of seeds is:

$$P \geq G \quad (1)$$

Where: P is the inertia force of seeds (N), G is weight of seeds (N)

The periodical harmonic excitation equation of disk is:

$$x = Ae^{-\varepsilon t} \sin(\omega_d t + \varphi) \quad (2)$$

Without considering the system damping, the motion is:

$$x = A \sin(\omega t + \varphi) \quad (3)$$

Where: t is vibration time(s), φ is the initial phase of vibration(rad), ω is natural frequency(Hz).

The initial acceleration of seeds is equal to disk's:

$$\alpha_s = \alpha_d = A\omega^2 \quad (4)$$

According to Newton Second Law:

$$P = m\alpha_s = \frac{G}{g} A\omega^2 \quad (5)$$

Puts (5) into (1):

$$P = \frac{G}{g} A\omega^2 \geq G \quad (6)$$

The ejection strength coefficient K is:

$$K = \frac{A\omega^2}{g} \geq 1 \quad (7)$$

When k is greater than 1, seeds are tossed.

As shows in Fig.2,

$$P + (M + m)g = k(\Delta x + \delta) \quad (8)$$

$$\delta = \frac{(M + m)g}{k} \quad (9)$$

Where: k is the coefficient of stiffness of spring Δx is the amount of compression, δ is the static Deformation between seed and disk.

Puts (9) into (8):

$$k = P / \Delta x \quad (10)$$

According to the structural characteristics of the ejection mechanism:

$P=80$ N, $\Delta x=20$ mm, $k = 4$ N/mm.

1.cotton seed 2. disk 3. reset spring

Fig.2 Motion State of ejection mechanism

The natural frequency of the ejection system is:

$$\omega = \sqrt{\frac{\kappa}{m_s}} = \sqrt{\frac{4 \times 1000}{3}} = 36.5 \text{ rad/s}$$

Where: m_s is the total mass of seed and disk

The amplitudes of disk are:

$$A = \sqrt{x_{i1}^2 + \left(\frac{x_{r1}}{\omega_n}\right)^2} = \sqrt{20^2 + 0} = 20 \text{ mm}$$

Put it into (7)

$$K = \frac{A\omega^2}{g} = \frac{0.02 \times 36.5^2}{9.8} = 2.718 \geq 1$$

The results meet the requirement.

3.2 Analysis on ejecting height of seed

As shown in Fig.2, at the position of B, According to the conservation of mechanical energy:

$$\frac{1}{2}(M+m)v^2 + (M+m)g\Delta x + \frac{1}{2}k\delta^2 = Es \quad (11)$$

Elastic potential energy is

$$Es = \frac{1}{2}k(\Delta x + \delta)^2 \quad (12)$$

Puts (12) into (11)

$$v = \sqrt{\frac{k\Delta x^2(\Delta x + \delta)}{(M+m)} - 2g\Delta x} \quad (13)$$

Where M is the weight of the disk, m is the weight of seeds, v is the speed before separation.

Throwing height of seed is:

$$h' = \frac{v^2}{2g} = \frac{k\Delta x^2(\Delta x + \delta)}{2g(M + m)} - \Delta x \quad (14)$$

According to the conservation of mechanical energy:

$$kh^2 + 2Mgh - Mv^2 + 2Mg\delta - k\delta^2 = 0 \quad (15)$$

$$h = \sqrt{\frac{Mv^2 + k\delta^2}{k} - \frac{2Mg\delta}{k} - \frac{Mg}{k}} \quad (16)$$

Puts $M = 33\text{kg}$, $m = 0.096\text{g}$, $P = 80\text{N}$ into (11), (13), (14)

$v = 735\text{mm/s}$, $h = 12.59\text{mm}$, $h' = 26.67\text{mm}$, $h' - h = 14.08\text{mm}$.

4. MULTI-BODY DYNAMICS SIMULATION OF THE EJECTION VIBRATION MECHANISM

4.1 Model establishment of ejection mechanism

The ejection mechanism model consisting of seed disk, seeds and working table was established using SolidWorks software. In the seamless simulation environment of CosmosMotion, the distance between seed disk and working table was set 42.5mm, namely, electromagnet can draw spring 27.5mm from original position.

4.2 Definition of constraint

The constraints of parts in ejection mechanism model can be automatically created in CosmosMotion environment according the mating counterpart. Seed disk and seeds were defined as motion body and working table was defined as stationary body. The simulation parameters were set as follows: material of disk is alloy steel; density of cotton seed is $1.06 \times 10^3\text{kg/m}^3$, weight is 0.96g, restitution coefficient is 0.5, friction coefficient is 0.3; Stiffness of each reset spring (adding four spring between seed disk and spring seat) is 1N/mm, length is 70mm, diameter is 16mm, wire diameter is 1.6mm, cycle number is 11.3d. 3d elastic collision between disk and seeds is defined (friction is set dynamic). The parameters of equation solver was defined as follows: ADAMS GSTIFF was set 0.5s; frame numbers was 100 and other parameters are defaulted.

4.3 simulation results

Mesh was automatically calculated by equation solver. The curve of velocity and centroid displacement of seed and disk are as shown in fig 4 (red represents seeds, blue represents disk). The Seed moved to a static balance position while the disk reached the maximal rate, and then they began to separate. Subsequently the seed was ejected and the disk started to decrease in velocity, which is consistent with the theoretical analysis. The highest ejection height of seed above disk was 13.5mm, which is close to the theoretical calculated value of 14.08mm. The difference between values comes from the energy loss caused by collision friction.

Fig.3 Motion trajectory of speed

Fig.4 Motion trajectory of centroid position

5. CONCLUSION

1. The results of theoretical analysis on ejection mechanism motion showed that seed could be ejected completely when the coefficient of stiffness of spring $k \geq 1$. The ejection height was determined by the static deformation between seed and disk (δ), ejection velocity (ν), the coefficient of stiffness of spring (k).

2. Motion simulation of disk and seed showed the consistence with the results of theoretical analysis. The difference between values comes from the energy loss caused by collision friction. When the seed moved to the static balance position together with the seed disk, they began to separate for their velocities decrease at different rate.

3. The physical prototype is simple, which has a reliable performance and the rising height of the seeds are even. The tests have confirmed that the ratio of single-seed was over 97%, The ratio of non-seed was below 2%, completely to satisfy the requirements of precision seeder.
