HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Loop freedom of the (untimed) AODV routing protocol

Abstract

The Ad hoc On-demand Distance Vector (AODV) routing protocol [6] allows the nodes in a Mobile Ad hoc Network (MANET) or a Wireless Mesh Network (WMN) to know where to forward data packets. Such a protocol is ‘loop free’ if it never leads to routing decisions that forward packets in circles.

This development mechanises an existing pen-and-paper proof of loop freedom of AODV [4]. The protocol is modelled in the Algebra of Wireless Networks (AWN), which is the subject of an earlier paper [3] and mechanization [1]. The proof relies on a novel compositional approach for lifting invariants to networks of nodes.

We exploit the mechanization to analyse several variants of AODV and show that Isabelle/HOL can re-establish most proof obligations automatically and identify exactly the steps that are no longer valid. Each of the variants is essentially a modified copy of the main development.

Further documentation is available in [2].

0.1 Basic data types and constants

```
theory Aodv_Basic
imports Main "../AWN/AWN_SOS"
begin

These definitions are shared with all variants.

type_synonym rreqid = nat
type_synonym sqn = nat

datatype k = Known | Unknown
abbreviation kno where "kno ≡ Known"
abbreviation unk where "unk ≡ Unknown"

datatype p = NoRequestRequired | RequestRequired
abbreviation noreq where "noreq ≡ NoRequestRequired"
abbreviation req where "req ≡ RequestRequired"

datatype f = Valid | Invalid
abbreviation val where "val ≡ Valid"
abbreviation inv where "inv ≡ Invalid"

lemma not_ks [simp]:
  "(x ≠ kno) = (x = unk)"
  "(x ≠ unk) = (x = kno)"
  by (cases x, clarsimp)+

lemma not_ps [simp]:
  "(x ≠ noreq) = (x = req)"
  "(x ≠ req) = (x = noreq)"
  by (cases x, clarsimp)+

lemma not_ffs [simp]:
  "(x ≠ val) = (x = inv)"
  "(x ≠ inv) = (x = val)"
  by (cases x, clarsimp)+

end
```

0.2 Predicates and functions used in the AODV model

```
theory Aodv_Data
imports Aodv_Basic
begin
```

0.2.1 Sequence Numbers

Sequence numbers approximate the relative freshness of routing information.

```
definition inc :: "sqn ⇒ sqn"
  where "inc sn ≡ if sn = 0 then sn else sn + 1"

lemma less_than_inc [simp]: "x ≤ inc x"
  unfolding inc_def by simp

lemma inc_minus_suc_0 [simp]:
  "inc x - Suc 0 = x"
  unfolding inc_def by simp

lemma inc_never_one' [simp, intro]: "inc x ≠ Suc 0"
  unfolding inc_def by simp

lemma inc_never_one [simp, intro]: "inc x ≠ 1"
  by simp
```

0.2.2 Modelling Routes

A route is a 6-tuple, $(dsn, dsk, flag, hops, nhop, pre)$ where dsn is the ‘destination sequence number’, dsk is the ‘destination-sequence-number status’, $flag$ is the route status, $hops$ is the number of hops to the destination, $nhop$ is the next hop toward the destination, and pre is the set of ‘precursor nodes’ those interested in hearing about changes to the route.

```

type_synonym r = "sqn × k × f × nat × ip × ip set"

definition proj2 :: "r ⇒ sqn" ("π₂")
  where "π₂ ≡ λ(dsn, _, _, _, _, _). dsn"

definition proj3 :: "r ⇒ k" ("π₃")

0.2.7 Comparison with the original technical report

The major differences with the AODV technical report of Fehnker et al are:

1. *nhop* is partial, thus a ‘*the*’ is needed, similarly for *dhops* and *addpreRT*.
2. *precs* is partial.
3. $\sigma_{p\text{-}flag}(store, dip)$ is partial.
4. The routing table (*rt*) is modelled as a map ($ip \Rightarrow r\ option$) rather than a set of 7-tuples, likewise, the *r* is a 6-tuple rather than a 7-tuple, i.e., the destination ip-address (*dip*) is taken from the argument to the function, rather than a part of the result. Well-definedness then follows from the structure of the type and more related facts are available automatically, rather than having to be acquired through tedious proofs.
5. Similar remarks hold for the dests mapping passed to *invalidate*, and *store*.

end

0.3 AODV protocol messages

```

theory Aodv_Message
imports Aodv_Basic
begin

datatype msg =
  Rreq nat rreqid ip sqn k ip sqn ip
  | Rrep nat ip sqn ip ip

```

```

| Rerr "ip → sqn" ip
| Newpkt data ip
| Pkt data ip ip

instantiation msg :: msg
begin
  definition newpkt_def [simp]: "newpkt ≡ λ(d, dip). Newpkt d dip"
  definition eq_newpkt_def: "eq_newpkt m ≡ case m of Newpkt d dip ⇒ True | _ ⇒ False"

  instance by intro_classes (simp add: eq_newpkt_def)
end

The msg type models the different messages used within AODV. The instantiation as a msg is a technicality due to the special treatment of newpkt messages in the AWN SOS rules. This use of classes allows a clean separation of the AWN-specific definitions and these AODV-specific definitions.

Proposition 7.16

Some well-definedness obligations are irrelevant for the Isabelle development:

1. In each routing table there is at most one entry for each destination: guaranteed by type.
2. In each store of queued data packets there is at most one data queue for each destination: guaranteed by structure.
3. Whenever a set of pairs (rip, rsn) is assigned to the variable dests of type $ip \rightarrow \text{sqn}$, or to the first argument of the function $rerr$, this set is a partial function, i.e., there is at most one entry (rip, rsn) for each destination rip : guaranteed by type.

```

Chapter 1

Variant A: Skipping the RREQ ID

Explanation [4, §10.1]: AODV does not need the route request identifier. This number, in combination with the IP address of the originator, is used to identify every RREQ message in a unique way. This variant shows that the combination of the originators IP address and its sequence number is just as suited to uniquely determine the route request to which the message belongs. Hence, the route request identifier field is not required. This can then reduce the size of the RREQ message.

1.1 Predicates and functions used in the AODV model

```
theory A_Aodv_Data
imports A_Norreqid
begin
```

1.1.1 Sequence Numbers

Sequence numbers approximate the relative freshness of routing information.

```

  unfolding inc_def by simp

lemma inc_never_one [simp, intro]: "inc x ≠ 1"
  by simp
```

1.1.2 Modelling Routes

A route is a 6-tuple, $(dsn, dsk, flag, hops, nhip, pre)$ where dsn is the ‘destination sequence number’, dsk is the ‘destination-sequence-number status’, $flag$ is the route status, $hops$ is the number of hops to the destination, $nhip$ is the next hop toward the destination, and pre is the set of ‘precursor nodes’ those interested in hearing about changes to the route.

1.1.7 Comparison with the original technical report

The major differences with the AODV technical report of Fehnker et al are:

1. *nhop* is partial, thus a ‘*the*’ is needed, similarly for *dhops* and *addpreRT*.
2. *precs* is partial.
3. $\sigma_{p\text{-}flag}(store, dip)$ is partial.
4. The routing table (*rt*) is modelled as a map ($ip \Rightarrow r\ option$) rather than a set of 7-tuples, likewise, the *r* is a 6-tuple rather than a 7-tuple, i.e., the destination ip-address (*dip*) is taken from the argument to the function, rather than a part of the result. Well-definedness then follows from the structure of the type and more related facts are available automatically, rather than having to be acquired through tedious proofs.
5. Similar remarks hold for the dests mapping passed to *invalidate*, and *store*.

end

1.2 AODV protocol messages

```

theory A_Aodv_Message
imports A_Norreqid
begin

datatype msg =
  Rreq nat ip sqn k ip sqn ip
  | Rrep nat ip sqn ip ip
  | Rerr "ip → sqn" ip
  | Newpkt data ip
  | Pkt data ip ip

instantiation msg :: msg
begin
  definition newpkt_def [simp]: "newpkt ≡ λ(d, dip). Newpkt d dip"
  definition eq_newpkt_def: "eq_newpkt m ≡ case m of Newpkt d dip ⇒ True | _ ⇒ False"

  instance by intro_classes (simp add: eq_newpkt_def)
end

```

The *msg* type models the different messages used within AODV. The instantiation as a *msg* is a technicality due to the special treatment of *newpkt* messages in the AWN SOS rules. This use of classes allows a clean separation of the AWN-specific definitions and these AODV-specific definitions.

```

Proposition 7.16

Some well-definedness obligations are irrelevant for the Isabelle development:

1. In each routing table there is at most one entry for each destination: guaranteed by type.
2. In each store of queued data packets there is at most one data queue for each destination: guaranteed by structure.
3. Whenever a set of pairs (rip, rsn) is assigned to the variable $dests$ of type $ip \rightarrow sqn$, or to the first argument of the function $rerr$, this set is a partial function, i.e., there is at most one entry (rip, rsn) for each destination rip : guaranteed by type.

Chapter 2

Variant B: Forwarding the Route Reply

Explanation [4, §10.2]: In AODVs route discovery process, a RREP message from the destination node is unicast back along a route towards the originator of the RREQ message. Every intermediate node on the selected route will process the RREP message and, in most cases, forward it towards the originator node. However, there is a possibility that the RREP message is discarded at an intermediate node, which results in the originator node not receiving a reply. The discarding of the RREP message is due to the RFC specification of AODV [6] stating that an intermediate node only forwards the RREP message if it is not the originator node and it has created or updated a routing table entry to the destination node described in the RREP message. The latter requirement means that if a valid routing table entry to the destination node already exists, and is not updated when processing the RREP message, then the intermediate node will not forward the message. A solution to this problem is to require intermediate nodes to forward all RREP messages that they receive.

2.1 Predicates and functions used in the AODV model

```
theory B_Aodv_Data
imports B_Fwdrreps
begin
```

2.1.1 Sequence Numbers

Sequence numbers approximate the relative freshness of routing information.

```
definition inc :: "sqn ⇒ sqn"
  where "inc sn ≡ if sn = 0 then sn else sn + 1"

lemma less_than_inc [simp]: "x ≤ inc x"
  unfolding inc_def by simp

lemma inc_minus_suc_0 [simp]:
  "inc x - Suc 0 = x"
  unfolding inc_def by simp

lemma inc_never_one' [simp, intro]: "inc x ≠ Suc 0"
  unfolding inc_def by simp

lemma inc_never_one [simp, intro]: "inc x ≠ 1"
  by simp
```

2.1.2 Modelling Routes

A route is a 6-tuple, $(dsn, dsk, flag, hops, nhop, pre)$ where dsn is the ‘destination sequence number’, dsk is the ‘destination-sequence-number status’, $flag$ is the route status, $hops$ is the number of hops to the destination, $nhop$ is the next hop toward the destination, and pre is the set of ‘precursor nodes’ those interested in hearing about changes to the route.

2.1.7 Comparison with the original technical report

The major differences with the AODV technical report of Fehnker et al are:

1. *nhop* is partial, thus a ‘*the*’ is needed, similarly for *dhops* and *addpreRT*.
2. *precs* is partial.
3. $\sigma_{p\text{-}flag}(store, dip)$ is partial.
4. The routing table (*rt*) is modelled as a map ($ip \Rightarrow r\ option$) rather than a set of 7-tuples, likewise, the *r* is a 6-tuple rather than a 7-tuple, i.e., the destination ip-address (*dip*) is taken from the argument to the function, rather than a part of the result. Well-definedness then follows from the structure of the type and more related facts are available automatically, rather than having to be acquired through tedious proofs.
5. Similar remarks hold for the dests mapping passed to *invalidate*, and *store*.

end

2.2 AODV protocol messages

```

theory B_Aodv_Message
imports B_Fwdrreps
begin

datatype msg =
  Rreq nat rreqid ip sqn k ip sqn ip
  | Rrep nat ip sqn ip ip
  | Rerr "ip → sqn" ip
  | Newpkt data ip
  | Pkt data ip ip

instantiation msg :: msg
begin
  definition newpkt_def [simp]: "newpkt ≡ λ(d, dip). Newpkt d dip"
  definition eq_newpkt_def: "eq_newpkt m ≡ case m of Newpkt d dip ⇒ True | _ ⇒ False"

  instance by intro_classes (simp add: eq_newpkt_def)

```

end

The `msg` type models the different messages used within AODV. The instantiation as a `msg` is a technicality due to the special treatment of `newpkt` messages in the AWN SOS rules. This use of classes allows a clean separation of the AWN-specific definitions and these AODV-specific definitions.

```

definition rreq :: "nat × rreqid × ip × sqn × k × ip × sqn × ip ⇒ msg"

Proposition 7.16

Some well-definedness obligations are irrelevant for the Isabelle development:

1. In each routing table there is at most one entry for each destination: guaranteed by type.
2. In each store of queued data packets there is at most one data queue for each destination: guaranteed by structure.
3. Whenever a set of pairs (rip, rsn) is assigned to the variable $dests$ of type $ip \rightarrow sqn$, or to the first argument of the function $rerr$, this set is a partial function, i.e., there is at most one entry (rip, rsn) for each destination rip : guaranteed by type.

Chapter 3

Variant C: From Groupcast to Broadcast

Explanation [4, §10.4]: A node maintains a set of ‘precursor nodes’ for each of its valid routes. If the link to a route’s next hop is lost, an error message is groupcast to the associated precursor nodes. The idea is to reduce the number of messages received and handled. However, precursor lists are incomplete. They are updated only when a RREP message is sent. This can lead to packet loss. A possible solution is to abandon precursors and to replace every groupcast by a broadcast. At first glance this strategy seems to need more bandwidth, but this is not the case. Sending error messages to a set of precursors is implemented at the link layer by broadcasting the message anyway; a node receiving such a message then checks the header to determine whether it is one of the intended recipients. Instead of analysing the header only, a node can just as well read the message and decide whether the information contained in the message is of use. To be more precise: an error message is useful for a node if the node has established a route to one of the nodes listed in the message, and the next hop to a listed node is the sender of the error message. In case a node finds useful information inside the message, it should update its routing table and distribute another error message.

3.1 Predicates and functions used in the AODV model

```
theory C_Aodv_Data
imports C_Gtobcast
begin
```

3.1.1 Sequence Numbers

Sequence numbers approximate the relative freshness of routing information.

```
definition inc :: "sqn ⇒ sqn"
  where "inc sn ≡ if sn = 0 then sn else sn + 1"

lemma less_than_inc [simp]: "x ≤ inc x"
  unfolding inc_def by simp

lemma inc_minus_suc_0 [simp]:
  "inc x - Suc 0 = x"
  unfolding inc_def by simp

lemma inc_never_one' [simp, intro]: "inc x ≠ Suc 0"
  unfolding inc_def by simp

lemma inc_never_one [simp, intro]: "inc x ≠ 1"
  by simp
```

3.1.2 Modelling Routes

A route is a 5-tuple, $(dsn, dsk, flag, hops, nhop)$ where dsn is the ‘destination sequence number’, dsk is the ‘destination-sequence-number status’, $flag$ is the route status, $hops$ is the number of hops to the destination, and $nhop$ is the next hop toward the destination. In this variant, the set of ‘precursor nodes’ is not modelled.

```
type_synonym r = "sqn × k × f × nat × ip"
```

```

definition proj2 :: "r ⇒ sqn" ("π₂")
  where "π₂ ≡ λ(dsn, _, _, _, _). dsn"

3.1.7 Comparison with the original technical report

The major differences with the AODV technical report of Fehnker et al are:

1. *nhop* is partial, thus a ‘*the*’ is needed, similarly for *dhops* and *addpreRT*.
2. *precs* is partial.
3. $\sigma_{p\text{-}flag}(store, dip)$ is partial.
4. The routing table (*rt*) is modelled as a map ($ip \Rightarrow r\ option$) rather than a set of 7-tuples, likewise, the *r* is a 6-tuple rather than a 7-tuple, i.e., the destination ip-address (*dip*) is taken from the argument to the function, rather than a part of the result. Well-definedness then follows from the structure of the type and more related facts are available automatically, rather than having to be acquired through tedious proofs.
5. Similar remarks hold for the dests mapping passed to *invalidate*, and *store*.

end

3.2 AODV protocol messages

```

theory C_Aodv_Message
imports C_Gtobcast
begin

datatype msg =
  Rreq nat rreqid ip sqn k ip sqn ip
  | Rrep nat ip sqn ip ip
  | Rerr "ip → sqn" ip
  | Newpkt data ip
  | Pkt data ip ip

instantiation msg :: msg
begin
  definition newpkt_def [simp]: "newpkt ≡ λ(d, dip). Newpkt d dip"
  definition eq_newpkt_def: "eq_newpkt m ≡ case m of Newpkt d dip ⇒ True | _ ⇒ False"

  instance by intro_classes (simp add: eq_newpkt_def)
end

```

The *msg* type models the different messages used within AODV. The instantiation as a *msg* is a technicality due to the special treatment of *newpkt* messages in the AWN SOS rules. This use of classes allows a clean separation of the AWN-specific definitions and these AODV-specific definitions.

```

Proposition 7.16

Some well-definedness obligations are irrelevant for the Isabelle development:

1. In each routing table there is at most one entry for each destination: guaranteed by type.
2. In each store of queued data packets there is at most one data queue for each destination: guaranteed by structure.
3. Whenever a set of pairs (rip, rsn) is assigned to the variable $dests$ of type $ip \rightarrow sqn$, or to the first argument of the function $rerr$, this set is a partial function, i.e., there is at most one entry (rip, rsn) for each destination rip : guaranteed by type.

Chapter 4

Variant D: Forwarding the Route Request

Explanation [4, §10.5]: In AODVs route discovery process, a destination node (or an intermediate node with an active route to the destination) will generate a RREP message in response to a received RREQ message. The RREQ message is then dropped and not forwarded. This termination of the route discovery process at the destination can lead to other nodes inadvertently creating non-optimal routes to the source node [5]. A possible modification to solve this problem is to allow the destination node to continue to forward the RREQ message. A route request is only stopped if it has been handled before. The forwarded RREQ message from the destination node needs to be modified to include a Boolean flag `handled` that indicates a RREP message has already been generated and sent in response to the former message. In case the flag is set to true, it prevents other nodes (with valid route to the destination) from sending a RREP message in response to their reception of the forwarded RREQ message.

4.1 Predicates and functions used in the AODV model

```
theory D_Aodv_Data
imports D_Fwdreqs
begin
```

4.1.1 Sequence Numbers

Sequence numbers approximate the relative freshness of routing information.

```
definition inc :: "sqn ⇒ sqn"
  where "inc sn ≡ if sn = 0 then sn else sn + 1"

lemma less_than_inc [simp]: "x ≤ inc x"
  unfolding inc_def by simp

lemma inc_minus_suc_0 [simp]:
  "inc x - Suc 0 = x"
  unfolding inc_def by simp

lemma inc_never_one' [simp, intro]: "inc x ≠ Suc 0"
  unfolding inc_def by simp

lemma inc_never_one [simp, intro]: "inc x ≠ 1"
  by simp
```

4.1.2 Modelling Routes

A route is a 6-tuple, $(dsn, dsk, flag, hops, nhop, pre)$ where dsn is the ‘destination sequence number’, dsk is the ‘destination-sequence-number status’, $flag$ is the route status, $hops$ is the number of hops to the destination, $nhop$ is the next hop toward the destination, and pre is the set of ‘precursor nodes’ those interested in hearing about changes to the route.

```

4.1.7 Comparison with the original technical report

The major differences with the AODV technical report of Fehnker et al are:

1. *nhop* is partial, thus a ‘*the*’ is needed, similarly for *dhops* and *addpreRT*.
2. *precs* is partial.
3. $\sigma_{p\text{-}flag}(store, dip)$ is partial.
4. The routing table (*rt*) is modelled as a map ($ip \Rightarrow r\ option$) rather than a set of 7-tuples, likewise, the *r* is a 6-tuple rather than a 7-tuple, i.e., the destination ip-address (*dip*) is taken from the argument to the function, rather than a part of the result. Well-definedness then follows from the structure of the type and more related facts are available automatically, rather than having to be acquired through tedious proofs.
5. Similar remarks hold for the dests mapping passed to *invalidate*, and *store*.

end

4.2 AODV protocol messages

```

theory D_Aodv_Message
imports D_Fwdrreqs
begin

datatype msg =
  Rreq nat rreqid ip sqn k ip sqn ip bool
  | Rrep nat ip sqn ip ip
  | Rerr "ip → sqn" ip
  | Newpkt data ip
  | Pkt data ip ip

instantiation msg :: msg
begin
  definition newpkt_def [simp]: "newpkt ≡ λ(d, dip). Newpkt d dip"
  definition eq_newpkt_def: "eq_newpkt m ≡ case m of Newpkt d dip ⇒ True | _ ⇒ False"

  instance by intro_classes (simp add: eq_newpkt_def)

```

end

The `msg` type models the different messages used within AODV. The instantiation as a `msg` is a technicality due to the special treatment of `newpkt` messages in the AWN SOS rules. This use of classes allows a clean separation of the AWN-specific definitions and these AODV-specific definitions.

```

Proposition 7.16

Some well-definedness obligations are irrelevant for the Isabelle development:

1. In each routing table there is at most one entry for each destination: guaranteed by type.
2. In each store of queued data packets there is at most one data queue for each destination: guaranteed by structure.
3. Whenever a set of pairs (rip, rsn) is assigned to the variable $dests$ of type $ip \rightarrow sqn$, or to the first argument of the function $rerr$, this set is a partial function, i.e., there is at most one entry (rip, rsn) for each destination rip : guaranteed by type.

Chapter 5

Variants A–D: All proposed modifications

This model combines the changes proposed in each of the individual variant models.

5.1 Predicates and functions used in the AODV model

```
theory E_Aodv_Data
imports E_All_ABCD
begin
```

5.1.1 Sequence Numbers

Sequence numbers approximate the relative freshness of routing information.

```
definition inc :: "sqn ⇒ sqn"
  where "inc sn ≡ if sn = 0 then sn else sn + 1"
```

```

```
lemma inc_never_one' [simp, intro]: "inc x ≠ Suc 0"
  unfolding inc_def by simp
```

```
lemma inc_never_one [simp, intro]: "inc x ≠ 1"
  by simp
```

5.1.2 Modelling Routes

A route is a t-tuple, $(dsn, dsk, flag, hops, nhop)$ where dsn is the ‘destination sequence number’, dsk is the ‘destination-sequence-number status’, $flag$ is the route status, $hops$ is the number of hops to the destination, and $nhop$ is the next hop toward the destination.

```
type_synonym r = "sqn × k × f × nat × ip"
```

```

```

5.1.7 Comparison with the original technical report

The major differences with the AODV technical report of Fehnker et al are:

1. `nhop` is partial, thus a ‘`the`’ is needed, similarly for `dhops` and `addpreRT`.
2. `precs` is partial.

3. $\sigma_{p\text{-}flag}(store, dip)$ is partial.
4. The routing table (rt) is modelled as a map ($ip \Rightarrow r\ option$) rather than a set of 7-tuples, likewise, the r is a 6-tuple rather than a 7-tuple, i.e., the destination ip-address (dip) is taken from the argument to the function, rather than a part of the result. Well-definedness then follows from the structure of the type and more related facts are available automatically, rather than having to be acquired through tedious proofs.
5. Similar remarks hold for the dests mapping passed to `invalidate`, and `store`.

end

5.2 AODV protocol messages

```
theory E_Aodv_Message
imports E_All_ABCD
begin

datatype msg =
  Rreq nat ip sqn k ip sqn ip bool
  / Rrep nat ip sqn ip ip
  / Rerr "ip → sqn" ip
  / Newpkt data ip
  / Pkt data ip ip

instantiation msg :: msg
begin
  definition newpkt_def [simp]: "newpkt ≡ λ(d, dip). Newpkt d dip"
  definition eq_newpkt_def: "eq_newpkt m ≡ case m of Newpkt d dip ⇒ True / _ ⇒ False"

  instance by intro_classes (simp add: eq_newpkt_def)
end
```

The `msg` type models the different messages used within AODV. The instantiation as a `msg` is a technicality due to the special treatment of `newpkt` messages in the AWN SOS rules. This use of classes allows a clean separation of the AWN-specific definitions and these AODV-specific definitions.

```
definition rreq :: "nat × ip × sqn × k × ip × sqn × ip × bool ⇒ msg"

Proposition 7.16

Some well-definedness obligations are irrelevant for the Isabelle development:

1. In each routing table there is at most one entry for each destination: guaranteed by type.
2. In each store of queued data packets there is at most one data queue for each destination: guaranteed by structure.
3. Whenever a set of pairs (rip, rsn) is assigned to the variable $dests$ of type $ip \rightarrow sqn$, or to the first argument of the function $rerr$, this set is a partial function, i.e., there is at most one entry (rip, rsn) for each destination rip : guaranteed by type.
