Abstract

Given two coprime polynomials P and Q in $\mathbb{Z}[x, y]$ of degree bounded by d and bitsize bounded by τ , we address the problem of solving the system $\{P, Q\}$. We are interested in certified numerical approximations or, more precisely, isolating boxes of the solutions. We are also interested in computing, as intermediate symbolic objects, rational parameterizations of the solutions, and in particular Rational Univariate Representations (RURs), which can easily turn many queries on the system into queries on univariate polynomials. Such representations require the computation of a separating form for the system, that is a linear combination of the variables that takes different values when evaluated at the distinct solutions of the system.

We present new algorithms for computing linear separating forms, RUR decompositions and isolating boxes of the solutions. We show that these three algorithms have worst-case bit complexity $\tilde{O}_B(d^6 + d^5\tau)$, where \tilde{O} refers to the complexity where polylogarithmic factors are omitted and O_B refers to the bit complexity. We also present probabilistic Las-Vegas variants of our two first algorithms, which have expected bit complexity $\tilde{O}_B(d^5 + d^4\tau)$. A key ingredient of our proofs of complexity is an amortized analysis of the triangular decomposition algorithm via subresultants, which is of independent interest.

1 Introduction

There are numerous alternatives for solving algebraic systems. Typically, isolating boxes of the solutions can be computed either directly from the input system using numerical methods (such as subdivision or homotopy) or indirectly by first computing intermediate symbolic representations such as triangular sets, Gröbner bases, or rational parameterizations. However, only little work analyzes the bit complexity of isolating the solutions without any restriction, in particular for non-generic or non-radical systems. We address in this paper the problem of solving systems of *bivariate* polynomials with integer coefficients and we focus on the bit complexity of these methods in the RAM model. We focus in particular on the worst-case bit complexity in a deterministic setting and on the expected bit complexity in a probabilistic Las-Vegas setting. Recall that, in Las-Vegas algorithms, the sequence and number of operations are probabilistic but the output is deterministic, unlike Monte-Carlo algorithms in which the output is only correct with some

probability. We consider throughout the paper input polynomials of total degree at most d with integer coefficients of bitsize at most τ .

A classical approach for solving a system of polynomials with a finite number of solutions is to compute a rational parameterization of its solutions. A rational parameterization is a representation of the (complex) solutions by a set of univariate polynomials and associated rational one-to-one mappings that send the roots of the univariate polynomials to the solutions of the system. With such a representation, many queries on the system can be transformed into queries on univariate polynomials, which ease the computations. For instance, isolating the solutions of the system can be done by isolating the roots of the univariate polynomials of the rational parameterization and by computing the image of the resulting intervals through the associated mappings. Similarly, querying whether a polynomial P vanishes at the solutions of the system can be done by substituting in P the variables by their images in each of the one-to-one mappings and by testing whether this resulting univariate polynomial vanishes at the roots of the associated univariate polynomial in the rational parameterization.

The core of the algorithms that compute such rational parameterizations (see for example [ABRW96, BSS03, DET09, GLS01, GVEK96, Rou99] and references therein) is the computation of a so-called *linear separating form* for the solutions, that is, a linear combination of the coordinates that takes different values when evaluated at different solutions of the system. Then, a shear of the coordinate system using such a linear form ensures that the system is in generic position, in the sense that no two solutions are vertically aligned. Since a linear form chosen randomly in a sufficiently large finite set is separating with probability close to one, probabilist Monte-Carlo algorithms can avoid this computation by considering a random linear form. However, when it comes to deterministically computing a linear separating form, or even to check that an arbitrary (e.g. random) linear form is separating, this, surprisingly, was until very recently the bottleneck in the computation of rational parameterizations, even for bivariate systems, as discussed below.

For arbitrary multivariate systems, Rouillier [Rou99] gives an algorithm for deterministically computing a separating form, which computes the number of solutions of a system with the rank of the Hermite's quadratic form of a quotient algebra. The complexity of this computation dominates the one that follows for computing the rational representation. Considering the special case of systems of two bivariate polynomials of total degree bounded by d with integer coefficients of bitsize bounded by τ , another approach, based on a triangular decomposition, has been presented by Gonzalez-Vega and El Kahoui [GVEK96] for computing a separating linear form together with a rational parameterization of the solutions. The best-known bit complexity of this approach, analyzed by Diochnos et al. [DET09, Lemma 16 & Theorem 19]¹, shows a bit complexity in $\tilde{O}_B(d^{10} + d^9\tau)$ for computing a separating form and a bit complexity in $\tilde{O}_B(d^7 + d^6\tau)$ for computing the corresponding rational parameterization. The computation of a separating linear form was still the bottleneck in the computation of the rational parameterization. An algorithm using modular arithmetic was then introduced by Bouzidi et al. [BLPR15] reducing the complexity to $\tilde{O}_B(d^8 + d^7\tau)$. This algorithm was later simplified and improved by transforming the problem into the computation of a separating form for the critical points of a curve, which improved the bit complexity to $\tilde{O}_B(d^7 + d^6\tau)$ in the worst case and to $\tilde{O}_B(d^5 + d^4\tau)$ in a probabilistic Las Vegas setting [BLP+14]. Bouzidi et al. [BLPR15] also showed that, given such a separating linear form, an alternative rational parameterization called Rational Univariate Representation (RUR) [Rou99] can be computed using $\tilde{O}_B(d^7 + d^6\tau)$ bit operations. For the first time, the worst-case bit complexities of computing linear

¹The overall bit complexity stated in [DET09, Theorem 19] is $\tilde{O}_B(d^{12} + d^{10}\tau^2)$ because it includes the isolation of the solutions of the system. Note, however, that the complexity of the isolation phase, and thus of the whole algorithm, decreases to $\tilde{O}_B(d^{10} + d^9\tau)$ using Pan [Pan02] results on the complexity of isolating the real roots of a univariate polynomial.

separating forms and rational parameterizations (even RURs) of bivariate systems were both in the same class of complexity $\tilde{O}_B(d^7 + d^6\tau)$ and, also for the first time, the expected bit complexity for computing linear separating forms, in a Las-Vegas setting, was in a smaller class of complexity, $\tilde{O}_B(d^5 + d^4\tau)$.

Very recently, Kobel and Sagraloff [KS14] presented an algorithm of worst-case bit complexity $\tilde{O}_B(d^6 + d^5\tau)$ for computing isolating boxes of the solutions of bivariate systems. Their approach is based on resultant computations, projecting the solutions on the x and y -axes, thus defining a grid of candidate solutions. Then, approximate evaluations combined with adaptive evaluation bounds enable to identify the solutions from the grid. This method does not need the knowledge of a separating form, but once the solutions are isolated with enough precision, such a separating form can be computed in $\tilde{O}_B(d^6 + d^5\tau)$ bit operations [KS14]. This approach for computing separating linear forms has the best known worst-case complexity. However, it would be surprising that computing a separating form with such complexity would require to first isolate the solutions of the system, since separating forms are precisely instrumental for solving systems in parameterization-based approaches. The present work indeed demonstrates that separating linear forms and rational parameterizations (including RURs) can be directly computed with this $\tilde{O}_B(d^6 + d^5\tau)$ state-of-the-art worst-case bit complexity, and that the solutions of the system can be isolated from the RUR in the same worst-case complexity.

Main results. Let P and Q be two coprime polynomials in $\mathbb{Z}[x, y]$ of degree bounded by d and bitsize bounded by τ . We present three algorithms, one for each of the main steps of solving a bivariate system $\{P, Q\}$ via RURs, that is, computing (i) a linear separating form, (ii) a RUR decomposition of the system, and (iii) isolating boxes of the solutions. Each of these algorithms has worst-case bit complexity $\tilde{O}_B(d^6 + d^5\tau)$ and we also present Las-Vegas variants of expected bit complexity $\tilde{O}_B(d^5 + d^4\tau)$ of our two first algorithms (see Theorems 28, 29, 45, 46, 62). We do not present a Las-Vegas variant of our last algorithm for computing isolating boxes but it should be noticed that the complexity of that subdivision-based algorithm actually depends on the distances between the solutions and thus its worst-case complexity is not always reached.

Our algorithm for computing a separating linear form is based on the one presented in [BLP⁺14], while improving its worst-case bit complexity by a factor d . Furthermore, its Las-Vegas variant is simpler than the one presented in [BLP⁺14] and it has the same expected bit complexity. As mentioned above the worst-case complexity of this new algorithm also matches the recent one by Kobel and Sagraloff [KS14]. Our algorithm for computing a RUR decomposition of $\{P, Q\}$ improves by a factor d the state-of-the-art worst-case bit complexity [BLPR15]. Furthermore, our Las-Vegas variant is, up to our knowledge, the first Las-Vegas algorithm whose expected complexity is asymptotically better than the worst-case complexity and, as a result, our Las-Vegas algorithm improves the state-of-the-art expected bit complexity by a factor d^2 . For the isolation problem from the RURs, we improve the state-of-the-art complexity by a factor d^2 [BLPR15, Proposition 35], while matching the resultant-based complexity presented by Kobel and Sagraloff [KS14].

Last but not least, we present an amortized analysis of the classical triangular decomposition via subresultants of bivariate systems [GVEK96], proving that the decomposition can be computed in $\tilde{O}_B(d^6 + d^5\tau)$ bit operations in the worst case (Proposition 16), which improves by a factor d the state-of-the-art analysis [DET09, Proof of Theorem 19]. This result, while instrumental for the worst-case complexity analyses of our algorithms, is also of independent interest.

We first present a detailed overview of our contributions in Section 2. Notation and preliminaries are then introduced in Section 3. We present in Section 4 our amortized analysis of the triangular decomposition and a related luckiness certificate which is a key feature of the following multi-modular algorithms. Sections 5, 6 and 7 present respectively our algorithms for computing

separating forms, RUR decompositions and isolating boxes of the solutions.

2 Overview

We present in this section a detailed overview of our contributions and strategies. Recall that P and Q denote two coprime polynomials in $\mathbb{Z}[x, y]$ of total degree at most d and maximum bitsize τ .

2.1 Triangular decomposition and luckiness certificate

We first recall in Section 4.1 the classical subresultant-based algorithm for computing the triangular decomposition of a zero-dimensional bivariate system $\{P, Q\}$. This decomposition appears, for instance, for solving bivariate systems [LMMRS11] or for the computation of the topology of curves [GVEK96]. This triangular decomposition algorithm will be used in our algorithm for computing a RUR decomposition of $\{P, Q\}$.

We then present in Section 4.2 a straightforward variation on this algorithm, which only computes the degree of this triangular decomposition (see Definition 11). This variation decreases the expected bit complexity of the algorithm and it is critical for our Las-Vegas algorithm for computing a separating linear form.

We then present in Section 4.3 another variation on the triangular decomposition algorithm, which computes a luckiness certificate for this triangular decomposition. A luckiness certificate of $\{P, Q\}$ is an integer such that if a prime μ does not divide it, then μ is lucky for the triangular decomposition of $\{P, Q\}$, in the sense that the decomposition commutes with the reduction modulo μ (see Definition 13). Our deterministic algorithms for the separating form and the RUR computations will both use this luckiness certificate.

In Section 4.4, we prove that the worst-case bit complexities of these three algorithms are in $\tilde{O}_B(d^6 + d^5\tau)$ and that the expected bit complexity of the one for computing the degree of the triangular decomposition is in $\tilde{O}_B(d^5 + d^4\tau)$ (Proposition 16). The worst-case complexity is obtained by considering amortized bounds on the degrees and bitsizes of factors of the resultant and it improves by a factor d the state-of-the-art complexity for computing the triangular decomposition [DET09, Proof of Theorem 19]. Besides of being of independent interest, these improvements are critical for the complexity analysis of the following algorithms.

2.2 Separating linear form

In Section 5, we present a new algorithm for computing separating linear forms for a bivariate system $\{P, Q\}$. We actually present two algorithms, a deterministic one of worst-case bit complexity $\tilde{O}_B(d^6 + d^5\tau)$ and a probabilistic Las-Vegas variant of expected bit complexity $\tilde{O}_B(d^5 + d^4\tau)$ (Theorems 28 and 29).

Our approach is based on the algorithms presented in [BLPR15] and [BLP⁺14] while improving the worst-case bit complexity by one order of magnitude. We briefly recall the essence of these algorithms. The first step of the algorithm presented in [BLPR15] is to compute the number of distinct solutions and a so-called lucky prime for the system. Such a lucky prime is, roughly speaking, a prime such that the system has the same number of distinct solutions as its image modulo μ (see Definition 18). In a second step, all polynomials and computations are considered modulo μ . The algorithm then considers iteratively a candidate separating form $x + ay$ with an integer a incrementing from 0. The algorithm computes the number of distinct solutions after projection along the direction of the line $x + ay = 0$ and stops when a value a is found such that the

number of distinct projected solutions equals that of the system. The worst-case bit complexity of this algorithm is in $\tilde{O}_B(d^8 + d^7\tau)$.

The main additional ideas introduced in [BLP⁺14] are that it is sufficient to compute a separating form for the system $\{H, \frac{\partial H}{\partial y}\}$ of critical points of a curve H associated to the input system $\{P, Q\}$ (see Section 5.2) and that the number of critical points can easily be computed as the difference between the degrees of the triangular decompositions of the systems $\{H, (\frac{\partial H}{\partial y})^2\}$ and $\{H, \frac{\partial H}{\partial y}\}$ (see Definition 11). This improves the worst-case bit complexity of the algorithm to $\tilde{O}_B(d^7 + d^6\tau)$.

In Section 5.3, we show how these algorithms can be again improved by one order of magnitude in the worst-case. The main ideas of these improvements are as follows. First, in Section 5.3.1, we show how our improvement on the complexity analysis of triangular decompositions presented in Section 4.4 improves the complexity of the computation of the number of solutions of $\{H, \frac{\partial H}{\partial y}\}$.

In Section 5.3.2, we present a new algorithm for computing a lucky prime for the system $\{H, \frac{\partial H}{\partial y}\}$ using the luckiness certificates for triangular decompositions presented in Section 4.3. More precisely, we compute a lucky prime for $\{H, \frac{\partial H}{\partial y}\}$ by computing a prime μ that, essentially, does not divide the product of the luckiness certificates of the two systems $\{H, \frac{\partial H}{\partial y}\}$ and $\{H, (\frac{\partial H}{\partial y})^2\}$. By definition of the luckiness certificates, the degrees of the triangular decompositions of these two systems are the same over \mathbb{Z} and \mathbb{Z}_μ . The difference of these degrees, which is the number of solution of $\{H, \frac{\partial H}{\partial y}\}$, is thus also the same over \mathbb{Z} and \mathbb{Z}_μ , which essentially yields that μ is lucky for $\{H, \frac{\partial H}{\partial y}\}$.

The last ingredient of our algorithm is to show, in Section 5.3.3, how, given the number of solutions and a lucky prime for the system $\{H, \frac{\partial H}{\partial y}\}$, the bit complexity of the algorithm presented in [BLPR15] for computing a separating linear form for $\{H, \frac{\partial H}{\partial y}\}$ can be improved from $\tilde{O}_B(d^8 + d^7\tau)$ to $\tilde{O}_B(d^6 + d^5\tau)$ by using multipoint evaluation and changing the organization of the computations.

In Section 5.4, we wrap up these results, which prove that we can compute a separating linear form for the input system $\{P, Q\}$ in $\tilde{O}_B(d^6 + d^5\tau)$ bit operations in the worst case (Theorem 28).

Finally, we show in Section 5.5 that our deterministic algorithm can be modified in a straightforward manner into a probabilistic Las-Vegas algorithm of expected bit complexity $\tilde{O}_B(d^5 + d^4\tau)$ (Theorem 29). This is done by choosing randomly a linear form $x + ay$ and a prime μ for the system $\{H, \frac{\partial H}{\partial y}\}$, until the number of distinct solutions of $\{H, \frac{\partial H}{\partial y}\}$ is equal to the number of distinct solutions of that system modulo μ and after projection along the direction of the line $x + ay = 0$.

This new algorithm is similar to one presented in [BLP⁺14] and it has the same expected bit complexity, while its worst-case counterpart is improved by a factor d . Furthermore, this new algorithm is simpler because, in particular, (i) we choose random values for a and μ together instead of first computing a lucky prime and only then a separating form and (ii) we avoid the explicit computation of the constant in the asymptotic upper bound on the number of unlucky prime.

2.3 Multimodular RUR decomposition

We present in Section 6 a new algorithm for computing a rational parameterization of the solutions of a bivariate system $\{P, Q\}$. As in Section 5, we actually present two algorithms, a deterministic one of worst-case bit complexity $\tilde{O}_B(d^6 + d^5\tau)$ and a probabilistic Las-Vegas variant of expected bit complexity $\tilde{O}_B(d^5 + d^4\tau)$ (Theorems 45 and 46). We consider here that a separating form $x + ay$ has been computed for $\{P, Q\}$ as shown in Section 5.

Recall that the two algorithms with best known bit complexity for computing rational parameterizations of the solutions are those by Gonzalez-Vega and El Kahoui [GVEK96] and by Bouzidi et al. [BLPR15], both of complexity $\tilde{O}_B(d^7 + d^6\tau)$. The former algorithm first shears the input polynomials according the separating form (to ensure that no two solutions are vertically aligned)

and then computes a parameterization of the solutions of every system of the triangular decomposition of the sheared system; the multiplicities of the solutions of $\{P, Q\}$ are thus not preserved. The latter algorithm computes a single RUR of $\{P, Q\}$, which preserves the multiplicities of the solutions (see Proposition 35). In this latter approach, the input bivariate polynomials are formally sheared using an additional variable that parameterizes a generic linear form, and the resultant of these (trivariate) polynomials is computed. The polynomials of the RUR are then expressed (and computed) as combinations of this resultant and its partial derivatives, specialized at the value a associated with the given linear separating form.

Here, we combine in essence these two approaches and compute a RUR for every system of the triangular decomposition of the sheared input system. However, in order to obtain the claimed complexities, we do not compute a RUR of every triangular system using the approach of [BLPR15]. Instead, Algorithm 6 works as follows. First, we compute the triangular decomposition of the sheared input system as in [GVEK96]. We then show that the radical ideals of the triangular systems can easily be obtained (Lemma 39). Using the simple structure of these radical ideals, we derive formulas for their RURs (Lemma 40). For complexity issues, we do not use these formulas to directly compute RURs over \mathbb{Q} but we use instead a multi-modular approach. For that purpose, we use known bounds on the size of the RUR coefficients and the luckiness certificate of the triangular decomposition introduced in Section 4.3 to select the primes.

Finally, we show in Section 6.3 how our deterministic algorithm can be transformed into a probabilistic Las-Vegas one of expected bit complexity $\tilde{O}_B(d^5 + d^4\tau)$. In order to obtain this complexity, we cannot compute the triangular decomposition as described above. Instead, we show in Section 6.3.1 that we can only compute the coefficients of these triangular systems that are needed for obtaining their radicals, within the targeted bit complexity. We also choose randomly the primes in the multi-modular computation described above. This can be done in a Las-Vegas setting because we show that we can choose good primes with sufficiently high probability and that we can check whether the primes are good within the targeted complexity.

2.4 Computing isolating boxes from a RUR decomposition

Section 7 introduces Algorithm 10 computing isolating boxes for the complex solutions from a RUR. By definition, the RUR of an ideal I defines a mapping between the roots of a univariate polynomial and the solutions of I . A RUR is hence naturally designed to compute isolating boxes using univariate isolation and interval evaluation.

An algorithm with bit complexity $\tilde{O}_B(d^8 + d^7\tau)$ was presented in [BLPR15, §5.1 and Proposition 35] for the isolation of the real solutions of a system $\{P, Q\}$ of two bivariate polynomials of degree bounded by d and bitsize bounded by τ . Section 7.2 presents a modified algorithm that isolates all complex solutions. Using several amortized bounds for the roots of polynomials (Section 7.1), we show that Algorithm 10 applied to a RUR decomposition of a system $\{P, Q\}$, isolates all complex solutions in $\tilde{O}_B(d^6 + d^5\tau)$ (Theorem 62).

3 Notation and preliminaries

We introduce notation and recall some classical material about subresultants, gcds, lucky primes for gcd computations, and multiplicities. Experienced readers can skip this classical material at first and later return to it for reference.

The bitsize of an integer p is the number of bits needed to represent it, that is $\lceil \log p \rceil + 1$ (\log refers to the logarithm in base 2). The bitsize of a rational is the maximum bitsize of its numerator and its denominator. The bitsize of a polynomial with integer coefficients is the

maximum bitsize of its coefficients. As mentioned earlier, O_B refers to the bit complexity and \tilde{O} and \tilde{O}_B refer to complexities where polylogarithmic factors are omitted, i.e., $f(n) \in \tilde{O}(g(n))$ if $f(n) \in O(g(n) \log^k(n))$ for some $k \in \mathbb{N}$.

In this paper, we consider algorithms both in the worst-case and the probabilistic Las-Vegas setting. Recall that in Las-Vegas algorithms the sequence and number of operations are probabilistic but the output is deterministic. The expected complexities of these algorithms refer to average number of bit operations that are performed for distributions of random variables considered in the process of the algorithms; these expected complexities hold without any assumption on the distribution of the input.

In the following, μ is a prime number and we denote by \mathbb{Z}_μ the quotient $\mathbb{Z}/\mu\mathbb{Z}$. We denote by $\phi_\mu: \mathbb{Z} \rightarrow \mathbb{Z}_\mu$ the reduction modulo μ , and extend this definition to the reduction of polynomials with integer coefficients. We denote by \mathbb{D} a unique factorization domain, typically $\mathbb{Z}[x, y]$, $\mathbb{Z}[x]$, $\mathbb{Z}_\mu[x]$, \mathbb{Z} or \mathbb{Z}_μ . We also denote by \mathbb{F} a field, typically \mathbb{Q} , \mathbb{C} , or \mathbb{Z}_μ and by $\mathbb{F}_\mathbb{D}$ the fraction field of \mathbb{D} .

For any polynomial P in $\mathbb{D}[x]$, let $\text{Lc}_x(P)$ denote its leading coefficient with respect to the variable x and $\text{d}_x(P)$ its degree with respect to x . The degree of a polynomial refers to its *total* degree, unless specified otherwise. For any curve defined by $H(x, y)$ in $\mathbb{D}[x, y]$, we call the critical points of H with respect to x or more shortly the critical point of H , the points that are solutions of the system $\{H, \frac{\partial H}{\partial y}\}$. In this paper, the solutions of a system of polynomials are always considered in the algebraic closure of $\mathbb{F}_\mathbb{D}$.

Subresultant and gcd. We first recall the concept of *polynomial determinant* of a matrix which is used in the definition of subresultants. Let M be an $m \times n$ matrix with $m \leq n$ and M_i be the square submatrix of M consisting of the first $m - 1$ columns and the i -th column of M , for $i = m, \dots, n$. The *polynomial determinant* of M is the polynomial defined as $\det(M_m)y^{n-m} + \det(M_{m+1})y^{n-(m+1)} + \dots + \det(M_n)$.

Let $P = \sum_{i=0}^p a_i y^i$ and $Q = \sum_{i=0}^q b_i y^i$ be two polynomials in $\mathbb{D}[y]$ and assume, without loss of generality, that $a_p b_q \neq 0$ and $p \geq q$.

The Sylvester matrix of P and Q , $\text{Syl}_y(P, Q)$ is the $(p + q)$ -square matrix whose rows are $y^{q-1}P, \dots, P, y^{p-1}Q, \dots, Q$ considered as vectors in the basis $y^{p+q-1}, \dots, y, 1$.

$$\text{Syl}_y(P, Q) = \begin{array}{c} \overbrace{\hspace{10em}}^{p+q \text{ columns}} \\ \left(\begin{array}{cccccccc} a_p & a_{p-1} & \cdots & \cdots & a_0 & & & \\ & a_p & a_{p-1} & \cdots & \cdots & a_0 & & \\ & & \ddots & & & & \ddots & \\ & & & a_p & a_{p-1} & \cdots & \cdots & a_0 \\ b_q & b_{q-1} & \cdots & & b_0 & & & \\ & b_q & b_{q-1} & \cdots & b_0 & & & \\ & & \ddots & & & \ddots & & \\ & & & \ddots & & & \ddots & \\ & & & & b_q & b_{q-1} & \cdots & b_0 \end{array} \right) \begin{array}{l} \left. \vphantom{\begin{array}{c} a_p \\ \vdots \\ a_0 \end{array}} \right\} q \text{ rows} \\ \left. \vphantom{\begin{array}{c} b_q \\ \vdots \\ b_0 \end{array}} \right\} p \text{ rows} \end{array} \end{array}$$

For $i = 0, \dots, \min(q, p - 1)$, let $\text{Syl}_{y,i}(P, Q)$ be the $(p + q - 2i) \times (p + q - i)$ matrix obtained from $\text{Syl}_y(P, Q)$ by deleting the i last rows of the coefficients of P , the i last rows of the coefficients of Q , and the i last columns.

Definition 1. ([EK03, §3]). For $i = 0, \dots, \min(q, p - 1)$, the i -th polynomial subresultant of P and Q , denoted by $\text{Sres}_{y,i}(P, Q) = \text{sres}_{y,i}(P, Q)y^i + \text{sres}_{y,i,i-1}(P, Q)y^{i-1} + \dots + \text{sres}_{y,i,0}(P, Q)$ is the polynomial determinant of $\text{Syl}_{y,i}(P, Q)$.

For practical consideration, when $q = p$, we define the q -th polynomial subresultant of P and Q as Q .² The polynomial $\text{Sres}_i(P, Q)$ has degree at most i in y and it can be written as $\text{sres}_{y,i}(P, Q)y^i + \text{sres}_{y,i,i-1}(P, Q)y^{i-1} + \cdots + \text{sres}_{y,i,0}(P, Q)$, where the coefficient of its monomial of degree i in y , $\text{sres}_i(P, Q)$, is called the i -th *principal subresultant coefficient*. Unless specified otherwise, the subresultants are always considered with respect to the variable y and then, for simplicity, we do not explicitly refer to the variable in the notation. Note that $\text{Sres}_0(P, Q) = \text{sres}_0(P, Q)$ is the *resultant* of P and Q with respect to y , which we also denote by $\text{Res}_y(P, Q)$. Again, when the resultant is considered with respect to y , we omit the reference to the variable and denote it by $\text{Res}(P, Q)$.

The matricial definition of subresultants implies the so-called *specialization property* of subresultants, that is $\phi(\text{Sres}_i(P, Q)) = \text{Sres}_i(\phi(P), \phi(Q))$ for any morphism ϕ between \mathbb{D} and another unique factorization domain \mathbb{D}' such that none of the leading coefficients of P and Q vanishes through ϕ . More generally, the equality holds up to a non-zero multiplicative constant in \mathbb{D}' when only one of the leading coefficients vanishes [EK03, Lemmas 2.3, 3.1].

We state in Lemma 2 a fundamental property of subresultants which is instrumental in the triangular decomposition algorithm. For clarity, we state this property for bivariate polynomials $P = \sum_{i=0}^p a_i y^i$ and $Q = \sum_{i=0}^q b_i y^i$ in $\mathbb{D}[x, y]$, with $p \geq q$. This property is a direct consequence of the specialization property of subresultants and of the gap structure theorem; see for instance [EK03, Lemmas 2.3, 3.1 and Cor. 5.1].

Before stating Lemma 2, we recall that a greatest common divisor (gcd) of P and Q is a polynomial in $\mathbb{D}[x, y]$ that divides P and Q such that any common divisor of P and Q also divides the gcd in $\mathbb{D}[x, y]$. The greatest common divisor is unique only up to the multiplication by an invertible element of \mathbb{D} . When \mathbb{D} is equal to \mathbb{Z} , the gcd of P and Q is unique up to its sign and we refer to any of them as *the* gcd for simplicity. On the other hand, when \mathbb{D} is a field, we refer to the monic gcd (with respect to a given ordering of the variables) as *to the* gcd. Furthermore, in the sequel, we sometimes compare gcds defined in $\mathbb{Z}_\mu[x, y]$ and the reduction modulo μ of gcds defined in $\mathbb{Z}[x, y]$; for simplicity, we often say they are equal if they are equal up to the multiplication by a non-zero constant in \mathbb{Z}_μ . Note finally that if P and Q are coprime in $\mathbb{Z}[x, y]$, then they define a zero-dimensional system.

Lemma 2. *For any α such that $a_p(\alpha)$ and $b_q(\alpha)$ do not both vanish,³ the first subresultant polynomial $\text{Sres}_k(P, Q)(\alpha, y)$ (for k increasing) that does not identically vanish is of degree k , and it is the gcd of $P(\alpha, y)$ and $Q(\alpha, y)$ (up to the multiplication by a non-zero constant in the fraction field of $\mathbb{D}(\alpha)$).*

We recall complexity results, using fast algorithms, on subresultants and gcd computations.

Lemma 3 ([BPR06, Prop. 8.46] [Rei97, §8] [vzGG03, §11.2]). *Let P and Q be in $\mathbb{Z}[x_1, \dots, x_n][y]$ (n fixed) with coefficients of bitsize at most τ such that their degrees in y are bounded by d_y and their degrees in the other variables are bounded by d .*

- *The coefficients of $\text{Sres}_i(P, Q)$ have bitsize in $\tilde{O}(d_y \tau)$.*
- *The degree in x_j of $\text{Sres}_i(P, Q)$ is at most $2d(d_y - i)$.*

² It can be observed that, when $p > q$, the q -th subresultant is equal to $b_q^{p-q-1}Q$, however it is not defined when $p = q$. In this case, El Kahoui suggests to extend the definition to $b_q^{-1}Q$ assuming that the domain \mathbb{D} is integral. However, b_q^{-1} does not necessarily belong to \mathbb{D} , which is not practical. Note that it is important to define the q -th subresultant to be a multiple of Q so that Lemma 2 holds when $P(\alpha, y)$ and $Q(\alpha, y)$ have same degree and are multiple of one another.

³Note that this property is often stated with a stronger assumption, that is, that *none* of the leading coefficients $a_p(\alpha)$ and $b_q(\alpha)$ vanishes.

- For any $i \in \{0, \dots, \min(d_y(P), d_y(Q))\}$, the i -th Bézout's relation i.e. the polynomials $\text{Sres}_i(P, Q)$, U_i and V_i can be computed in $\tilde{O}(d^n d_y^{n+1})$ arithmetic operations and $\tilde{O}_B(d^n d_y^{n+2} \tau)$ bit operations. These complexities also hold for the computation of the sequence of principal subresultant coefficients $\text{sres}_i(P, Q)$.⁴

In the univariate case, we need a refinement of the previous lemma in the case of two polynomials with different degrees and bitsizes. In addition, we often consider the gcd of two univariate polynomials P and Q and the gcd-free part of P with respect to Q , that is $\frac{P}{\gcd(P, Q)}$. Note that when $Q = P'$, the latter is the squarefree part of P . Since the gcd and gcd-free part can be computed via subresultants, we summarize all these complexity results in the following lemma. Since we do not know a proper reference for these results in the case of different degrees and bitsizes, we provide a proof.

Lemma 4 ([LR01] [vzGG03, §11.2]). *Let P and Q be two polynomials in $\mathbb{Z}[y]$ of degrees p and $q \leq p$ and of bitsizes τ_P and τ_Q , respectively.*

- *The coefficients of $\text{Sres}_i(P, Q)$ have bitsize in $\tilde{O}(p\tau_Q + q\tau_P)$.*
- *Any subresultant $\text{Sres}_i(P, Q)$ as well as the sequence of principal subresultant coefficients $\text{sres}_i(P, Q)$ can be computed in $\tilde{O}(p)$ arithmetic operations, and $\tilde{O}_B(p(p\tau_Q + q\tau_P))$ bit operations.*
- *In $\mathbb{Z}[y]$, the gcd of P and Q has bitsize $O(\min(p + \tau_P, q + \tau_Q))$ and it can be computed in $\tilde{O}(p)$ arithmetic operations, and $\tilde{O}_B(p(p\tau_Q + q\tau_P))$ bit operations. The gcd-free part of P with respect to Q has bitsize $O(p + \tau_P)$ and it can be computed in the same complexities.*

Proof. Using the well-known half-gcd approach, the algorithm in [LR01] computes any polynomial in the Sylvester-Habicht and cofactors sequence in a softly-linear number of arithmetic operations, and it exploits Hadamard's inequality on the Sylvester matrix to bound the size of the coefficients. The Sylvester-Habicht sequence is a signed variant of the subresultant sequence thus the same complexity bounds apply for both. The same approach is also used in [vzGG03, §11] to compute the sequence of principal subresultant coefficients.

When the two input polynomials have different degrees and bitsizes, Hadamard's inequality reads as $\tilde{O}(p\tau_Q + q\tau_P)$ instead of simply $\tilde{O}(d\tau)$ when both polynomials have degree bounded by d and bitsize bounded by τ . Using the Chinese Remainder Algorithm, the algorithms in [LR01] and in [vzGG03, §11] hence compute any subresultant polynomial as well as the sequence of principal subresultant coefficients in $\tilde{O}_B(p(p\tau_Q + q\tau_P))$ bit operations instead of simply $\tilde{O}(d^2\tau)$. One subresultant and a cofactor are, up to integer factors, the gcd and gcd-free part of P and Q ([BPR06, Prop. 10.14]). These polynomials in $\mathbb{Z}[y]$ are thus computed in $\tilde{O}_B(p(p\tau_Q + q\tau_P))$ and have bitsize in $\tilde{O}(p\tau_Q + q\tau_P)$. On the other hand, Mignotte's lemma (see e.g. [BPR06, Corollary 10.12]) gives the stated better bounds for the bitsize of the gcd and the gcd-free part. Thus, dividing the computed polynomials by the gcd of their coefficients, which can be done with $\tilde{O}_B(p(p\tau_Q + q\tau_P))$ bit operations, yields the primitive parts of the gcd and gcd-free part in $\mathbb{Z}[y]$ (when input polynomials are not primitive, the gcd is obtained by multiplying this primitive gcd by the gcd of the contents of the input polynomials). \square

We also state the following complexity on the computation of the gcd and gcd-free parts of bivariate polynomials, whose proof is a minor refinement of one in [MSW15].

⁴The complexity of computing the sequence of principal subresultant coefficients is stated in [vzGG03, §. 11.2] only for univariate polynomials, however, one can use the binary segmentation technique described in [Rei97, §8] to generalize the latter to multivariate polynomials.

Lemma 5. *Given P and Q in $\mathbb{Z}[x, y]$ of maximum degree d and maximum bitsize τ , their gcd and the gcd-free parts can be computed in $\tilde{O}_B(d^5 + d^4\tau)$ bit operations in the worst case.*

Proof. [MSW15, Lemma 13] proves that G , the gcd of P and Q , can be computed in $\tilde{O}_B(d^6 + d^5\tau)$ bit complexity. More precisely, they prove a complexity in $\tilde{O}_B(d^5 + d^4\tau)$ plus that of computing the whole subresultant sequence of two bivariate polynomials of total degree $O(d)$ and bitsize $O(d + \tau)$ (that is of P and Q sheared so that their leading coefficients in y is in \mathbb{Z}). However, only the first non-zero subresultant is needed and the bit complexity of this computation is in $\tilde{O}_B(d^5 + d^4\tau)$ by Lemma 3.

We now consider P and G , the gcd of P and Q , as polynomials in y with coefficients in $\mathbb{Z}[x]$. The gcd-free part of P with respect to Q is the quotient of the Euclidean division between P and G . This division can be run in $\mathbb{Z}[x][y]$. Indeed, since the leading coefficient of G divides that of P , it also divides the leading coefficient of each intermediate remainder $r_i = P - q_i G$ where q_i refers to the i -th truncation (with respect to y) of the quotient of P by G . Moreover, since G divides P and by Mignotte's lemma (see e.g. [BPR06, Corollary 10.12]), the polynomials q_i have coefficients of degree in $O(d)$ in x and bitsize in $O(d + \tau)$, and so as for the intermediate remainders r_i . The Euclidean division can thus be done using $O(d^2)$ additions and multiplications and $O(d)$ exact divisions between polynomials in $\mathbb{Z}[x]$ of degree in $O(d)$ and bitsize in $O(d + \tau)$, which yields a bit complexity in $\tilde{O}_B(d^4 + d^3\tau)$.

Note that, alternatively, the gcd-free parts of P and Q could be obtained almost directly as i -th subresultant cofactors of P and Q (see [BPR06, Proposition 10.14 & Corollary 8.32 & §1.2]). \square

Lucky primes for gcd computations. We use in this paper three notions of lucky primes. We recall here the definition of lucky primes for gcds and we later introduce the definition of lucky primes for algebraic systems (Definition 18) and for triangular decompositions (Definition 13). Let A and B be polynomials in $\mathbb{Z}[x]$.

Definition 6 ([Yap00, §4.4]). *A prime number μ is lucky for the gcd of A and B if*

- $\phi_\mu(\text{Lc}(A) \cdot \text{Lc}(B)) \neq 0$, and
- $\text{gcd}(A, B)$ has the same degree as $\text{gcd}(A_\mu, B_\mu)$.

Lemma 7 ([Yap00, Lemmas 4.11 and 4.12]). *A prime number is lucky for the gcd of A and B if and only if it divides the leading coefficient of neither A , nor B , nor $\text{Sres}_d(A, B)$ where d is the degree of $\text{gcd}(A, B)$. When μ is lucky for the gcd of A and B , then $\phi_\mu(\text{gcd}(A, B)) = \text{gcd}(A_\mu, B_\mu)$ (up to a non-null factor in \mathbb{Z}_μ).*

Multiplicities. We define the two notions of multiplicities that we use for the solutions of a system and show an inequality that they satisfy, which is used for the amortized complexity analysis of the triangular decomposition (Proposition 15).

Definition 8. *Let I be an ideal of $\mathbb{D}[x, y]$ and denote by \mathbb{F} the algebraic closure of \mathbb{D} . To each zero (α, β) of I corresponds a local ring $(\mathbb{F}[x, y]/I)_{(\alpha, \beta)}$ obtained by localizing the ring $\mathbb{F}[x, y]/I$ at the maximal ideal $\langle x - \alpha, y - \beta \rangle$. When this local ring is finite dimensional as \mathbb{F} -vector space, this dimension is called the **multiplicity of (α, β) as a zero of I** and is noted $\text{mult}((\alpha, \beta), I)$ [CLO05, §4.2].*

*We call the **fiber** of a point $\mathbf{p} = (\alpha, \beta)$ the vertical line of equation $x = \alpha$. The **multiplicity of \mathbf{p} in its fiber** with respect to a system of polynomials $\{P, Q\}$ in $\mathbb{F}[x, y]$, noted $\text{mult}_{\text{fiber}}((\alpha, \beta), \{P, Q\})$, is the multiplicity of β in the univariate polynomial $\text{gcd}(P(\alpha, y), Q(\alpha, y))$.⁵ (This multiplicity is zero if P or Q does not vanish at \mathbf{p} .)*

⁵The gcd is naturally considered over $\overline{\mathbb{F}(\alpha)[y]}$, the ring of polynomials in y with coefficients in the field extension of \mathbb{F} by α .

Lemma 9. *The multiplicity of any solution in its fiber with respect to the system $\{P, Q\}$ is smaller than or equal to its multiplicity in $\{P, Q\}$.*

Proof. Let (α, β) be a solution of the system $\{P, Q\}$. We have the inclusion of ideals

$$\begin{aligned} \langle P(x, y), Q(x, y) \rangle &\subseteq \langle P(x, y), Q(x, y), x - \alpha, \gcd(P(\alpha, y), Q(\alpha, y)) \rangle \\ &\subseteq \langle P(\alpha, y), Q(\alpha, y), x - \alpha, \gcd(P(\alpha, y), Q(\alpha, y)) \rangle \\ &\subseteq \langle x - \alpha, \gcd(P(\alpha, y), Q(\alpha, y)) \rangle. \end{aligned}$$

Indeed, the first and last inclusions are trivial and the second one follows from the fact that $P(x, y) \in \langle P(\alpha, y), x - \alpha \rangle$ since $P(x, y)$ can be written as $P(\alpha, y) + \sum_{i \geq 1} \frac{\partial^i P(\alpha, y)}{\partial x^i} (x - \alpha)^i$. This ideal inclusion implies that the multiplicity of (α, β) in $\langle P, Q \rangle$ is larger than or equal to its multiplicity in $\langle x - \alpha, \gcd(P(\alpha, y), Q(\alpha, y)) \rangle$, which is equal to the multiplicity of β in $\gcd(P(\alpha, y), Q(\alpha, y))$ since $x - \alpha$ is squarefree. The latter is by definition the multiplicity in its fiber of the solution (α, β) with respect to the system $\{P, Q\}$. \square

4 Triangular decomposition and luckiness certificate

This section presents an improved complexity analysis of the classical triangular decomposition via subresultants and two variants of this algorithm that we will need in the following sections. The improvement comes from new amortized bounds on the degree and bitsize of factors of the resultant, which we prove in Proposition 15. Besides of being of independent interest, this improvement is critical for the complexity analysis of our two variants of this algorithm.

In Section 4.1, we recall Algorithm 1, the classical algorithm for computing the triangular decomposition of a zero-dimensional bivariate system $\{P, Q\}$. In Section 4.2, we present Algorithm 1', a variant that only computes the “degree” of the triangular decomposition. In Section 4.3, we present Algorithm 2, another variant that computes a luckiness certificate (see Definition 13) for the triangular decomposition. Finally, in Section 4.4, we present an amortized complexity analysis of these algorithms.

4.1 Triangular decomposition via subresultants

The idea is based on Lemma 2 which states that, after specialization at $x = \alpha$, the first (with respect to increasing i) non-zero subresultant $\text{Sres}_i(P, Q)(\alpha, y)$ is of degree i and is equal to the gcd of $P(\alpha, y)$ and $Q(\alpha, y)$. This induces a decomposition into triangular subsystems $\{A_i(x), \text{Sres}_i(P, Q)(x, y)\}$ where a solution α of $A_i(x) = 0$ is such that the system $\{P(\alpha, y), Q(\alpha, y)\}$ admits exactly i roots (counted with multiplicity), which are exactly those of $\text{Sres}_i(P, Q)(\alpha, y)$. Furthermore, these triangular subsystems are regular chains, i.e., the leading coefficient of the bivariate polynomial (seen in y) is coprime with the univariate polynomial. We recall in Algorithm 1 how this decomposition is computed. Note that this algorithm performs $\tilde{O}(d^4)$ arithmetic operations. Indeed, the computation of the subresultant sequence has complexity $\tilde{O}(d^4)$ and there are at most

Algorithm 1 Triangular decomposition [GVEK96, LMMRS11]

Input: P, Q in $\mathbb{D}[x, y]$ coprime such that $\text{Lc}_y(P)$ and $\text{Lc}_y(Q)$ are coprime

Output: Triangular decomposition $\{(A_i(x), B_i(x, y))\}_{i \in \mathcal{I}}$ such that the set of solutions of $\{P, Q\}$ is the disjoint union of the sets of solutions of $\{(A_i(x), B_i(x, y))\}_{i \in \mathcal{I}}$

- 1: If needed, exchange P and Q so that $d_y(Q) \leq d_y(P)$
 - 2: Compute the subresultant sequence of P and Q with respect to y : $B_i = \text{Sres}_i(P, Q)$
 - 3: $G_0 = \text{squarefree part}(\text{Res}(P, Q))$ and $\mathcal{T} = \emptyset$
 - 4: **for** $i = 1$ **to** $d_y(Q)$ **do**
 - 5: $G_i = \text{gcd}(G_{i-1}, \text{sres}_i(P, Q))$
 - 6: $A_i = G_{i-1}/G_i$
 - 7: if $d_x(A_i) > 0$, add (A_i, B_i) to \mathcal{T}
 - 8: **return** $\mathcal{T} = \{(A_i(x), B_i(x, y))\}_{i \in \mathcal{I}}$
-

Algorithm 1' Degree of the triangular decomposition

Input: P, Q in $\mathbb{D}[x, y]$ coprime such that $\text{Lc}_y(P)$ and $\text{Lc}_y(Q)$ are coprime

Output: The degree of the triangular decomposition of $\{P, Q\}$

- 1: If needed, exchange P and Q so that $d_y(Q) \leq d_y(P)$
 - 2: Compute the sequence of principal subresultant coefficients of P and Q with respect to y : $\text{sres}_i(P, Q)$
 - 3: $G_0 = \text{squarefree part}(\text{Res}(P, Q))$
 - 4: **for** $i = 1$ **to** $d_y(Q)$ **do**
 - 5: $G_i = \text{gcd}(G_{i-1}, \text{sres}_i(P, Q))$
 - 6: **return** $\sum_{i \in \mathcal{I}} (d_x(G_{i-1}) - d_x(G_i)) i$
-

d gcd computations each of complexity $\tilde{O}(d^2)$ (see e.g. [BLPR15, Lemma 15] for details). The next lemma summarizes the main properties of this triangular decomposition.

Lemma 10 ([GVEK96, LMMRS11]). *Algorithm 1 computes a triangular decomposition $\{(A_i(x), B_i(x, y))\}_{i \in \mathcal{I}}$ such that*

- *the set of distinct solutions of $\{P, Q\}$ is the disjoint union of the sets of distinct solutions of the $\{A_i(x), B_i(x, y)\}$, $i \in \mathcal{I}$,*
- *$\prod_{i \in \mathcal{I}} A_i$ is squarefree,*
- *for any root α of A_i , $B_i(\alpha, y)$ is of degree i and equals $\text{gcd}(P(\alpha, y), Q(\alpha, y))$ (up to a constant factor),*
- *A_i is coprime with $\text{Lc}_y(B_i) = \text{sres}_i(P, Q)$.*

4.2 Degree of a triangular decomposition

Definition 11. *The degree of a triangular decomposition $\{(A_i(x), B_i(x, y))\}_{i \in \mathcal{I}}$ of is the sum of the degrees of these systems, that is*

$$\sum_{i \in \mathcal{I}} d_x(A_i(x)) d_y(B_i(x, y))$$

where d_x refers to the degree of the polynomial with respect to x and similarly for y . For simplicity, we refer to the degree of the triangular decomposition of $\{P, Q\}$ as to the degree of the triangular decomposition computed by Algorithm 1 on $\{P, Q\}$.

Algorithm 2 Luckiness certificate

Input: P, Q in $\mathbb{Z}[x, y]$ coprime such that $\text{Lc}_y(P)$ and $\text{Lc}_y(Q)$ are coprime

Output: A luckiness certificate of $\{P, Q\}$, that is, an integer Π such that if μ does not divide Π , then it is lucky for the triangular decomposition of $\{P, Q\}$ according to Definition 13

- 1: If needed, exchange P and Q so that $d_y(Q) \leq d_y(P)$
 - 2: Compute the sequence of principal subresultant coefficients of P and Q with respect to y : $\text{sres}_i(P, Q)$
 - 3: $G_0 = \text{squarefree part}(\text{Res}(P, Q))$
 - 4: $SG_0 = \text{sres}_{x,k}(\text{Res}(P, Q), \frac{\partial \text{Res}(P, Q)}{\partial x})$ the first non-null principal subresultant coefficient (for k increasing)
 - 5: **for** $i = 1$ **to** $d_y(Q)$ **do**
 - 6: $SG_i = \text{sres}_{x,k}(G_{i-1}, \text{sres}_i(P, Q))$ the first non-null principal subresultant coefficient (for k increasing)
 - 7: $G_i = \text{gcd}(G_{i-1}, \text{sres}_i(P, Q))$
 - 8: $\Pi = \text{Lc}_x(\text{Lc}_y(P)) \cdot \text{Lc}_x(\text{Lc}_y(Q)) \cdot \text{Res}_x(\text{Lc}_y(P), \text{Lc}_y(Q)) \cdot d_x(\text{Res}(P, Q)) \cdot \prod_{i=0}^{d_y(Q)} SG_i \cdot \text{Lc}_x(\text{sres}_i(P, Q))$
 - 9: **return** Π
-

Algorithm 1', a straightforward variant of Algorithm 1, computes the degree of triangular decomposition of $\{P, Q\}$. The difference with Algorithm 1 is that we do not compute (in Line 2) the whole subresultant sequence but only the sequence of their principal coefficients. In other words, we do not compute the bivariate polynomials $B_i(x, y)$ of the triangular decomposition but only their leading terms (seen as polynomials in y). Furthermore, we do not compute the univariate polynomials $A_i(x)$ of the decomposition but only their degrees. This simplification does not modify the worst-case bit complexity of the algorithm but it decreases its expected bit complexity (see Proposition 16 and its proof). This simplification is thus not needed in the deterministic version of our algorithm for computing a separating linear form but it is needed in our randomized version (see Section 5.5).

Lemma 12 (Correctness of Algorithm 1'). *Algorithm 1' computes the degree of the triangular decomposition of $\{P, Q\}$.*

Proof. Let $\{(A_i(x), B_i(x, y))\}_{i \in \mathcal{I}}$ denote the triangular decomposition of $\{P, Q\}$. By Lemma 10, $B_i(x, y)$ is of degree i in y . On the other hand, $A_i(x)$ is defined in Algorithm 1 Line 6 as G_{i-1}/G_i thus its degree is $d_x(G_{i-1}) - d_x(G_i)$. It follows that the degree of the triangular decomposition is $\sum_{i \in \mathcal{I}} (d_x(G_{i-1}) - d_x(G_i)) i$. \square

4.3 Lucky primes for a triangular decomposition

In this section, we define the lucky primes for the triangular decomposition of Algorithm 1 and introduce Algorithm 2 that computes a luckiness certificate i.e. an integer that is divisible by all the unlucky primes.

Definition 13. *A prime μ is lucky for the triangular decomposition of Algorithm 1 applied to P and Q if the decomposition commutes with the morphism ϕ_μ . In other words, the image modulo μ of the sequence of triangular systems output by Algorithm 1 applied to P and Q is equal to the sequence of triangular systems output by Algorithm 1 applied to $\phi_\mu(P)$ and $\phi_\mu(Q)$ (the equality of two polynomials is here considered up to a non-zero constant in \mathbb{Z}_μ).*

Lemma 14 (Correctness of Algorithm 2). *The integer Π output by Algorithm 2 is a luckiness certificate of $\{P, Q\}$, that is, if μ does not divide Π , then it is lucky for the triangular decomposition of $\{P, Q\}$.*

Proof. For convenience, we simply denote by ϕ the morphism ϕ_μ that performs a reduction modulo μ . Let P and Q be two coprime polynomials in $\mathbb{Z}[x, y]$ such that $\text{Lc}_y(P)$ and $\text{Lc}_y(Q)$ are coprime. Let G_i, A_i, B_i be the polynomials computed in Algorithm 1 on the input P and Q , and $G_i^\mu, A_i^\mu, B_i^\mu$ be the polynomials computed in Algorithm 1 on the input $\phi(P)$ and $\phi(Q)$.

Showing that μ is lucky for the decomposition of $\{P, Q\}$ amounts to proving that $\phi(P)$ and $\phi(Q)$ satisfy the conditions of Algorithm 1 and that $\phi(A_i) = A_i^\mu$ and $\phi(B_i) = B_i^\mu$ (where the equality is considered up to a non-null factor in \mathbb{Z}_μ).

We first prove that $\phi(P)$ and $\phi(Q)$ satisfy the conditions of Algorithm 1, that is that they are coprime and that their leading coefficients are coprime. Observe first that $\phi(\text{Lc}_y(P)) = \text{Lc}_y(\phi(P))$ since μ does not divide $\text{Lc}_x(\text{Lc}_y(P))$, and similarly for Q . Furthermore, since μ does not divide the leading coefficients of $\text{Lc}_y(P)$ and $\text{Lc}_y(Q)$, their resultant and ϕ commute. Hence, $\phi(\text{Res}_x(\text{Lc}_y(P), \text{Lc}_y(Q))) = \text{Res}_x(\text{Lc}_y(\phi(P)), \text{Lc}_y(\phi(Q)))$ and, since the left-hand-side term is non-zero by assumption, so is the right-hand side, which means that the leading coefficients of $\phi(P)$ and $\phi(Q)$ are coprime. Furthermore, since μ does not divide $\text{sres}_0(P, Q) = \text{Res}(P, Q)$, we also have that $\text{Res}(\phi(P), \phi(Q)) \neq 0$. We have proved that $\phi(P)$ and $\phi(Q)$ have a non-zero resultant and that their leading coefficients are coprime, which implies that $\phi(P)$ and $\phi(Q)$ are coprime. Hence, they satisfy the conditions of Algorithm 1.

We now prove that $\phi(A_i) = A_i^\mu$ and $\phi(B_i) = B_i^\mu$. Since μ divides neither the leadings of P nor Q , the specialization property of the subresultant polynomials writes as $\phi(B_i) = \phi(\text{Sres}_i(P, Q)) = \text{Sres}_i(\phi(P), \phi(Q)) = B_i^\mu$. We now show by induction on $i \geq 0$ that $\phi(G_i) = G_i^\mu$, which implies that $\phi(A_i) = A_i^\mu$ for $i > 0$ since $A_i = G_{i-1}/G_i$.

Case $i = 0$. μ is lucky for the gcd of $\text{sres}_0(P, Q)$ and $\frac{\partial \text{sres}_0(P, Q)}{\partial x}$ by Lemma 7. Indeed, first, μ does not divide the leading coefficient $\text{Lc}_x(\text{sres}_0(P, Q))$ of $\text{sres}_0(P, Q)$. It follows that μ does not divide the leading coefficient of $\frac{\partial \text{sres}_0(P, Q)}{\partial x}$ since μ does not divide $d_x(\text{Res}(P, Q)) = d_x(\text{sres}_0(P, Q))$. Finally, μ does not divide SG_0 . It follows, still by Lemma 7, that ϕ and gcd commute on $\text{sres}_0(P, Q)$ and $\frac{\partial \text{sres}_0(P, Q)}{\partial x}$. Hence, $\phi(G_0) = G_0^\mu$ by the specialization property of the subresultants since the leading coefficients of P, Q do not vanish modulo μ .

Case $i > 0$. We assume that $\phi(G_{i-1}) = G_{i-1}^\mu$ and prove that $\phi(G_i) = G_i^\mu$. By Lemma 7, μ is lucky for the gcd of G_{i-1} and $\text{sres}_i(P, Q)$. Indeed, μ divides none of the leading coefficients of G_{i-1} and $\text{sres}_i(P, Q)$ (since G_{i-1} is a factor of $\text{sres}_{i-1}(P, Q)$), and μ does not divide SG_i either. This implies, still by Lemma 7, that $\phi(G_i) = \phi(\text{gcd}(G_{i-1}, \text{sres}_i(P, Q))) = \text{gcd}(\phi(G_{i-1}), \phi(\text{sres}_i(P, Q)))$. This is also equal to $\text{gcd}(G_{i-1}^\mu, \text{sres}_i(\phi(P), \phi(Q)))$ by the induction hypothesis and the property of specialization of the subresultants. Hence, $\phi(G_i) = G_i^\mu$, which concludes the proof by induction. \square

4.4 Amortized complexity analysis

For the analysis of Algorithms 1, 1' and 2, we first prove amortized bounds on the degree and bitsize of the factors G_i of the resultant in the triangular decomposition.

Proposition 15. *For $i = 0, \dots, d_y(Q) - 1$, let d_i and τ_i be the degree and bitsize of the polynomial G_i in the triangular decomposition of P and Q computed in Algorithm 1. We have:*

- $d_i \leq \frac{d^2}{i+1}$ and $\tau_i = \tilde{O}(\frac{d^2+d\tau}{i+1})$,
- $\sum_{i=0}^{d_y(Q)-1} d_i \leq d^2$ and $\sum_{i=0}^{d_y(Q)-1} \tau_i = \tilde{O}(d^2 + d\tau)$.

Proof. Let $\{(A_i(x), B_i(x, y))\}_{i \in \mathcal{I}}$ be the sequence of triangular systems output by Algorithm 1 on P and Q . By the properties of the triangular decomposition (Lemma 10), for any root α of A_i ,

$$d_y(B_i(\alpha, y)) = i \text{ and } B_i(\alpha, y) = \gcd(P(\alpha, y), Q(\alpha, y))$$

up to the multiplication by a constant factor.

By Definition 8, the multiplicity of (α, β) in its fiber with respect to system $\{P, Q\}$, denoted by $\text{mult}_{\text{fiber}}((\alpha, \beta), \{P, Q\})$, is the multiplicity of β in the univariate polynomial $\gcd(P(\alpha, y), Q(\alpha, y))$. Thus, for any root α of A_i ,

$$\sum_{\beta \text{ s.t. } B_i(\alpha, \beta)=0} \text{mult}_{\text{fiber}}((\alpha, \beta), \{P, Q\}) = i.$$

According to Lemma 9, the multiplicity of a solution in its fiber is smaller than its multiplicity in the system thus, for any root α of A_i ,

$$i \leq \sum_{\beta \text{ s.t. } B_i(\alpha, \beta)=0} \text{mult}((\alpha, \beta), \{P, Q\}).$$

This latter sum is the multiplicity of α in the resultant $\text{Res}(P, Q)$ because the set of solutions of $\{P, Q\}$ is the disjoint union of the sets of solutions of the $\{(A_i(x), B_i(x, y))\}_{i \in \mathcal{I}}$ (Lemma 10). Hence the multiplicity in $\text{Res}(P, Q)$ of any root α of A_i is at least i and since A_i is squarefree (Lemma 10), A_i^i divides $\text{Res}(P, Q)$. In addition, the A_i are pairwise coprime thus $\prod_{i=1}^{d_y(Q)} A_i^i$ divides $\text{Res}(P, Q)$. On the other hand, $G_i = \prod_{j>i} A_j$ by construction, thus $\prod_{i=0}^{d_y(Q)-1} G_i = \prod_{i=1}^{d_y(Q)} A_i^i$ divides $\text{Res}(P, Q)$.

The bound on the degrees, $\sum_{i=0}^{d_y(Q)-1} d_i \leq d_x(\text{Res}(P, Q)) \leq d^2$, is then a consequence of Bézout's bound on the system $\{P, Q\}$. In addition, A_i^i divides $\text{Res}(P, Q)$ implies that $G_i^{i+1} = \prod_{j>i} A_j^{i+1}$ also divides $\text{Res}(P, Q)$, which yields $d_i \leq \frac{d^2}{i+1}$.

For proving the bounds on the bitsize of G_i , we introduce Mahler's measure. For a univariate polynomial f with integer coefficients, its Mahler measure is $M(f) = |\text{Lc}(f)| \prod_{z_i \text{ s.t. } f(z_i)=0} \max(1, |z_i|)$, where every complex root appears with its multiplicity. Mahler's measure is multiplicative: $M(fg) = M(f)M(g)$ and, since it is at least 1 for any polynomial with integer coefficients, f divides g implies that $M(g) \geq M(f)$. We also prove two inequalities connecting the bitsize τ and degree d of f and its Mahler measure $M(f)$.

- (i) $\tau \leq 1 + d + \log M(f)$. Indeed, [BPR06, Prop. 10.8] states that $\|f\|_1 \leq 2^d M(f)$, thus $\|f\|_\infty \leq 2^d M(f)$ and $\log \|f\|_\infty \leq d + \log M(f)$, which yields the result since $\tau = \lfloor \log \|f\|_\infty \rfloor + 1$.
- (ii) $\log M(f) = O(\tau + \log d)$. Indeed, [BPR06, Prop. 10.9] states that $M(f) \leq \|f\|_2$, thus $M(f) \leq \sqrt{d+1} \|f\|_\infty$ and $\log M(f) \leq \log \sqrt{d+1} + \log \|f\|_\infty$.

The fact that G_i^{i+1} divides $\text{Res}(P, Q)$ implies that $M(G_i)^{i+1} \leq M(\text{Res}(P, Q))$ and thus that $\log M(G_i) \leq \frac{\log M(\text{Res}(P, Q))}{i+1}$. Inequality (i) together with $d_i \leq \frac{d^2}{i+1}$ then yields

$$\tau_i \leq 1 + \frac{d^2}{i+1} + \frac{\log M(\text{Res}(P, Q))}{i+1}.$$

Inequality (ii) then yields $\tau_i = \tilde{O}(\frac{d^2+d\tau}{i+1})$ since the bitsize of $\text{Res}(P, Q)$ is in $\tilde{O}(d\tau)$. The bound on the sum of the bitsizes is then straightforward using the fact that $\sum_{i=0}^{d_y(Q)-1} \frac{1}{i+1} = O(\log d)$. \square

Proposition 16. *If P, Q in $\mathbb{Z}[x, y]$ have degree at most d and bitsize at most τ , Algorithms 1, 1' and 2 perform $\tilde{O}_B(d^6 + d^5\tau)$ bit operations in the worst case. Algorithm 1' performs $\tilde{O}_B(d^5 + d^4\tau)$ bit operations on average. The integer Π output by Algorithm 2 has bitsize $\tilde{O}(d^4 + d^3\tau)$.*

Proof. By Lemma 3, the sequence of the subresultants $\text{Sres}_i(P, Q)$ can be computed in $\tilde{O}_B(d^5\tau)$ bit operations and the sequence of their principal coefficients $\text{sres}_i(P, Q)$ (including the resultant) can be computed in $\tilde{O}_B(d^4\tau)$ bit operations. Thus, Line 2 has complexity $\tilde{O}_B(d^5\tau)$ in Algorithm 1 and $\tilde{O}_B(d^4\tau)$ in Algorithms 1' and 2.

By Lemma 3, each of the principal subresultant coefficients sres_i (including the resultant) has degree $O(d^2)$ and bitsize $\tilde{O}(d\tau)$. Thus, by Lemma 4, in Line 3 of all three algorithms and in Line 4 of Algorithm 2, G_0 and SG_0 can be computed in $\tilde{O}_B((d^2)^2(d\tau)) = \tilde{O}_B(d^5\tau)$ bit operations.

In their loops, the three algorithms perform (in total) the computations of at most d gcd (or sequences of principal subresultant coefficients) between polynomials G_{i-1} and sres_i . Polynomial sres_i has bitsize $\tilde{O}(d\tau)$ and degree $O(d^2)$, and denoting by τ_i and d_i the bitsize and degree of G_i , Lemma 4 yields a complexity in $\tilde{O}_B(d^2(d^2\tau_{i-1} + d_{i-1}d\tau))$ for the computation of G_i and SG_i . According to Proposition 15, these complexities sum up over all i to $\tilde{O}_B(d^6 + d^5\tau)$. Finally, in Line 6 of Algorithm 1, the division of G_{i-1} by G_i can be done in a bit complexity of the order of the square of their maximum degree times their maximum bitsize [vzGG03, Theorem 9.6 and subsequent discussion], that is in $O_B(d_i^2\tau_i)$ (or actually $O_B(d_i^2 + d_i\tau_i)$ according to [vzGG03, Exercise 10.21]). By Proposition 15, $d_i \leq d^2$ and $\tau_i = \tilde{O}(\frac{d^2 + d\tau}{i+1})$, thus $\sum_i O_B(d_i^2\tau_i) = \tilde{O}_B(d^6 + d^5\tau)$. Hence the worst-case bit complexity of all three algorithms is in $\tilde{O}_B(d^6 + d^5\tau)$.

We now show that the expected bit complexity of Algorithm 1' is in $\tilde{O}_B(d^5 + d^4\tau)$. As above the worst-case bit complexity of Line 2 is in $\tilde{O}_B(d^4\tau)$. The rest of the algorithm performs $O(d)$ gcd computations and one exact division (in Line 3) between polynomials of degree $O(d^2)$ and bitsize $\tilde{O}(d\tau)$. Each of these operations can be done with an expected bit complexity of $\tilde{O}_B((d^2)^2 + d^2 \cdot d\tau)$ (the squared degree plus the degree times the bitsize) [vzGG03, Corollary 11.11 & Exercice 9.14]. The expected bit complexity of Algorithm 1' is thus in $\tilde{O}_B(d^5 + d^4\tau)$.

Concerning the last claim of the lemma, recall that

$$\Pi = \text{Lc}_x(\text{Lc}_y(P)) \cdot \text{Lc}_x(\text{Lc}_y(Q)) \cdot \text{Res}_x(\text{Lc}_y(P), \text{Lc}_y(Q)) \cdot d_x(\text{Res}(P, Q)) \cdot \prod_{i=0}^{d_y(Q)} SG_i \cdot \text{Lc}_x(\text{sres}_i(P, Q)).$$

Since P and Q have degree at most d and bitsize at most τ , the first two terms have bitsize at most τ and, by Lemma 4, $\text{Res}_x(\text{Lc}_y(P), \text{Lc}_y(Q))$ has bitsize $\tilde{O}(d\tau)$. Furthermore, as noted above, every $\text{sres}_i(P, Q)$ (including the resultant of P and Q) has degree $O(d^2)$ and bitsize $\tilde{O}(d\tau)$. In particular the bitsize of $d_x(\text{Res}(P, Q))$ is in $O(\log d)$ and that of $\text{Lc}_x(\text{sres}_i(P, Q))$ is in $\tilde{O}(d\tau)$. In addition, still by Lemma 4, SG_0 has bitsize $\tilde{O}(d^2 \cdot d\tau)$. On the other hand, by Lemma 4, for $i \geq 1$, SG_i has bitsize $\tilde{O}(d^2\tau_{i-1} + d_{i-1}d\tau)$ with d_i and τ_i the degree and bitsize of G_i . By Proposition 15, these bitsizes sum up to $\tilde{O}(d^4 + d^3\tau)$. The bitsize of Π is bounded by the sum of all these bitsizes and is thus in $\tilde{O}(d^4 + d^3\tau)$. \square

Remark 17. *Following the proof for the expected complexity of Algorithm 1', we directly get that Algorithm 1, except for Line 2, performs $\tilde{O}_B(d^5 + d^4\tau)$ bit operations on average. This will be useful for the proof of complexity of Algorithm 6'.*

5 Separating linear form

This section presents a new algorithm of worst-case bit complexity $\tilde{O}_B(d^6 + d^5\tau)$ for computing a separating linear form for a bivariate system of two coprime polynomials P, Q in $\mathbb{Z}[x, y]$ of total

degree at most d and maximum bitsize τ (Theorem 28). We also present a randomized version of this algorithm of expected bit complexity $\tilde{O}_B(d^5 + d^4\tau)$ (Theorem 29).

As mentioned in Section 2, this algorithm is based on those presented in [BLPR15] and [BLP+14]. In Section 5.2, we improve a result from [BLP+14] showing that computing a separating linear form for a system $\{P, Q\}$ is essentially equivalent (in terms of asymptotic bit complexity) to computing a separating linear form for the critical points of a curve. Section 5.3 then presents our algorithm for computing a separating linear form for the critical points of such a curve. In Section 5.4, we gather our results for deterministically computing separating linear forms of bivariate systems. Finally, in Section 5.5, we present the randomized version of our algorithm.

5.1 Notation and definitions

We first introduce some notation and formally define lucky primes for a system. Given the two input polynomials P and Q , we consider the “generic” change of variables $x = t - sy$, and define the “sheared” polynomials $P(t - sy, y)$, $Q(t - sy, y)$, and their resultant with respect to y ,

$$R(t, s) = \text{Res}(P(t - sy, y), Q(t - sy, y)).$$

We introduce the following notation for the leading coefficients of these polynomials;

$$L_P(s) = \text{Lc}_y(P(t - sy, y)), \quad L_Q(s) = \text{Lc}_y(Q(t - sy, y)). \quad (1)$$

Note that these polynomials do not depend on t .

Definition 18 ([BLPR15, Definition 8]). *A prime number μ is said to be **lucky for a zero-dimensional system** $\{P, Q\}$ if $\{P, Q\}$ and $\{\phi_\mu(P), \phi_\mu(Q)\}$ have the same number of distinct solutions (in their respective algebraic closures), $\mu > 2d^4$ and $\phi_\mu(L_P(s)) \phi_\mu(L_Q(s)) \neq 0$.*

Note that we consider μ in $\Omega(d^4)$ in Definition 18 because, in Algorithm 5, we want to ensure that there exists, for the system $\{\phi_\mu(P), \phi_\mu(Q)\}$ (resp. $\{P, Q\}$), a separating form $x + ay$ with a in \mathbb{Z}_μ (resp. $0 \leq a < \mu$ in \mathbb{Z}). The constant 2 in the bound $2d^4$ is an overestimate, which simplifies some proofs in [BLPR15].

Definition 19. *Let H be a polynomial in $\mathbb{Z}[x, y]$. A **separating form for the curve** defined by H is a separating form for the system $\{H, \frac{\partial H}{\partial y}\}$ of critical points of the curve.*

Remark that shearing the critical points of a curve (with respect to x) is not the same as taking the critical points of a sheared curve. In particular, given a separating form $x + ay$ for a curve, it is possible that the shearing $(x, y) \mapsto (x' = x + ay, y)$ does not shear the curve in a generic position in the sense of Gonzalez-Vega et al. [GVEK96], that is the critical points (with respect to x') of the sheared curve may be vertically aligned.

5.2 From a system to a curve

We prove here Proposition 22, which states that it is essentially equivalent from an asymptotic bit complexity point of view to compute a separating linear form for a system $\{P, Q\}$ and to compute a separating linear form for the critical points of a curve H . According to Definition 19, we refer to the latter as a separating linear form for H . The proof essentially follows that of [BLP+14, Lemma 7] but we improve by a factor d the complexity of computing the curve H .

The critical points of a curve of equation H are the solutions of the system $\{H, \frac{\partial H}{\partial y}\}$, thus computing a separating linear form for a curve amounts, by definition, to computing a separating

linear form for a system of two equations. Conversely, a separating linear form for the curve PQ is also separating for the system $\{P, Q\}$ since any solution of $\{P, Q\}$ is also solution of PQ and of $\frac{\partial PQ}{\partial y} = P \frac{\partial Q}{\partial y} + \frac{\partial P}{\partial y} Q$.

However, it may happen that the curve PQ admits no separating linear form even if $\{P, Q\}$ admits one. Indeed, $\{P, Q\}$ can be zero-dimensional while PQ is not squarefree (and such that the infinitely many critical points cannot be separated by a linear form). Nevertheless, if P and Q are coprime and squarefree, then PQ is squarefree and thus it has finitely many singular points. Still the curve $H = PQ$ may contain vertical lines, and thus infinitely many critical points, but this issue can easily be handled by shearing the coordinate system.

We analyze in the next lemma the complexity of computing a proper shearing of the coordinate system. Then, in the following lemma, we prove that the product of the squarefree parts of the two sheared polynomials does indeed define a curve for which separating linear forms exist and are all separating of the input system. Proposition 22 gather these two results.

Lemma 20. *Given P and Q in $\mathbb{Z}[x, y]$ of maximum degree d and maximum bitsize τ , we can compute a shearing of the coordinate system from (x, y) to $(t = x + \alpha y, y)$ with α an integer in $[0, 2d]$, such that the sheared polynomials \tilde{P} and \tilde{Q} have coefficients of bitsize $\tilde{O}(d + \tau)$ and have their leading coefficients $\text{Lc}_y(\tilde{P})$ and $\text{Lc}_y(\tilde{Q})$ in \mathbb{Z} . This computation can be done with $\tilde{O}_B(d^4 + d^3\tau)$ bit operations in the worst case.*

Proof. We consider a generic shearing of the coordinate system from (x, y) to $(t = x + sy, y)$ in order to find a value $s = \alpha$ so that the sheared curves $\tilde{P}(t, y) = P(t - \alpha y, y)$ and $\tilde{Q}(t, y) = Q(t - \alpha y, y)$ have no vertical asymptote, that is $\text{Lc}_y(\tilde{P})$ and $\text{Lc}_y(\tilde{Q})$ are in \mathbb{Z} .

The leading coefficient of $P(t - sy, y)$ (seen as a polynomial in y) is a polynomial of degree at most d in $\mathbb{Z}[s]$ (t does not appear in the leading term); furthermore an expanded form of $P(t - sy, y)$ can be computed in complexity $\tilde{O}_B(d^4 + d^3\tau)$ and the coefficients have bitsize $\tilde{O}(d + \tau)$ (see e.g. [BLPR15, Lemma 7]). Finding an integer value $s = \alpha$ where the leading coefficient does not vanish can thus be done in d evaluations of complexity $\tilde{O}_B(d(d + \tau))$ each [BLPR15, Lemma 6] and such α can be found in $[0, d]$. Then, computing $P(t - \alpha y, y)$ can be done by evaluating each of the coefficients of $P(t - sy, y)$ at $s = \alpha$, which can again be done with $O(d^2)$ evaluations of complexity $\tilde{O}_B(d(d + \tau))$ each. Thus, we can shear the curve in complexity $\tilde{O}_B(d^4 + d^3\tau)$ so that the leading coefficient of the resulting polynomial $\tilde{P}(t, y) = P(t - \alpha y, y)$ (seen as a polynomial in y) is a constant. These computations can trivially be done for P and Q simultaneously and α in $[0, 2d]$. \square

Lemma 21. *Let P and Q be two coprime polynomials in $\mathbb{Z}[x, y]$ of maximum degree d , maximum bitsize τ , and with $\text{Lc}_y(P)$ and $\text{Lc}_y(Q)$ in \mathbb{Z} . The product, H , of the squarefree parts of P and Q is squarefree, it has degree at most $2d$, bitsize $\tilde{O}(d + \tau)$, with $\text{Lc}_y(H)$ in \mathbb{Z} , and it can be computed using $\tilde{O}_B(d^5 + d^4\tau)$ bit operations in the worst case. System $\{H, \frac{\partial H}{\partial y}\}$ is zero-dimensional and its separating forms are also separating for $\{P, Q\}$.*

Proof. The squarefree parts of P and Q can be computed in $\tilde{O}_B(d^5 + d^4\tau)$ bit complexity (by Lemma 5) and they have bitsizes in $\tilde{O}(d + \tau)$ by Mignotte's lemma (see e.g. [BPR06, Corollary 10.12]). The sum of $O(d^2)$ terms of bitsize $\tilde{O}(d + \tau)$ increases the bitsize bound by $O(\log d^2)$, thus H has coefficients of bitsizes $\tilde{O}(d + \tau)$. Thus, the $O(d^4)$ arithmetic operations for computing all these coefficients can be done in $\tilde{O}_B(d^4(d + \tau))$ bit operations in the worst case.

Every solution of $\{P, Q\}$ is trivially solution of $\{H, \frac{\partial H}{\partial y}\}$, thus any separating linear form for $\{H, \frac{\partial H}{\partial y}\}$ is separating for $\{P, Q\}$. Furthermore, since P and Q are coprime with constant leading terms, H is squarefree with a constant leading term, which implies that H has finitely many critical points, that is $\{H, \frac{\partial H}{\partial y}\}$ is zero-dimensional. \square

Algorithm 3 Number of critical points of H

Input: H in $\mathbb{Z}[x, y]$ squarefree such that $\text{Lc}_y(H)$ is in \mathbb{Z}

Output: The number of critical points of H

1: **return** Algo 1'(H, $(\frac{\partial H}{\partial y})^2$) - Algo 1'(H, $\frac{\partial H}{\partial y}$)

We can summarize the last two lemmas in the following proposition.

Proposition 22. *Let P and Q be two coprime polynomials in $\mathbb{Z}[x, y]$ of maximum degree d and maximum bitsize τ . We can compute a shearing of the coordinate system from (x, y) to $(t = x + \alpha y, y)$, with α an integer in $[0, 2d]$, and a squarefree polynomial H in $\mathbb{Z}[t, y]$ of degree at most $2d$, bitsize $\tilde{O}(d + \tau)$, with $\text{Lc}_y(H)$ in \mathbb{Z} , so that any separating linear form for the zero-dimensional system $\{H, \frac{\partial H}{\partial y}\}$ is also separating for $\{P, Q\}$ after being sheared back. The worst-case complexity of this computation is in $\tilde{O}_B(d^5 + d^4\tau)$.*

5.3 Separating linear form of a curve

In this section, we consider an arbitrary curve defined by H in $\mathbb{Z}[x, y]$ of degree d and bitsize τ , squarefree and with a constant leading coefficient in y . In particular, the polynomial H defined in Proposition 22 satisfies these two last conditions, which yield that the curve has a finite number of critical points. We show in the following three subsections that computing (i) the number of the critical points of H , (ii) a lucky prime for the system of critical points $\{H, \frac{\partial H}{\partial y}\}$ (see Definition 18), and finally (iii) a separating form for the curve H (Definition 19) can be done with a bit complexity in $\tilde{O}_B(d^6 + d^5\tau)$.

5.3.1 Number of critical points

Algorithm 3 computes the number of critical points of a curve H as the difference between the degrees of the triangular decompositions of the systems $\{H, (\frac{\partial H}{\partial y})^2\}$ and $\{H, \frac{\partial H}{\partial y}\}$. This algorithm is identical to the one we presented in [BLP⁺14, Algorithm 4], however, our improvement on the complexity analysis of the triangular decomposition (Proposition 16) immediately improves the complexity of this counting algorithm. The correctness and complexity of Algorithm 3 follows directly from that of [BLP⁺14, Algorithm 4] and from Proposition 16. For the reader's convenience, we explicit this proof here.

Proposition 23. *If H in $\mathbb{Z}[x, y]$ has degree d and bitsize τ , Algorithm 3 computes the number of distinct critical points of H in $\tilde{O}_B(d^6 + d^5\tau)$ bit operations in the worst case and $\tilde{O}_B(d^5 + d^4\tau)$ bit operations on average.*

Proof. The complexity analysis of the algorithm directly follows from Proposition 16 noticing that $\frac{\partial H}{\partial y}$ and $(\frac{\partial H}{\partial y})^2$ have degrees at most $2d$ and bitsizes $O(\tau + \log d)$ (since $\frac{\partial H}{\partial y}$ has bitsize $O(\tau + \log d)$ and that the sum of $O(d^2)$ terms of such bitsizes adds $O(\log d^2)$ to the bitsize bound, and that $(\frac{\partial H}{\partial y})^2$ can be computed from $\frac{\partial H}{\partial y}$ in complexity $\tilde{O}_B(d^2\tau)$ [vzGG03, Cor. 8.28].

We now prove the correctness of the algorithm. Observe that systems $\{H, \frac{\partial H}{\partial y}\}$ and $\{H, (\frac{\partial H}{\partial y})^2\}$ satisfy the input requirements of Algorithm 1' since H is squarefree and $\text{Lc}_y(H)$ is in \mathbb{Z} .

We first prove that for any critical point (α, β) of H , the multiplicity of β in $\text{gcd}(H(\alpha, y), (\frac{\partial H}{\partial y})^2(\alpha, y))$ is greater by one than the multiplicity of β in $\text{gcd}(H(\alpha, y), \frac{\partial H}{\partial y}(\alpha, y))$. Since (α, β) is a critical point of H , it is solution of both the systems $\{H, \frac{\partial H}{\partial y}\}$ and $\{H, (\frac{\partial H}{\partial y})^2\}$.

This implies that β is a root of both $\gcd(H(\alpha, y), \frac{\partial H}{\partial y}(\alpha, y))$ and $\gcd(H(\alpha, y), (\frac{\partial H}{\partial y})^2(\alpha, y))$. If m is the multiplicity of β in $H(\alpha, y)$ then β has multiplicity $m - 1$ in $\frac{\partial H}{\partial y}(\alpha, y)$ and thus, that it has multiplicity $2m - 2$ in $(\frac{\partial H}{\partial y})^2$. It follows that β has multiplicity $m - 1$ in $\gcd(H(\alpha, y), \frac{\partial H}{\partial y}(\alpha, y))$ and m in $\gcd(H(\alpha, y), (\frac{\partial H}{\partial y})^2(\alpha, y))$ because $m \leq 2m - 2$, that is $m - 1 \geq 1$, since β is solution of $\frac{\partial H}{\partial y}(\alpha, y)$.

We denote the multiplicity of β in $\gcd(P(\alpha, y), Q(\alpha, y))$ as $\text{mult}(\beta, \gcd(P(\alpha, y), Q(\alpha, y)))$. Summing over all the critical points of H and noticing that the set V_H of distinct solutions of $\{H, \frac{\partial H}{\partial y}\}$ is the same as that of $\{H, (\frac{\partial H}{\partial y})^2\}$, we obtain that the number of critical points is

$$\#V_H = \sum_{(\alpha, \beta) \in V_H} \text{mult}(\beta, \gcd(H(\alpha, y), (\frac{\partial H}{\partial y})^2(\alpha, y))) - \sum_{(\alpha, \beta) \in V_H} \text{mult}(\beta, \gcd(H(\alpha, y), \frac{\partial H}{\partial y}(\alpha, y))).$$

It remains to prove that this difference is equal to the difference of the degrees of the decompositions of $\{H, (\frac{\partial H}{\partial y})^2\}$ and $\{H, \frac{\partial H}{\partial y}\}$. More generally, we prove that the degree of the triangular decomposition of $\{P, Q\}$ is equal to the sum, over all distinct solutions (α, β) of $\{P, Q\}$, of the multiplicities of β in $\gcd(P(\alpha, y), Q(\alpha, y))$. Indeed, by Lemma 10, the sets of solutions of the systems of the triangular decomposition of Algorithm 1 are disjoint and polynomials A_i are squarefree. The degree of the triangular decomposition of $\{P, Q\}$ is thus

$$\sum_{i \in \mathcal{I}} d_x(A_i(x)) d_y(B_i(x, y)) = \sum_{(\alpha, \beta) \in V} \text{mult}(\beta, B_i(\alpha, y)),$$

where V is the set of solutions of $\{P, Q\}$ and $\text{mult}(\beta, B_i(\alpha, y))$ denotes the multiplicity of β in $B_i(\alpha, y)$. The claim follows since $B_i(\alpha, y) = \gcd(P(\alpha, y), Q(\alpha, y))$ by Lemma 10 and this concludes the proof of correctness of the algorithm. \square

5.3.2 Lucky prime for the system of critical points

Let $\Pi = \text{Algo 2}(H, \frac{\partial H}{\partial y}) \cdot \text{Algo 2}(H, (\frac{\partial H}{\partial y})^2)$ be the product of the luckiness certificates output by Algo 2 for the triangular decompositions of $\{H, \frac{\partial H}{\partial y}\}$ and $\{H, (\frac{\partial H}{\partial y})^2\}$. Lemma 24 shows that we can easily check using a divisibility test on Π whether a prime number is lucky for the system $\{H, \frac{\partial H}{\partial y}\}$ (see Definition 18). Algorithm 4 finds such a lucky prime by an iterative application of this divisibility test. To keep the complexity in the desired bound, the primes to be tested are grouped and a remainder tree is used for the computation of the reduction of Π modulo all the primes in a group. In the following, $L_H(s)$ and $L_{\frac{\partial H}{\partial y}}(s)$ are defined similarly as in Section 5.1.

Lemma 24. *Let μ be a prime such that $\mu > 2d^4$ and $\phi_\mu(L_H(s)) \phi_\mu(L_{\frac{\partial H}{\partial y}}(s)) \neq 0$. If μ does not divide Π then μ is lucky for the system $\{H, \frac{\partial H}{\partial y}\}$.*

Proof. If μ does not divide Π then it is a lucky prime for the triangular decompositions of $\{H, \frac{\partial H}{\partial y}\}$ and $\{H, (\frac{\partial H}{\partial y})^2\}$ (by Lemma 14). By definition of a lucky prime for a triangular decomposition (Definition 13), the degrees of all polynomials in the decomposition are the same over \mathbb{Z} or \mathbb{Z}_μ . Algorithm 3 computes the number of solutions of the system $\{H, \frac{\partial H}{\partial y}\}$ only from these degrees and thus the results are the same over \mathbb{Z} or \mathbb{Z}_μ . Together with the assumptions that $\mu > 2d^4$ and $\phi_\mu(L_H(s)) \phi_\mu(L_{\frac{\partial H}{\partial y}}(s)) \neq 0$, this yields that μ is lucky for the system $\{H, \frac{\partial H}{\partial y}\}$. \square

Algorithm 4 Lucky prime for $\{H, \frac{\partial H}{\partial y}\}$

Input: H in $\mathbb{Z}[x, y]$ of degree d and bitsize τ , squarefree such that $\text{Lc}_y(H)$ is in \mathbb{Z} and $\Pi = \text{Algo } 2(H, \frac{\partial H}{\partial y}) \cdot \text{Algo } 2(H, (\frac{\partial H}{\partial y})^2)$

Output: A lucky prime μ for the system $\{H, \frac{\partial H}{\partial y}\}$

- 1: Compute $L_H(s)$ and $L_{\frac{\partial H}{\partial y}}(s)$ (defined as in Section 5.1)
 - 2: $m = 2d^4$
 - 3: **while** true **do**
 - 4: Compute the set B of the first $d^4 + d^3\tau$ primes $> m$
 - 5: **for all** μ in B **do**
 - 6: Compute the reduction mod. μ of $\Pi, L_H, L_{\frac{\partial H}{\partial y}}$
 - 7: **if** $\phi_\mu(\Pi) \phi_\mu(L_H(s)) \phi_\mu(L_{\frac{\partial H}{\partial y}}(s)) \neq 0$ **then**
 - 8: **return** μ
 - 9: $m =$ the largest prime in B
-

Proposition 25. *Given H in $\mathbb{Z}[x, y]$ of degree d and bitsize τ , Algorithm 4 computes a lucky prime of bitsize $O(\log d\tau)$ for the system $\{H, \frac{\partial H}{\partial y}\}$ using $\tilde{O}_B(d^4 + d^3\tau)$ bit operations.*

Proof. The correctness of Algorithm 4 follows directly from Lemma 24 since the condition in Line 7 (together with $\mu > 2d^4$) matches exactly the assumptions of Lemma 24.

We now analyze the complexity of this algorithm. It is straightforward that, in Line 1, $L_H(s)$ and $L_{\frac{\partial H}{\partial y}}(s)$ can be computed with $\tilde{O}_B(d^4 + d^3\tau)$ bit operations and that they have coefficients of bitsizes $\tilde{O}(d + \tau)$ (see e.g. [BLPR15, Lemma 7]). Furthermore, since Π has bitsize $\tilde{O}(d^4 + d^3\tau)$ (by Proposition 16), the number of prime divisors of $\Pi, L_H(s)$, and $L_{\frac{\partial H}{\partial y}}(s)$ is in $\tilde{O}(d^4 + d^3\tau)$. Hence, the number of iterations of the loop in Line 3 is polylogarithmic in d and τ .

Each iteration of this loop consists in testing, for the $d^4 + d^3\tau$ primes in B , the non-vanishing of the reduction of the integer Π and of the two polynomials $L_H(s), L_{\frac{\partial H}{\partial y}}(s)$. The product of Π and of all these coefficients has bitsize $\tilde{O}(d^4 + d^3\tau)$ and it can be computed in bit complexity $\tilde{O}_B(d^4 + d^3\tau)$. The reduction of this product modulo all the primes in B can be computed via a remainder tree in a bit complexity that is soft linear in the total bitsize of the input [MB74, Theorem 1], which is in $\tilde{O}(d^4 + d^3\tau)$ because the sum of the bitsizes of the $d^4 + d^3\tau$ primes in B is also in $\tilde{O}(d^4 + d^3\tau)$ since each of these primes has bitsize $O(\text{polylog}(d\tau))$ (since there are $O(\text{polylog}(d\tau))$ iterations of the loop in Line 3). Hence, the bit complexity of one iteration of the loop of Line 3 is $\tilde{O}_B(d^4 + d^3\tau)$ and since at most $O(\text{polylog}(d\tau))$ iterations are performed, the overall bit complexity of Algorithm 4 is in $\tilde{O}_B(d^4 + d^3\tau)$.

Finally, the bitsize of every considered prime is in $O(\log(d^4 + d^3\tau))$. Indeed, the number of loop iterations is in $O(\text{polylog}(d\tau))$, thus the algorithm considers the first $O((d^4 + d^3\tau)\text{polylog}(d\tau))$ first primes. The largest considered prime is thus in $\tilde{O}(d^4 + d^3\tau)$ [vzGG03, Theorem 18.10] and its bitsize is thus in $O(\log d\tau)$. \square

5.3.3 Separating linear form of a curve

In this section, we assume that we have already computed, using Algorithms 3 and 4, the number of distinct (complex) critical points of a curve and a lucky prime μ for the system of critical points. With this information, Algorithm 4 of [BLPR15] computes a separating form with a bit complexity $\tilde{O}_B(d^8 + d^7\tau)$. In this section, we slightly modify this algorithm to improve its complexity to

Algorithm 5 Separating form of a curve

Input: H in $\mathbb{Z}[x, y]$ of degree d and bitsize τ , squarefree and such that $\text{Lc}_y(H)$ is in \mathbb{Z}

Output: A separating linear form $x + ay$ of the curve H , with $a < 2d^4$

- 1: Compute $N = \text{Algorithm 3}(H)$, the number of distinct (complex) critical points of H
 - 2: Compute $\Pi = \text{Algo 2}(H, \frac{\partial H}{\partial y}) \cdot \text{Algo 2}(H, (\frac{\partial H}{\partial y})^2)$, the product of the luckiness certificates output by Algo 2 for the triangular decompositions of $\{H, \frac{\partial H}{\partial y}\}$ and $\{H, (\frac{\partial H}{\partial y})^2\}$
 - 3: Compute $\mu = \text{Algorithm 4}(H, \Pi)$, a lucky prime for $\{H, \frac{\partial H}{\partial y}\}$
 - 4: Compute $H(t - sy, y)$ and $\frac{\partial H}{\partial y}(t - sy, y)$
 - 5: Compute $\Upsilon_\mu(s)$ the reduction modulo μ of $L_H(s) \cdot L_{\frac{\partial H}{\partial y}}(s)$
 - 6: Compute the resultant $R_\mu(t, s)$ of the reductions modulo μ of $H(t - sy, y)$ and $\frac{\partial H}{\partial y}(t - sy, y)$
 - 7: Compute $R_\mu(t, a)$ for all a in $\{0, \dots, 2d^4\}$ using multipoint evaluation
 - 8: $a := 0$
 - 9: **repeat**
 - 10: Compute the degree N_a of the squarefree part of $R_\mu(t, a)$
 - 11: $a := a + 1$
 - 12: **until** $\Upsilon_\mu(a) \neq 0^6$ and $N_a = N$
 - 13: **return** The linear form $x + ay$
-

$\tilde{O}_B(d^6 + d^5\tau)$.

More precisely, Algorithm 4 of [BLPR15] computes a separating linear form for a system $\{P, Q\}$ by considering iteratively linear forms $x + ay$, where a is an integer incrementing from 0 and by computing the degree of the squarefree part of the reduction modulo μ of $R(t, a)$ until this degree is equal to the (known) number of distinct solutions of the system and such that $\phi_\mu(L_P(a)) \phi_\mu(L_Q(a)) \neq 0$. Doing so, the algorithm computes a separating form for the system modulo μ , which, under the hypothesis of the luckiness of μ , is proven to be also separating for the system $\{P, Q\}$ [BLPR15, Proposition 9].

Specialized to the system of critical points, Algorithm 5 follows the same approach except for the way the reductions modulo μ of the $R(t, a)$ are computed.

Proposition 26. *Given H in $\mathbb{Z}[x, y]$ of degree d and bitsize τ , Algorithm 5 computes, with a worst-case bit complexity $\tilde{O}_B(d^6 + d^5\tau)$, an integer a in $[0, 2d^4 - 2d]$ such that the linear form $x + ay$ is separating for the the system $\{H, \frac{\partial H}{\partial y}\}$ of critical points of the curve $H = 0$.*

Proof. We first prove the correctness of Algorithm 5 which essentially follows from [BLPR15, Algorithm 4]. The only relevant difference for the correctness is the way to compute $R_\mu(t, s)$. In [BLPR15], $R_\mu(t, s)$ is computed by computing the resultant $R(t, s)$ of $H(t - sy, y)$ and $\frac{\partial H}{\partial y}(t - sy, y)$, and reducing it modulo μ . Here, we first reduce the polynomials modulo μ before computing the resultant. This yields the same result since μ is known to be lucky for the system $\{H, \frac{\partial H}{\partial y}\}$, thus it does not divide the leading terms $L_H(s)$ and $L_{\frac{\partial H}{\partial y}}(s)$. This proves the correctness of Algorithm 5. Note, furthermore, that the correctness of [BLPR15, Algorithm 4] also implies that the value a output by our algorithm is less than $2d^4 - 2d$.⁷

We now prove the complexity of our algorithm. First, observe that, as argued in the proof of Proposition 23, $\frac{\partial H}{\partial y}$ and $(\frac{\partial H}{\partial y})^2$ have degrees at most $2d$, bitsizes $O(\tau + \log d)$, and that they can

⁶ $\Upsilon_\mu(s) \in \mathbb{Z}_\mu[s]$ and we consider $\Upsilon_\mu(a)$ in \mathbb{Z}_μ .

⁷[BLPR15, Theorem 19] is stated with $a < 2d^4$ but its proof establishes $a \leq \binom{d^2}{2} + 2(d^2 + d)$ which is less than $2d^4 - 2d$ for $d > 1$. This refined bound will be convenient for yielding the simple bound of $2d^4$ when shearing back the separating form in Theorem 28.

be computed in complexity $\tilde{O}_B(d^2\tau)$. Furthermore, in Lines 1–3, the input of Algorithms 2, 3, and 4 satisfy the requirements of these algorithms, since H is squarefree with $\text{Lc}_y(H)$ in \mathbb{Z} . The bit complexity of Lines 1–3 is thus in $\tilde{O}_B(d^6 + d^5\tau)$ by Propositions 16, 23, 25.

It is straightforward that, in Line 4, the sheared polynomials $H(t - sy, y)$ and $\frac{\partial H}{\partial y}(t - sy, y)$ can be computed in bit complexity $\tilde{O}_B(d^4 + d^3\tau)$ and that their bitsizes are in $\tilde{O}(d + \tau)$ (see e.g. [BLPR15, Lemma 7]). In Lines 5 and 6, the polynomials to be reduced modulo μ , in one or three variables, have degree at most d and bitsize $\tilde{O}(d + \tau)$. The reduction of each of their $O(d^3)$ coefficients modulo μ can be done in a bit complexity that is softly linear in the maximum bitsizes [vzGG03, Theorem 9.8], that is in a total bit complexity of $\tilde{O}_B(d^4 + d^3\tau)$. Then, computing in Line 5 the product of $\phi_\mu(L_H(s))$ and $\phi_\mu(L_{\frac{\partial H}{\partial y}(t-sy,y)}(s))$ amounts to computing $O(d^2)$ arithmetic operations in \mathbb{Z}_μ .

The resultant in Line 6 can be computed in $O(d^5)$ arithmetic operations in \mathbb{Z}_μ (see Lemma 3). In Line 7, $R_\mu(t, s)$ is a polynomial of degree $O(d^2)$ in t with coefficients in s of degree $O(d^2)$. The arithmetic complexity, in \mathbb{Z}_μ , of the evaluation of one such coefficient at $s = a$ is linear in its degree (using for instance Horner’s scheme) but, using multipoint evaluation, the arithmetic complexity of the evaluation of one such coefficient at $O(d^2)$ values is in $\tilde{O}(d^2)$ [vzGG03, Theorem 10.5]. It follows that the evaluation of all the $O(d^2)$ coefficients of $R_\mu(t, s)$ at d^2 values of a can be done with $\tilde{O}(d^4)$ arithmetic operations in \mathbb{Z}_μ . The overall arithmetic complexity of Line 7 is thus $\tilde{O}(d^6)$. In Line 10, since $R_\mu(t, a)$ has degree $O(d^2)$, its squarefree part can be computed with $\tilde{O}(d^2)$ arithmetic operations in \mathbb{Z}_μ (see Lemma 4) and, in Line 12, each evaluation of $\Upsilon(a)$ can be done in $O(d)$ arithmetic operations since Υ has degree $O(d)$. Furthermore, since the algorithm stops with $a < 2d^4$, the arithmetic complexity of the whole loop is in $\tilde{O}(d^6)$.

We have shown that Lines 6 to 12 perform $\tilde{O}(d^6)$ arithmetic operations in \mathbb{Z}_μ . Since μ has bitsize $O(\log d\tau)$, the bit complexity of these lines is in $O_B(d^6 \text{polylog}(d\tau))$, which concludes the proof. \square

Remark 27. *From a worst-case complexity point of view, the knowledge of the number N of (distinct) complex critical points of the input curve in Algorithm 5 is not mandatory since one could instead compute the number of solutions N_a of $R_\mu(t, a)$ for all integers a smaller than $2d^4$ and output a value of a that maximizes N_a . However, knowing N , the algorithm can stop as soon as a value of a is found such that $N_a = N$, which improves the expected complexity of the algorithm in a Las-Vegas setting, as discussed in Section 5.5.*

5.4 Separating linear form of a system

Propositions 22 and 26 directly yield the following theorem where the separating form is obtained by shearing back the separating form output by Algorithm 5.

Theorem 28. *Let P, Q in $\mathbb{Z}[x, y]$ be of total degree at most d and maximum bitsize τ . A separating linear form $x + by$ for $\{P, Q\}$ with an integer b in $[0, 2d^4]$ can be computed using $\tilde{O}_B(d^6 + d^5\tau)$ bit operations in the worst case. Furthermore, b is such that the leading coefficients of $P(t - by, y)$ and $Q(t - by, y)$ in y are in \mathbb{Z} .*

Proof. The first statement of the theorem follows directly from Propositions 22 and 26 where the integer b is the sum of the integers α and a defined in these propositions. We prove below the second statement. The integer a computed by Algorithm 5 is such that $\Upsilon(a) \neq 0$ and thus $L_H(a) \neq 0$. Since $L_H(a) \in \mathbb{Z}$ is non-zero, it is the leading coefficient in y of the sheared polynomial $H(t - ay, y)$. H is the product of the squarefree parts of the sheared polynomials \tilde{P} and \tilde{Q} where

Algorithm 5' Separating form of a curve – Las-Vegas version

Input: H in $\mathbb{Z}[x, y]$ of degree d and bitsize τ , squarefree and such that $\text{Lc}_y(H)$ is in \mathbb{Z}

Output: A separating linear form $x + ay$ of the curve H , with $a < 2d^4$

- 1: Compute $N = \text{Algorithm 3}(H)$, the number of distinct (complex) critical points of H
 - 2: Compute $H(t - sy, y)$, $\frac{\partial H}{\partial y}(t - sy, y)$, and $\Upsilon(s) = L_H(s) \cdot L_{\frac{\partial H}{\partial y}}(s)$
 - 3: $M := 2d^4$
 - 4: **repeat**
 - 5: $M := 2M$
 - 6: Choose uniformly at random an integer a in $[0, 2d^4 - 2d]$ and a prime μ in $(2d^4, M)$
 - 7: Compute $\Upsilon_\mu(a) = \phi_\mu(\Upsilon)(a)$
 - 8: Compute $\phi_\mu(H(t - ay, y))$, $\phi_\mu(\frac{\partial H}{\partial y}(t - ay, y))$ and their resultant $R_{\mu,a}(t)$ with respect to y
 - 9: Compute the degree⁸ N_a of the squarefree part of $R_{\mu,a}(t)$
 - 10: **until** $\Upsilon_\mu(a) \neq 0$ ⁶ and $N_a = N$
 - 11: **return** The linear form $x + ay$
-

$\tilde{P}(t, y) = P(t - \alpha y, y)$ and similarly for \tilde{Q} (see Lemmas 20 and 21). Hence, the leading coefficient in y of the sheared polynomial $\tilde{P}(t - ay, y) = P(t - ay - \alpha y, y) = P(t - by, y)$ divides $L_H(a)$, which is an integer. Similarly for \tilde{Q} . \square

5.5 Las-Vegas algorithm

We show here that the algorithm presented above for computing a separating linear form can easily be transformed into an efficient Las-Vegas algorithm.

Theorem 29. *Let P, Q in $\mathbb{Z}[x, y]$ be of total degree at most d and maximum bitsize τ . A separating linear form $x + by$ for $\{P, Q\}$ with an integer b in $[0, 2d^4]$ can be computed with $\tilde{O}_B(d^5 + d^4\tau)$ bit operations on average. Furthermore, b is such that the leading coefficients of $P(t - by, y)$ and $Q(t - by, y)$ in y are in \mathbb{Z} .*

Our Las-Vegas algorithm is obtained from our deterministic version by only modifying Algorithm 5 into a randomized version, Algorithm 5'. The main difference between these two versions is that, in Algorithm 5', we choose randomly a candidate separating linear form $x + ay$ and a candidate lucky prime μ for $\{H, \frac{\partial H}{\partial y}\}$ (Definition 18) until the degree N_a of the squarefree part of $R_\mu(t, a)$ is equal to the known number of solutions N . If a and μ are chosen randomly in sufficiently large sets, the probability that $x + ay$ is separating and that μ is lucky is larger than a positive constant, which implies that the expected number of such choices is a constant.

This modification yields a major simplification: since we do not compute anymore a lucky prime in a deterministic way, we do not need Algorithm 4 (Lucky prime), which again implies that Algorithm 2 (Luckiness certificate) is not needed. Furthermore, note that, in Algorithm 5', we do not need anymore to use multipoint evaluation for evaluating $R_\mu(t, s)$ at a since the expected number of choices of a is a constant. Note finally that we choose the candidate lucky prime μ in increasingly larger sets. The reason is that, if we wanted to compute a unique set for which a random prime would be lucky with probability at least some constant, we would need an explicit

⁸We use the convention that the degree of the zero polynomial is $+\infty$ because we want N_a to be the number of distinct roots of $R_{\mu,a}(t)$. Note that in Algorithm 5, this issue was not relevant because μ was known to be lucky for the zero-dimensional system $\{H, \frac{\partial H}{\partial y}\}$, implying by Definition 18 that the system $\{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}$ was zero dimensional and thus that $R_\mu(t, a) \neq 0$.

upper bound (without \tilde{O} notation) on the number of unlucky primes and such a computation is highly unappealing.

We now prove the correctness and complexity of Algorithm 5' in the two following lemmas and in Proposition 33, which, together with Proposition 22, yield Theorem 29 similarly as for Theorem 28.

Lemma 30 (Correctness of Algorithm 5'). *Algorithm 5' terminates if and only if the values of the random variables a and μ are such that $\Upsilon_\mu(a) \neq 0$, μ is lucky for $\{H, \frac{\partial H}{\partial y}\}$ and $x + ay$ is separating for $\{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}$, which implies that $x + ay$ is also separating for $\{H, \frac{\partial H}{\partial y}\}$.*

Proof. The proof relies on Lemma 10 and Propositions 9 and 12 in [BLPR15] which, together, require the hypotheses that $\Upsilon_\mu(a) \neq 0$, $a < \mu$, $2d^4 < \mu$, and $\{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}$ is zero dimensional. We first prove that these hypotheses are satisfied when either side of the if-and-only-if claim holds in the statement of the lemma.

First, $\Upsilon_\mu(a) \neq 0$ follows from Line 10 if Algorithm 5' terminates and it appears in the right hand side of the if-and-only-if claim. Second, $a \leq 2d^4 < \mu$ by definition of a and μ (Line 6). Finally, if Algorithm 5' terminates, $\{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}$ is zero dimensional because, otherwise, $R_{\mu,a}(t) \equiv 0$, thus $N_a = +\infty$ cannot be equal to N in Line 10 (since $\{H, \frac{\partial H}{\partial y}\}$ is zero dimensional). On the other hand, if μ is lucky for $\{H, \frac{\partial H}{\partial y}\}$ then $\{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}$ is zero dimensional since it has the same number of solution as $\{H, \frac{\partial H}{\partial y}\}$.

We can now apply Lemma 10 and Proposition 12 in [BLPR15], which state

$$d_t(\text{squarefree part}(R_\mu(t, a))) \leq \#V(I_\mu) \leq \#V(I)$$

where $R_\mu(t, s)$ refers to the resultant with respect to y of $\phi_\mu(H)(t - sy, y)$ and $\phi_\mu(\frac{\partial H}{\partial y})(t - sy, y)$, and $\#V(I)$ and $\#V(I_\mu)$ are the number of distinct solutions of the systems $\{H, \frac{\partial H}{\partial y}\}$ and $\{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}$, respectively.

Assume for now that $R_\mu(t, a) = R_{\mu,a}(t)$ (as defined in Line 8). This implies that $d_t(\text{squarefree part}(R_\mu(t, a))) = N_a$ (Line 9). Since $N = \#V(I)$ by definition (Line 1), the algorithm terminates if and only if a and μ are such that $\Upsilon_\mu(a) \neq 0$ and $N_a = N$ (Line 10), which is equivalent to $\Upsilon_\mu(a) \neq 0$ and

$$d_t(\text{squarefree part}(R_\mu(t, a))) = \#V(I_\mu) = \#V(I).$$

The first equality holds if and only if $x + ay$ is separating for $\{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}$ [BLPR15, Lemma 10] and the second equality holds if and only if μ is lucky for the system $\{H, \frac{\partial H}{\partial y}\}$ (Definition 18). This proves the if-and-only-if claim of the lemma (assuming that $R_\mu(t, a) = R_{\mu,a}(t)$). Furthermore, when both equalities hold, $x + ay$ is also separating for the system $\{H, \frac{\partial H}{\partial y}\}$ by Proposition 9 in [BLPR15].

It remains to show that $R_\mu(t, a) = R_{\mu,a}(t)$, that is that the resultant commutes with the evaluation at $s = a$ in the following way:

$$\text{Res}(\phi_\mu(H)(t - sy, y), \phi_\mu(\frac{\partial H}{\partial y})(t - sy, y))|_{s=a} = \text{Res}(\phi_\mu(H)(t - ay, y), \phi_\mu(\frac{\partial H}{\partial y})(t - ay, y)).$$

This equality holds if the polynomials in the left-hand side resultant are such that their leading coefficients (in y) $L_{\phi_\mu(H)}(s)$ and $L_{\phi_\mu(\frac{\partial H}{\partial y})}(s)$ do not vanish at $s = a$. This follows from the hypothesis that $\Upsilon_\mu(a) \neq 0$. Indeed, $\Upsilon_\mu(a) \neq 0$ implies $\phi_\mu(L_H(a)) \neq 0$. Then, $\phi_\mu(L_H(s)) \neq 0$ implies $\phi_\mu(L_H(s)) = L_{\phi_\mu(H)}(s)$ and thus $L_{\phi_\mu(H)}(a) \neq 0$. Similarly for $\frac{\partial H}{\partial y}$, $L_{\phi_\mu(\frac{\partial H}{\partial y})}(a) \neq 0$, which concludes the proof. \square

Lemma 31. *The expected number of iterations of the loop in Algorithm 5' is in $O(\log d\tau)$. More precisely, after $O(\log d\tau)$ iterations, the probability that the algorithm terminates is at least $1/8$ at every iteration.*

Proof. The number of unlucky primes for $\{H, \frac{\partial H}{\partial y}\}$ is in $\tilde{O}(d^4 + d^3\tau)$ [BLPR15, Proposition 13]. Let $K(d, \tau)$ in $\tilde{O}(d^4 + d^3\tau)$ be an upper bound on the number of unlucky primes, which we denote for simplicity by K . If the algorithm terminates with a value of M such that $\frac{M/2}{2 \ln M/2} \leq 2K$, the number of loop iterations is in $O(\log d\tau)$. Indeed, the number of iterations is less than $\log M$ which is in $O(\log K)$ since $\sqrt{M/2} < \frac{M/2}{\ln M/2} \leq 4K$. It is thus sufficient to prove that, for any iteration such that $\frac{M/2}{2 \ln M/2} > 2K$, the probability that $\Upsilon_\mu(a) \neq 0$ and $N_a = N$ (Line 10) is at least $1/8$. Note that this implies that the expected number of such iterations is at most 8 and thus that the expected number of all iterations in the loop is in $O(\log d\tau)$.

We can thus assume that, in Line 6, μ is chosen uniformly at random in a set of primes of cardinality at least $2K$. Indeed, μ is chosen in $(2d^4, M) \supseteq (M/2, M)$ and the number of primes in $(M/2, M)$ is at least $\frac{M/2}{2 \ln M/2}$ [vzGG03, Theorem 18.7 (see also Exercise 18.18)].

By Lemma 30, the algorithm terminates if and only if a and μ are such that $\Upsilon_\mu(a) \neq 0$, μ is lucky for $\{H, \frac{\partial H}{\partial y}\}$ (Definition 18) and $x + ay$ is separating for $\{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}$. Let P denote the probability that these three events simultaneously occur. We have

$$\begin{aligned} P &= \Pr(\mu \text{ is lucky for } \{H, \frac{\partial H}{\partial y}\} \text{ and } x + ay \text{ is separating for } \{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}) \\ &\quad \cdot \Pr(\Upsilon_\mu(a) \neq 0 \mid \mu \text{ is lucky for } \{H, \frac{\partial H}{\partial y}\} \text{ and } x + ay \text{ is separating for } \{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}) \\ &= \Pr(\mu \text{ is lucky for } \{H, \frac{\partial H}{\partial y}\}) \\ &\quad \cdot \Pr(x + ay \text{ is separating for } \{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\} \mid \mu \text{ is lucky for } \{H, \frac{\partial H}{\partial y}\}) \\ &\quad \cdot \Pr(\Upsilon_\mu(a) \neq 0 \mid \mu \text{ is lucky for } \{H, \frac{\partial H}{\partial y}\} \text{ and } x + ay \text{ is separating for } \{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}). \end{aligned}$$

The probability that μ is lucky for $\{H, \frac{\partial H}{\partial y}\}$ is at least $1/2$ since, as argued above, μ is chosen uniformly at random in a set of primes of cardinality at least $2K$ and there are at most K unlucky primes.

The conditional probability that $x + ay$ is separating for $\{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}$ is also at least $1/2$. Indeed, we prove that the conditional probability that $x + ay$ is *not* separating for that system is at most $1/2$. For any choice of a lucky μ , $\{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}$ is zero dimensional since it has the same number of distinct solutions as $\{H, \frac{\partial H}{\partial y}\}$, number which is at most d^2 solutions by Bézout's bound. Thus, for any choice of a lucky μ , there are at most $\binom{d^2}{2} < d^4 - d$ directions in which two distinct solutions of $\{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}$ are aligned, that is, at most $d^4 - d$ values of a for which $x + ay$ is not separating for that system. Since a is chosen uniformly at random in a set of cardinality $2d^4 - 2d + 1$, the conditional probability that $x + ay$ is not separating for $\{\phi_\mu(H), \phi_\mu(\frac{\partial H}{\partial y})\}$ is thus at most $d^4 - d$ times the number of choices of a lucky μ over the number of choices of couples of a and a lucky μ . In other words, it is at most $d^4 - d$ over $2d^4 - 2d + 1$, which is less than $1/2$, and thus proves the claim.

Finally, we show that the conditional probability that $\Upsilon_\mu(a) \neq 0$ is also at least $1/2$. Given that μ is lucky, $\Upsilon_\mu(s) \not\equiv 0$, by Definition 18. Thus, for any given lucky μ , $\Upsilon_\mu(s)$ has degree at most $2d$ and it vanishes for at most $2d$ values of a . The conditional probability that $\Upsilon_\mu(a) = 0$ is thus at most $2d$ times the number of choices of a lucky μ over the number of choices of couples of a lucky μ and a value a such that $x + ay$ is separating. This probability is thus equal to $2d$ over the number of choices of such values a . The number of such choices for a is at least d^4 since a is considered in

$[0, 2d^4 - 2d]$ and there are at most $\binom{d^2}{2} < d^4 - 2d$ choices for which $x + ay$ is not separating. Hence the conditional probability that $\Upsilon_\mu(a) = 0$ is at most $2d/d^4$, which is less than $1/2$ for $d \geq 2$. This proves the claim that the conditional probability that $\Upsilon_\mu(a) \neq 0$ is at least $1/2$ and concludes the proof. \square

The next lemma factorizes a technical part of the expected complexity analysis of Propositions 33 and 50.

Lemma 32. *If a while-loop is such that (i) the expected bit complexity of the i -th iteration is $\tilde{O}_B(Ai^k)$ where A is a polynomial in the input parameter sizes and (ii) the probability that the loop ends at the i -th iteration, given that it has not stopped before, is at least a constant $c > 0$, then the expected bit complexity of the entire loop is $\tilde{O}_B(A)$.*

Proof. Let $x_j > c$ be the probability that the loop stops at the j -th iteration given that it has not yet stopped before. The probability that the loop stops at the i -th iteration is $x_i \prod_{j=1}^{i-1} (1 - x_j) \leq (1 - c)^{i-1}$. On the other hand, the total expected bit complexity of all the iterations until the i -th is $\tilde{O}_B(Ai^{k+1})$. Hence the total expected bit complexity of the entire loop is

$$\sum_{i=1}^{\infty} \tilde{O}_B(Ai^{k+1}(1 - c)^{i-1}) = \tilde{O}_B(A) \sum_{i=1}^{\infty} i^{k+1}(1 - c)^{i-1}.$$

The series $\sum_{i=0}^{\infty} W(i)\lambda^i$ is convergent for any polynomial W and $0 < \lambda < 1$. Indeed, $|W(i)| < \delta^i$ for any $1 < \delta < \frac{1}{\lambda}$ and i sufficiently large, which implies $|W(i)\lambda^i| < (\delta\lambda)^i$ with $0 < \delta\lambda < 1$. Therefore, the expected bit complexity of the entire loop is in $\tilde{O}_B(A)$. \square

Proposition 33. *Given H in $\mathbb{Z}[x, y]$ of degree d and bitsize τ , Algorithm 5' computes, with an expected bit complexity $\tilde{O}_B(d^5 + d^4\tau)$, an integer a in $[0, 2d^4 - 2d]$ such that the linear form $x + ay$ is separating for the critical points of H .*

Proof. By Proposition 23, Line 1 has expected complexity $\tilde{O}_B(d^5 + d^4\tau)$. In Line 2, similarly as in Line 4 of Algorithm 5, $H(t - sy, y)$ and $\frac{\partial H}{\partial y}(t - sy, y)$ have coefficients of bitsize $\tilde{O}(d + \tau)$ and they can be computed with $\tilde{O}_B(d^4 + d^3\tau)$ bit operations (see the proof of Proposition 26). Still in Line 2, $\Upsilon(s)$ can be computed with $O(d^2)$ arithmetic operations on integers of bitsize $O(\tau + \log d)$, and thus with $\tilde{O}_B(d^2\tau)$ bit operations. The worst-case bit complexity of Lines 1 and 2 is thus in $\tilde{O}_B(d^5 + d^4\tau)$.

Consider now one iteration of the loop in Algorithm 5' and let I_M denote the interval $(2d^4, M)$. In Line 6, we can compute a prime μ by choosing uniformly at random an integer in I_M and testing whether it is prime until a prime is found. Finding a random integer smaller than M amounts to computing a sequence of $\log M$ random bits, which we assume can be done in $O_B(\log M)$ bit operations. A random integer smaller than M is larger than $2d^4$ with probability at least $1/2$, thus a random integer in I_M can be computed in $O_B(\log M)$ bit operations. The number of primes in $(M/2, M) \subseteq I_M$ is at least $\frac{M/2}{2 \ln M/2}$ [vzGG03, Theorem 18.7 (see also Exercise 18.18)]. The probability that a randomly chosen integer in I_M is prime is thus at least $\frac{1}{4 \ln M/2}$ and a prime is thus found after at most $4 \ln M/2$ trials on average. Testing whether an integer in I_M is prime can be done with a polynomial bit complexity in the bitsize of M , $\tilde{O}_B(\log^{7.5} M)$ [AKS04]. The expected bit complexity of computing a prime in Line 6 is thus in $\tilde{O}_B(\log^{8.5} M)$. Furthermore, since a random integer a in $[0, 2d^4]$ can be computed in $\tilde{O}_B(\log d)$ bit operations, the expected bit complexity of one iteration of Line 6 is in $\tilde{O}_B(\log^{8.5} M)$.

In Line 7, $O(d)$ coefficients of bitsize $O(\tau + \log d)$ are reduced modulo μ . Each reduction can be done in a bit complexity that is softly linear in the maximum bitsizes [vzGG03, Theorem 9.8], that is in a total bit complexity of $\tilde{O}_B(d(\tau + \log d + \log M))$. Evaluating $\Upsilon(s)$ at a can then be done with $O(d)$ arithmetic operations in \mathbb{Z}_μ and thus with $\tilde{O}_B(d \log M)$ bit operations. The total bit complexity of one iteration of Line 7 is thus in $\tilde{O}_B(d(\tau + \log M))$.

In Line 8, first notice that $\phi_\mu(H(t-ay, y)) = \phi_\mu(H(t-sy, y))|_{s=a}$. Similarly as above, the $O(d^3)$ coefficients of $H(t-sy, y)$ of bitsize $\tilde{O}(d + \tau)$ can be reduced modulo μ with $\tilde{O}_B(d^3(d + \tau + \log M))$ bit operations in total. The evaluation at $s = a$ in \mathbb{Z}_μ then amounts to evaluating $O(d^2)$ univariate polynomials in s of degree $O(d)$. Similarly as above, this can be done with $O(d^3)$ arithmetic operations in \mathbb{Z}_μ and thus with $\tilde{O}_B(d^3 \log M)$ bit operations. Thus, $\phi_\mu(H(t-ay, y))$ and similarly $\phi_\mu(\frac{\partial H}{\partial y}(t-ay, y))$ can be computed with $\tilde{O}_B(d^3(d + \tau + \log M))$ bit operations in the worst case. By Lemma 4, their resultant $R_{\mu,a}(t)$ has degree $O(d^2)$, and it can be computed with $\tilde{O}(d^3)$ arithmetic operations in \mathbb{Z}_μ and thus with $\tilde{O}_B(d^3 \log M)$ bit operations. The bit complexity of one iteration of Line 8 is thus in $\tilde{O}_B(d^3(d + \tau + \log M))$ in the worst-case.

In Line 9, the squarefree part of $R_{\mu,a}(t)$, and thus its degree, can be computed with $\tilde{O}(d^2)$ arithmetic operations in \mathbb{Z}_μ (by Lemma 4) and thus with $\tilde{O}_B(d^2 \log M)$ bit operations in the worst case.

Hence, the expected bit complexity of one iteration of the loop is in $\tilde{O}_B(d^3(d + \tau + \log M) + \log^{8.5} M)$, which is also in $\tilde{O}_B(d^3(d + \tau + \log^9 M))$. More precisely, at the end of the j -th iteration of the loop, $M = 2^{j+1}d^4$, thus the expected bit complexity of the j -th iteration of the loop is in $\tilde{O}_B(d^4 + d^3\tau + d^3j^9)$. The expected bit complexity of the entire loop is thus $\tilde{O}_B(d^4 + d^3\tau)$, by Lemmas 31 and 32. Summing up with the complexity of Lines 1 and 2, we obtain that the expected bit complexity of the algorithm is in $\tilde{O}_B(d^5 + d^4\tau)$. \square

6 RUR decomposition

In this section, we consider that a separating form for the bivariate system $\{P, Q\}$ as been computed as shown in Section 5 and we focus on the computation of Rational Univariate Representations of the solutions. We present a new algorithm of worst-case bit complexity $\tilde{O}_B(d^6 + d^5\tau)$ for computing a RUR decomposition of $\{P, Q\}$, that is a sequence of RURs that encodes the solutions of $\{P, Q\}$ (see Definition 36 and Theorem 45). This algorithm is multi-modular and it relies on both the triangular decomposition and the luckiness certificate of Section 4. We also present a Las-Vegas version of this algorithm, of expected bit complexity $\tilde{O}_B(d^5 + d^4\tau)$ (Theorem 46), which only computes some coefficients of the above triangular decomposition and avoids computing the luckiness certificate.

In Section 6.1, we first recall the definitions and main properties of RURs. We present our deterministic algorithm and its complexity analysis in Section 6.2 and its Las-Vegas version in Section 6.3.

6.1 RUR definition and properties

Definition 34 ([Rou99, Definition 3.3]). *Let $I \subset \mathbb{Q}[x, y]$ be a zero-dimensional ideal, $V(I) = \{\sigma \in \mathbb{C}^2, v(\sigma) = 0, \forall v \in I\}$ its associated variety, and let $(x, y) \mapsto x + ay$ be a linear form with a in \mathbb{Q} . The RUR-candidate of I associated to $x + ay$ (or simply, to a), denoted $\text{RUR}_{I,a}$, is the following*

set of four univariate polynomials in $\mathbb{C}[t]$

$$\begin{aligned} f_{I,a}(t) &= \prod_{\sigma \in V(I)} (t - x(\sigma) - ay(\sigma))^{\mu_I(\sigma)} \\ f_{I,a,v}(t) &= \sum_{\sigma \in V(I)} \mu_I(\sigma)v(\sigma) \prod_{\varsigma \in V(I), \varsigma \neq \sigma} (t - x(\varsigma) - ay(\varsigma)), \quad \text{for } v \in \{1, x, y\} \end{aligned} \quad (2)$$

where, for σ in $V(I)$, $\mu_I(\sigma)$ denotes the multiplicity of σ in I . If $(x, y) \mapsto x + ay$ is injective on $V(I)$, we say that the linear form $x + ay$ separates $V(I)$ (or is separating for I) and $\text{RUR}_{I,a}$ is called a RUR (the RUR of I associated to a).

The following proposition states fundamental properties of RURs, which are all straightforward from the definition except for the fact that the RUR polynomials have rational coefficients [Rou99, Theorem 3.1].

Proposition 35 ([Rou99, Theorem 3.1]). *If $I \subset \mathbb{Q}[x, y]$ is a zero-dimensional ideal and a in \mathbb{Q} , the four polynomials of the RUR-candidate $\text{RUR}_{I,a}$ have rational coefficients. Furthermore, if $x + ay$ separates $V(I)$, the following mapping between $V(I)$ and $V(f_{I,a}) = \{\gamma \in \mathbb{C}, f_{I,a}(\gamma) = 0\}$*

$$\begin{aligned} V(I) &\rightarrow V(f_{I,a}) \\ (\alpha, \beta) &\mapsto \alpha + a\beta \\ \left(\frac{f_{I,a,x}}{f_{I,a,1}}(\gamma), \frac{f_{I,a,y}}{f_{I,a,1}}(\gamma) \right) &\leftarrow \gamma \end{aligned}$$

is a bijection, which preserves the real roots and the multiplicities.

Next, we define a RUR decomposition of an ideal.

Definition 36. *Let $I \subset \mathbb{Q}[x, y]$ be a zero-dimensional ideal, $V(I) = \{\sigma \in \mathbb{C}^2, v(\sigma) = 0, \forall v \in I\}$ its associated variety, and let $(x, y) \mapsto x + ay$ be a linear form with a in \mathbb{Q} . A RUR-candidate decomposition of I is a sequence of RUR-candidates, associated to $x + ay$, of ideals $I_i \supseteq I$, $i \in \mathcal{I}$ such that $V(I)$ is the disjoint union of the varieties $V(I_i)$, $i \in \mathcal{I}$. If $x + ay$ separates $V(I_i)$ for all $i \in \mathcal{I}$, the RUR-candidate decomposition is a RUR decomposition of I .*

The following proposition recalls an upper bound on the bitsize of a RUR of an ideal containing two coprime polynomials P and Q , that is a RUR parameterizing a subset of the solutions of the system $\{P, Q\}$. This bound applies to the RURs of our RUR decomposition and is used in Algorithm 6.

Proposition 37 ([BLPR15, Proposition 28]). *Let P and Q in $\mathbb{Z}[x, y]$ be two coprime polynomials of total degree at most d and maximum bitsize τ , let a be a rational of bitsize τ_a , and let J be any ideal of $\mathbb{Z}[x, y]$ containing P and Q . The polynomials of the RUR-candidate of J associated to a have degree at most d^2 and bitsize in $\tilde{O}(d^2\tau_a + d\tau)$.*

Note that according to Theorem 28, a separating form $x + ay$ can be computed with an integer a of bitsize $O(\log d)$ and the bound in Proposition 37 becomes $\tilde{O}(d^2 + d\tau)$. In addition, even if Proposition 37 only states an asymptotic upper bound, an explicit upper bound $C(d^2 + d\tau) \log^k d\tau$ with $C, k \in \mathbb{Z}$ can be obtained from straightforward, although unappealing, computations following the proof of that proposition. Indeed, this proof is based on Hadamard's inequality and Mignotte's lemma, which both state explicit bounds.

Proposition 37 also yields the following bound on the total bisize of any RUR decomposition.

Algorithm 6 RUR decomposition

Input: P, Q coprime in $\mathbb{Z}[x, y]$ of degree at most d and bitsize at most τ

Output: RUR decomposition of $\{P, Q\}$ of total bitsize $\tilde{O}(d^4 + d^3\tau)$

- 1: Compute a separating form $x + ay$ for $\{P, Q\}$ with $a \in \mathbb{Z}$ of bitsize $O(\log d)$ such that the leading coefficients of $P(t - ay, y)$ and $Q(t - ay, y)$ with respect to y are coprime (see Theorem 28)
 - 2: Compute $\tilde{P}(t, y) = P(t - ay, y)$ and $\tilde{Q}(t, y) = Q(t - ay, y)$, and let \tilde{d} and $\tilde{\tau}$ be their maximum degree and bitsize
 - 3: Compute $\{T_i\}_{i \in \mathcal{I}} = \text{Algorithm 1}(\tilde{P}, \tilde{Q})$
Recall that $T_i = \{A_i(t), B_i(t, y)\}$ with $B_i(t, y) = \text{sres}_i(\tilde{P}, \tilde{Q})(t) y^i + \text{sres}_{i-1}(\tilde{P}, \tilde{Q})(t) y^{i-1} + \dots$
Let $\hat{T}_i = \langle A_i, i \text{sres}_i(\tilde{P}, \tilde{Q}) y + \text{sres}_{i-1}(\tilde{P}, \tilde{Q}) \rangle$ be the radical ideal of T_i (see Lemma 39)
 - 4: Let $K = \lceil C(\tilde{d}^2 + \tilde{d}\tilde{\tau}) \log^k \tilde{d}\tilde{\tau} \rceil$ be an integer that bounds from above the bitsize of the coefficients of the RURs of the systems \hat{T}_i (see Proposition 37 and subsequent discussion) and let $\Pi = \text{Algorithm 2}(\tilde{P}, \tilde{Q})$. Compute the set \mathcal{L} of the $2K$ first prime numbers that are larger than \tilde{d} and that do not divide Π . Let $\Pi_{\mathcal{L}}$ be the product of all primes in \mathcal{L} .
 - 5: **for all** i in \mathcal{I} **do**
 - 6: **for all** μ in \mathcal{L} **do**
 - 7: Compute $\phi_{\mu}(\hat{T}_i)$ by reducing modulo μ the polynomials $A_i, \text{sres}_i(\tilde{P}, \tilde{Q})$ and $\text{sres}_{i-1}(\tilde{P}, \tilde{Q})$
 - 8: Compute RUR_{μ}^i the RUR in \mathbb{Z}_{μ} of $\phi_{\mu}(\hat{T}_i)$ associated to the separating form $(t, y) \mapsto t$ (see Lemma 40)
 - 9: Lift $\{\text{RUR}_{\mu}^i\}_{\mu \in \mathcal{L}}$ to $\text{RUR}_i^{\Pi_{\mathcal{L}}}$ in $\mathbb{Z}_{\Pi_{\mathcal{L}}}$ using the Chinese Remainder Algorithm
 - 10: Compute $\text{RUR}_i^{\mathbb{Q}}$, the RUR in \mathbb{Q} of \hat{T}_i associated to the separating form $(t, y) \mapsto t$, with a rational reconstruction from $\text{RUR}_i^{\Pi_{\mathcal{L}}}$ (see the proof of Proposition 43)
 - 11: **return** the image of $\text{RUR}_i^{\mathbb{Q}}$, $i \in \mathcal{I}$, through the reverse shearing from (t, y) to (x, y) (see Lemma 42)
-

Corollary 38. *Let P and Q in $\mathbb{Z}[x, y]$ be two coprime polynomials of total degree at most d and maximum bitsize τ , and let a be a rational of bitsize τ_a . The sum of the bitsizes of all coefficients of any RUR-candidate decomposition of $\langle P, Q \rangle$, associated to $x + ay$, is in $\tilde{O}(d^4\tau_a + d^3\tau)$.*

Proof. By Definition 36, the ideals I_i defining a RUR-candidate decomposition of $\langle P, Q \rangle$ are such that (i) the solutions of I_i (counted with multiplicity) are included in those of $\langle P, Q \rangle$ (since $I_i \supseteq \langle P, Q \rangle$) and (ii) the sets $V(I_i)$ of (distinct) solutions of I_i are pairwise disjoint. Hence, the sum over all i of the number of solutions of I_i , counted with multiplicity, is at most d^2 , the Bézout bound of $\{P, Q\}$. By Definition 34, the sum over all i of the degrees of the first polynomial of the RUR-candidate of I_i is thus also at most d^2 . Moreover, still by Definition 34, the degree the first polynomial of a RUR-candidate bounds from above the degrees of the other polynomials of the RUR-candidate. Hence, the total number of coefficients of the RUR-candidate decomposition is $O(d^2)$. The result then follows from Proposition 37. \square

6.2 Decomposition algorithm

Algorithm 6 computes a RUR decomposition of a zero-dimensional system $\{P, Q\}$, by first computing a separating form $x + ay$ as shown in Section 5 (Line 1). We then use this separating form to shear the system in generic position (Line 2) and compute the radical of a triangular decomposition of this system (Line 3). Then, using a multimodular approach, we compute RURs of each of the resulting radical systems (Lines 4–10) and return these RURs after a shear back

(Line 11).

The section is organized as follows. We first prove some preliminary lemmas that are instrumental for the proof of correctness of Algorithm 6. We show in Lemma 39 that the ideals we compute in Line 3 are the radicals of the ideals output by the triangular decomposition of Algorithm 1. We then determine in Lemma 40 formulas for the RURs of these radical ideals. These formulas are valid over the rationals but, for complexity issues, we use these formulas in a multimodular setting, in Lines 4 to 10. For this purpose, Lemma 41 states conditions on primes μ under which the reductions modulo μ of the RURs of these ideals are equal to the RURs of the reductions modulo μ of these ideals. We also show in Lemma 42 how to compute the image of the computed RURs through the reverse shearing of the one performed in Line 2. With these lemmas, we prove in Propositions 43 and 44 the correctness and complexity of Algorithm 6. Theorem 45 finally gathers these results.

Lemma 39. *The radical \widehat{T}_i of ideal T_i is $\langle A_i, i \operatorname{sres}_i(\widetilde{P}, \widetilde{Q})y + \operatorname{sres}_{i,i-1}(\widetilde{P}, \widetilde{Q}) \rangle$ where A_i is squarefree and coprime with $\operatorname{sres}_i(\widetilde{P}, \widetilde{Q})$.*

Proof. Since $x + ay$ separates the solutions of $\{P, Q\}$, the system $\{\widetilde{P}, \widetilde{Q}\}$ is in generic position in the sense that no two of its solutions are vertically aligned. The systems $T_i = \{A_i(t), B_i(t, y)\}$ of the triangular decomposition of $\{\widetilde{P}, \widetilde{Q}\}$ are thus also in generic position (since the set of solutions of $\{\widetilde{P}, \widetilde{Q}\}$ is the disjoint union of those of the T_i by Lemma 10). $B_i(t, y) = \operatorname{sres}_i(\widetilde{P}, \widetilde{Q})y^i + \operatorname{sres}_{i,i-1}(\widetilde{P}, \widetilde{Q})y^{i-1} + \dots$ is of degree i in y and its leading coefficient $\operatorname{sres}_i(\widetilde{P}, \widetilde{Q})$ is coprime with A_i (by Lemma 10). Hence, for any α solution of $A_i(t)$, $B_i(\alpha, y)$ has a unique root, which is of multiplicity i . This multiple root is thus also root of the $(i - 1)$ -th derivative of $B_i(\alpha, y)$, which is $i! \operatorname{sres}_i(\widetilde{P}, \widetilde{Q})(\alpha)y + (i - 1)! \operatorname{sres}_{i,i-1}(\widetilde{P}, \widetilde{Q})(\alpha)$. Hence, the distinct solutions of T_i are exactly those of \widehat{T}_i . Finally, \widehat{T}_i is radical because $A_i(t)$ is univariate and squarefree (by Lemma 10) and $i \operatorname{sres}_i(\widetilde{P}, \widetilde{Q})y + \operatorname{sres}_{i,i-1}(\widetilde{P}, \widetilde{Q})$ has degree one in the other variable, y . \square

The next lemma states formulas for the RURs of the radical ideals \widehat{T}_i . We state this lemma in general form because we also use it for computing the RURs of $\phi_\mu(\widehat{T}_i)$.

Lemma 40. *Let \mathbb{F} be a field, A, B_0, B_1 be three polynomials in $\mathbb{F}[t]$ and let $I = \langle A(t), B_1(t)y + B_0(t) \rangle$ be an ideal such that A is squarefree and coprime with B_1 . The linear form $(t, y) \mapsto t$ is separating for that ideal and its associated RUR is given by⁹*

$$f_I = \frac{A}{\operatorname{Lc}(A)} \quad f_{I,1} = f'_I \quad f_{I,t} = t f_{I,1} \operatorname{rem} A \quad f_{I,y} = -B_0 U f_{I,1} \operatorname{rem} A$$

where $U \in \mathbb{F}[t]$ is the inverse of B_1 modulo A , defined by Bézout's identity $UB_1 + VA = 1$ and where $f \operatorname{rem} g$ denotes the remainder of the Euclidean division of f by g .

Proof. By Definition 34, the first polynomial of the RUR of I associated to the form $(t, y) \mapsto t$ is the unique monic polynomial that encodes the t -coordinates of the solutions of I , counted with multiplicity in I . Since A is squarefree and coprime with B_1 , the solutions of I have multiplicity one and their t -coordinates are exactly the roots of A . Hence, since A is squarefree, the first polynomial of the RUR is $f_I = \frac{A}{\operatorname{Lc}(A)}$. It also follows from the definition of the RUR that if f_I is squarefree then $f_{I,1} = f'_I$.

By Proposition 35, $\frac{f_{I,t}}{f_{I,1}}(\alpha) = \alpha$ for any root α of $f_I = \frac{A}{\operatorname{Lc}(A)}$, since the separating form is $(t, y) \mapsto t$. Hence, $f_{I,t}(t) = t f_{I,1}(t) \operatorname{mod} A$. It follows that $f_{I,t} = t f_{I,1} \operatorname{rem} A$ since $f_{I,t}$ has the degree of A minus 1 by Definition 34.

⁹We omit in the subscript of the polynomials of the RUR the reference to the parameter, 0, of the separating form $(t, y) \mapsto t + 0y$.

We also have by Proposition 35 that $f_{I,1}y - f_{I,y}$ is in I . Multiplying it by B_1 and subtracting $f_{I,1}(B_1y + B_0)$, which is also in I , we obtain that $B_1f_{I,y} + f_{I,1}B_0$ is in I . This polynomial is univariate in t , hence it is equal to zero modulo A . On the other hand, since A and B_1 are coprime, by Bézout's identity, there exists a pair (U, V) of polynomials in $\mathbb{F}[t]$ such that $UB_1 + VA = 1$, and we have that $UB_1 = 1 \pmod{A}$. It follows that $f_{I,y} + Uf_{I,1}B_0 = 0 \pmod{A}$ and thus that $f_{I,y} = -Uf_{I,1}B_0 \pmod{A}$ since $f_{I,y}$ has the degree of A minus 1 by Definition 34. \square

Even if the bitsize of the RUR of \widehat{T}_i is known to be in $\widetilde{O}(d^2 + d\tau) = \widetilde{O}(d^2 + d\tau)$ (Proposition 37 and [BLPR15, Lemma 7]), the naive computation of these RURs using the above formulas over the rationals would suffer from large intermediate bitsizes.¹⁰ To overcome this difficulty, we use in Algorithm 6 a classical multimodular technique, which consists in first computing the polynomials modulo a set of primes whose product is larger than the bitsize of the output coefficients, then lifting the result using the Chinese Remainder Algorithm and finally performing a rational reconstruction. However, to output a correct result, this technique requires that, for any selected prime μ , the formulas of Lemma 40 commute with the reduction modulo μ . We show in Lemma 41 how to satisfy this requirement using the luckiness certificate output by Algorithm 2. This lemma is instrumental for the proof of correctness of Algorithm 6.

Lemma 41. *Let $\mu > i$ be a prime that does not divide Π . The ideals \widehat{T}_i and $\phi_\mu(\widehat{T}_i)$ satisfy the hypotheses of Lemma 40. In particular, the linear form $(t, y) \mapsto t$ is separating for both ideals. For this linear form, the RUR of $\phi_\mu(\widehat{T}_i)$ is equal to the reduction modulo μ of the RUR of \widehat{T}_i .*

Proof. By Lemma 39, the ideal $\widehat{T}_i = \langle A_i, i \text{sres}_i(\widetilde{P}, \widetilde{Q})y + \text{sres}_{i,i-1}(\widetilde{P}, \widetilde{Q}) \rangle$ is such that A_i is squarefree and coprime with $\text{sres}_i(\widetilde{P}, \widetilde{Q})$. Lemma 40 thus applies and yields that the linear form $(t, y) \mapsto t$ is separating for ideal \widehat{T}_i and that the associated RUR can be computed with the given formulas.

In the following, we assume that $\mu > i$ is a prime that does not divide Π . We first show that the ideal $\phi_\mu(\widehat{T}_i) = \langle \phi_\mu(A_i), i \phi_\mu(\text{sres}_i(\widetilde{P}, \widetilde{Q}))y + \phi_\mu(\text{sres}_{i,i-1}(\widetilde{P}, \widetilde{Q})) \rangle$ also satisfies the hypotheses of Lemma 40. Recall the notation used in the proof of Lemma 14: let $(A_i^\mu(t), B_i^\mu(t, y))$ be the triangular systems computed by Algorithm 1 applied to $\phi_\mu(\widetilde{P}(t, y))$ and $\phi_\mu(\widetilde{Q}(t, y))$. Lemma 14 implies that μ is lucky for the triangular decomposition of $\{\widetilde{P}, \widetilde{Q}\}$, hence $\phi_\mu(A_i) = A_i^\mu$ and $\phi_\mu(B_i) = B_i^\mu$, the latter being equivalent to $\phi_\mu(\text{sres}_i(\widetilde{P}, \widetilde{Q})) = \text{sres}_i(\phi_\mu(\widetilde{P}), \phi_\mu(\widetilde{Q}))$. We thus have that $\gcd(\phi_\mu(A_i), i \phi_\mu(\text{sres}_i(\widetilde{P}, \widetilde{Q}))) = \gcd(A_i^\mu, i \text{sres}_i(\phi_\mu(\widetilde{P}), \phi_\mu(\widetilde{Q})))$, which is a non-zero constant in \mathbb{Z}_μ by Lemma 10. In addition, Lemma 10 implies that $\phi_\mu(A_i) = A_i^\mu$ is squarefree. Lemma 40 thus applies to the ideal $\phi_\mu(\widehat{T}_i)$. Hence, the linear form $(t, y) \mapsto t$ is separating for $\phi_\mu(\widehat{T}_i)$ and the associated RUR can be computed with the formulas of Lemma 40.

Second, we prove that μ does not divide any denominator of the rational coefficients of the polynomials of the RUR of \widehat{T}_i and thus that the images of these polynomials by ϕ_μ are well defined. By definition, A_i divides the resultant of \widetilde{P} and \widetilde{Q} , which is equal to $\text{sres}_0(\widetilde{P}, \widetilde{Q})$. It follows that μ does not divide $\text{Lc}(A_i)$ because μ does not divide $\text{Lc}(\text{sres}_0(\widetilde{P}, \widetilde{Q}))$ by definition of Π . Thus μ does not divide any denominator of the coefficients of the RUR polynomials $f_{\widehat{T}_i} = \frac{A_i}{\text{Lc}(A_i)}$ and $f'_{\widehat{T}_i,1} = f'_{\widehat{T}_i}$. On the other hand, if F is a polynomial in $\mathbb{Q}[t]$ such that μ does not divide the denominators of its coefficients, then μ does not divide the denominators of the coefficients of $F \pmod{A_i}$ (the denominator of a coefficient of the remainder is the product of $\text{Lc}(A_i)$ and some denominators of coefficients of F). It follows that μ does not divide the denominators of the

¹⁰More precisely, the computation of the RURs using the formulas of Lemma 40 over the rationals would require $\widetilde{O}_B(d^8 + d^7\tau)$ bit operations for each triangular system and $\widetilde{O}_B(d^9 + d^8\tau)$ for all of them. This bit complexity corresponds roughly to the cost of multiplications and divisions involving the inverse of $\text{sres}_i(\widetilde{P}, \widetilde{Q}) \pmod{A_i}$, which is a polynomial of degree $O(d^2)$ and bitsize in $\widetilde{O}(d^4 + d^3\tau)$.

coefficients of $f_{\widehat{T}_i,t} = t f_{\widehat{T}_i,1} \bmod A_i$. Similarly, to prove that μ does not divide the denominators of the coefficients of $f_{\widehat{T}_i,y} = -\text{sres}_{i,i-1}(\widetilde{P}, \widetilde{Q}) U f_{\widehat{T}_i,1} \bmod A_i$, it is sufficient to prove the μ does not divide the denominators of the coefficients of U , the inverse of $i \text{sres}_i(\widetilde{P}, \widetilde{Q})$ modulo A_i (since $\text{sres}_{i,i-1}(\widetilde{P}, \widetilde{Q})$ has integer coefficients). By definition of Π , μ does not divide $\text{Lc}(\text{sres}_i(\widetilde{P}, \widetilde{Q}))$. In addition, we have shown that μ does not divide $\text{Lc}(A_i)$, A_i and $i \text{sres}_i(\widetilde{P}, \widetilde{Q})$ are coprime by Lemma 39 and we have shown above that $\phi_\mu(A_i)$ and $\phi_\mu(i \text{sres}_i(\widetilde{P}, \widetilde{Q}))$ are also coprime. It follows that μ is lucky for $\text{gcd}(A_i, i \text{sres}_i(\widetilde{P}, \widetilde{Q}))$ (Definition 6). Thus, by Lemma 7, μ does not divide $\text{res} = \text{Res}_t(A_i, i \text{sres}_i(\widetilde{P}, \widetilde{Q}))$. By [BPR06, Prop. 8.38.a] and since A_i and $i \text{sres}_i(\widetilde{P}, \widetilde{Q})$ are coprime, there exist u, v in $\mathbb{Z}[t]$ such that, $d_t(u) < d_t(A)$ and $u i \text{sres}_i(\widetilde{P}, \widetilde{Q}) + v A_i = \text{res}$, which is equivalent to $\frac{u}{\text{res}} i \text{sres}_i(\widetilde{P}, \widetilde{Q}) + \frac{v}{\text{res}} A_i = 1$. By unicity of Bézout's coefficients in $\mathbb{Q}[t]$, U the inverse of $i \text{sres}_i(\widetilde{P}, \widetilde{Q})$ modulo A_i is equal to $\frac{u}{\text{res}}$ and μ does not divide any denominator of its coefficients.

It is now clear that the image by ϕ_μ of the RUR polynomials $f_{\widehat{T}_i}, f_{\widehat{T}_i,1}, f_{\widehat{T}_i,t}$ are those of the RUR of $\phi_\mu(\widehat{T}_i)$. For $f_{\widehat{T}_i,y} = -\text{sres}_{i,i-1}(\widetilde{P}, \widetilde{Q}) U f_{\widehat{T}_i,1} \bmod A_i$, since we have shown that $\phi_\mu(\text{Sres}_i(\widetilde{P}, \widetilde{Q})) = \text{Sres}_i(\phi_\mu(\widetilde{P}), \phi_\mu(\widetilde{Q}))$, it is sufficient to show that $\phi_\mu(U)$ is the inverse of $\phi_\mu(i \text{sres}_i(\widetilde{P}, \widetilde{Q}))$ modulo $\phi_\mu(A_i)$. As shown above, $\phi_\mu(U)$ is well defined and the relation $\phi_\mu(\frac{u}{\text{res}}) \phi_\mu(i \text{sres}_i(\widetilde{P}, \widetilde{Q})) + \phi_\mu(\frac{v}{\text{res}}) \phi_\mu(A_i) = 1$ implies that it is the inverse of $\phi_\mu(i \text{sres}_i(\widetilde{P}, \widetilde{Q}))$ modulo $\phi_\mu(A_i)$. \square

Lemma 42. *Let $\{f_I, f_{I,1}, f_{I,t}, f_{I,y}\}$ be the RUR⁹ of an ideal I in $\mathbb{Q}[t, y]$ associated to the separating linear form $(t, y) \mapsto t$. Let J in $\mathbb{Q}[x, y]$ be the image of I through the mapping $(t, y) \mapsto (x = t - ay, y)$. The linear form $(x, y) \mapsto x + ay$ is separating for J and its associated RUR is given by*

$$f_{J,a} = f_I, \quad f_{J,a,1} = f_{I,1}, \quad f_{J,a,x} = f_{I,t} - a f_{I,y}, \quad f_{J,a,y} = f_{I,y}.$$

Proof. By Definition 34, the RURs of I and J are defined by

$$\begin{aligned} f_I(t) &= \prod_{\sigma \in V(I)} (t - t(\sigma))^{\mu_I(\sigma)} & f_{I,v}(t) &= \sum_{\sigma \in V(I)} \mu_I(\sigma) v(\sigma) \prod_{\varsigma \in V(I), \varsigma \neq \sigma} (t - t(\varsigma)) \\ & & & \text{for } v \in \{1, t, y\}, \\ f_{J,a}(t) &= \prod_{\sigma' \in V(J)} (t - x(\sigma') - ay(\sigma'))^{\mu_J(\sigma')} & f_{J,a,v}(t) &= \sum_{\sigma' \in V(J)} \mu_J(\sigma') v(\sigma') \prod_{\varsigma' \in V(J), \varsigma' \neq \sigma'} (t - x(\varsigma') - ay(\varsigma')) \\ & & & \text{for } v \in \{1, x, y\}. \end{aligned}$$

The change of coordinates $(t, y) \mapsto (x = t - ay, y)$ induces an affine transformation of the solutions that preserves their multiplicities, such that, for every solution σ of I , there exists a unique solution σ' of J with the same multiplicity and satisfying $x(\sigma') = t(\sigma) - ay(\sigma)$ and $y(\sigma') = y(\sigma)$. This directly implies all four equalities of the lemma. \square

We finally prove the correctness and analyze the complexity of Algorithm 6 in the following two propositions.

Proposition 43 (Correctness of Algorithm 6). *Algorithm 6 computes a RUR decomposition of $\{P, Q\}$ of total bitsize $\widetilde{O}(d^4 + d^3\tau)$.*

Proof. The correctness of Line 1 follows directly from Theorem 28. In particular, the sheared polynomials \widetilde{P} and \widetilde{Q} are coprime and their leading coefficients with respect to y are also coprime. In Line 3, Algorithm 1 can thus be applied to compute the ideals T_i . By Lemma 39, \widehat{T}_i is the

radical ideal of T_i and, since both ideals have the same (distinct) solutions, the set of solutions of $\{\tilde{P}, \tilde{Q}\}$ is the disjoint union of the sets of solutions of all \hat{T}_i , by Lemma 10.

In Line 4, the upper bound K can be computed according Proposition 37 and the subsequent discussion.

In Line 8, the RUR of $\phi_\mu(\hat{T}_i)$ can be computed using the formulas of Lemma 40 (which applies by Lemma 41). Moreover, by Lemma 41, the RUR of $\phi_\mu(\hat{T}_i)$ is the reduction modulo μ of the RUR of \hat{T}_i . Thus, in Line 9, by the Chinese Remainder Theorem, $\text{RUR}_i^{\Pi_{\mathcal{L}}}$ is the reduction modulo $\Pi_{\mathcal{L}}$ of the RUR of \hat{T}_i .

Finally, in Line 10, we use a rational number reconstruction [vzGG03, Section 5.10] with parameter $2M$ with $M = 2^K$: for any coefficient c of $\text{RUR}_i^{\Pi_{\mathcal{L}}}$ in $\mathbb{Z}_{\Pi_{\mathcal{L}}}$ a rational number $\frac{r}{t}$ with r, t in \mathbb{Z} is computed such that $\gcd(r, t) = 1$, $\gcd(t, \Pi_{\mathcal{L}}) = 1$, $rt^{-1} = c \pmod{\Pi_{\mathcal{L}}}$, $|r| < 2M$, $0 < t \leq \frac{\Pi_{\mathcal{L}}}{2M}$. According to [vzGG03, Theorem 5.26 (iv)], there exists at most one solution such that $|r| < M$. On the other hand, $\text{RUR}_i^{\mathbb{Q}}$, the RUR of \hat{T}_i computed in \mathbb{Q} defines such a solution for each coefficient. Indeed, let \tilde{r}/\tilde{t} be the coefficient in $\text{RUR}_i^{\mathbb{Q}}$ corresponding to c , with $\gcd(\tilde{r}, \tilde{t}) = 1$ and $\tilde{t} > 0$. By definition, M is larger than $|\tilde{r}|$ and \tilde{t} . In Line 4, $\Pi_{\mathcal{L}}$ is defined such that $\Pi_{\mathcal{L}} > 2M^2$ (indeed, $\Pi_{\mathcal{L}}$ is the product of $2K$ primes and with $K > 1$ at least one is larger than 4 thus $\Pi_{\mathcal{L}} > 2^{2K+1} = 2M^2$), thus $0 < \tilde{t} < M < \frac{\Pi_{\mathcal{L}}}{2M}$. On the other hand, we prove in Lemma 41 that, modulo a prime $\mu > i$ that does not divide Π , the reduction of $\text{RUR}_i^{\mathbb{Q}}$ is well defined, thus $\gcd(\tilde{t}, \Pi_{\mathcal{L}}) = 1$. Finally, since, as shown above, $\text{RUR}_i^{\Pi_{\mathcal{L}}}$ is the reduction modulo $\Pi_{\mathcal{L}}$ of $\text{RUR}_i^{\mathbb{Q}}$, the RUR of \hat{T}_i , we have that $c = \phi_{\Pi_{\mathcal{L}}}(\tilde{r}/\tilde{t})$, that is $\tilde{r}\tilde{t}^{-1} = c \pmod{\Pi_{\mathcal{L}}}$. The unique solution of the rational reconstruction of $\text{RUR}_i^{\Pi_{\mathcal{L}}}$ is thus well defined and equal to the RUR of \hat{T}_i in \mathbb{Q} .

At the end of Line 10, we have thus computed the sequence of RURs of \hat{T}_i associated to the separating form $(t, y) \mapsto t$, for all $i \in \mathcal{I}$. This is a RUR decomposition of $\langle \tilde{P}, \tilde{Q} \rangle$ since as shown above, the set of solutions of $\{\tilde{P}, \tilde{Q}\}$ is the disjoint union of the sets of solutions of all \hat{T}_i and since $\langle \tilde{P}, \tilde{Q} \rangle \subseteq T_i \subseteq \hat{T}_i$ by Lemma 10.

By definition of \tilde{P} and \tilde{Q} , the images of these RURs through the mapping $(t, y) \mapsto (x = t - ay, y)$ yield a RUR decomposition of $\langle P, Q \rangle$ associated to the form $(x, y) \mapsto x + ay$. This RUR decomposition is computed in Line 11 using the formulas of Lemma 42.

Finally, the total bitsize of $\tilde{O}(d^4 + d^3\tau)$ of all the coefficients of this RUR decomposition follows from Corollary 38 since the bitsize of a is in $O(\log d)$ by Theorem 28. \square

Proposition 44. *Algorithm 6 computes a RUR decomposition of $\{P, Q\}$ with $\tilde{O}_B(d^6 + d^5\tau)$ bit operations in the worst case.*

Proof. The bit complexity of Line 1 is $\tilde{O}_B(d^6 + d^5\tau)$ by Theorem 28. In Line 2, since a has bitsize in $O(\log d)$, the sheared polynomials \tilde{P} and \tilde{Q} can be computed in bit complexity $\tilde{O}_B(d^4 + d^3\tau)$ and their maximum degrees \tilde{d} and bitsizes $\tilde{\tau}$ are in $O(d)$ and $\tilde{O}(d + \tau)$, respectively (see e.g. [BLPR15, Lemma 7]).

In Lines 3 and 4, the bit complexities of Algorithms 1 and 2 applied on $\{\tilde{P}, \tilde{Q}\}$ are in $\tilde{O}_B(\tilde{d}^6 + \tilde{d}^5\tilde{\tau})$ by Proposition 16. In Line 4, computing K has bit complexity $\tilde{O}_B(\log \tilde{d}\tilde{\tau})$ (since the constants C and k are known according to the discussion following Proposition 37). Still in Line 4, computing \mathcal{L} can be done by (i) computing the first $2K + \lceil \log \Pi \rceil$ primes larger than \tilde{d} , then (ii) reducing Π modulo these primes using a remainder tree [MB74] and (iii) keeping the first $2K$ primes that do not dividing Π (there exists at least $2K$ primes that do not dividing Π since the number of primes that divide Π is smaller than $\lceil \log \Pi \rceil$). The bit complexity of computing the r first prime numbers is in $\tilde{O}_B(r)$ and their maximum is in $\tilde{O}(r)$ [vzGG03, Theorem 18.10]. Hence, since Π has bitsize $\tilde{O}(\tilde{d}^4 + \tilde{d}^3\tilde{\tau})$ by Proposition 16, phase (i) has bit complexity $\tilde{O}(\tilde{d}^4 + \tilde{d}^3\tilde{\tau})$, every prime has bitsize $O(\log \tilde{d}\tilde{\tau})$ and their product has bitsize $\tilde{O}(\tilde{d}^4 + \tilde{d}^3\tilde{\tau})$. Phase (ii) can be computed in a bit complexity

that is soft linear in the total bitsize of the input [MB74, Theorem 1], hence in $\tilde{O}(\tilde{d}^4 + \tilde{d}^3\tilde{\tau})$ bit operations. Therefore, the bit complexity of Lines 3 and 4 is $\tilde{O}(\tilde{d}^4 + \tilde{d}^3\tilde{\tau})$.

In Lines 5 and 6, the cardinality of \mathcal{I} is $O(\tilde{d})$ (see Algorithm 1) and the cardinality of \mathcal{L} is $2K = \tilde{O}(\tilde{d}^2 + \tilde{d}\tilde{\tau})$.

In Line 7, every subresultant of \tilde{P} and \tilde{Q} (including the resultant) has degree $O(\tilde{d}^2)$ in t and its coefficients have bisize $\tilde{O}(\tilde{d}\tilde{\tau})$ by Lemma 3. Furthermore, A_i is factor of $\text{Res}(\tilde{P}, \tilde{Q})$ by construction, hence the bitsize of its coefficients is in $\tilde{O}(\tilde{d}^2 + \tilde{d}\tilde{\tau})$ by Mignotte's lemma (see e.g. [BPR06, Corollary 10.12]). Hence, in Line 7, A_i , $\text{sres}_i(\tilde{P}, \tilde{Q})$ and $\text{sres}_{i,i-1}(\tilde{P}, \tilde{Q})$ have degree $O(\tilde{d}^2)$ and coefficients of bisize $\tilde{O}(\tilde{d}^2 + \tilde{d}\tilde{\tau})$. For every i , the reductions of each of these coefficients modulo the $\tilde{O}(\tilde{d}^2 + \tilde{d}\tilde{\tau})$ primes μ (of bitsize $O(\log d\tau)$) in \mathcal{L} can be done, using again a remainder tree, in bit complexity $\tilde{O}_B(\tilde{d}^2 + \tilde{d}\tilde{\tau})$. The reductions of all $O(\tilde{d}^2)$ coefficients for all $O(\tilde{d})$ $i \in \mathcal{I}$ and all $\mu \in \mathcal{L}$ can thus be done in bit complexity $\tilde{O}_B(\tilde{d}^5 + \tilde{d}^4\tilde{\tau})$.

In Line 8, for every i and μ , we compute RUR_i^μ using the formulas of Lemma 40 where the input polynomials are $A = \phi_\mu(A_i)$, $B_1 = \phi_\mu(\text{sres}_i(\tilde{P}, \tilde{Q}))$ and $B_0 = \phi_\mu(\text{sres}_{i,i-1}(\tilde{P}, \tilde{Q}))$ in $\mathbb{Z}_\mu[t]$. Following these formulas, computing RUR_i^μ can be done with $O(1)$ additions, multiplication and inverse computations in $\mathbb{Z}_\mu[t]/\langle A \rangle$ once B_0 and B_1 are reduced in $\mathbb{Z}_\mu[t]/\langle A \rangle$. These reductions amount to computing the remainders of the divisions of B_0 and B_1 by A , whose arithmetic complexity in \mathbb{Z}_μ is softly linear in their degrees $O(\tilde{d}^2)$ [vzGG03, Theorem 9.6]. Furthermore, the arithmetic complexity in \mathbb{Z}_μ of every operation in $\mathbb{Z}_\mu[t]/\langle A \rangle$ is softly linear in the degree $O(\tilde{d}^2)$ of A [vzGG03, Corollary 11.8]. Summing over all $i \in \mathcal{I}$ and all $\mu \in \mathcal{L}$, the $\tilde{O}(\tilde{d}^3 + \tilde{d}^2\tilde{\tau})$ RUR_i^μ can be computed with $\tilde{O}(\tilde{d}^5 + \tilde{d}^4\tilde{\tau})$ arithmetic operations in $\mathbb{Z}_{\mu \in \mathcal{L}}$. Finally, since every $\mu \in \mathcal{L}$ has bitsize $O(\log \tilde{d}\tilde{\tau})$, the total bit complexity of Line 8 is $\tilde{O}_B(\tilde{d}^5 + \tilde{d}^4\tilde{\tau})$.

In Line 9, for any given i , the complexity of lifting $\{\text{RUR}_i^\mu\}_{\mu \in \mathcal{L}}$ to $\text{RUR}_i^{\Pi_{\mathcal{L}}}$ in $\mathbb{Z}_{\Pi_{\mathcal{L}}}$ is the complexity of lifting its $O(\tilde{d}^2)$ coefficients. Every coefficient reconstruction in $\mathbb{Z}_{\Pi_{\mathcal{L}}}$ can be done using the Chinese Remainder Algorithm with $\tilde{O}_B(\log \Pi_{\mathcal{L}}) = \tilde{O}_B(\tilde{d}^2 + \tilde{d}\tilde{\tau})$ bit operations [vzGG03, Theorem 10.25]. Summing over all coefficients and all i , the total bit complexity of Line 9 is thus in $\tilde{O}_B(\tilde{d}^5 + \tilde{d}^4\tilde{\tau})$.

In Line 10, for any given i , the complexity of the rational reconstruction of $\text{RUR}_i^{\mathbb{Q}}$ from $\text{RUR}_i^{\Pi_{\mathcal{L}}}$ is the complexity of the rational reconstructions with parameter $2M = 2^{K+1}$ of the $O(\tilde{d}^2)$ rationals coefficients of $\text{RUR}_i^{\mathbb{Q}}$ from those of $\text{RUR}_i^{\Pi_{\mathcal{L}}}$ (see the proof of Proposition 43 for details). The rational reconstruction $r/t \in \mathbb{Q}$ of $c \in \mathbb{Z}_{\Pi_{\mathcal{L}}}$ with parameter $2M$ is the cost of computing the first line of the Extended Euclidean Algorithm (EEA) for $\Pi_{\mathcal{L}}$ and c such that the remainder is smaller than $2M$ [vzGG03, Theorem 5.26]. Using binary search, we can compute at most a logarithmic number of lines of the EEA. Since the total number of lines of the EEA and the bit complexity of computing one line of the EEA are (at most) softly linear in the bitsize of the input [vzGG03, Corollary 11.6], the rational reconstruction of one rational has bit complexity $\tilde{O}_B(\tilde{d}^2 + \tilde{d}\tilde{\tau})$. Summing over all coefficients and all i , the total bit complexity of Line 10 is thus in $\tilde{O}_B(\tilde{d}^5 + \tilde{d}^4\tilde{\tau})$.

In Line 11, for every i , the image of $\text{RUR}_i^{\mathbb{Q}}$ through the reverse shearing can be computed with $O(\tilde{d}^2)$ arithmetic operations on integers of bitsize $\tilde{O}(\tilde{d}^2 + \tilde{d}\tilde{\tau})$ by Lemma 42. Hence, the bit complexity of Line 11 is trivially $\tilde{O}_B(\tilde{d}^5 + \tilde{d}^4\tilde{\tau})$. (Note that in Lines 9, 10 and 11 an amortized analysis yields a complexity of $\tilde{O}_B(\tilde{d}^4 + \tilde{d}^3\tilde{\tau})$ by observing that the degrees $\tilde{d}_i \in O(\tilde{d}^2)$ of the first polynomials of RUR_i^μ sum up, over all i , to at most \tilde{d}^2 .)

Finally, since \tilde{d} and $\tilde{\tau}$ are in $O(d)$ and $\tilde{O}(d + \tau)$, the total bit complexity of Algorithm 6 is in $\tilde{O}_B(\tilde{d}^6 + \tilde{d}^5\tilde{\tau})$. \square

Propositions 43 and 44 directly yield the following theorem.

Algorithm 6' RUR decomposition – Las-Vegas version

Input: P, Q coprime in $\mathbb{Z}[x, y]$ of degree at most d and bitsize at most τ

Output: RUR decomposition of $\{P, Q\}$ of total bitsize $\tilde{O}(d^4 + d^3\tau)$

- 1: Compute a separating form $x + ay$ for $\{P, Q\}$ with $a \in \mathbb{Z}$ of bitsize $O(\log d)$ such that the leading coefficients of $P(t - ay, y)$ and $Q(t - ay, y)$ with respect to y are coprime (see Theorem 29)
 - 2: Compute $\tilde{P}(t, y) = P(t - ay, y)$ and $\tilde{Q}(t, y) = Q(t - ay, y)$, and let \tilde{d} and $\tilde{\tau}$ be their maximum degree and bitsize
 - 3: Compute the coefficients $\text{sres}_i(\tilde{P}, \tilde{Q})(t)$ of subresultant sequence of \tilde{P} and \tilde{Q} with respect to y and, for i such that $\text{sres}_i(\tilde{P}, \tilde{Q}) \neq 0$, compute $\text{sres}_{i,i-1}(\tilde{P}, \tilde{Q})(t)$ (see Corollary 52)
Compute the polynomials $A_i(t)$, $i \in \mathcal{I}$, of the triangular decomposition of \tilde{P} and \tilde{Q} following Algorithm 1.
Let $\hat{T}_i = \langle A_i, i \text{sres}_i(\tilde{P}, \tilde{Q})y + \text{sres}_{i,i-1}(\tilde{P}, \tilde{Q}) \rangle$, $i \in \mathcal{I}$, be the radicals of the ideals output by Algorithm 1(\tilde{P}, \tilde{Q}) (see Lemma 39 and note that, in Algorithm 1, $\text{sres}_i(\tilde{P}, \tilde{Q}) \neq 0$ for $i \in \mathcal{I}$)
 - 4: Let $K = \lceil C(\tilde{d}^2 + \tilde{d}\tilde{\tau}) \log^k \tilde{d}\tilde{\tau} \rceil$ be an integer that bounds from above the bitsize of the coefficients of the RURs of the systems \hat{T}_i (see Proposition 37 and subsequent discussion). Let $U = 8K$ and $\mathcal{L} = \emptyset$
 - 5: **repeat**
 - 6: Double U , choose uniformly at random $8K$ primes in $[1, U]$, and let \mathcal{P} be the resulting set
 - 7: For all $i \in \mathcal{I}$, $\mu \in \mathcal{P}$, reduce A_i and $i \text{sres}_i(\tilde{P}, \tilde{Q})$ modulo μ (using remainder trees)
 - 8: Add in \mathcal{L} the $\mu \in \mathcal{P}$ such that, $\forall i$, $\phi_\mu(A_i)$ is squarefree and coprime with $\phi_\mu(i \text{sres}_i(\tilde{P}, \tilde{Q}))$
 - 9: **until** \mathcal{L} contains at least $2K$ distinct primes
 - 10: **return** the image of $\text{RUR}_i^{\mathbb{Q}}$, the RUR of \hat{T}_i , $i \in \mathcal{I}$, through the reverse shearing from (t, y) to (x, y) , as in Algorithm 6, Lines 5-11
-

Theorem 45. *Let P, Q in $\mathbb{Z}[x, y]$ be of total degree at most d and maximum bitsize τ . Algorithm 6 computes, with $\tilde{O}_B(d^6 + d^5\tau)$ bit operations in the worst case, a RUR decomposition of $\{P, Q\}$ of total bitsize $\tilde{O}(d^4 + d^3\tau)$.*

6.3 Las-Vegas algorithm

We show here that the algorithm presented above for computing a RUR decomposition can easily be transformed into an efficient Las-Vegas algorithm. We prove here the following.

Theorem 46. *Let P, Q in $\mathbb{Z}[x, y]$ be of total degree at most d and maximum bitsize τ . Algorithm 6' computes, with $\tilde{O}_B(d^5 + d^4\tau)$ bit operations on average, a RUR decomposition of $\{P, Q\}$ of total bitsize $\tilde{O}(d^4 + d^3\tau)$.*

Algorithm 6', our Las-Vegas version of Algorithm 6, is obtained from the latter with only three modifications. First, in Line 2, we use the Las-Vegas version of our algorithm for computing a separating linear form for $\{P, Q\}$, described in Section 5.5.

Second, in Line 3, we modify the way we compute the radicals \hat{T}_i of the ideals T_i output by Algorithm 1(\tilde{P}, \tilde{Q}). We still use the formula $\hat{T}_i = \langle A_i, i \text{sres}_i(\tilde{P}, \tilde{Q})y + \text{sres}_{i,i-1}(\tilde{P}, \tilde{Q}) \rangle$ of Lemma 39 for computing these radical ideals, but instead of computing the T_i with Algorithm 1, we show in Section 6.3.1 that the subresultant coefficients $\text{sres}_i(\tilde{P}, \tilde{Q})$ and $\text{sres}_{i,i-1}(\tilde{P}, \tilde{Q})$ can be computed more efficiently.

Third, we modify the way we compute in Algorithm 6, Line 4, a set \mathcal{L} of $2K$ prime numbers $\mu > \tilde{d}$ that do not divide $\Pi = \text{Algorithm 2}(\tilde{P}, \tilde{Q})$. Here, in Line 9, we weaken the constraints on these primes and we avoid, in particular, computing Π .

We prove Theorem 46 by first proving its correctness in Proposition 47 and then its complexity in Proposition 50.

Proposition 47 (Correctness of Algorithm 6'). *Algorithm 6' computes a RUR decomposition of $\{P, Q\}$ of total bitsize $\tilde{O}(d^4 + d^3\tau)$.*

Proof. As described above, Algorithm 6' is obtained with only three modifications from Algorithm 6, whose correctness is proved in Proposition 43. The first two modifications do not jeopardize the correctness of Algorithm 6' since we compute the same objects as in Algorithm 6 (in particular, we use the same formula for \hat{T}_i , $i \in \mathcal{I}$). However, in the third modification, we weaken the constraints on the primes of \mathcal{L} . In the proof of correctness of Algorithm 6, the constraints on the primes of \mathcal{L} (that $\mu > \tilde{d}$ does not divide Π) are only used in Lemma 41. Furthermore, in proof of Lemma 41, these constraints are only used for proving that $\phi_\mu(\hat{T}_i) = \langle \phi_\mu(A_i), \phi_\mu(i \text{ sres}_i(\tilde{P}, \tilde{Q})) y + \phi_\mu(\text{sres}_{i,i-1}(\tilde{P}, \tilde{Q})) \rangle$ satisfies the hypotheses of Lemma 40, that is that $\phi_\mu(A_i)$ is squarefree and coprime with $\phi_\mu(i \text{ sres}_i(\tilde{P}, \tilde{Q}))$, which are the constraints on μ we impose in Line 8 of Algorithm 6'. The correctness of Algorithm 6' thus follows from that of Algorithm 6. \square

We now analyse the complexity of Algorithm 6'. A key step of this algorithm is the computation, in Line 3, of $\text{sres}_i(\tilde{P}, \tilde{Q})$ and $\text{sres}_{i,i-1}(\tilde{P}, \tilde{Q})$, which we postpone to Section 6.3.1. Before proving Proposition 50, which states the complexity of Algorithm 6', we prove two lemmas. The first one bounds the number of primes that are rejected in Line 8 and the second one will be instrumental for bounding the probability that the loop ends in Line 9.

Lemma 48. *There are $\tilde{O}(\tilde{d}^5 + \tilde{d}^4\tilde{\tau})$ primes that are unlucky for $\gcd(A_i, i \text{ sres}_i(\tilde{P}, \tilde{Q}))$ or $\gcd(A_i, A'_i)$, for some i . Furthermore, if prime μ is lucky for these two gcds, for some i , then $\phi_\mu(A_i)$ is squarefree and coprime with $\phi_\mu(i \text{ sres}_i(\tilde{P}, \tilde{Q}))$.*

Proof. By Lemma 7, the unlucky primes for the gcd of two polynomials A and B in $\mathbb{Z}[t]$ are exactly the divisors of their leading coefficients and the divisors of $\text{sres}_d(A, B)$ where d is the degree of $\gcd(A, B)$. In order to bound the number of unlucky primes, we bound the bitsizes of the relevant coefficients.

By Lemma 10, A_i divides the resultant $\text{Res}(\tilde{P}, \tilde{Q})$. Thus, A_i has degree $O(\tilde{d}^2)$ and coefficients of bitsize $\tilde{O}(\tilde{d}^2 + \tilde{d}\tilde{\tau})$, as shown in the proof of Proposition 44. It follows that the same bounds also apply to A'_i . On the other hand, $i \text{ sres}_i(\tilde{P}, \tilde{Q})$ has degree $O(\tilde{d}^2)$ and coefficients of bitsize $\tilde{O}(\tilde{d}\tilde{\tau})$, by Lemma 3. Still by Lemma 3, the coefficients of the subresultant polynomials of any two of these polynomials have bitsize $\tilde{O}(\tilde{d}^2(\tilde{d}^2 + \tilde{d}\tilde{\tau}))$. The number of primes divisor of any such coefficient is thus also in $\tilde{O}(\tilde{d}^4 + \tilde{d}^3\tilde{\tau})$. Since i varies from 1 to at most \tilde{d} (see Algorithm 1), the number of unlucky primes is in $\tilde{O}(\tilde{d}^5 + \tilde{d}^4\tilde{\tau})$.

Finally, for any i , both $\gcd(A_i, i \text{ sres}_i(\tilde{P}, \tilde{Q}))$ and $\gcd(A_i, A'_i)$ are equal to constants, by Lemma 10. Furthermore, if μ is lucky for these gcds, these gcds commute with ϕ_μ , by Lemma 7. Hence, $\phi_\mu(A_i)$ is squarefree and coprime with $\phi_\mu(i \text{ sres}_i(\tilde{P}, \tilde{Q}))$. \square

Lemma 49. *Let n_{2p} be the random variable that represents the number of distinct elements obtained by choosing uniformly at random $2p$ elements among n with replacement. If $n \geq 2p \geq 4$, then the probability that $n_{2p} > p$ is larger than $\frac{1}{2}$.*

Proof. Consider one of the $\binom{n}{d}$ sets of d distinct elements among n . Denote it by S_d , denote the set of p random elements by S and its cardinal by $|S|$. The probability that $S \subseteq S_d$, which is the probability that the p random elements in S are all in S_d is $(\frac{d}{n})^p$. On the other hand, $\Pr(|S| \leq d)$

is less than the sum of all $\Pr(S \subseteq S_d)$ for the $\binom{n}{d}$ choices of sets S_d . Hence, $\Pr(|S| \leq d) < \binom{n}{d} \left(\frac{d}{n}\right)^p$ and $\Pr(|S| > d) \geq 1 - \binom{n}{d} \left(\frac{d}{n}\right)^p$.

Setting $p = 2d$ and using Stirling's approximation $\sqrt{2\pi} n^{n+1/2} e^{-n} \leq n! \leq e n^{n+1/2} e^{-n}$, we obtain that

$$\binom{n}{d} \left(\frac{d}{n}\right)^{2d} = \frac{n!}{d!(n-d)!} \frac{d^{2d}}{n^{2d}} \quad (3)$$

$$\leq \frac{e n^{n+\frac{1}{2}} e^{-n}}{2\pi d^{d+\frac{1}{2}} e^{-d} (n-d)^{n-d+\frac{1}{2}} e^{-(n-d)}} \frac{d^{2d}}{n^{2d}} = \frac{e}{2\pi} \frac{n^{n+\frac{1}{2}-2d} d^{d-\frac{1}{2}}}{(n-d)^{n-d+\frac{1}{2}}}. \quad (4)$$

Replacing n by kd with $k \geq 2$, we get

$$\binom{n}{d} \left(\frac{d}{n}\right)^{2d} \leq \frac{e}{2\pi} \frac{\left(\frac{k}{k-1}\right)^{(k-2)d+\frac{1}{2}}}{d^{\frac{1}{2}} (k-1)^d} \quad (5)$$

and the derivative with respect to d of the right-hand side of the inequality is

$$\frac{e}{2\pi} \frac{\left(\frac{k}{k-1}\right)^{(k-2)d+\frac{1}{2}}}{d^{\frac{3}{2}} (k-1)^d} \left(-1 + 2d \ln \frac{k^{k-2}}{(k-1)^{k-1}}\right). \quad (6)$$

It is straightforward to prove that the function $k \mapsto \frac{k^{k-2}}{(k-1)^{k-1}}$ is decreasing for $k \geq 2$, hence $\ln \frac{k^{k-2}}{(k-1)^{k-1}}$ is negative for $k > 2$ and (6) is negative for $k \geq 2$. It follows that, for $d > 2$, the right-hand side of (5) is smaller than $\frac{e}{2\pi} \frac{\left(\frac{k}{k-1}\right)^{2k-\frac{7}{2}}}{\sqrt{2}(k-1)^2}$. It is straightforward to show that this is decreasing for $k \geq 2$ and it is thus less than $\frac{e}{2\pi} \frac{\sqrt{2}}{\sqrt{2}} = \frac{e}{2\pi} < \frac{1}{2}$. Therefore, for $n \geq 2d$ and $d \geq 2$, $\binom{n}{d} \left(\frac{d}{n}\right)^{2d} < \frac{1}{2}$ and thus $\Pr(|S| > d) > \frac{1}{2}$. \square

Proposition 50. *Algorithm 6' computes a RUR decomposition of $\{P, Q\}$ with $\tilde{O}_B(d^5 + d^4\tau)$ bit operations on average.*

Proof. The expected bit complexity of Line 1 is $\tilde{O}_B(d^5 + d^4\tau)$ by Theorem 29 and, as in Algorithm 6, the (worst-case) bit complexity of Line 2 is $\tilde{O}_B(d^4 + d^3\tau)$ and \tilde{P} and \tilde{Q} have maximum degree $\tilde{d} \in O(d)$ and maximum bitsize $\tilde{\tau} \in \tilde{O}(d + \tau)$ (see the proof of Proposition 44).

In Line 3, the sequence of coefficients $\text{sres}_i(\tilde{P}, \tilde{Q})$ and, for those that do not identically vanish, the coefficients $\text{sres}_{i,i-1}(\tilde{P}, \tilde{Q})$ can be computed in $\tilde{O}_B(\tilde{d}^4\tilde{\tau})$ bit operations by Corollary 52. Hence, the sequence of polynomials A_i can be computed in $\tilde{O}_B(\tilde{d}^5 + \tilde{d}^4\tilde{\tau})$ bit operations by Remark 17. We thus get, in Line 3, the sequence of ideals \hat{T}_i in $\tilde{O}_B(\tilde{d}^5 + \tilde{d}^4\tilde{\tau})$ bit operations.

In Line 4, the complexity of computing K and U is $\tilde{O}_B(\log \tilde{d}\tilde{\tau})$, as in Algorithm 6.

In Line 6, we choose uniformly at random, one at a time, $8K$ primes in $[1, U]$. Some primes might be chosen more than once and thus the resulting set of primes, \mathcal{P} , may be of cardinality smaller than $8K$. The analysis is similar to the one in Proposition 33. A random integer in $[1, U]$ can be computed in $O_B(\log U)$ bit operations. There are at least $\frac{U}{\ln U}$ primes in $[1, U]$ [vzGG03, Theorem 18.7]. The probability that a randomly chosen integer in $[1, U]$ is prime is thus at least $\frac{1}{\ln U}$ and a prime is thus found after at most $\ln U$ trials on average. Testing whether an integer in $[1, U]$ is prime can be done with a polynomial bit complexity in the bitsize of U , $\tilde{O}_B(\log^{7.5} U)$ [AKS04].

The expected bit complexity of computing a prime in Line 7 is thus $\tilde{O}_B(\log^{8.5} U)$ and the expected bit complexity of computing $8K \in \tilde{O}(\tilde{d}^2 + \tilde{d}\tilde{\tau})$ primes in Line 7 is thus in $\tilde{O}_B((\tilde{d}^2 + \tilde{d}\tilde{\tau}) \log^{8.5} U)$.

In Line 7, each of the $O(\tilde{d})$ polynomials A_i and $i \text{ sres}_i(\tilde{P}, \tilde{Q})$ have $O(\tilde{d}^2)$ coefficients of bitsize $\tilde{O}(\tilde{d}^2 + \tilde{d}\tilde{\tau})$, as shown in the proof of Lemma 48. Using remainder trees [MB74], the reductions of one coefficient modulo all the primes in \mathcal{L} can be done in a bit complexity that is softly linear in the maximum bitsize of the coefficient and the product of the primes, that is in $\tilde{O}_B((\tilde{d}^2 + \tilde{d}\tilde{\tau}) + (\tilde{d}^2 + \tilde{d}\tilde{\tau}) \log U)$. Hence, the bit complexity of Line 7 is $\tilde{O}_B((\tilde{d}^5 + \tilde{d}^4\tilde{\tau}) \log U)$.

In Line 8, for any i , $\gcd(\phi_\mu(A_i), \phi_\mu(i \text{ sres}_i(\tilde{P}, \tilde{Q})))$ and $\gcd(\phi_\mu(A_i), \phi_\mu(A'_i))$ can be computed in $\tilde{O}_B(d^4 \log U)$ bit operations, by Lemma 4, since the polynomials have degree $O(\tilde{d}^2)$ and μ has bitsize $O(\log U)$. Hence, the bit complexity of Line 8 is $\tilde{O}_B(\tilde{d}^5 \log U)$. (Note that considering the degrees d_i of the A_i , which sum up to $O(\tilde{d}^2)$ yields a finer bound of $\tilde{O}_B(\tilde{d}^4 \log U)$.)

We have shown that the expected bit complexity of one iteration of the loop in Lines 5 to 9 is in $\tilde{O}_B((\tilde{d}^5 + \tilde{d}^4\tilde{\tau}) \log^9 U)$. At the end of the j -th iteration of the loop, $U = 2^j \cdot 8K$, thus the expected bit complexity of the j -th iteration of the loop is in $\tilde{O}_B((\tilde{d}^5 + \tilde{d}^4\tilde{\tau}) j^9)$.

We now bound the total expected bit complexity of all the iterations of the loop in Lines 5 to 9. By Lemma 48, the primes that are rejected in Line 8 are unlucky for some $\gcd(A_i, i \text{ sres}_i(\tilde{P}, \tilde{Q}))$ or $\gcd(A_i, A'_i)$ and there are less than $\Gamma = C'(\tilde{d}^5 + \tilde{d}^4\tilde{\tau}) \log^{k'} \tilde{d}\tilde{\tau}$ such unlucky primes for some constants C' and k' . We refer in the rest of the proof to *these* unlucky primes simply as unlucky primes. It follows that the probability that the loop ends in Line 9 is larger than the probability that \mathcal{P} contains at least $2K$ distinct lucky primes. Furthermore,

$$\begin{aligned} \Pr(\mathcal{P} \text{ contains } 2K \text{ lucky primes}) &\geq \Pr(\mathcal{P} \text{ contains } 2K \text{ lucky primes and } 4K \text{ primes}) \\ &\geq \Pr(\mathcal{P} \text{ contains } 4K \text{ primes}) \\ &\quad \cdot \Pr(\mathcal{P} \text{ contains } 2K \text{ lucky primes} \mid \mathcal{P} \text{ contains } 4K \text{ primes}). \end{aligned}$$

As seen above, $[1, U]$ contains at least $\frac{U}{\ln U}$ primes. Thus, when $\frac{U}{\ln U} \geq 8K$, \mathcal{P} contains at least $4K$ distinct primes with probability at least $\frac{1}{2}$, by Lemma 49. On the other hand, the primes in \mathcal{P} are chosen uniformly at random among at least $\frac{U}{\ln U}$ primes, thus if $\frac{U}{\ln U} \geq 2\Gamma$, the primes in \mathcal{P} are lucky with probability at least $\frac{1}{2}$. Thus, if $\frac{U}{\ln U} \geq 2\Gamma$, given that \mathcal{P} contains at least $4K$ primes, the probability that \mathcal{P} contains at least $2K$ lucky primes is at least $\frac{1}{2}$. We thus have proved that, if $\frac{U}{\ln U} \geq \max(8K, 2\Gamma)$, the loop ends in Line 9 with probability at least $\frac{1}{4}$.

There are $O(\log \tilde{d}\tilde{\tau})$ loop iterations that are performed while $\frac{U}{\ln U}$ is smaller than $\max(8K, 2\Gamma)$. Indeed, $\log U \in O(\log \tilde{d}\tilde{\tau})$ while $\frac{U}{\ln U} < \max(8K, 2\Gamma) \in \tilde{O}(\tilde{d}^5 + \tilde{d}^4\tilde{\tau})$ since $\sqrt{U} < \frac{U}{\ln U}$. The overall bit complexity of these iterations is thus in $\tilde{O}_B(\tilde{d}^5 + \tilde{d}^4\tilde{\tau})$. It follows that the expected bit complexity of the entire loop is in $\tilde{O}_B(\tilde{d}^5 + \tilde{d}^4\tilde{\tau})$, by Lemma 32.

Summing up the complexities of all lines and since $\tilde{d} \in \tilde{O}(d)$ and $\tilde{\tau} \in \tilde{O}(d + \tau)$, we obtain that the expected bit complexity of the algorithm is $\tilde{O}_B(\tilde{d}^5 + \tilde{d}^4\tilde{\tau})$. \square

6.3.1 Computation of subresultant coefficients

A key step of Algorithm 6' is the computation of $\text{sres}_i(\tilde{P}, \tilde{Q})$ and $\text{sres}_{i,i-1}(\tilde{P}, \tilde{Q})$. We show that these coefficients can be computed in $\tilde{O}_B(d^4\tau)$ bit complexity in Corollary 52, which follows from the following theorem. This theorem generalizes [vzGG03, Theorem 11.5] to the case where one wants to compute the k terms of greater degrees of the sequence of remainders in the Euclidean algorithm.

Notation 1. If $P \in \mathbb{F}[y]$ is a polynomial of degree d and n is an integer, we denote by $P^{>n}$ the truncated polynomial that consists of the terms of P of degree greater than n and let $P|_n = P^{>d-n}$.

We denote by r_j and ρ_j the sequence of monic polynomials and coefficients appearing in the Euclidean algorithm such that $\rho_0 r_0 = P$, $\rho_1 r_1 = Q$ and $\rho_{j+1} r_{j+1} = r_{j-1} \bmod r_j$.

Let d_j denote the degree of r_j and let $\eta(\delta)$ be, for $\delta > 0$, the unique index j such that $d_j \geq d_0 - \delta > d_{j+1}$ and $\eta(0) = 0$ otherwise.

Algorithm 9 Generalized Fast Extended Euclidean Algorithm

Input: Two integers k, δ and the terms of degree greater than $d(P) - k - 2\delta$ of two polynomials P, Q in $\mathbb{F}[y]$ such that $\deg(P) \geq \deg(Q)$

Output: The sequence of truncated monic remainders $r_{i|k}$ for all integers $i \leq \eta(\delta)$ and a matrix

$$R_{\eta(\delta)} \text{ such that } \begin{pmatrix} r_{\eta(\delta)} \\ r_{\eta(\delta)+1} \end{pmatrix} = R_{\eta(\delta)} \begin{pmatrix} r_0 \\ r_1 \end{pmatrix}$$

- 1: **if** $\delta = 0$ **then**
 - 2: **return** $r_{0|k}^*, \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$
 - 3: $\delta_{1/2} := \lfloor \frac{\delta}{2} \rfloor$
 - 4: $n := d(P) - k - 2\delta$
 - 5: $r_0^* := P^{>n} / \text{Lc}_y(P)$, $r_1^* := Q^{>n} / \text{Lc}_y(Q)$
 - 6: $(r_{0|k}, \dots, r_{\eta(\delta_{1/2})|k}), R_{\eta(\delta_{1/2})} := \text{Algorithm 9}(r_0^*, r_1^*, k, \delta_{1/2})$
 - 7: $\begin{pmatrix} r_{\eta(\delta_{1/2})}^* \\ r_{\eta(\delta_{1/2})+1}^* \end{pmatrix} := R_{\eta(\delta_{1/2})} \begin{pmatrix} r_0^* \\ r_1^* \end{pmatrix}$
 - 8: **if** $r_{\eta(\delta_{1/2})+1} = 0$ **or** $d_{\eta(\delta_{1/2})+1} < d_0 - \delta$ **then**
 - 9: **return** $(r_{1|k}, \dots, r_{\eta(\delta_{1/2})|k}), R_{\eta(\delta_{1/2})}$
 - 10: $q := r_{\eta(\delta_{1/2})}^* \text{ quo } r_{\eta(\delta_{1/2})+1}^*$
 - 11: $\rho := \text{Lc}(r_{\eta(\delta_{1/2})}^* \bmod r_{\eta(\delta_{1/2})+1}^*)$
 - 12: $r_{\eta(\delta_{1/2})+2}^* := (r_{\eta(\delta_{1/2})}^* \bmod r_{\eta(\delta_{1/2})+1}^*) / \rho$
 - 13: $\delta_{1/2}^* := \delta - (d_0 - d_{\eta(\delta_{1/2})+1})$
 - 14: $(r_{\eta(\delta_{1/2})+1|k}, \dots, r_{\eta(\delta)|k}), R := \text{Algorithm 9}(r_{\eta(\delta_{1/2})+1}^*, r_{\eta(\delta_{1/2})+2}^*, k, \delta_{1/2}^*)$
 - 15: $R_{\eta(\delta)} := R \cdot \begin{pmatrix} 0 & 1 \\ \rho^{-1} & \rho^{-1}q \end{pmatrix} \cdot R_{\eta(\delta_{1/2})}$
 - 16: **return** $(r_{1|k}, \dots, r_{\eta(\delta)|k}), R_{\eta(\delta)}$
-

Theorem 51. For a given integer k and two polynomials $P, Q \in \mathbb{F}[y]$ with $d(P) \geq d(Q)$, Algorithm 9($P, Q, k, d(P)$) computes the sequence of truncated monic remainders $r_{i|k}$ appearing in the Euclidean algorithm in $O(M(k)d + M(d) \log d)$ arithmetic operations.

Before proving this theorem, we state the following corollary, which we use in the analysis of Algorithm 6'.

Corollary 52. Let $P, Q \in \mathbb{Z}[x, y]$ be of degree at most d with coefficients of bitsize at most τ . The sequence of subresultant coefficients $\text{sres}_i(P, Q)$ and $\text{sres}_{i,i-1}(P, Q)$ such that $\text{sres}_i(P, Q) \neq 0$ can be computed in $\tilde{O}_B(d^4\tau)$ bit operations in the worst case.

Proof. The subresultants coefficients $\text{sres}_i(P, Q)$ and $\text{sres}_{i,i-1}(P, Q)$ have degrees $O(d^2)$, and coefficients of bitsize $\tilde{O}_B(d\tau)$ (Lemma 3). More precisely there exists a constant c such that the bitsize of the coefficients of the subresultants is lower than $N := cd(\tau + \log d)$. Then, compute $\mu_j \in \mathbb{Z}$ the N first primes of bitsizes τ_j that don't divide the head coefficients of P and Q , such that $\sum_j \tau_j \geq N$ in $\tilde{O}_B(N)$ bit operations ([vzGG03, Theorem 18.10]). And let k_j be an integer

lower than $3d^2$ that don't vanish the head coefficients of P and Q modulo μ_j . Using [vzGG03, Corollary 11.15] we can compute each $\text{sres}_i(P(k_j, Y), Q(k_j, Y)) \text{ rem } \mu_j$ in $\tilde{O}_B(d\tau_j)$ bit operations and using Theorem 51 we can compute $r_{i|2}(P(k_j, Y), Q(k_j, Y)) \text{ rem } \mu_j$ in $\tilde{O}_B(d\tau_j)$ bit operations. If $\text{sres}_i(P, Q) \neq 0$, then $\text{sres}_{i,i-1}(P(k_j, Y), Q(k_j, Y)) \text{ rem } \mu_j$ is the coefficient of degree $i-1$ of $\text{sres}_i(P(k_j, Y), Q(k_j, Y)) \cdot r_{i|2}(P, Q) \text{ rem } \mu_j$. For a given μ_j , computing them for $2d^2$ integers k_j lower than $3d^2$ costs $\tilde{O}_B(d^3\tau_j)$ bit operations. Then using fast interpolation, we can recover $\text{sres}_{i,i}(P, Q) \text{ rem } \mu_j$ and $\text{sres}_{i,i-1}(P, Q) \text{ rem } \mu_j$ in $\tilde{O}_B(d_3\tau_j)$ bit operations. Finally, recovering all the $O(d^3)$ coefficients, of bitsize lower than N , of $\text{sres}_i(P, Q)$ and $\text{sres}_{i,i-1}(P, Q)$ can be done through a chinese remainder tree, in $\tilde{O}_B(d^3N) = \tilde{O}_B(d^4\tau)$ bit operations. \square

Before proving Theorem 51, we prove this small Lemma, which is a variant of [vzGG03, Lemma 11.1].

Lemma 53. *Let P and Q be two polynomials of $\mathbb{F}[y]$ of degrees d_P and d_Q respectively. Then, if $k > d_P - d_Q$ we have:*

$$\begin{aligned} P \text{ quo } Q &= P^{>d_Q-k} \text{ quo } Q^{>d_Q-k} \\ (P \text{ rem } Q)^{>d_P-k} &= (P^{>d_Q-k} \text{ rem } Q^{>d_Q-k})^{>d_P-k} \end{aligned}$$

Proof. According to [vzGG03, Lemma 11.1], $P \text{ quo } Q = P^{\geq d_Q-(d_P-d_Q)} \text{ quo } Q^{\geq d_Q-(d_P-d_Q)}$. This implies that for all $k > d_P - d_Q$, $P \text{ quo } Q = P^{>d_Q-k} \text{ quo } Q^{>d_Q-k}$. To compute the remainder, we use the formula $P \text{ rem } Q = P - (P \text{ quo } Q) \cdot Q$. If n is a given integer, this allows us to compute the terms of degree greater to n of the remainder if we know the terms of degree greater to $n - (d_P - d_Q)$ of P and Q . In particular, if $k > (d_P - d_Q)$ and if we know the terms of degree greater than $d_Q - k$ of P and Q , then we can compute the quotient, and we can compute the remainders terms of degree greater than $d_Q - k + (d_P - d_Q) = d_P - k$. \square

Proof of Theorem 51. The proof of this theorem is a variant the proof of [vzGG03, Theorem 11.5 and Corollary 11.6].

First, let's focus on the correctness of the algorithm. The main issue is to check that the polynomials r_i^* computed in the algorithm match the polynomials r_i for sufficiently many terms. If that is the case, then it is not difficult to check that the algorithm is correct.

On Line 6, we check easily that $r_0^{*>d_0-k-2\delta_{1/2}} = r_0^{>d_0-k-2\delta_{1/2}}$ and $r_1^{*>d_0-k-2\delta_{1/2}} = r_1^{>d_0-k-2\delta_{1/2}}$ since $d_0 - k - 2\delta_{1/2} \geq d_0 - k - 2\delta$.

On Lines 10 and 11, [vzGG03, Lemma 11.1] ensures that the terms of degree greater or equal to $D_q := d_{\eta(\delta_{1/2})+1} - (d_{\eta(\delta_{1/2})} - d_{\eta(\delta_{1/2})+1})$ are enough to compute q and ρ , necessary in Line 15. Thus we must ensure that $r_{\eta(\delta_{1/2})}^{* \geq D_q} = r_{\eta(\delta_{1/2})}^{\geq D_q}$ and $r_{\eta(\delta_{1/2})+1}^{* \geq D_q} = r_{\eta(\delta_{1/2})+1}^{\geq D_q}$. The entries of the matrix $R_{\eta(\delta_{1/2})}$ are of degree at most $d_0 - d_{\eta(\delta_{1/2})}$ ([vzGG03, Lemma 3.10]) and by construction $r_0^{*>d_0-k-2\delta} = r_0^{>d_0-k-2\delta}$ and $r_1^{*>d_0-k-2\delta} = r_1^{>d_0-k-2\delta}$. Thus, letting $D_1 := d_0 - k - 2\delta + d_0 - d_{\eta(\delta_{1/2})}$, we have $r_{\eta(\delta_{1/2})}^{*>D_1} = r_{\eta(\delta_{1/2})}^{>D_1}$ and $r_{\eta(\delta_{1/2})+1}^{*>D_1} = r_{\eta(\delta_{1/2})+1}^{>D_1}$. Moreover, after Line 8 we have $d_{\eta(\delta_{1/2})+1} \geq d_0 - \delta$, such that $D_1 \leq 2d_{\eta(\delta_{1/2})+1} - k - d_{\eta(\delta_{1/2})} < 2d_{\eta(\delta_{1/2})+1} - d_{\eta(\delta_{1/2})} = D_q$, which ensures that q is also the quotient of $r_{\eta(\delta_{1/2})}$ by $r_{\eta(\delta_{1/2})+1}$.

For Line 14, we denote $\delta - d_0 + d_{\eta(\delta_{1/2})+1}$ by $\delta_{1/2}^*$. We can note that $D_1 = d_{\eta(\delta_{1/2})+1} - k - 2\delta_{1/2}^* - (d_{\eta(\delta_{1/2})} - d_{\eta(\delta_{1/2})+1})$, which ensures us that $r_{\eta(\delta_{1/2})+1}^{*>d_{\eta(\delta_{1/2})+1}-k-2\delta_{1/2}^*} = r_{\eta(\delta_{1/2})+1}^{>d_{\eta(\delta_{1/2})+1}-k-2\delta_{1/2}^*}$, which is a first necessary condition for the correctness of the recursion call. Finally, using Lemma 53 again we can notice that $r_{\eta(\delta_{1/2})+1}^{*>D_2} = r_{\eta(\delta_{1/2})+1}^{>D_2}$ where $D_2 := D_1 + (d_{\eta(\delta_{1/2})} - d_{\eta(\delta_{1/2})+1}) = d_0 - k - 2\delta_{1/2}^*$.

Thus $r_{\eta(\delta_{1/2})+2}^* > d_{\eta(\delta_{1/2})+1-k-2\delta_{1/2}^*} = r_{\eta(\delta_{1/2})+2}^{>d_{\eta(\delta_{1/2})+1-k-2\delta_{1/2}^*}}$ which concludes the correctness of the line 14 and the correctness of the algorithm.

We will prove in the following that the number of arithmetic operations to compute $R_{\eta(\delta)}$ and $r_{0|k}, \dots, r_{\eta(\delta)|k}$ with Algorithm 9 does not depend on d . Let denote this complexity by $T(k, \delta)$ and let the c_i be universal constants.

We will prove that $T(k, \delta) = O(M(k)\delta + M(\delta) \log \delta)$ for all $k \in \mathbb{N}$. More precisely, we will prove by recurrence on $\log \delta$ that for all $k, \delta \geq 1$ we have $T(k, \delta) \leq c_0[M(k)(2\delta - 1) + M(\delta) \log \delta]$.

For $\delta = 1$ we consider three cases. If $d(Q) < d(P) - 1$, then on Line 6, the procedure is called recursively with $\delta_{1/2} = 0$, which uses a constant number of arithmetic operations. Then the condition on Line 8 is satisfied and the program exists with a constant number of operations. In the second case where $d(Q) = d(P) - 1$, we need to compute on Line 10,11,12 and 15 a constant number of products, quotients and remainders of polynomials of sizes $O(k)$, which can be done in $O(M(k))$ arithmetic operations ([vzGG03]). In this case we also have $\delta_{1/2}^* = 0$, such that the recursive call on Line 14 uses a constant number of arithmetic operations. Finally, in the third case where $d(Q) = d(P)$, we have $\delta_{1/2}^* = 1$ and the recursive call is done with $d_{\eta(\delta_{1/2})+1}^* > d_{\eta(\delta_{1/2})+2}^*$, such that it uses $O(M(k))$ operations. The other lines also use no more than $O(M(k))$ operations. Thus, for $\delta = 1$, Algorithm 9 uses at most $c_0 M(k)$ operations for a universal constant c_0 .

Now fix $2^l < \delta \leq 2^{l+1}$ and assume that we proved $T(k, \delta) \leq c_0[M(k)(2\delta - 1) + M(\delta) \log \delta]$ for all $\delta \leq 2^l$ and for all k . First, we can notice that appart from Line 6 and 14, the procedure involve only multiplication, quotient and remainder computations of polynomials of size $O(k + 2\delta)$, which requires $O(M(k + 2\delta)) = O(M(k) + M(\delta))$ arithmetic operations. Finally, the two recursive call on Lines 6 and 14 use respectively $T(k, \delta_{1/2})$ and $T(k, \delta_{1/2}^*)$ operations.

Gathering the different steps of the computation, we have:

$$T(k, \delta) = T(k, \delta_{1/2}) + T(k, \delta_{1/2}^*) + c_1(M(k) + M(\delta))$$

Moreover, $\delta_{1/2}^* = \delta - (d_0 - d_{\eta(\delta_{1/2})+1}) < \delta - \delta_{1/2}$ by definition of $\eta(\delta_{1/2})$. Such that $\delta_{1/2}$ and $\delta_{1/2}^*$ are both lower or equal to $\frac{\delta}{2} \leq 2^l$ and we have by recurrence hypothesis :

$$\begin{aligned} T(k, \delta) &= c_0[M(k)(2\delta_{1/2} - 1) + M(\delta_{1/2}) \log \delta_{1/2}] + c_0[M(k)(2\delta_{1/2}^* - 1) + M(\delta_{1/2}^*) \log \delta_{1/2}^*] + c_1(M(k) + M(\delta)) \\ &\leq \max(c_0, c_1)[M(k)(2\delta - 1) + M(\delta_{1/2}) \log \delta_{1/2} + M(\delta_{1/2}^*) \log \delta_{1/2}^* + M(\delta)] \\ &\leq \max(c_0, c_1)[M(k)(2\delta - 1) + (M(\delta_{1/2}) + M(\delta_{1/2}^*)) \log \frac{\delta}{2} + M(\delta)] \\ &\leq \max(c_0, c_1)[M(k)(2\delta - 1) + M(\delta)(\log \frac{\delta}{2} + 1)] \\ &\leq \max(c_0, c_1)[M(k)(2\delta - 1) + M(\delta) \log \delta] \end{aligned}$$

This yields $T(k, \delta) \leq c_0[M(k)(2\delta - 1) + M(\delta) \log \delta]$ as soon as $c_0 \geq c_1$, which concludes the proof by recurrence. \square

7 Computing isolating boxes from a RUR decomposition

By definition, the RUR of an ideal I defines a mapping between the roots of a univariate polynomial and the solutions of I . Based on this mapping, Algorithm 10 computes isolating boxes using univariate isolation and approximate polynomial evaluation. Section 7.1 recalls or proves several

complexity results on isolation and evaluation of univariate polynomials. In Section 7.2, the isolation algorithm using adaptive refinement is presented and analyzed in Theorem 62.

7.1 Preliminaries

We start with some basic definitions. In addition, we recall some bounds on univariate polynomial roots and their separation (for a single root and also amortized over all the roots), the complexity of isolating the roots of a univariate polynomial, and elementary results on approximate polynomial evaluation.

For an arbitrary complex value x , we denote $M(x) := \max(1, |x|)$. In addition, let L be an arbitrary positive integer. Then, we denote $\tilde{x} \in \mathbb{Q} + i \cdot \mathbb{Q}$ an *absolute dyadic L -bit approximation* of x (or just L -bit approximation for short) if \tilde{x} is of the form $\tilde{x} = (m_{\Re} + i \cdot m_{\Im}) \cdot 2^{-L-2}$, with $m_{\Re}, m_{\Im} \in \mathbb{Z}$, and $|x - \tilde{x}| < 2^{-L}$. Notice that, from any (rational) approximation $\bar{x} := \frac{p}{q} + i \cdot \frac{p'}{q'}$ of x , with integers $p, p', q, q' \in \mathbb{Z}$ of bit size less than μ , and $|x - \bar{x}| < 2^{-L-2}$, we can compute an L -bit approximation \tilde{x} using $\tilde{O}(\mu + L)$ bit operations by simply approximating \bar{x} by an $(L + 1)$ -bit approximation $(m + m' \cdot i) \cdot 2^{-L-3}$ and then rounding its real and complex part to an absolute precision of 2^{-L-2} . Further notice that an L -bit approximation $\tilde{x} = (m_{\Re} + i \cdot m_{\Im}) \cdot 2^{-L-2}$ of some point $x \in \mathbb{C}$ naturally defines a box

$$B(\tilde{x}) = \frac{[m_{\Re} - 4, m_{\Re} + 4]}{2^{L+2}} + i \cdot \frac{[m_{\Im} - 4, m_{\Im} + 4]}{2^{L+2}} \subset \mathbb{C} \quad (7)$$

of width 2^{-L+1} in \mathbb{C} that contains x . Now suppose that \tilde{x}_1 and \tilde{x}_2 are L -bit approximations two distinct complex values x_1 and x_2 , respectively. Then, we can decide whether $|\tilde{x}_1 - \tilde{x}_2| > 2^{-L+2}$ using $O(\log \min(M(x_1), M(x_2)) + \min(L, \log M(|x_1 - x_2|^{-1})))$ bit operations. Namely, the first term bounds the number of bits before the binary point that we need to consider when comparing \tilde{x}_1 and \tilde{x}_2 , whereas the second term bounds the number of bits after the binary point that need to be considered. In addition, the inequality $|\tilde{x}_1 - \tilde{x}_2| > 2^{-L+2}$ holds for sure as soon as $L > \log M(|x_1 - x_2|^{-1}) + 3$, and thus, the cost of checking the inequality is always bounded by $O(\log \min(M(x_1), M(x_2)) + \log M(|x_1 - x_2|^{-1}))$ bit operations. Further notice that the latter inequality also implies that the boxes $B(\tilde{x}_1)$ and $B(\tilde{x}_2)$ do not overlap.

For a complex root γ of a polynomial $f \in \mathbb{Z}[x]$ and an arbitrary positive integer L , we say that a connected region D in \mathbb{C} (typically, we consider a disk or a box) is isolating for γ (or that B_γ isolates γ) if it contains γ but no other root of f . We define the *separation of γ* (with respect to f), denoted $\text{sep}(\gamma, f)$, to be the minimal distance between γ and any root γ' of f , with $\gamma' \neq \gamma$. The *separation of f* is defined as $\text{sep}(f) := \min_{\gamma: f(\gamma)=0} \text{sep}(\gamma, f)$. Given two co-prime polynomials $P, Q \in \mathbb{Z}[x, y]$ and an ideal J of $\mathbb{Z}[x, y]$ containing P and Q , we say that a connected region $D \subset \mathbb{C}^2$ is isolating for a solution σ of J (i.e. $\sigma \in V(J)$) if D contains σ but no other solution of J . The *separation of σ* (with respect to J), denoted $\text{sep}(\sigma, J)$, is defined as the minimal distance of σ to any solution σ' of J , with $\sigma \neq \sigma'$. The *separation of J* is defined as $\text{sep}(J) := \min_{\sigma \in V(J)} \text{sep}(\sigma, J)$.

We will now recall some well-known facts about the separations and the magnitudes of the complex roots of a univariate polynomial $f \in \mathbb{Z}$ of degree d with integer coefficients of bitsize at most τ .

Lemma 54 ([Yap00, §6.2 Lemma 6.5]) and [BPR06, Proposition 10.9]. *For any root γ of f , it holds that $M(\gamma) = 2^{O(\tau)}$ and $\prod_{\{\gamma \text{ complex root of } f\}} M(\gamma) = 2^{O(\tau + \log d)}$.*

Lemma 55 ([EMT10, Theorem 1], [ES12, Theorem 2], and [Sag14, Theorem 1]). *For any root γ of f , it holds that $\text{sep}(\gamma, f) = 2^{-O(d(\log d + \tau))}$ and $\prod_{\{\gamma \text{ complex root of } f\}} \min(1, \text{sep}(\gamma, f)) = 2^{-\tilde{O}(d\tau + d^2)}$, where each γ occurs as often in the latter product as its multiplicity as a root of f .*

Lemma 56. *Let f and g be integer polynomials of degree bounded by d and bitsize bounded by τ . Then, for any root γ of f , $|g(\gamma)| = 2^{-O(d(\tau + \log d))}$ and $\prod_{\{\gamma \text{ complex root of } f\}} \min(1, |g(\gamma)|) = 2^{-O(d(\tau + \log d))}$.*

Proof. The bound for a single root is stated in [Yap00, Lemma 6.34]. The resultant $\text{Res}(f, g)$ of f and g can be written (see for instance [Yap00, Theorem 6.15]) as $\text{Res}(f, g) = \text{Lc}(f)^d \prod_{\{\gamma \text{ root of } f\}} g(\gamma)$. Since f and g are coprime, this resultant is a non-null integer. Also, $|\text{Lc}(f)|$ is bounded by 2^τ , and thus it follows that $\prod_{\{\gamma \text{ root of } f\}} |g(\gamma)| = \left| \frac{\text{Res}(f, g)}{\text{Lc}(f)^d} \right| \geq \left| \frac{1}{\text{Lc}(f)^d} \right| \geq 2^{-d\tau}$. In addition, we have $|g(\gamma)| \leq (d+1) \max(1, |\gamma|)^d$, and thus $\prod_{\{\gamma \text{ root of } f\}} \min(1, |g(\gamma)|) \geq 2^{-d\tau} \cdot (d+1)^{-d}$. $\prod_{\{\gamma \text{ root of } f\}} \max(1, |\gamma|)^d = 2^{-O(d(\tau + \log d))}$ due to Lemma 54. \square

Lemma 57 ([MSW15, Theorem 5]). *We can compute isolating disks D_i with radius $r_i < \frac{\text{sep}(\gamma_i, f)}{64d}$ for all roots γ_i of f using $\tilde{O}_B(d^3 + d^2\tau)$ bit operations. For an arbitrary positive integer L , we can compute corresponding L -approximations $\tilde{\gamma}_i$ for all complex roots using $\tilde{O}_B(d^3 + d^2\tau + dL)$ bit operations.*

Proof. The first part follows directly from [MSW15, Theorem 5]. In addition, [MSW15, Theorem 5] also states that we can further refine the disks D_i such that each of them has radius less than 2^{-L-2} using $\tilde{O}_B(d^3 + d^2\tau + dL)$ bit operations. Then, we can round the center of each disk D_i to an absolute precision of size 2^{-L-2} to obtain an L -bit approximation $\tilde{\gamma}_i$ of each root γ_i of f . \square

Now, suppose that we want to approximately evaluate a polynomial $g \in \mathbb{Z}[x]$ of degree d_g and with integer coefficients of bit size τ_g at all roots of f . More precisely, for a given positive integer L , we are aiming for L -bit approximations \tilde{y}_i of the values $y_i := g(\gamma_i)$, where γ_1 to γ_m denote the distinct roots of f . For this, we use fast approximate multipoint evaluation:

Lemma 58 ([KS14, Theorem 22]). *For arbitrary values $x_1, \dots, x_d \in \mathbb{C}$, and an arbitrary positive integer L , we can compute L -bit approximations \tilde{y}_i of all values $y_i := f(x_i)$ using $\tilde{O}(d(L + \tau + d\Gamma))$ bit operations, where $\Gamma \geq 1$ is an upper bound on the maximum of all values $\log M(x_i)$. For the computation, we need L' -bit approximations \tilde{x}_i of all points x_i , where $L' = -L - \tilde{O}(\tau + d\Gamma)$.*

We remark that the multipoint evaluation algorithm from [KS14] uses certified interval arithmetic based on fixed point computation. It adaptively increases the (absolute) working precision L' during the computation. That is, in each iteration, it asks for L' -bit approximations \tilde{x}_i of the points x_i , and if it does not succeed to compute L -bit approximations \tilde{y}_i of the values y_i , it doubles the precision and restarts. Hence, the algorithm might also succeed with a lower precision than the precision predicted in the worst-case. Now, from Lemma 57, Lemma 58, and the fact that $\log |\gamma_i| = O(\tau)$ for all roots γ_i of f , we immediately obtain the following result:

Lemma 59. *Let $g \in \mathbb{Z}[x]$ be a polynomial of degree d_g , with $d_g = O(d)$, and with integer coefficients of bit size less than τ_g . Then, for any given positive integer L , we can compute L -bit approximations \tilde{y}_i of all values $y_i = g(\gamma_i)$ using a number of bit operations bounded by*

$$\tilde{O}(d^3 + d^2\tau + d \cdot (L + \tau_g + d_g\tau)) = \tilde{O}(d^3 + d^2\tau + d \cdot (L + \tau_g)).$$

We can further extend the above result to the evaluation of a fraction $G := \frac{g_1}{g_2}$ at the roots γ_i of f , where g_1 and g_2 are both polynomials of degree bounded by $O(d)$ and with integer coefficients of bit size less than τ_G , and g_2 is co-prime with f .

Lemma 60. *Let $G := \frac{g_1}{g_2}$, with $g_1, g_2 \in \mathbb{Z}[x]$ polynomials of degree less than d_G , with $d_g = O(d)$, and with coefficients of bit size less than τ_G . Suppose that g_2 does not vanish at any of the roots γ_1 to γ_m of f . Then, for any given positive integer L , we can compute L -bit approximations \tilde{y}_i of all values $y_i = G(\gamma_i)$ using a number of bit operations bounded by*

$$\tilde{O}(d^3 + d^2(\tau + \tau_g) + d \cdot L).$$

Proof. According to Lemma 56, it holds that $|g_2(\gamma_i)| = 2^{-\tilde{O}(d(\tau + \tau_g))}$ for all i . Now, in a first step, we compute L' -approximations $\tilde{y}_{2,i}$ of all $y_{2,i} := g_2(\gamma_i)$ for $L' = 1, 2, 4, \dots$ until $|\tilde{y}_{2,i}| > 2^{-L'+1}$, and thus $2|\tilde{y}_{2,i}| > |y_{2,i}| > |\tilde{y}_{2,i}|/2$. Notice that we succeed in doing so for an $L' = L'_0$ of size $\tilde{O}(d(\tau + \tau_g))$. Then, for an $L' \geq L'_0$, we can compute L' -approximations $\tilde{y}_{1,i} = 2^{-L'-2} \cdot (m_{1,i} + i \cdot n_{1,i})$ and $\tilde{y}_{2,i} = 2^{-L'-2} \cdot (m_{2,i} + i \cdot n_{2,i})$ of the values $y_{1,i} := g_1(\gamma_i)$ and $y_{2,i}$, respectively, with $m_{1,i}, m_{2,i}, n_{1,i}, n_{2,i} \in \mathbb{Z}$. Notice that each of the latter integers has bit size bounded by $\tilde{O}(\tau_g + d\tau)$ as $|g_1(\gamma_i)|, |g_2(\gamma_i)| \leq d_G \cdot 2^{\tau_G} \cdot M(\gamma_i)^{d_G} \leq 2^{O(\log d + \tau_G + d\tau)}$ for all i . Hence, we conclude that

$$\begin{aligned} \left| \frac{\tilde{y}_{1,i}}{\tilde{y}_{2,i}} - G(x_i) \right| &= \frac{|\tilde{y}_{1,i} \cdot y_{2,i} - y_{1,i} \cdot \tilde{y}_{2,i}|}{|y_{2,i} \cdot \tilde{y}_{2,i}|} \leq \frac{|\tilde{y}_{1,i} - y_{1,i}| \cdot |y_{2,i}| + |y_{1,i}| \cdot |y_{2,i} - \tilde{y}_{2,i}|}{|y_{2,i} \cdot \tilde{y}_{2,i}|} \\ &\leq 2^{-L'} \cdot \frac{4}{|\tilde{y}_{2,i}|^2} \cdot d_G \cdot 2^{\tau_G} \cdot M(\gamma_i)^{d_G} = 2^{-L'} \cdot 2^{-\tilde{O}(d(\tau + \tau_g))} \end{aligned}$$

Notice that the above bound on the approximation error is an explicit (i.e. computable) bound. Thus, we can directly estimate the error from the given values $L', |\tilde{y}_{2,i}|, d_G, \tau_G$, and $M(\gamma_i)$. Hence, we may consider $L' = L'_0, L'_0 + 2, L'_0 + 4, \dots$ until we can guarantee that $\left| \frac{\tilde{y}_{1,i}}{\tilde{y}_{2,i}} - G(x_i) \right| < 2^{-L-2}$. For this, we need to increase L' at most $O(\log(d(\tau + \tau_g)))$ many times, and we succeed for an L' of size $\tilde{O}(L + d(\tau + \tau_g))$. Then, we approximate each fraction $\frac{\tilde{y}_{1,i}}{\tilde{y}_{2,i}} = \frac{m_{1,i} + i \cdot n_{1,i}}{m_{2,i} + i \cdot n_{2,i}}$ by a corresponding $(L + 1)$ -bit approximation to obtain an L -bit approximation of $G(x_i)$. Due to Lemma 59, the total cost for computing the fractions $\frac{\tilde{y}_{1,i}}{\tilde{y}_{2,i}}$ is bounded by $\tilde{O}(d^3 + d^2\tau + d \cdot (L + d(\tau + \tau_g) + \tau_g)) = \tilde{O}(d^3 + d^2\tau + d^2\tau_g + d \cdot L)$, whereas the total cost for computing the $(L + 1)$ -bit approximations of the fractions $\frac{\tilde{y}_{1,i}}{\tilde{y}_{2,i}}$ is bounded by $\tilde{O}(d^2(\tau + \tau_g) + dL)$. \square

7.2 Isolating boxes

We now give a method for computing disjoint isolating boxes for the solutions $\sigma \in \mathbb{C}^2$ of a zero-dimensional system $P = Q = 0$, where $P, Q \in \mathbb{Z}[x, y]$ are co-prime polynomials of total degree d or less and with integer coefficients of bit size τ or less. More specifically, for a given L , we first compute L -bit approximations¹¹ $\tilde{\sigma}_{i,j}$ of the solutions $\sigma_{i,j} = (x_{i,j}, y_{i,j})$, $1 \leq j \leq d_i := \deg f_i$, of each factor $\text{RUR}_i = (f_i, f_{i,1}, f_{i,x}, f_{i,y})$ in the RUR decomposition $(\text{RUR}_i)_{i \leq d}$ of $\{P, Q\}$ as computed by Algorithm 6. This is achieved by first computing sufficiently small isolating disks for the roots $\gamma_{i,j}$ of the univariate polynomial $f_i \in \mathbb{Z}[x]$ in RUR_i , and then evaluating the fractions $\frac{f_{i,x}}{f_{i,1}}$ and $\frac{f_{i,y}}{f_{i,1}}$ at the roots $\gamma_{i,j}$ to an absolute error less than 2^{-L} . From the corresponding L -bit approximations $\tilde{x}_{i,j}$ and $\tilde{y}_{i,j}$, we can then derive corresponding boxes $B_{i,j} := B(\tilde{\sigma}_{i,j}) = B(\tilde{x}_{i,j}) \times B(\tilde{y}_{i,j}) \subset \mathbb{C}^2$ of width

¹¹We extend the definition of an L -bit approximation \tilde{x} of a point $x \in \mathbb{C}$ to that of an L -bit approximation (\tilde{x}, \tilde{y}) of a point $(x, y) \in \mathbb{C}^2$ by requiring that both \tilde{x} and \tilde{y} are L -bit approximations of x and y , respectively.

Algorithm 10 Isolating boxes for a RUR-factor RUR_i

Input: $(f_i, f_{i,1}, f_{i,x}, f_{i,y})$ the polynomials of the factor RUR_i in the RUR decomposition of $\{P, Q\}$ as computed by Algorithm 6.

Output: isolating boxes $B_{i,j} \subset \mathbb{C}^2$, $1 \leq j \leq d_i := \deg(f_i)$ for the solutions $\sigma_{i,j}$ of I_i .

- 1: Compute isolating disks $D_\gamma \subset \mathbb{C}$ for all complex roots γ of f_i
 - 2: $P = \{(\gamma, \gamma') : \gamma \text{ and } \gamma' \text{ distinct roots of } f\}$
 - 3: $L = 1$
 - 4: **while** $P \neq \emptyset$ **do**
 - 5: For all roots γ of f_i , compute L -bit approximations $\tilde{\sigma}_{\gamma,x}$ and $\tilde{\sigma}_{\gamma,y}$ of $\sigma_{\gamma,x} = \frac{f_{i,y}(\gamma)}{f_{i,1}(\gamma)}$ and $\sigma_{\gamma,y} = \frac{f_{i,y}(\gamma)}{f_{i,1}(\gamma)}$, respectively. (Lemma 60)
 - 6: **if** there exists a pair $(\gamma, \gamma') \in P$ with $|\tilde{\sigma}_{\gamma,x} - \tilde{\sigma}_{\gamma',x}| \geq 2^{-L+2}$ or $|\tilde{\sigma}_{\gamma,y} - \tilde{\sigma}_{\gamma',y}| \geq 2^{-L+2}$ **then**
 - 7: $L' = 2L'$
 - 8: $P = P$
 - 9: **else**
 - 10: $P = \emptyset$
 - 11: Result = $\{B(\gamma) \times B(\gamma') : \gamma \text{ root of } f_i\}$
 - 12: **return** Result
-

2^{-L+1} containing all solutions of RUR_i ; see (7) for the definition of $B(\tilde{x}_{i,j})$ and $B(\tilde{y}_{i,j})$. If, for a fixed i , the boxes $B_{i,j}$ do not overlap, then they are already isolating for the solutions of RUR_i . Otherwise, we have to increase L until the boxes do not overlap. For the isolation of all solutions of $P = Q = 0$, we have to further refine all boxes $B_{i,j}$ until no two of them overlap. We provide details in Algorithm 10.

In order to bound the cost of the above approach, we first need to derive bounds on the separations of the solutions $\sigma_{i,j} := (x_{i,j}, y_{i,j})$ of the factor RUR_i . In addition, we derive amortized bounds on the separations of all solutions of the system $P = Q = 0$.

Lemma 61. *Let $\text{RUR}_i = (f_i, f_{i,1}, f_{i,x}, f_{i,y})$, with $1 \leq i \leq d$, be the RUR decomposition of $\{P, Q\}$ associated to the separating form $(x, y) \mapsto x + ay$, with a an integer of bit size $O(\log d)$. In addition, let $I_i \supseteq I = (P, Q)$ be the corresponding ideals and $V(I_i)$ be the corresponding zero-sets of each factor RUR_i such that the set of solutions of $P = Q = 0$ decomposes into the zero-sets $V(I_i)$. Let d_i denote the degree of f_i and τ_i the maximum bit size of the coefficients of the polynomials in RUR_i , then it holds:*

$$(a) \sum_{\sigma: \sigma \in V(I_i)} \log M(\text{sep}(\sigma, I_i)^{-1}) = \tilde{O}(d_i \tau_i) = \tilde{O}(d_i(d^2 + d\tau)) = \tilde{O}(d^4 + d^3\tau).$$

$$(b) \log M(|\sigma|) = \tilde{O}(d\tau) \text{ for all } \sigma = (\sigma_x, \sigma_y) \in V(I_i), \text{ where } |\sigma| := \max(|\sigma_x|, |\sigma_y|),$$

$$(c) \sum_{\sigma: \sigma \in V(I)} \log M(\text{sep}(\sigma, I)^{-1}) = \tilde{O}(d^4 + d^3\tau).$$

Proof. The separating form $x + a \cdot y$ defines a one-to-one onto mapping from the set of solutions $\sigma \in V(I_i)$ to the set of roots γ of f_i . Now let $\sigma = (\sigma_x, \sigma_y) \in V(I_i)$ and $\sigma' = (\sigma'_x, \sigma'_y) \in V(I_i)$ be two solutions with $\text{sep}(\sigma, I_i) = |\sigma - \sigma'|$, and let γ and γ' be the correspondent roots of f_i . Then, it holds that $\text{sep}(\gamma, f_i) \leq |\sigma_x - \sigma'_x| + |a| \cdot |\sigma_y - \sigma'_y| \leq |a + 1| \cdot \text{sep}(\sigma, I_i)$, and thus Part (a) follows directly from Lemma 55, where we further use that $d_i \leq d^2$ and $\tau_i = \tilde{O}(d^2 + d\tau)$. Part (b) follows directly from the fact that each coordinate of a solution σ is a root of either the resultant polynomial $\text{Sres}_{x,0}(P, Q) \in \mathbb{Z}[y]$ or $\text{Sres}_{y,0}(P, Q) \in \mathbb{Z}[x]$, and both of the latter polynomials have integer coefficients of bit size $\tilde{O}(d\tau)$. For part (c), notice that $f := \prod_i f_i$ is a polynomial of degree at most d^2 and with integer coefficients of bit size $\tilde{O}(d^2 + d\tau)$. Hence, using the

Algorithm 11 Isolating boxes for the solutions of $P = Q = 0$

Input: $(\text{RUR}_i)_{1 \leq i \leq d} = (f_i, f_{i,1}, f_{i,x}, f_{i,y})_{1 \leq i \leq d}$ the RUR decomposition of $\{P, Q\}$ as computed computed by Algorithm 6.

Output: isolating boxes $B_{i,j} \subset \mathbb{C}^2$, $1 \leq i \leq d$ and $1 \leq j \leq d_i := \deg(f_i)$, for all solutions $\sigma_{i,j}$ of $P = Q = 0$.

- 1: Compute isolating disks $D_{i,j} \subset \mathbb{C}$ for the complex roots $\gamma_{i,j}$ of all f_i , with $1 \leq i \leq d$ and $1 \leq j \leq d_i$
 - 2: $P = \{(\gamma, \gamma') : \gamma \text{ and } \gamma' \text{ distinct roots of } f := \prod_{i=1}^d f_i\}$
 - 3: $L = 2$
 - 4: **while** $P \neq \emptyset$ **do**
 - 5: **for** $i = 1, \dots, d$ **do**
 - 6: For all roots γ of f_i , compute L -bit approximations $\tilde{\sigma}_{\gamma,x}$ and $\tilde{\sigma}_{\gamma,y}$ of $\sigma_{\gamma,x} = \frac{f_{i,y}(\gamma)}{f_{i,1}(\gamma)}$ and $\sigma_{\gamma,y} = \frac{f_{i,y}(\gamma)}{f_{i,1}(\gamma)}$, respectively. (Lemma 60)
 - 7: **if** there exists a pair $(\gamma, \gamma') \in P$ with $|\tilde{\sigma}_{\gamma,x} - \tilde{\sigma}_{\gamma',x}| \geq 2^{-L+2}$ or $|\tilde{\sigma}_{\gamma,y} - \tilde{\sigma}_{\gamma',y}| \geq 2^{-L+2}$ **then**
 - 8: $L = 2L$
 - 9: $P = P$
 - 10: **else**
 - 11: $P = \emptyset$
 - 12: Result = $\{B(\gamma) \times B(\gamma') : \gamma \text{ root of } f\}$
 - 13: **return** Result
-

same argument as for the proof of part (a) shows that $\text{sep}(\gamma, f) \leq |a + 1| \cdot \text{sep}(\sigma, I)$, and thus $\sum_{\sigma: \sigma \in V(I)} \log M(\text{sep}(\sigma, I)^{-1}) \leq \sum_{\gamma: f(\gamma)=0} \log M(\text{sep}(\gamma, f)^{-1}) = \tilde{O}(d^2(d^2 + d\tau))$. \square

The following proposition analyzes the complexity of the isolation of a system $\{P, Q\}$ from a RUR decomposition as computed in Section 6. It is worth mentioning that using the same algorithm with the rational parameterization of Gonzalez-Vega et al. [GVEK96, DET09] instead of the RUR would a priori increase the complexity of the isolation. Indeed, as discussed in Section 6, the polynomials of this parameterization have larger degrees and if they are reduced modulo their univariate polynomials, their bitsizes would increase.

Theorem 62. *Let P and Q be coprime polynomials in $\mathbb{Z}[x, y]$ of degree bounded by d and bitsize bounded by τ . Let $(\text{RUR}_i)_{1 \leq i \leq d}$ be the RUR decomposition of the system $\{P, Q\}$ associated to the separating form $x + ay$, with a a positive integer of bitsize $O(\log d)$, as computed by Algorithm 6. Suppose that $(\text{RUR}_i)_{1 \leq i \leq d}$ is given, then*

- (a) Algorithm 10 computes isolating boxes $B_{i,j} \subset \mathbb{C}^2$ for all solutions $\sigma_{i,j} \in \mathbb{C}^2$ of I_i , with $1 \leq j \leq d_i = \deg f_i$, using $\tilde{O}(d_i^2(d^2 + d\tau))$ bit operations, where d_i denotes the degree of f_i and τ_i the maximum of the bit sizes of the polynomials in RUR_i .
- (b) Algorithm 11 computes isolating boxes $B_{i,j} \subset \mathbb{C}^2$ for all solutions $\sigma_{i,j} \in \mathbb{C}^2$ of $P = Q = 0$, with $1 \leq i \leq d$ and $1 \leq j \leq d_i = \deg f_i$, using $\tilde{O}(d^6 + d^5\tau)$ bit operations.

Proof. We first prove part (a): According to Lemma 61 (a), Algorithm 10 succeeds for an L of size $\tilde{O}(d_i\tau_i) = \tilde{O}(d_i(d^2 + d\tau))$ because the distance between any two solutions in I_i is lower bounded by $2^{-\tilde{O}(d_i\tau_i)}$ and $\tau_i = \tilde{O}(d^2 + d\tau)$. Hence, from Lemma 60, we conclude that the cost for computing the corresponding L -bit approximations in Step 5 is bounded by $\tilde{O}(d_i^3 + d_i^2(d^2 + d\tau) + d_i \cdot d_i\tau_i) = \tilde{O}(d_i^3 + d_i^2(d^2 + d\tau))$ bit operations. Here, we use that the polynomials occurring

in the fractions $G_{i,x} := \frac{f_{i,x}}{f_{i,1}}$ and $G_{i,y} := \frac{f_{i,y}}{f_{i,1}}$ have degree bounded by d_i and bit size bounded by $\tau_i = \tilde{O}(d^2 + d\tau)$. For the cost in Step 6, consider a fixed pair (γ, γ') with distinct roots γ and γ' of f_i . Let $\sigma = (G_{i,x}(\gamma), G_{i,y}(\gamma))$ and $\sigma' = (G_{i,x}(\gamma'), G_{i,y}(\gamma'))$ be the corresponding solutions in I_i . Then, for testing the inequalities $|\tilde{\sigma}_{\gamma,x} - \tilde{\sigma}_{\gamma',x}| \geq 2^{-L+2}$ and $|\tilde{\sigma}_{\gamma,y} - \tilde{\sigma}_{\gamma',y}| \geq 2^{-L+2}$, we need $O(\min(M(|\sigma|), M(|\sigma'|)) + \log \min(M(\text{sep}(\sigma, I_i)^{-1}), M(\text{sep}(\sigma', I_i)^{-1})))$ bit operations. Hence, summing over all pairs yields the claimed bound, where we use Lemma 61 and the fact that there exist less than d_i^2 pairs. We can now prove part (b) in an almost analogous manner. Namely, Algorithm 11 succeeds for an L of size $\tilde{O}(d^4 + d^3\tau)$ because the distance between any two solutions in $P = Q = 0$ is lower bounded by $2^{-\tilde{O}(d^4 + d^3\tau)}$. Hence, for a fixed i , the cost in Step 6 is bounded by $\tilde{O}(d_i^3 + d_i^2(d^2 + d\tau) + d_i(d^4 + d^3\tau)) = \tilde{O}(d_i(d^4 + d^3\tau))$. Summing over all i yields that bound $\tilde{O}(d^6 + d^5\tau)$ as $\sum_i d_i \leq d^2$. The cost for checking the inequality in Step 7 for a fixed pair (γ, γ') , with γ and γ' distinct roots of $f := \prod_i f_i$, is now bounded by $O(\min(M(|\sigma|), M(|\sigma'|)) + \log \min(M(\text{sep}(\sigma, I)^{-1}), M(\text{sep}(\sigma', I)^{-1})))$ bit operations, where I is the ideal generated by P and Q . Using Lemma 61 and the fact that there exist less than d^4 many pairs then yields the bound $\tilde{O}(d^6 + d^5\tau)$ for the total cost. □

8 Conclusion

We have studied the problem of solving a bivariate system of two polynomials of degree bounded by d and bitsize bounded by τ via a combination of triangular decomposition and RUR. We have designed algorithms of worst-case complexity $\tilde{O}_B(d^6 + d^5\tau)$ for all the steps: finding a separating linear form, computing a RUR decomposition and computing isolating boxes of the solutions. This worst-case upper bound is not likely to be easily improved since it is also the best one known for the isolation of the roots of the resultant of the input polynomials [MSW15, Theorem 5]. However, one hope to improve this complexity is to consider an adaptive complexity that depends on geometric parameters such as the minimal distance between two roots, as in [KS15] for example.

In the Las Vegas setting, we also proposed an algorithm of expected complexity $\tilde{O}_B(d^5 + d^4\tau)$ for finding a separating form and computing a RUR decomposition. In the radical and generic case, the Monte-Carlo algorithm of [LMS13] computes a modified equiprojectable decomposition that coincides in this case to a RUR. Even if it restricted to the radical case, this algorithm is remarkable since it is almost optimal, with a complexity in $\tilde{O}_B(d^{4+\varepsilon} + d^{3+\varepsilon}\tau)$ for $\varepsilon > 0$ arbitrarily small, which almost matches the size of the output (see Corollary 38). One natural question is whether it is possible to achieve such a complexity in the Las Vegas setting.

Finally, we note that, for computing a separating linear form of an *arbitrary* system $\{P, Q\}$, the algorithm presented here is likely to be purely theoretical because (i) considering the system $\{PQ, \frac{\partial PQ}{\partial y}\}$ instead $\{P, Q\}$ essentially doubles the degree of the input polynomials, and (ii) the shearing of the coordinate systems, done to avoid vertical asymptotes, spoils the sparsity of the coefficients and increases their bitsize, which is not efficient in practice. However, for the problem of computing the critical points of a curve, there is some hope that our algorithm can be efficient not only in theory but also in practice.
