Abstract
In this paper, we propose to use Hybrid Logic (HL) as a means to combine frame-based lexical semantics with quantification. We integrate this into an LTAG syntax-semantics interface and show that this architecture allows a fine-grained description of event structures by quantifying for instance over subevents. As a case study we provide an analysis of iteration and progression in combination with for-adverbials. With the HL approach and with standard techniques of underspecification we can account for the behaviour of these adverbials without the assumption of an additional iteration operator on events. This is due to the fact that frame semantics allows to express general constraints on event types that require an event to be an iteration in certain contexts.

1 Introduction
An important topic for theories of aspectual composition and coercion is the interaction of lexical aspect (Aktionsart) and temporal adverbials. On the one hand, in- and for-adverbials have been in use since Vendler (1957) as indicators for distinguishing between activities and accomplishments, among others. On the other hand, there are many types of sentences in which a temporal adverbial is not compatible with the lexical aspect of the verb but which have nevertheless a regular interpretation; cf., e.g., Egg (2005). For example, while in (1-a), the verb cry denotes an activity and is thus immediately compatible with the for-adverbial,

(1) a. Peter cried for ten minutes.

b. Peter coughed for ten minutes.

In the present case, the necessary adjustment consists is interpreting (1-b) as describing a sequence or iteration of coughings. In a recent paper, Champollion (2013) proposes an account of for-adverbials that explains the coercion phenomena in cases like (1-b), the associated processing costs, and the scopal behavior of the adverbials in the transitive case. The present paper aims at extending and revising this approach towards a model of the syntax-semantics interface which combines a model for syntactic composition (Lexicalized Lexicalized Tree Adjoining Grammar) with underspecified descriptions (using Hybrid Logic) of decompositional semantic frames.

Frames emerged as a representation format of conceptual and lexical knowledge (Fillmore, 1982; Barsalou, 1992; Löbner, 2014). They are commonly presented as semantic graphs with labelled nodes and edges, as in Fig. 1, where nodes correspond to entities (individuals, events, ...) and edges to (functional or non-functional) relations between these entities. In Fig. 1 all relations except part-of are

![Figure 1: Frame for the meaning of the man walked to the house (adapted from Kallmeyer and Osswald (2013))](image-url)
meant to be functional. This representation offers a fine-grained decomposition of meaning and should not be confused with the FrameNet frames, although the former can help to capture the structural relations of the latter as shown by Osswald and Van Valin Jr. (2014). Frames can be formalized as extended typed feature structures (Petersen, 2007; Kallmeyer and Osswald, 2013) and specified as models of a suitable logical language. Such a language allows for the composition of lexical frames on the sentential level by means of an explicit syntax-semantics interface (Kallmeyer and Osswald, 2013). Yet, this logical framework does not provide means for the lexical items to introduce explicit quantification over entities or events. To this end, we use Hybrid Logic (HL) (Areces and ten Cate, 2007). HL is an extension of modal logic. As such, it is well-suited to the description of graph structures, such as the one of Fig. 1. We use in particular two features of HL. First, we use nominals, that allow the logical formulas to refer to specific nodes of the graph. It is then possible, for example, to specify that the AGENT and the MOVER edges from the node \( n_0 \) should meet on the \( n_1 \) node in Fig. 1. Second, we use variables for nodes, and the associated quantifiers, that can appear in the logical formulas. Using these language features, we provide lexical items with a logical meaning describing a property that should hold for any node of the frame.

2 The Formal Framework

2.1 Hybrid Logic and Semantic Frames

We slightly adapt the notation of hybrid logical formulas given in Areces and ten Cate (2007) to our purposes. Let \( \text{Rel} = \text{Func} \cup \text{PropRel} \) be a set of functional and non-functional relation symbols, \( \text{Type} \) a set of type symbols, \( \text{Nom} \) of nominals (node names), and \( \text{NVar} \) a set of node variables, with \( \text{Node} = \text{Nom} \cup \text{NVar} \). Formulas are defined as:

\[
\text{(2) } \text{Forms} ::= \top | p | n | \neg \phi | \phi_1 \land \phi_2 | (R)\phi | \\
\exists \phi | \forall \phi | \exists x. \phi
\]

where \( p \in \text{Type}, n \in \text{Node}, x \in \text{NVar}, R \in \text{Rel} \) and \( \phi, \phi_1, \phi_2 \in \text{Forms} \). Moreover, \( \forall \phi \equiv -\exists \neg \phi, \phi \rightarrow \psi \equiv -\neg \phi \lor \psi, \) etc. The elements of \( \text{Func} \) will be written in small caps.

Due to lack of space, we keep the definition of satisfaction and truth of a formula in a model under an assignment at an in-
Figure 2: Derivation of every dog barked
Such a set of subevents is assumed by the for-adverbial (see the variable $e$ in Fig. 3). The semantics of for one hour states that all segments of $e$, i.e., all relevant subevents, have to satisfy $\Box$ where $\Box$ will be filled by the formulas stating those aspects of the modified event that apply also to its subevents. In our case, we obtain $\Box = l_3$.

A crucial difference to (7) is that we do not require the entire event to satisfy the formula inserted in $\Box$, i.e., we do not assume $P(I)$. If $e$ is a progression, we assume that this follows from a general constraint stating that a progression is a segment of itself:

$$
\forall (e \in \text{progression}) (\rightarrow (\text{segment-of})e)
$$

We will see in the next section that this is different for iterations.

The substitution and adjunction in Fig. 3 trigger the unifications $\Box = \Box \vee \Box = i, \Box = l_3$ on the interface features. As a result, when applying these and collecting the formulas, we obtain the following underspecified semantic formula:

$$
\overset{\Box}{\Box}, \text{person} \wedge (\text{NAME})\text{Peter},
\begin{align*}
    l_1 & : \exists \Box, l_2 : \Box, \\
    l_3 & : e \in \text{progression} \\
    & \wedge (\text{DURATION})\text{one-hour} \\
    \wedge \forall ((\text{segment-of})e \rightarrow l_3), \\
    l_4 & : \forall e \in \text{progression} \\
    & \wedge (\text{DURATION})\text{one-hour} \\
    & \wedge \forall ((\text{segment-of})e) \rightarrow \Box), \\
\end{align*}
\begin{align*}
\Box & \searrow l_4, \Box \searrow l_2, \Box \searrow l_3
\end{align*}

With $\Box \searrow l_3$, we obtain $\Box \searrow l_4$ since the syntactic structures of our formulas have to be tree-shaped. Then the only possible disambiguation mapping is $\Box \mapsto l_2, \Box \mapsto l_4$, which yields, with an additional conjunctive interpretation of the set, (10):

$$
\overset{\Box}{\Box}, \text{person} \wedge (\text{NAME})\text{Peter} \\
\exists e (e \in \text{progression} \wedge (\text{DURATION})\text{one-hour} \\
\wedge \forall ((\text{segment-of})e \rightarrow \text{swimming} \wedge (\text{AGENT})i))
$$

Furthermore, with (8), swimming $\wedge (\text{AGENT})i$ also holds at $e$.

### 3.2 Punctual Events and for-Adverbials

Now we consider cases where a for-adverbial combines with a punctual event. In this case, the event is reinterpreted as an iteration.

(11) Peter knocked at the door for ten minutes.

The meaning of (11) is that we have an iteration of knocking events, each of them involving Peter as an agent and the same door as a patient. This entire iteration takes ten minutes.

$$
\exists (e \in \text{iteration} \wedge (\text{DURATION})\text{ten-minutes} \\
\wedge \forall ((\text{segment-of})e \rightarrow \text{knocking} \wedge (\text{AGENT})i \wedge (\text{PATIENT})j)) \\
\wedge \Box (\text{person} \wedge (\text{NAME})\text{Peter} \wedge \Box, \text{door})
$$

We propose to extend the semantics of for-adverbials given in Fig. 3 by adopting a more general type $\text{nq-event}$ which is a supertype of progression and iteration and which is intended to capture non-quantized event types in the sense of Krifka (1998). Furthermore, the following constraints make sure that every $\text{nq-event}$ is either an iteration or a progression and it cannot be both at the same time.

$$
\forall (\text{nq-event} \leftrightarrow \text{iteration} \vee \text{progression}) \\
\forall (\text{iteration} \leftrightarrow \neg \text{progression})
$$

The derivation of (11) (Fig. 4) yields (14):

$$
\exists (e \in \text{iteration} \wedge (\text{DURATION})\text{ten-minutes} \\
\wedge \forall ((\text{segment-of})e \rightarrow \text{knocking} \wedge (\text{AGENT})i \wedge (\text{PATIENT})j)) \\
\wedge \Box (\text{person} \wedge (\text{NAME})\text{Peter} \wedge \Box, \text{door})
$$

With $\Box \searrow l_4$, we obtain $\Box \searrow l_4$ since the syntactic structures of our formulas have to be tree-shaped. Then the only possible disambiguation mapping is $\Box \mapsto l_2, \Box \mapsto l_4$, which yields, with an additional conjunctive interpretation of the resulting set, (15):

$$
\exists (e \in \text{iteration} \wedge (\text{DURATION})\text{ten-minutes} \\
\wedge \forall ((\text{segment-of})e \rightarrow \text{knocking} \wedge (\text{AGENT})i \wedge (\text{PATIENT})j)) \\
\wedge \Box (\text{person} \wedge (\text{NAME})\text{Peter} \wedge \Box, \text{door})
$$

The only possible mapping is $\Box \mapsto l_4$, which leads, with a conjunctive interpretation of the resulting set, to (15).
We further adopt additional constraints on iterations and progressions concerning the possible types of their segments:

\[(16)\quad \forall (\text{segment-of} \rightarrow \text{iteration} \rightarrow \text{bounded})\]

\[(17)\quad \forall (\text{punctual} \rightarrow \text{bounded})\]

\[(18)\quad \forall (\text{segment-of} \rightarrow \text{progression} \rightarrow \neg \text{bounded})\]

With these constraints, \(e\) in \((15)\) necessarily has to be of type iteration since its segments are knocking events, which are punctual. In the case of combining with an atelic event as in \((6)\), we can also use the more general entry for for-adverbials. We then obtain that the \(\text{for-event}\) has to become a progression since its segments are not bounded.

As already mentioned, this analysis of for-adverbials differs from (Champollion, 2013) in that it does not assume that the predicate the adverbial applies to necessarily holds for the entire iteration/progression event. In the case of progression, this follows from a general constraint on progression. In the case of an iteration, the subevents are single bounded events (e.g., knocking events) while only the entire event is an iteration of bounded events. In contrast to this, Champollion takes also the subevents to be iterations, i.e., an iteration operator applies first and then the for-adverbial is applied to the iteration. According to his analysis, the semantics of \((11)\) is \((17)\) where “knock” is an iteration of knockings:

\[(17)\quad \lambda P\exists l_1 [\exists e [\neg \exists (\text{knock}(e, \text{Peter, the door}) \land I = \pi(e) \land \text{hours}(I) = 1) \lor \forall J [J \in R^\text{door}(I) \rightarrow \exists e' [\neg \exists (\text{knock}(e', \text{Peter, the door}) \land J = \pi(e'))]]]]\]

We do not need this additional iteration operator since our analysis allows to embed the specification of a bounded event under an iteration during composition, for instance with a for-adverbial. It seems much more appropriate to conceive an iteration of knocking events as a set of single knocking events.

4 Conclusion

In this paper, we used HL as a way to include quantification into frame semantics. HL is particularly well-suited for this purpose since it supports the object-centered view that comes with frames and event semantics. We presented a syntax-semantics interface that couples LTAG with HL enriched with holes and labels. This approach allows us to recover analyses of scope and underspecification from previous work. As a test case for the ability to account for interesting cases of event structure, we then considered the combination of telic and atelic events with modifiers that trigger an interpretation as a progression or an iteration, respectively, such as for-adverbials. The ingredients of our analysis are that 1) our logic allows quantification over subevents and 2) the types and constraints possible with frames together with underspecification techniques allow to trigger the choice between progression or iteration in a principled way. As a consequence, we have a single entry for for-adverbials and we do not require an additional iteration operator. The extended paper will also cover interactions with quantifier scope.
