1 Explaining Query Results

The problem of querying description logic (DL) knowledge bases (KBs) using database-style queries (in particular, conjunctive queries) has been a major focus of recent DL research. Since scalability is a key concern, much of the work has focused on lightweight DLs for which query answering can be performed in polynomial time w.r.t. the size of the ABox. The DL-Lite family of lightweight DLs [10] is especially popular due to the fact that query answering can be reduced, via query rewriting, to the problem of standard database query evaluation.

Since the TBox is usually developed by experts and subject to extensive debugging, it is often reasonable to assume that its contents are correct. By contrast, the ABox is typically substantially larger and subject to frequent modifications, making errors almost inevitable. As such errors may render the KB inconsistent, several inconsistency-tolerant semantics have been introduced in order to provide meaningful answers to queries posed over inconsistent KBs. Arguably the most well-known is the AR semantics [17], inspired by work on consistent query answering in databases (cf. [4] for a survey). Query answering under AR semantics amounts to considering those answers (w.r.t. standard semantics) that can be obtained from every repair, the latter being defined as an inclusion-maximal subset of the ABox that is consistent with the TBox. A more cautious semantics, called IAR semantics [17] queries the intersection of the repairs and provides a lower bound on AR semantics. The brave semantics [7], which considers the answers holding in some repair, provides a natural upper bound. This extended abstract presents our work [6] on explaining why a tuple is a (non-)answer to a query under AR, IAR, or brave semantics.

The need to equip reasoning systems with explanation services is widely acknowledged by the DL community. Indeed, there have been numerous works on axiom pinpointing, in which the objective is to identify (minimal) subsets of a KB that entail a given TBox axiom (or ABox assertion) [18, 9, 21, 16, 22, 20, 14, 15]. With regards to conjunctive queries (CQs), a proof-theoretic approach to explaining positive answers to CQs over DL-Lite₄ KBs was introduced in [8], and, more recently, the problem of explaining negative query answers over DL-Lite₄
KBs has been studied in [11–13]. Explanation facilities are all the more essential when using inconsistency-tolerant semantics, as recently argued in [1, 2]. Indeed, the brave, AR, and IAR semantics allow query answers to be classified into three categories of increasing reliability, and a user may naturally wonder why a given tuple was assigned to, or excluded from, one of these categories. To help the user understand this classification, we introduce the notion of explanation for positive and negative query answers under brave, AR, and IAR semantics. Formally, the explanations we consider take either the form of a set of ABox assertions (viewed as a conjunction) or a set of sets of assertions (disjunction of conjunctions).

The simplest answers to explain are positive brave- and IAR-answers (i.e., answers that hold under brave, resp. IAR, semantics). For the former, we can use as explanations the query’s causes, which are the minimal consistent sets of assertions that entail the answer together with the TBox, and for the latter, we consider the causes that do not participate in any contradictions. To explain why a tuple is an AR-answer, it is no longer sufficient to give a single cause since different repairs may use different causes. We therefore define explanations as (minimal) disjunctions of causes that ‘cover’ all repairs, i.e., minimal sets of causes such that every repair contains at least one of them. To explain negative AR-answers, the idea is to give a (minimal) subset of the ABox that is consistent with the TBox and contradicts every cause of the query, since any such subset can be extended to a repair that omits all causes. For negative IAR-answers, we need only ensure that every cause is contradicted by some consistent subset.

When there are a large number of explanations for a given result, it may be impractical to present them all to the user. In such cases, one may choose instead to rank the explanations according to some preference criteria, and to present one or a small number of most preferred explanations. In the present work, we use cardinality to rank explanations for brave- and IAR-answers and negative AR- and IAR-answers. For positive AR-answers, we consider two ways of ranking explanations: the number of disjuncts, since fewer disjuncts requires less case-based reasoning, and the total number of assertions, to favour disjunctions of causes that share assertions. A complementary approach is to concisely summarize the set of explanations in terms of the necessary assertions (that occur in every explanation) and the relevant assertions (occurring in some explanation).

2 Complexity Results and Connections to SAT

In addition to the problem of computing explanations, we consider four natural decision problems: decide whether a given assertion appears in some explanation (rel) or in every explanation (nec), decide whether a candidate is an explanation (rec), resp. a best explanation according a given criteria (best rec). For our study, we consider ontologies formulated in the lightweight logic DL-LiteR that underlies the OWL 2 QL profile [19].

The results of our complexity analysis are displayed in Figure 1. For the explanation tasks that are shown to be intractable, we have exhibited tight connections with variants of propositional satisfiability that enable us to exploit
facilities of modern SAT solvers. We use the encoding \( \varphi_{\neg q} \land \varphi_{\text{cons}} \) introduced in [5] which is unsatisfiable iff the corresponding answer is entailed under AR semantics. Intuitively, \( \varphi_{\neg q} \) gives the ways of contradicting every cause, and \( \varphi_{\text{cons}} \) enforces consistency. We can show that the explanations for positive AR-answers correspond to the minimal unsatisfiable subsets of \( \varphi_{\neg q} \) w.r.t. \( \varphi_{\text{cons}} \), while the smallest explanations for negative AR-answers (resp. negative IAR-answers) correspond to the cardinality-minimal models of \( \varphi_{\neg q} \land \varphi_{\text{cons}} \) (resp. \( \varphi_{\neg q} \)).

3 System and Experiments

We extended the CQAPri system [5] to implement our framework, relying on the SAT4J SAT solver to compute minimal unsatisfiable subsets and cardinality-minimal models [3]. Our prototype runs in two modes: either it explains some selected query answers, or all the answers as they are being computed. These answers are divided into three classes: Possible (brave-answers not entailed under the AR semantics), Likely (AR-answers not entailed under IAR semantics), and Sure (IAR-answers). Concretely, explaining an answer \( \mathbf{a} \) consists in providing, for the relevant semantics \( S, S' \) according to the class of \( \mathbf{a} \): (i) all explanations of \( \mathbf{a} \) being an \( S \)-answer, as well as necessary and relevant assertions, and (ii) one smallest explanation of \( \mathbf{a} \) not being an \( S' \)-answer, with necessary and relevant assertions when \( S' = \text{IAR} \), and necessary assertions when \( S' = \text{AR} \) together with necessary and relevant assertions for explaining \( \mathbf{a} \) not being an IAR-answer. Positive explanations are ranked as explained in Section 1.

The experimental evaluation of our prototype system over the slightly modified CQAPri benchmark shows that explanations of query (non-)answers can be generated very quickly (typically less than 1ms), although we did find some rare difficult cases for which computing a smallest explanation for a negative answer is long (more than 1h). Finally, we observed that the average number of explanations per answer is often reasonably low, although some answers have a large number of explanations (e.g., 654 for an IAR-answer, 243 for an AR-answer, and 693 for a brave-answer), showing the practical interest of presenting such explanations in a concise way.
