**Abstract.** This work is motivated by the challenging problem of the computer-aided generation of approximations (viewed as a series of transformations) of partial derivative equations. In this framework, the approximations posed over complex settings are incrementally constructed by extending an approximation posed on a simple setting and combining these extensions.

In order to formalize these extensions and their combination, we introduce a class of rewriting strategies, called context-embedding iterative strategies (CE-strategies, for short). Roughly speaking, the class of CE-strategies is constructed by means of adding contexts and an iteration operator allowing the definition of recursive strategies. We show that the class of CE-strategies is closed under combination with respect to a correctness-completeness criterion. It turns out that the class CE-strategies enjoy nice algebraic properties, namely, the combination is associative, has a neutral element, and all the elements are idempotents.

## 1 Introduction

The motivation of this work originates in an undergoing project for the modeling and simulation of complex systems in micro or nano-technologies, e.g. [12, 2, 3]. The systems under consideration are governed by partial differential equations (PDEs) and are too complex to be simulated by straightforward numerical methods, at least in the time-scale of design engineering. In mathematics the asymptotic methods, also called perturbation methods in physics, have been developed for more than seventy years for PDEs with the purpose of their transformation to “simpler” PDEs when they involve one or several small parameters. The latter can refer to geometry characteristics of the PDE domain or to coefficients. They are used in all fields where PDEs are used for modeling ranging from physics, biology, finance etc. As an illustration, we refer to the review paper [6] for some applications in mechanics of periodic media where the small parameter is the ratio of a periodic cell size to the full body size. Today, asymptotic methods are developed for producing models with drastically reduced simulation

\* This work was supported by LABEX ACTION ANR-11-LABX-0001-01.

time together with keeping the essence of the model. Their main drawback preventing their dissemination in the engineering community is their case-by-case derivation. That is, for each new problem, the full process of model derivation is redone from the scratch even though the new problem shares many features with an already solved problem. Thus, they are implemented only in specialized software. We adopted an alternate approach by developing a software package called **MEMSALab** (for MEMS Array Lab) whose aim is to incrementally derive asymptotic models for input equations by taking into account their own features e.g. the scalar valued or vector valued solution, different estimates on the solutions and sources, thin structures, periodic structures, multiple nested scales, heterogeneity etc.

Our approach takes advantage of the modularity and the algebraic flavour of the asymptotic method of [10]. It relies on the so called *by-extension-combination method* [3] that we sketch. An asymptotic model derivation starts with an input PDE coming from any scientific field to which a derivation, also said proof, is applied ending to the expected model. This scheme is build for a reference case, which is the simplest that we can consider, so we call it the *reference scheme*. Then, it is complexified, we say extended, in several manners to take into account new features yielding new schemes. The input PDEs still arise from an application area but with additional features. Accordingly, the reference proof is extended in different ways to cover the new features. Applying the *extended proofs* to the enriched PDEs yields new asymptotic models. Finally, a new scheme for an input PDE covering a group of new features is built by *combination*. Precisely, its input PDE is still issued from a practical problem. Its proof is obtained by applying a combination of two or more extensions, built in the previous step, to the reference proof. Finally, applying the resulting proof to the input PDE yields an asymptotic model enjoying the groups of features. In summary, combining extensions related to new elementary features allows for building new proofs and therefore new asymptotic models in an incremental manner.

The above concept of combination is not an isolated one, we identified works in several fields involving different techniques but with the same key idea. We refer to combination of logics [9, 4], algorithms, verification methods [5], and decision procedures [11]. These works share a common principle of incremental design of complex systems by integration of simple and heterogeneous subsystems.

The above idea of extension and their combination was introduced in [12], but in this seminal work the combination of extensions was done via composition, not allowing for conflicts between extensions. The complete principle of the extension-combination method was introduced in [3]. In this work, we have presented the design and implementation of a user language for the specification of rewriting strategies based proofs and extensions. We also stated computation rules for combinations of extensions. Although we considered combinations for a small class of usual rewriting strategies as **TopDown** and **BottomUp**, the question whether this class, or possibly a wider class, is closed under combination was left

open, as well as the question of the correctness and soundness of the combination formulae.

Here, we address these two questions, in a framework involving more elementary operations but generating a wider class of rewriting strategies called *CE-strategies*. Although the idea of combination is kept the same, the tools and the techniques are different. The elementary extension operation on a term is still an enrichment by context insertion. However, the traversal strategies in a CE-strategy are built with a jump operator and an iterator/fixed-point operator instead of **TopDown** a more complex strategy. The resulting strategy language was inspired from [1] wherein it was shown that many syntactic iterative objects, like automata, games, logic, strategies etc, can be turned into a  $\mu$ -calculus. In other words, instead of formulating the strategy language as in [7], the  $\mu$ -calculus-like approach makes the strategy constructors more rudimentary and therefore tractable the question of language closure for combinations. Moreover, the formulae of combination of CE-strategies strategies together with their verification is also much simplified. Technically speaking, the fixed-point constructor is finer and more powerful than the **repeat** constructor used e.g. in [7].

It is worth noting that the way we combine the CE-strategies is close to the concept of unification of algebraic infinite trees introduced in [8] since a CE-strategy can be viewed as an infinite tree.

**Organization of the paper.** The paper is structured as follows. In Section 3 we introduce the class of elementary CE-strategies, which is a subclass of CE-strategies. It provides an illustration of the concept of unification and combination in simple cases and serves as a set of basic building blocks for the class of CE-strategies. The syntax and the semantics of the latter as well as their unification and combination are introduced in Section 4. Finally, in Section 5 we show that the unification and combination of CE-strategies is sound and complete, and state its main algebraic properties. The proofs of the statement are put in appendix.

## 2 Preliminaries

We introduce preliminary definitions and notations.

*Terms, signature, contexts.* Let  $\mathcal{F} = \cup_{n \geq 0} \mathcal{F}_n$  be a set of symbols called *function symbols*. The *arity* of a symbol  $f$  in  $\mathcal{F}_n$  is  $n$  and is denoted  $ar(f)$ . Elements of arity zero are called *constants* and often denoted by the letters  $a, b, c$ , etc. The set  $\mathcal{F}_0$  of constants is always assumed to be not empty.  $\mathcal{F}$  is often called a set of ranked function symbols or *signature*. Given a denumerable set  $\mathcal{X}$  of *variable symbols*, the set of *terms*  $\mathcal{T}(\mathcal{F}, \mathcal{X})$ , is the smallest set containing  $\mathcal{X}$  and such that  $f(t_1, \dots, t_n)$  is in  $\mathcal{T}(\mathcal{F}, \mathcal{X})$  whenever  $ar(f) = n$  and  $t_i \in \mathcal{T}(\mathcal{F}, \mathcal{X})$  for  $i \in [1..n]$ . Let the function symbol  $\square \notin \mathcal{F}$  with arity zero, the set  $\mathcal{T}_{\square}(\mathcal{F}, \mathcal{X})$  of "*contexts*", denoted simply by  $\mathcal{T}_{\square}$ , is made with terms with symbols in  $\mathcal{F} \cup \mathcal{X} \cup \{\square\}$  which includes exactly one occurrence of  $\square$ . Evidently,  $\mathcal{T}_{\square}(\mathcal{F}, \mathcal{X})$  and  $\mathcal{T}(\mathcal{F}, \mathcal{X})$

are two disjoint sets. We shall write simply  $\mathcal{T}$  (resp.  $\mathcal{T}_\square$ ) instead of  $\mathcal{T}(\mathcal{F}, \mathcal{X})$  (resp.  $\mathcal{T}_\square(\mathcal{F}, \mathcal{X})$ ). We denote by  $\text{Var}(t)$  the set of variables occurring in  $t$ .

*Positions, prefix-order, combination of contexts.* Let  $t$  be a term in  $\mathcal{T}(\mathcal{F}, \mathcal{X})$ . A position in a tree is a sequence of integers of  $\mathbb{N}_\epsilon^\omega = \{\epsilon\} \cup \mathbb{N} \cup (\mathbb{N} \times \mathbb{N}) \cup \dots$ . Given two positions  $p = p_1 p_2 \dots p_n$  and  $q = q_1 q_2 \dots q_m$ , the *concatenation* of  $p$  and  $q$ , denoted by  $p \cdot q$  or simply  $pq$ , is the position  $p_1 p_2 \dots p_n q_1 q_2 \dots q_m$ . The set of positions of the term  $t$ , denoted by  $\text{Pos}(t)$ , is a set of positions of positive integers such that, if  $t \in \mathcal{X}$  is a variable or  $t \in \mathcal{F}_0$  is a constant, then  $\text{Pos}(t) = \{\epsilon\}$ . If  $t = f(t_1, \dots, t_n)$  then  $\text{Pos}(t) = \{\epsilon\} \cup \bigcup_{i=1, \dots, n} \{ip \mid p \in \text{Pos}(t_i)\}$ . The position  $\epsilon$  is called the root position of term  $t$ , and the function or variable symbol at this position is called root symbol of  $t$ . The set of all positions will be denoted by  $\text{Pos}$  and in particular we shall write  $\mathbb{N}_\epsilon$  for  $\mathbb{N} \cup \{\epsilon\}$ , which is clearly a subset of  $\text{Pos}$ .

The prefix order defined as  $p \leq q$  iff there exists  $p'$  such that  $pp' = q$ , is a partial order on positions. If  $p' \neq \epsilon$  then we obtain the strict order  $p < q$ . We write  $(p \parallel q)$  iff  $p$  and  $q$  are incomparable with respect to  $\leq$ . The binary relations  $\sqsubset$  and  $\sqsubseteq$  defined by  $p \sqsubset q$  iff  $(p < q \text{ or } p \parallel q)$  and  $p \sqsubseteq q$  iff  $(p \leq q \text{ or } p \parallel q)$ , are total relations on positions.

For any  $p \in \text{Pos}(t)$  we denote by  $t|_p$  the subterm of  $t$  at position  $p$ , that is,  $t|_\epsilon = t$ , and  $f(t_1, \dots, t_n)|_{iq} = (t_i)|_q$ . For a term  $t$ , we shall denote by  $\delta(t)$  the depth of  $t$ , defined by  $\delta(t_0) = 0$ , if  $t_0 \in \mathcal{X} \cup \mathcal{F}^0$  is a variable or a constant, and  $\delta(f(t_1, \dots, t_n)) = 1 + \max(\delta(t_i))$ , for  $i = 1, \dots, n$ .

For any position  $p \in \text{Pos}(t)$  we denote by  $t[s]_p$  the term obtained by replacing the subterm of  $t$  at position  $p$  by  $s$ :  $t[s]_\epsilon = s$  and  $f(t_1, \dots, t_n)[s]_{iq} = f(t_1, \dots, t_i[s]_q, \dots, t_n)$ .

For any  $\tau, \tau' \in \mathcal{T}_\square$ , we define the combination of two contexts by  $\tau[\tau'] = \tau[\tau']_{\text{Pos}(t, \square)}$ . For any two tuples of contexts  $\boldsymbol{\tau} = (\tau_1, \dots, \tau_n)$  and  $\boldsymbol{\tau}' = (\tau'_1, \dots, \tau'_m)$  in  $\mathcal{T}_\square^\omega = \mathcal{T}_\square \cup (\mathcal{T}_\square \times \mathcal{T}_\square) \cup \dots$ , we define the concatenation operation "·" by  $\boldsymbol{\tau} \cdot \boldsymbol{\tau}' = (\tau_1, \dots, \tau_n, \tau'_1, \dots, \tau'_m)$ . The evaluation of a tuple of contexts  $\boldsymbol{\tau} = \tau_1 \cdot \dots \cdot \tau_n$ , denoted as  $\text{eval}(\boldsymbol{\tau})$ , is inductively defined by

i.) if  $\tau_i = \tau_{i+1}$ , for some  $i \in [n]$ , then

$$\text{eval}(\tau_1 \cdot \dots \cdot \tau_i \cdot \tau_{i+1} \cdot \dots \cdot \tau_n) = \text{eval}(\tau_1 \cdot \dots \cdot \tau_i \cdot \tau_{i+2} \cdot \dots \cdot \tau_n),$$

ii.) otherwise,

$$\text{eval}((\tau_1, \dots, \tau_m)) = \begin{cases} \tau_1, & \text{if } m = 1 \\ \tau_1[\text{eval}((\tau_2, \dots, \tau_m))], & \text{if } m \geq 2. \end{cases}$$

A substitution is a mapping  $\sigma : \mathcal{X} \rightarrow \mathcal{T}(\mathcal{F}, \mathcal{X})$  such that  $\sigma(x) \neq x$  for only finitely many  $x$ s. The finite set of variables that  $\sigma$  does not map to themselves is called the domain of  $\sigma$ :  $\text{Dom}(\sigma) \stackrel{\text{def}}{=} \{x \in \mathcal{X} \mid \sigma(x) \neq x\}$ . If  $\text{Dom}(\sigma) = \{x_1, \dots, x_n\}$  then we write  $\sigma$  as:  $\sigma = \{x_1 \mapsto \sigma(x_1), \dots, x_n \mapsto \sigma(x_n)\}$ . A substitution  $\sigma : \mathcal{X} \rightarrow \mathcal{T}(\mathcal{F}, \mathcal{X})$  uniquely extends to an endomorphism  $\hat{\sigma} : \mathcal{T}(\mathcal{F}, \mathcal{X}) \rightarrow$

$\mathcal{T}(\mathcal{F}, \mathcal{X})$  defined by:  $\widehat{\sigma}(x) = \sigma(x)$  for all  $x \in \text{Dom}(\sigma)$ , and  $\widehat{\sigma}(x) = x$  for all  $x \notin \text{Dom}(\sigma)$ , and  $\widehat{\sigma}(f(t_1, \dots, t_n)) = f(\widehat{\sigma}(t_1), \dots, \widehat{\sigma}(t_n))$  for  $f \in \mathcal{F}$ . In what follows we do not distinguish between a substitution and its extension.

For two terms  $t, t' \in \mathcal{T}$ , we say that  $t$  matches  $t'$ , written  $t \ll t'$ , iff there exists a substitution  $\sigma$ , such that  $\sigma(t) = t'$ . It turns out that if such a substitution exists, then it is unique.

The most general unifier of the two terms  $u$  and  $u'$  is a substitution  $\gamma$  such that  $\gamma(u) = \gamma(u')$  and, for any other substitution  $\gamma'$  satisfying  $\gamma'(u) = \gamma'(u')$ , we have that  $\gamma'$  is subsumed by  $\gamma$ . Besides, we shall write  $u \wedge u'$  to denote the term  $\gamma(u)$ . The composition of functions will be denoted by “ $\circ$ ”. For a set  $A$ , the set of all functions from  $A$  to  $A$  will be denoted by  $\mathfrak{F}(A)$ . If  $l_1$  and  $l_2$  are lists, then we denote by  $l_1 \sqcup l_2$  (resp.  $l_1 \sqcap l_2$ ) their concatenation (resp. intersection). Sometimes we shall write  $\sqcup_{i=1, n} e_i$  to denote the list  $[e_1, \dots, e_n]$ .

### 3 Elementary CE-strategies and their combination

To define the elementary CE-strategies, we introduce two elementary strategies. For a position  $p$  and a tuple of context  $\tau$ , the jump strategy  $@p.\tau$  applied to a term  $t$  inserts  $\tau$  at the position  $p$  of the input term  $t$ . The failing strategy  $\emptyset$  fails when apply to any term. Their precise semantics are given in Definition below for Semantics of elementary CE-strategies.

**Definition 1 (Elementary CE-strategies).** *An elementary CE-strategy is either the failing strategy  $\emptyset$  or the list  $[@p_1.\tau_1, \dots, @p_n.\tau_n]$ , where  $n \geq 1$ , each  $p_i$  is a positions and each  $\tau_i$  is a tuple of contexts in  $\mathcal{T}_{\square}^{\omega}$ .*

We impose that the elementary CE-strategies respect some constraints on positions of insertions to avoid conflicts: the order of context insertions goes from the leave to the root.

**Definition 2 (Well-founded elementary CE-strategy).** *An elementary CE-strategy  $E = [@p_1.\tau_1, \dots, @p_n.\tau_n]$  is well-founded iff*

- i.) a position occurs at most one time in  $E$ , i.e.  $p_i \neq p_j$  for all  $i \neq j$ , and*
- ii.) insertions at lower positions occur earlier in  $E$ , i.e.  $i < j$  iff  $p_i \sqsubset p_j$ , for all  $i, j \in [n]$ .*

*In particular, the empty elementary CE-strategy  $\emptyset$  is well-founded.*

In all what follows we work only with the set of well-founded elementary CE-strategies, denoted by  $\mathcal{E}$ . For two elementary CE-strategies  $E'$  and  $E''$ , we shall write  $E = E'$  to mean that they are equal up to a permutation of their parallel positions. We next define the semantics of an elementary CE-strategy as a function in  $\mathfrak{F}(\mathcal{T} \cup \{\mathbb{F}\})$ , with the idea that if the application of an elementary CE-strategy to a term fails, the result is  $\mathbb{F}$ .

**Definition 3 (Semantics of elementary CE-strategies).** *The semantics of an elementary CE-strategy  $E$  is a function  $\llbracket E \rrbracket$  in  $\mathfrak{F}(\mathcal{T} \cup \{\mathbb{F}\})$  inductively defined by:*

$$\begin{aligned} \llbracket \emptyset \rrbracket(t) &\stackrel{def}{=} \mathbb{F}, & \llbracket @p.\tau \rrbracket(t) &\stackrel{def}{=} \begin{cases} t[\text{eval}(\tau)[t|_p]]_p & \text{if } p \in \text{Pos}(t) \\ \mathbb{F} & \text{otherwise,} \end{cases} \\ \llbracket E \rrbracket(\mathbb{F}) &\stackrel{def}{=} \mathbb{F}, & \llbracket [(p_1, \tau_1), \dots, (p_n, \tau_n)] \rrbracket(t) &\stackrel{def}{=} (\llbracket @p_n.\tau_n \rrbracket \circ \dots \circ \llbracket @p_1.\tau_1 \rrbracket)(t). \end{aligned}$$

*Example 1.* We illustrate the idea and the interest of elementary CE-strategies through the simple example, presented in [3], of an extension of a mathematical expression encountered in an extension of a proof. The context  $\tau = \text{list}(\square, j)$  depicted in Figure 1 captures the idea that the extension transforms a one-dimensional space coordinate variable  $x$  to an indexed multi-dimensional space coordinate variable  $x_j$ . The application of  $@p.\tau$  to the term  $t = \partial_x v(x)$  at the position of  $p$  of the variable  $x$  (the parameter of the differential operator  $\partial$ ) yields the term  $\llbracket @p.\tau \rrbracket(t) = \partial_{x_j} v(x)$ .

**Fig. 1.** Application of the elementary CE-strategy  $@p.\tau$  (with the context  $\tau = \text{list}(\square, j)$ ) to the term  $t = \partial_x v(x)$  at the position  $p$ , yielding the term  $\partial_{x_j} v(x)$ .

**Fig. 2.** Application of the elementary CE-strategy  $@q.\tau'$  (with the context  $\tau' = \text{list}(\square, i)$ ) to the term  $t = \partial_x v(x)$  at the position  $q$ , yielding the term  $\partial_{x_i} v(x)$ .

**Definition 4 (Unification of two elementary CE-strategies).** *The unification of two elementary CE-strategies is the binary operation  $\lambda : \mathcal{E} \times \mathcal{E} \rightarrow \mathcal{E}$  defined as*

$$E \lambda E' = \begin{cases} E'' & \text{if } E \neq \emptyset \text{ and } E' \neq \emptyset \\ \emptyset & \text{if } E = \emptyset \text{ or } E' = \emptyset \end{cases}$$

where the first case  $E = [@p_1.\tau_1, \dots, @p_n.\tau_n]$ ,  $E' = [@p'_1.\tau'_1, \dots, @p'_m.\tau'_m]$  and  $E'' = [@p''_1.\tau''_1, \dots, @p''_r.\tau''_r]$  with sets of positions  $P$ ,  $P'$  and  $P'' = P \cup P'$  and the contexts  $\tau''_k$  defined as follows. For a position  $p''_k \in P'' \setminus P \cap P'$ ,

$$\tau''_k = \tau_i \text{ if } p''_k = p_i \in P \quad \text{and} \quad \tau''_k = \tau'_j \text{ if } p''_k = p'_j \in P'.$$

Otherwise,  $p''_k = p_i = p'_j \in P \cap P'$  for some  $i, j$  and  $\tau''_k = \tau'_j \cdot \tau_i$ . Besides, the other of the positions in  $P''$  is chosen so that  $E''$  is well-founded.

Besides, Figure 2 illustrates the elementary CE-strategy  $@q.\tau'$  and its application to the term  $t = \partial_x v(x)$  at the position of the function  $v$  which yields the term  $\llbracket @q.\tau' \rrbracket(t) = \partial_x v_i(x)$ . When an elementary CE-strategy  $@p.\tau$ , where  $p$  is a position, is applied to a term  $t$  at the position  $p$ , the context  $\tau$  is inserted at the position  $p$  of  $t$ , and the subterm of  $t$  at the position  $p$  is inserted at  $\square$ . Figure 3 shows the combination of the two elementary CE-strategy  $@p.\tau$  and  $@q.\tau'$ .

**Fig. 3.** The elementary CE-strategy  $(@q.\tau) \vee (@p.\tau)$ , that is the combination of the two elementary CE-strategies  $@q.\tau$  and  $@p.\tau'$ , and its application to the term  $t = \partial_x v(x)$ , yielding the term  $\partial_{x_j} v_i(x)$ .

**Definition 5 (Combination of two elementary CE-strategies).** *The combination of two elementary CE-strategies is a binary operation  $\vee : \mathcal{E} \times \mathcal{E} \rightarrow \mathcal{E}$  defined for any  $E$  and  $E'$  in  $\mathcal{E}$  by*

$$E \vee E' = \begin{cases} E \wedge E' & \text{if } E \neq \emptyset \text{ and } E' \neq \emptyset \\ E & \text{if } E \neq \emptyset \text{ and } E' = \emptyset \\ E' & \text{if } E = \emptyset \text{ and } E' \neq \emptyset \\ \emptyset & \text{if } E = \emptyset \text{ and } E' = \emptyset \end{cases}$$

**Proposition 1.** *The following hold.*

1. *The set  $\mathcal{E}$  of elementary CE-strategies together with the unification and combination operations enjoys the following properties.*
  - (a) *The neutral element of the unification and combination is  $@\epsilon.\square$ .*
  - (b) *Every elementary CE-strategy  $E$  is idempotent for the unification and combination, i.e.  $E \wedge E = E$  and  $E \vee E = E$ .*
  - (c) *The unification and combination are associative.*
2. *The combination of elementary CE-strategies is non commutative.*

The idempotence follows from the equality  $\text{eval}(\tau \cdot \tau) = \text{eval}(\tau)$ , the associativity follows from the equality  $\text{eval}((\tau_1 \cdot \tau_2) \cdot \tau_3) = \text{eval}(\tau_1 \cdot (\tau_2 \cdot \tau_3))$ , and the non-commutativity is a consequence of  $\text{eval}(\tau_1 \cdot \tau_2) \neq \text{eval}(\tau_2 \cdot \tau_1)$  in general, for any tuples of contexts  $\tau, \tau_1, \tau_2$  and  $\tau_3$ .

## 4 The class of context-embedding strategies (CE-strategies)

We introduced the elementary CE-strategies to clarify the ideas behind contexts, their insertion as well as their combination. However, elementary CE-strategies

are not satisfactory for practical applications, since the positions are generally not accessible and cannot be used on a regular basis in applications. So, we enrich this framework by introducing navigation strategies to form a class of *CE-strategies* that is closed under combination.

#### 4.1 Specification of failure by Boolean formulas

The first enrichment of the elementary CE-strategies is to specify and handle the failure. Assume that we applied the elementary CE-strategy  $E = [@p_1.\tau_1, \dots, @p_n.\tau_n]$  to a term, and assume that one of the  $@p_i.\tau_i$  fails. In this case the whole elementary CE-strategy  $E$  fails. We shall relax this strong failure specification by allowing one to explicitly specify whether the application of a strategy to a term fails depending on the failure of the application of its sub-strategies. In this subsection we propose to specify the failure of by means of Boolean formulas that we next introduce. For this purpose, to each position  $p$  in  $\mathcal{Pos}$ , we associate a Boolean *position-variable* denoted by  $\widehat{p}$ . The idea is that when we apply a CE-strategy, say  $@p.\tau$ , to a term, then we get  $\widehat{p} := \mathbf{True}$  if this application succeeds, and  $\widehat{p} := \mathbf{False}$  if it fails. Assume that we want that the application of the elementary CE-strategy  $[@p_1.\tau_1, @p_2.\tau_2]$  succeeds if the application of  $@p_1.\tau_1$  succeeds *or* the application of  $@p_2.\tau_2$  succeeds. This is specified by the Boolean formula  $\widehat{p}_1 \vee \widehat{p}_2$ .

In what follows, the set of all Boolean position-variables is denoted by  $\widehat{\mathcal{Pos}}$ .

**Definition 6 (Boolean formulas over  $\widehat{\mathcal{Pos}}$ ).** *Let  $\widehat{\mathcal{Pos}}$  be the set of Boolean position-variables. The set of Boolean formulas over  $\widehat{\mathcal{Pos}}$ , denoted by  $\mathcal{Bool}(\widehat{\mathcal{Pos}})$ , is defined by the following grammar:*

$$\mathcal{B} ::= \mathbf{True} \mid \mathbf{False} \mid \widehat{p} \mid \mathcal{B} \wedge \mathcal{B} \mid \mathcal{B} \vee \mathcal{B}$$

where  $\widehat{p} \in \widehat{\mathcal{Pos}}$ . The domain of  $\phi \in \mathcal{Bool}(\widehat{\mathcal{Pos}})$  is defined as the set of position-variables of  $\phi$ . We shall write  $\phi(\widehat{p}_1, \dots, \widehat{p}_n)$  to make the domain  $\{\widehat{p}_1, \dots, \widehat{p}_n\}$  of  $\phi$  explicit. A valuation is a mapping  $\nu : \widehat{\mathcal{Pos}} \rightarrow \{\mathbf{True}, \mathbf{False}\}$ . We say that  $\nu$  validates  $\phi(\widehat{p}_1, \dots, \widehat{p}_n)$ , written  $\nu \models \phi(\widehat{p}_1, \dots, \widehat{p}_n)$ , iff  $\text{eval}(\phi(\nu(\widehat{p}_1), \dots, \nu(\widehat{p}_n))) = \mathbf{True}$ .

If  $\pi = \{\widehat{p}_1, \dots, \widehat{p}_n\}$  is a set of variable-positions, then we shall write  $\bigwedge \pi$  (resp.  $\bigvee \pi$ ) for the Boolean formula  $\widehat{p}_1 \wedge \dots \wedge \widehat{p}_n$  (resp.  $\widehat{p}_1 \vee \dots \vee \widehat{p}_n$ ). In particular,  $\bigwedge \emptyset = \bigvee \emptyset = \mathbf{False}$ .

#### 4.2 Syntax and semantics of CE-strategies

Besides the specification of failure, the second enrichment of the elementary CE-strategies is the introduction of navigation strategies. Namely, we shall introduce the left-choice strategy constructor ( $\oplus$ ), a restricted form of the composition (“;”), and the fixed-point constructor (“ $\mu$ ”) allowing the recursion in the definition of strategies. Thus we obtain the class of CE-strategies. In what follows we assume that there is a denumerable set of *fixed-point variables* denoted by  $\mathcal{Z}$ . Fixed-point variables in  $\mathcal{Z}$  will be denoted by  $X, Y, Z, \dots$

**Definition 7 (CE-strategies).** *The class of CE-strategies is defined by the following grammar:*

$$S ::= \emptyset \mid X \mid (u \rightarrow u); S \mid S \oplus S \mid u \rightarrow u[\tau] \mid \mu X.S \mid @p.S \mid @p.\tau \mid \langle [ @p_1.S_1 \dots, @p_n.S_n ] \mid \phi \rangle$$

where  $X$  is a fixed-point variable in  $\mathcal{Z}$ , and  $u$  is a term in  $\mathcal{T}$ , and  $\tau$  is a tuple of contexts in  $\mathcal{T}_{\square}^{\omega}$  and  $p, p_1, \dots, p_n$  are positions in  $\mathcal{Pos}$ , and  $\phi$  is a Boolean formula in  $\mathcal{Bool}(\widehat{\mathcal{Pos}})$  with  $\text{Dom}(\phi) = \{\widehat{p}_1, \dots, \widehat{p}_n\} \setminus \{\epsilon\}$ . The set of CE-strategies will be denoted by  $\mathcal{C}$ .

The strategy  $@p.S$  means to jump to the position  $p$  and to apply  $S$  there. The strategy  $\langle [ @p_1.S_1 \dots, @p_n.S_n ] \mid \phi \rangle$  consists in applying each of  $@p_i.S_i$ , which yields a valuation that sends the position-variable  $\widehat{p}_i$  to **False** iff the application of  $@p_i.S_i$  fails, then evaluating the Boolean formula  $\phi$ . If this evaluation is false then the whole strategy  $\langle [ @p_1.S_1 \dots, @p_n.S_n ] \mid \phi \rangle$  fails, otherwise, every sub-strategy  $@p_i.S_i$  that failed behaves like the identity, i.e. it does nothing, while the other non-failing sub-strategies  $@p_j.S_j$  are applied. For example, if we apply the CE-strategy  $S = \langle [ @p_1.S_1, @p_2.S_2 ] \mid \widehat{p}_1 \vee \widehat{p}_2 \rangle$  to a term  $t$ , and  $@p_1.S_1$  fails while  $@p_2.S_2$  does not, we get an evaluation  $\nu$  with  $\nu(\widehat{p}_1) = \mathbf{False}$  and  $\nu(\widehat{p}_2) = \mathbf{True}$ . Since  $\nu \models \widehat{p}_1 \vee \widehat{p}_2$ , then the result of the application of  $S$  to  $t$  is precisely the result of the application of  $@p_2.S_2$  to  $t$ , making  $@p_1.S_1$  behaving like the identity.

It's worth mentioning that the aim of incorporation of the Boolean formulas in CE-strategies is to make it expressive enough so we can write the standard traversal strategies (see Example 2). The fragment of CE-strategies without Boolean formulas remains closed under unification and combination.

We shall sometimes write  $\mu X.S(X)$  instead of  $\mu X.S$  to emphasize that the fixed-point variable  $X$  is free in  $S$ .

To define the semantics of CE-strategies we need to introduce an intermediary function  $\eta : \mathfrak{F}(\mathcal{T} \cup \{\mathbb{F}\}) \rightarrow \mathcal{T} \cup \{\mathbb{F}\} \rightarrow \mathcal{T} \cup \{\mathbb{F}\}$ , that stands for the *fail as identity*. It is defined for any function  $f$  in  $\mathfrak{F}(\mathcal{T} \cup \{\mathbb{F}\})$  and any term  $t \in \mathcal{T} \cup \{\mathbb{F}\}$  by

$$(\eta(f))(t) = \begin{cases} f(t) & \text{if } f(t) \neq \mathbb{F} \\ t & \text{otherwise.} \end{cases}$$

Beside, let  $S^{i+1}(S') \stackrel{def}{=} S^i(S(S'))$ , for all any CE-strategies  $S(X)$  and  $S'$  in  $\mathcal{C}$ .

**Definition 8 (Semantics of CE-strategies).** *Given an interpretation  $\mathfrak{f} : \mathcal{Z} \rightarrow \mathfrak{F}(\mathcal{T} \cup \mathbb{F})$  of fixed-point variables in the set of functions over  $\mathcal{T} \cup \mathbb{F}$ , the semantics of an CE-strategy strategy  $S$  is a function  $\llbracket S \rrbracket_{\mathfrak{f}}$  in  $\mathfrak{F}(\mathcal{T} \cup \mathbb{F})$ , which is defined inductively as follows.*

$$\begin{aligned} \llbracket \emptyset \rrbracket_{\mathfrak{f}}(t) &\stackrel{def}{=} \mathbb{F} & \llbracket Z \rrbracket_{\mathfrak{f}}(t) &\stackrel{def}{=} (\mathfrak{f}(Z))(t) \\ \llbracket (u, s') \rrbracket_{\mathfrak{f}}(t) &\stackrel{def}{=} \begin{cases} \llbracket s' \rrbracket_{\mathfrak{f}}(t) & \text{if } u \ll t, \\ \mathbb{F} & \text{otherwise.} \end{cases} & \llbracket @p.\tau \rrbracket_{\mathfrak{f}}(t) &\stackrel{def}{=} \begin{cases} t[\tau(t|_p)]_p & \text{if } p \in \mathcal{Pos}(t) \\ \mathbb{F} & \text{otherwise} \end{cases} \end{aligned}$$

$$\llbracket S_1 \oplus S_2 \rrbracket_{\mathfrak{f}}(t) \stackrel{def}{=} \begin{cases} \llbracket S_1 \rrbracket_{\mathfrak{f}}(t) & \text{if } \llbracket S_1 \rrbracket_{\mathfrak{f}}(t) \neq \mathbb{F} \\ \llbracket S_2 \rrbracket_{\mathfrak{f}}(t) & \text{otherwise.} \end{cases} \quad \llbracket \mu X.S(X) \rrbracket_{\mathfrak{f}}(t) \stackrel{def}{=} \llbracket \bigoplus_{i=1, \delta(t)} S^i(\emptyset) \rrbracket_{\mathfrak{f}}(t)$$

$$\llbracket @p.S \rrbracket_{\mathfrak{f}}(t) \stackrel{def}{=} \begin{cases} t[\llbracket S \rrbracket(t|_p)]_p & \text{if } \llbracket s \rrbracket_{\mathfrak{f}}(t|_p) \neq \mathbb{F} \text{ and } p \in \mathcal{Pos}(t) \\ \mathbb{F} & \text{otherwise} \end{cases}$$

$$\llbracket \langle \bigsqcup_{i=1, n} @p_i.S_i \mid \phi \rangle \rrbracket_{\mathfrak{f}}(t) \stackrel{def}{=} \begin{cases} (\eta(\llbracket @p_n.S_n \rrbracket_{\mathfrak{f}}) \circ \dots \circ \eta(\llbracket @p_1.S_1 \rrbracket_{\mathfrak{f}}))(t) & \text{if } \mathcal{V}_{\mathfrak{f}}(S, t) \models \phi \\ \mathbb{F} & \text{otherwise} \end{cases}$$

where  $S = [ @p_1.S_1, \dots, @p_n.S_n ]$ , and

$$\mathcal{V}_{\mathfrak{f}}(S, t)(\hat{p}_i) = \text{False iff } \llbracket @p_i.S_i \rrbracket_{\mathfrak{f}}(t) = \mathbb{F}$$

If the CE-strategy strategy  $S$  is closed, i.e. all its fixed-point variables are bound, then we shall simply write  $\llbracket S \rrbracket$  instead of  $\llbracket S \rrbracket_{\mathfrak{f}}$ , and  $\mathcal{V}(S, t)$  instead of  $\mathcal{V}_{\mathfrak{f}}(S, t)$ .

For any CE-strategies  $S, S'$  in  $\mathcal{C}$ , we shall write  $S \equiv S'$  iff  $\llbracket S \rrbracket = \llbracket S' \rrbracket$ . To simplify the presentation, we shall write  $(u, S)$  instead of  $(u \rightarrow u); S$  and we shall write  $(u, \tau)$  instead of  $u \rightarrow u[\tau]$ .

*Example 2.* We show how to encode some standard traversal strategies in our formalism using the fixed-point constructor. In what follows we assume that  $S$  is an CE-strategy. We recall that, when applied to a term  $t$ , the CE-strategy  $\text{OneLeft}(S)$  tries to apply  $S$  to the subterm of  $t$  (if any) which is the closest to the root and on the far-left. The CE-strategy  $\text{TopDown}(S)$  tries to apply  $S$  to the maximum of the sub-terms of  $t$  starting from the root of  $t$ , it stops when it is successfully applied. Hence,

$$\text{OneLeft}(S) = \mu X.(S \oplus \bigoplus_{f \in \mathcal{F}, ar(f)=n} (f(x_1, \dots, x_n), \bigoplus_{i=1, n} \langle [ @i.X \mid \bigvee_{i=1, n} \hat{i} \rangle \rangle)),$$

$$\text{TopDown}(S) = \mu X.(S \oplus \bigoplus_{f \in \mathcal{F}, ar(f)=n} (f(x_1, \dots, x_n), \langle [ @1.X, \dots, @i.X \mid \bigvee_{i=1, n} \hat{i} \rangle \rangle)).$$

We generalize next the condition of well-foundedness from elementary CE-strategies to CE-strategies. Before that, it is helpful to view an CE-strategy as a tree with back-edges. A tree with back-edges is an oriented tree with possible edges going from a node to at most one of its ancestors in the tree. (See Fig. 4 in the Appendix for an example).

**Definition 9 (Well-founded CE-strategies.).** *A CE-strategy  $S$  is well-founded iff*

- i.) Every cycle in  $S$  passes through a position delimiter<sup>3</sup>.*

<sup>3</sup> This constraint is similar to the one imposed on the modal  $\mu$ -calculus formulas in which each cycle has to pass through a modality [1].

- ii.) All its sub-strategies of the form  $\langle [\textcircled{p}_1.S_1, \dots, \textcircled{p}_n.S_n, \textcircled{q}_1.\tau_1, \dots, \textcircled{q}_m.\tau_m] \mid \phi \rangle$ , where  $n + m \geq 1$  and  $p_i, q_j$  are positions and  $\tau_i$  are tuples of contexts in  $T_{\square}^{\omega}$  and  $S_i$  are CE-strategies, are subject to the following conditions:
- (a)  $q_i \sqsubset q_j$ , for all  $i < j$ , where  $i, j \in [m]$ , and
  - (b)  $p_i \parallel p_j$ , for all  $i \neq j$ , where  $i, j \in [n]$ , and
  - (c)  $q_j \sqsubset p_i$ , for all  $j \in [m]$  and  $i \in [n]$ .

For instance the CE-strategy  $\mu X.((f(x), \tau) \oplus X)$  is not well-founded because the cycle that corresponds to the regeneration of the variable  $X$  does not cross a position delimiter, while the CE-strategy  $\mu X.((f(x), \tau) \oplus (\textcircled{1}.X))$  is well-founded. In all what follows we assume that the CE-strategies are well-founded. The set of well-founded CE-strategies is still denoted by  $\mathcal{C}$ . Notice that any CE-strategy is terminating. This is a direct consequence of Item (i) of the well-foundedness of CE-strategies, that is, every cycle in a well-founded CE-strategy passes through a position delimiter.

The set of Boolean formulas (resp. positions) of an CE-strategy  $S$ , will be denoted by  $\Phi(S)$  (resp.  $\mathcal{P}os(S)$ ). It is defined in a straightforward way (See Definition 14 in the Appendix).

### 4.3 Canonic form of CE-strategies

Instead of the direct combination of CE-strategies, we shall first simplify the CE-strategies by turning each CE-strategy into an equivalent CE-strategy in the *canonic form*. A CE-strategy is in the canonic form if each of its Boolean formulas is a conjunction of position-variables, where each position-variable is in  $\widehat{\mathbb{N}}_{\epsilon}$  instead of  $\widehat{\mathcal{P}os}$ . The advantage of the use of canonic CE-strategies is that their combination is much simpler.

**Definition 10 (Canonic form of CE-strategies).** *An CE-strategy strategy  $S$  is in the canonic form iff any Boolean formula  $\phi$  in  $\Phi(S)$  is of the form  $\phi = \bigwedge_i \widehat{p}_i$ , where  $\widehat{p}_i \in \widehat{\mathbb{N}}_{\epsilon}$ .*

It follows that if a CE-strategy strategy  $S$  is in the canonic form, then we have  $\mathcal{P}os(S) \subset \mathbb{N}_{\epsilon}$ .

**Lemma 1.** *Any CE-strategy can be turned into an equivalent CE-strategy in the canonic form.*

*Proof.* (Sketch) Firstly, we turn all the Boolean formulas of the CE-strategy into formulas in the disjunctive normal form. Then we express the disjunction in terms of the left-choice strategy (Lemmas 5 and 6 in Appendix). Secondly, we turn each position in  $\mathcal{P}os$  into a secession of positions in  $\mathbb{N}_{\epsilon}$  (Lemmas 7 in Appendix). We rely on observation that CE-strategy  $\textcircled{i}(ip).S$  is equivalent to  $\textcircled{i}.\textcircled{p}.S$ , where  $i \in \mathbb{N}_{\epsilon}$  and  $p \in \mathcal{P}os$ .  $\square$

#### 4.4 From CE-strategies to elementary CE-strategies

Out of a CE-strategy and a term it is possible to construct an elementary CE-strategy. The main purpose of this mapping is to formulate a correctness-completeness criterion for the unification and combination of CE-strategies in terms of elementary CE-strategies. Roughly speaking, this criterion imposes that the mapping of the combination of two CE-strategies is equivalent to the combination of their respective mapping. The definition of this mapping follows.

**Definition 11.** Define the function  $\Psi : \mathcal{C} \times \mathcal{T} \rightarrow \mathcal{E}$ , that associates to each closed CE-strategy  $S$  in  $\mathcal{C}$  and a term  $t$  in  $\mathcal{T}$  an elementary CE-strategy  $\Psi(S, t)$  in  $\mathcal{E}$  by

$$\begin{aligned} \Psi(\emptyset, t) &= \emptyset & \Psi(@p.\tau, t) &= @p.\tau \\ \Psi((u, \tau), t) &= \begin{cases} (\epsilon, \tau) & \text{if } u \ll t \\ \emptyset & \text{otherwise} \end{cases} & \Psi((u, S), t) &= \begin{cases} \Psi(S, t) & \text{if } u \ll t \\ \emptyset & \text{otherwise} \end{cases} \\ \Psi(\langle \bigsqcup_{i \in [n]} @p_i.\tau_i \mid \phi \rangle, t) &= \bigsqcup_{i \in [n]} @p_i.\tau_i & \Psi(@p.S, t) &= @p \cdot \Psi(S, t_{|p}) \\ \Psi(S_1 \oplus S_2, t) &= \begin{cases} \Psi(S_1, t) & \text{if } \Psi(S_1, t) \neq \emptyset \\ \Psi(S_2, t) & \text{otherwise} \end{cases} & \Psi(\mu X.S(X), t) &= \Psi\left(\bigoplus_{i=1, \delta(t)} S^i(\emptyset), t\right) \end{aligned}$$

If  $S = \sqcup_{i \in [n]} @p_i.S_i$ , then

$$\Psi(\langle S \mid \phi \rangle, t) = \begin{cases} \bigsqcup_{i \in [n]} @p_i.\eta(\Psi(S_i, t_{|p_i})) & \text{if } \mathcal{V}(S, t) \models \phi \\ \emptyset & \text{otherwise} \end{cases}$$

The application of the elementary CE-strategy  $\Psi(S, t)$  to the term  $t$  will be simply written as  $\Psi(S, t)(t)$  instead of  $\llbracket \Psi(S, t) \rrbracket(t)$ .

It turns out that the function  $\Psi$  (Definition 11) preserves the semantics of CE-strategies in the following sense.

**Lemma 2.** For any CE-strategy  $S$  in  $\mathcal{C}$  and any term  $t$  in  $\mathcal{T}$ , we have  $\llbracket S \rrbracket(t) = \Psi(S, t)(t)$ .

The proof of this Lemma does not provide any difficulties since the definition of  $\Psi$  is close to the definition of the semantics of CE-strategies. One can show that  $\Psi$  enjoys further properties.

**Lemma 3.** The function  $\Psi$  enjoys the following properties.

- i.) For any elementary CE-strategies  $E_1, E_2$  in  $\mathcal{E}$ , we have that  $E = E'$  iff  $\Psi(E, t) = \Psi(E', t)$  for any term  $t$ .
- ii.) For any CE-strategies  $S_1, S_2$  in  $\mathcal{C}$ , we have that  $S \equiv S'$  iff  $\Psi(S, t) = \Psi(S', t)$  for any term  $t$ .

## 5 Unification and combination of CE-strategies

The problem of the closure of the class of CE-strategies under combination asks whether, for any two CE-strategies  $S_1, S_2 \in \mathcal{C}$ , there exists a third CE-strategy  $S \in \mathcal{C}$  such that for every term  $t \in \mathcal{T}$ , we have that  $\Psi(S_1, t) \vee \Psi(S_2, t) = \Psi(S, t)$ . This can be understood as a correctness-completeness criterion of the combination of CE-strategies given in terms of the elementary CE-strategies. We define the combination of CE-strategies by means of their unification. Morally, this concept amounts to merging algebraic infinite trees introduced in [8], since CE-strategies can be viewed as infinite trees by unraveling their tree with back-edges like structure (Figure 4).

**Definition 12 (Unification of CE-strategies).** *The unification of CE-strategies (in the canonic form) is a binary operation  $\wedge : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C}$  inductively defined as follows.*

$$\begin{aligned}
\emptyset \wedge S &= \emptyset. & S \wedge \emptyset &= \emptyset. \\
@i.\tau \wedge @i.\tau' &= @i.(\tau \cdot \tau'). & @i.\tau \wedge @j.\tau' &= [@i.\tau, @j.\tau'], \text{ if } j \sqsubset i. \\
@i.\tau \wedge @i.S &= @i.(@\epsilon.\tau \wedge S). & @i.\tau \wedge @j.S &= [@i.\tau, @j.S], \text{ if } j \sqsubset i. \\
\\
(u, \tau) \wedge @i.\tau' &= (u, @\epsilon.\tau \wedge @i.\tau'), & (u, \tau) \wedge @i.\tau' &= \emptyset, \\
&\text{if } i \in [ar(u)] \cup \{\epsilon\}. & &\text{if } i \notin [ar(u)] \cup \{\epsilon\}. \\
@i.\tau \wedge (u, S) &= (u, (@i.\tau) \wedge S), & @i.\tau \wedge (u, S) &= \emptyset, \\
&\text{if } [ar(u)] \cup \{\epsilon\}. & &\text{if } i \notin [ar(u)] \cup \{\epsilon\}. \\
(u, \tau) \wedge (u', S') &= (u \wedge u', (@\epsilon.\tau \wedge S')). & (u, S) \wedge (u', S') &= (u \wedge u', S \wedge S').
\end{aligned}$$

For the rest, let  $\mathcal{L} = \bigsqcup_{i \in \mathcal{I}} @i.S_i \sqcup @\epsilon.\tau$  and  $\mathcal{L}' = \bigsqcup_{j \in \mathcal{J}} @j.S'_j \sqcup @\epsilon.\tau'$ . Define  $\mathcal{L}_1 = \bigsqcup_{i \in \mathcal{I} \cap \mathcal{J}} @i.(S_i \wedge S'_i)$ , and  $\mathcal{L}_2 = \bigsqcup_{i \in \mathcal{I} \setminus \mathcal{J}} @i.S_i$  and  $\mathcal{L}_3 = \bigsqcup_{i \in \mathcal{J} \setminus \mathcal{I}} @i.S'_i$ ,

$$\begin{aligned}
(u, S) \wedge \langle \mathcal{L} \mid \phi \rangle &= (u, S \wedge \langle \mathcal{L} \mid \phi \rangle). & \langle \mathcal{L} \mid \phi \rangle \wedge \langle \mathcal{L}' \mid \phi' \rangle &= \langle \mathcal{L}_1 \sqcup \mathcal{L}_2 \sqcup \mathcal{L}_3 \mid \phi \wedge \phi' \rangle. \\
(S_1 \oplus S_2) \wedge S &= (S_1 \wedge S) \oplus (S_2 \wedge S).
\end{aligned}$$

For the fixed-point CE-strategies,

$$\begin{aligned}
(\mu X.S(X)) \wedge S' &= S''(\mu X.S(X)), \text{ where } S''(X) = S(X) \wedge S' \text{ and } S' \text{ is } \dots \\
(\mu X.S(X)) \wedge (\mu X'.S'(X')) &= \mu Z.S''(\mu X.S(X), \mu X'.S'(X'), Z), \\
&\text{where } S''(X, X', Z) = [S(X) \wedge S'(X')]_{|X \wedge X' := Z}.
\end{aligned}$$

**Comments.** We comment on the key points in Definition 12. The unification of  $(u, S)$  with  $(u', S')$  is naturally  $(u \wedge u', S \wedge S')$  since we want to merge them. The idea behind the unification of  $\mu X.S(X)$  with  $\mu X'.S'(X')$  is to unfold  $\mu X.S(X)$  (resp.  $\mu X'.S'(X')$ ) to  $S(\mu X.S(X))$  (resp.  $S'(\mu X'.S'(X'))$ ) and to combine the resulting CE-strategy. This is achieved by firstly unifying  $S(X)$  with  $S'(X')$ ,

where clearly the fixed-point variable  $X$  (resp.  $X'$ ) being free in  $S(X)$  (res.  $S'(X')$ ). The resulting CE-strategy  $S''(X, X', X \lambda X')$  features three free fixed-point variables. The key point is to view  $X \lambda X'$  as a fresh fixed-point variable, say  $Z$ , and to bind it to the full expression  $S''(\mu X.S(X), \mu X'.S'(X'), Z)$ , meaning that  $Z$  corresponds exactly to the CE-strategy that we are defining.

*Example 3.* Let  $S(X) = (u, \tau) \oplus @1.X$  and  $S'(X') = (u', \tau') \oplus @1.X'$ , be two CE-strategies. We compute  $\mu X.S(X) \lambda \mu X'.S'(X')$ . Firstly, the unification  $(*)$  of  $S(X)$  and  $S'(X')$  yields:

$$\begin{aligned} (*) &= S(X) \lambda S'(X') \\ &= ((u, \tau) \oplus @1.X) \lambda ((u', \tau') \oplus @1.X') \\ &= ((u, \tau) \lambda (u', \tau')) \oplus (@1.X \lambda (u', \tau')) \oplus ((u', \tau) \lambda @1.X') \oplus (@1.X \lambda @1.X') \\ &= (u \lambda u', \tau' \cdot \tau) \oplus (u, [@1.X', @\epsilon.\tau]) \oplus (u', [@1.X, @\epsilon.\tau]) \oplus (@1.(X \lambda X')). \end{aligned}$$

Hence, combination of  $\mu X.S(X)$  and  $\mu X'.S'(X')$  is

$$\begin{aligned} (\mu X.S(X)) \lambda (\mu X'.S'(X')) &= \mu Z.((u \lambda u', \tau' \cdot \tau) \oplus (u, [@1.(\mu X'.S'(X')), @\epsilon.\tau]) \oplus \\ &\quad (u', [@1.(\mu X.S(X)), @\epsilon.\tau']) \oplus (@1.Z)). \end{aligned}$$

**Definition 13 (Combination of CE-strategies).** *The combination of CE-strategies is a binary operation  $\gamma : \mathcal{C} \times \mathcal{C} \rightarrow \mathcal{C}$ , defined for any  $\mathcal{S}_1$  and  $\mathcal{S}_2$  in  $\mathcal{C}$  by  $\mathcal{S}_1 \gamma \mathcal{S}_2 \stackrel{\text{def}}{=} (\mathcal{S}_1 \lambda \mathcal{S}_2) \oplus \mathcal{S}_1 \oplus \mathcal{S}_2$ .*

### 5.1 The correction and completeness of the unification and combination of CE-strategies

Now we are ready to state one of the main results of this paper. We shall argue that the unification of CE-strategies is sound and complete.

**Theorem 1.** *For every term  $t \in \mathcal{T}$  and for every CE-strategies  $S$  and  $S'$  in  $\mathcal{C}$  in the canonic form, we have that  $\Psi(S \lambda S', t) = \Psi(S, t) \lambda \Psi(S', t)$ .*

Similarly, the combination of the CE-strategies is sound and complete. The following Theorem is a consequence of Theorem 1.

**Theorem 2.** *For every term  $t \in \mathcal{T}$ , for every CE-strategies  $S$  and  $S'$  in  $\mathcal{C}$ , we have that  $\Psi(S \gamma S', t) = \Psi(S, t) \gamma \Psi(S', t)$ .*

Thanks to the fact that the function  $\Psi$  is an homomorphism (in the first argument), Theorems 1 and 2, one can transfer all the properties of the combination and unification of elementary CE-strategies (stated in Proposition 1) to CE-strategies, yielding:

**Proposition 2.** *The following hold.*

1. *The set  $\mathcal{C}$  of CE-strategies together with the unification and combination operations enjoy the following properties.*

- (a) The neutral element of the unification and combination is  $@\epsilon.\square$ .
  - (b) Every CE-strategy  $S$  is idempotent for the unification and combination, i.e.  $S \wedge S = S$  and  $S \vee S = S$ .
  - (c) The unification and combination are associative.
2. For any CE-strategies  $S$  and  $S'$  in  $\mathcal{C}$ , and for any term  $t$  in  $\mathcal{T}$ , we have that  $\Psi(S \wedge S', t) = \emptyset$ , iff  $\Psi(S, t) = \emptyset$  or  $\Psi(S', t) = \emptyset$ .
  3. The unification and combination of CE-strategies is a congruence, that is, for any CE-strategies  $S_1, S_2$  and  $S$  in  $\mathcal{C}$ , we have that: If  $S_1 \equiv S_2$  then  $S_1 \wedge S \equiv S_2 \wedge S$  and  $S \wedge S_1 \equiv S \wedge S_2$ . Besides, If  $S_1 \equiv S_2$  then  $S_1 \vee S \equiv S_2 \vee S$  and  $S \vee S_1 \equiv S \vee S_2$ .

## 6 Conclusion and future work

We have addressed the key problem of extension and combination of proofs encountered in the field of computer aided asymptotic model derivation. Precisely, an operation of combination over a class of extensions named CE-strategies, expressed as rewriting strategies that navigate along trees and insert contexts, has been identified. It has been proved that the class is closed by combination, and explicit formulae of combinations have been established. We also have introduced a correctness criteria that has the power to guaranty the validity of a combination formula. All of them have been rigorously proved, which is an important piece of this work. It was also shown that usual traversal strategies as `TopDown` or `BottomUp` belong to the class of CE-strategies. Finally, it is worth noting that we identified the class of CE-strategies as belonging to the framework of  $\mu$ -calculus. Therefore, we envision consequences of these results on the study of the syntactic (or modulo a theory) unification and the pattern-matching of infinite trees once the infinite trees are expressed as algebraic  $\mu$ -terms in the same way we expressed the iterative strategies. Thus, a rewriting language that transforms algebraic infinite trees can be elaborated. [[Our technique of unification and combination involving  $\mu$ -terms is novel.]]

## Appendix: detailed proofs for reviewers

### 7 Proofs for preliminary section 2

**Fact 3** *Let  $u, t$  be two terms and  $\gamma, \gamma'$  two substitutions. We have that, if  $\gamma(u) \ll t$  and  $\gamma$  is subsumed by  $\gamma'$ , then  $\gamma'(u) \ll t$  as well.*

**Lemma 4.** *Let  $u, u', t$  be terms in  $\mathcal{T}$ . Then,*

$$(u \wedge u') \ll t \quad \text{iff} \quad u \ll t \text{ and } u' \ll t.$$

*Proof.* For the direction  $(\Rightarrow)$ , let  $\gamma$  be the most general unifier of  $u$  and  $u'$ , and  $\alpha$  be a substitution such that  $\alpha(u \wedge u') = t$ . This means that  $\alpha(\gamma(u)) = t$  and  $\alpha(\gamma(u')) = t$ . That is,  $\gamma(u) \ll t$  and  $\gamma(u') \ll t$ .

For the direction  $(\Leftarrow)$ , let  $\sigma$  and  $\sigma'$  be substitutions such that  $\sigma(u) = t$  and  $\sigma'(u') = t$ . Consider the decomposition  $\sigma = \sigma_1 \uplus \sigma_2$  and  $\sigma' = \sigma'_1 \uplus \sigma'_2$ , where  $\text{Dom}(\sigma_1) \cap \text{Dom}(\sigma'_1) = \emptyset$  and  $\text{Dom}(\sigma_2) = \text{Dom}(\sigma'_2)$ . Since  $\sigma(u) = \sigma'(u')$ , it follows that  $\sigma_2 = \sigma'_2$ . But this means that  $\sigma_2(u) = \sigma_2(u')$ , and  $\sigma_2(u) \ll t$ . In other words,  $u$  and  $u'$  can be unified. Let  $\gamma$  be the most general unifier of  $u$  and  $u'$ . But since  $\sigma_2(u) \ll t$  and  $\sigma_2$  is subsumed by  $\gamma$ , then it follows from Fact 3 that  $\gamma(u) \ll t$ .

### 8 Proofs and formal definitions for section 4

#### 8.1 CE-strategies as tree-with back edges

It is helpful to view CE-strategies as trees with back-edges. For instance, the tree-like structure of the CE-strategy  $S(X) = (f(x), \tau) \oplus (@1.X)$ , where the fixed-point variable  $X$  being free, is depicted on the left of Figure 4. While the tree with back-edge related to  $\mu X.S(X)$  is depicted on the right.

**Fig. 4.** The tree-like structure of the CE-strategy  $S(X) = (f(x), \tau) \oplus (@1.X)$  (left) and  $\mu X.S(X)$  (right).

#### 8.2 Set of Boolean formulas and positions of a CE-strategy

**Definition 14 (Set of Boolean formulas and positions of a CE-strategy).**

*The set of Boolean formulas (resp. positions) of an CE-strategy  $S$ , denoted by*

$\Phi(S)$  (resp.  $\mathcal{P}os(S)$ ), is inductively defined by

$$\begin{array}{ll}
\Phi(@p.\tau) = \emptyset & \mathcal{P}os(@p.\tau) = \{p\} \\
\Phi((u, \tau)) = \emptyset & \mathcal{P}os((u, \tau)) = \emptyset \\
\Phi(X) = \emptyset & \mathcal{P}os(X) = \emptyset \\
\Phi((u, S)) = \Phi(S) & \mathcal{P}os((u, S)) = \mathcal{P}os(S) \\
\Phi(\bigoplus_{i \in [n]} S_i) = \bigcup_{i \in [n]} \Phi(S_i) & \mathcal{P}os(\bigoplus_{i \in [n]} S_i) = \bigcup_{i \in [n]} \mathcal{P}os(S_i) \\
\Phi(\langle \bigsqcup_{i \in [n]} @p_i.S_i \mid \phi \rangle) = \{\phi\} \cup \bigcup_{i \in [n]} \Phi(S_i) & \mathcal{P}os(\langle \bigsqcup_{i \in [n]} @p_i.S_i \mid \phi \rangle) = \bigcup_{i \in [n]} \{p_i\} \cup \mathcal{P}os(S_i) \\
\Phi(\mu X.S(X)) = \Phi(S(X)) & \mathcal{P}os(\mu X.S(X)) = \mathcal{P}os(S(X))
\end{array}$$

### 8.3 Depth of CE-strategies

Taking into account that the structure of a CE-strategy is no longer a tree but a tree with back-edges that may contains cycles, we slightly modify the standard measure of the depth of trees in order to capture both the number of nested loops, caused by the nested application of the constructor  $\mu$ , and the distance from the root of the tree to the leaves. Many proofs will be done by induction with respect to this measure.

**Definition 15 (Depth of a CE-strategy).** *The depth of an CE-strategy is function  $\Delta : \mathcal{C} \rightarrow \mathbb{N} \times \mathbb{N}$  defined inductively as follows.*

$$\begin{aligned}
\Delta(@p.\tau) &= (0, 0) \\
\Delta((u, \tau)) &= (0, 0) \\
\Delta(X) &= (0, 0) \\
\Delta((u, S)) &= (0, 1) + \Delta(S) \\
\Delta(S_1 \oplus \dots \oplus S_n) &= (0, 1) + \max(\Delta(S_1), \dots, \Delta(S_n)) \\
\Delta(\langle @p_n.S_1, \dots, @p_n.S_n \mid \phi \rangle) &= (0, 1) + \max(\Delta(S_1), \dots, \Delta(S_n)) \\
\Delta(\mu X.S(X)) &= (1, 0) + \Delta(S(X))
\end{aligned}$$

We shall denote by  $<, \leq$  and  $>, \geq$  the related lexicographic orders on  $\mathbb{N} \times \mathbb{N}$ .

Notice that if a CE-strategy  $S$  is iteration-free, i.e. it does not contain the constructor  $\mu$ , then its depth  $\Delta(S) = (0, n)$ , for some  $n \in \mathbb{N}$ .

### 8.4 Canonic form of CE-strategies

**Lemma 5.** *Let  $p_1, \dots, p_n$  be parallel positions in  $\mathcal{P}os$ , and  $S_1, \dots, S_n$  be CE-strategies, with  $n \geq 1$ . Let  $\pi, \pi' \subseteq \{\hat{p}_1, \dots, \hat{p}_n\}$  with  $\pi \cup \pi' = \{\hat{p}_1, \dots, \hat{p}_n\}$  and*

let  $\phi = \bigwedge \pi$  and  $\phi' = \bigwedge \pi'$  be Boolean formulas. Let  $\mathcal{S} = [\textcircled{p}_1.S_1, \dots, \textcircled{p}_n.S_n]$ . Then we have the equivalence

$$\begin{aligned} \langle \mathcal{S} \mid \phi \vee \phi' \rangle &\equiv \langle \mathcal{S} \mid \phi \wedge \phi' \rangle \oplus \\ &\quad \bigoplus_{\substack{\varphi' \subset \pi' \\ |\varphi'| = |\pi'| - 1}} \langle \mathcal{S}_{|\pi \cup \varphi'} \mid \phi \wedge \phi'_{|\varphi'} \rangle \oplus \dots \oplus \bigoplus_{\substack{\varphi' \subset \pi' \\ |\varphi'| = 1}} \langle \mathcal{S}_{|\pi \cup \varphi'} \mid \phi \wedge \phi'_{|\varphi'} \rangle \oplus \\ &\quad \bigoplus_{\substack{\varphi \subset \pi \\ |\varphi| = |\pi| - 1}} \langle \mathcal{S}_{|\varphi \cup \pi'} \mid \phi_{|\varphi} \wedge \phi' \rangle \oplus \dots \oplus \bigoplus_{\substack{\varphi \subset \pi \\ |\varphi| = 1}} \langle \mathcal{S}_{|\varphi \cup \pi'} \mid \phi_{|\varphi} \wedge \phi' \rangle \quad (1) \end{aligned}$$

*Proof.* Recall that

$$\llbracket \langle \mathcal{S} \mid \phi \vee \phi' \rangle \rrbracket(t) = \begin{cases} (\llbracket \eta(\textcircled{p}_n.S_n) \rrbracket \circ \dots \circ \llbracket \eta(\textcircled{p}_1.S_1) \rrbracket)(t) & \text{if } \mathcal{V}(\mathcal{S}, t) \models \phi \vee \phi', \\ \mathbb{F} & \text{otherwise.} \end{cases}$$

We discuss four cases depending on whether  $\mathcal{V}(\mathcal{S}, t) \models \phi$  or  $\mathcal{V}(\mathcal{S}, t) \models \phi'$ .

1. If  $\mathcal{V}(\mathcal{S}, t) \models \phi$  and  $\mathcal{V}(\mathcal{S}, t) \models \phi'$ , then in this case

$$\mathcal{V}(\mathcal{S}, t) \models \phi \wedge \phi' \quad \text{and} \quad \llbracket \langle \mathcal{S} \mid \phi \vee \phi' \rangle \rrbracket(t) = \llbracket \langle \mathcal{S} \mid \phi \wedge \phi' \rangle \rrbracket(t).$$

Thus Eq. (1) holds.

2. If  $\mathcal{V}(\mathcal{S}, t) \models \phi$  and  $\mathcal{V}(\mathcal{S}, t) \not\models \phi'$ , then we must show that

$$\llbracket \langle \mathcal{S} \mid \phi \wedge \phi' \rangle \rrbracket(t) = \mathbb{F}, \quad (2)$$

and

$$\exists! \varphi' \subset \pi', \quad \llbracket \langle \mathcal{S} \mid \phi \vee \phi' \rangle \rrbracket(t) = \llbracket \langle \mathcal{S}_{|\pi \cup \varphi'} \mid \phi \wedge \phi'_{|\varphi'} \rangle \rrbracket(t), \quad (3)$$

and

$$\begin{aligned} \forall \varrho' \subset \pi', \text{ where } |\varrho'| \geq |\varphi'| \text{ and} \\ \varrho' \neq \varphi', \quad \llbracket \langle \mathcal{S}_{|\pi \cup \varrho'} \mid \phi \wedge \phi'_{|\varrho'} \rangle \rrbracket(t) = \mathbb{F}. \end{aligned} \quad (4)$$

However, Eq. (2) follows from the fact that  $\mathcal{V}(\mathcal{S}, t) \models \phi$  and  $\mathcal{V}(\mathcal{S}, t) \not\models \phi'$ .

To prove Eq. (3), we let

$$\varphi' \stackrel{def}{=} \{\widehat{p}_i \in \pi \mid \mathcal{V}(\mathcal{S}, t)(\widehat{p}_i) = \mathbf{True}\} \cap \pi'.$$

Hence,  $\mathcal{V}(\mathcal{S}, t) \models \phi \vee \phi'$  if and only if  $\mathcal{V}(\mathcal{S}_{|\pi \cup \varphi'}, t) \models \phi \wedge \phi'_{|\varphi'}$ . Besides,

$$\forall \widehat{p}_i \in \pi \cup \pi', \quad \llbracket \eta(\textcircled{p}_i.S_i) \rrbracket(t) = \begin{cases} \llbracket \textcircled{p}_i.S_i \rrbracket(t) & \text{if } \mathcal{V}(\mathcal{S}, t)(\widehat{p}_i) = \mathbf{True} \\ t & \text{otherwise,} \end{cases}$$

and

$$\forall \widehat{p}_i \in \pi \cup \wp', \llbracket \eta(@p_i.S_i) \rrbracket(t) = \llbracket @p_i.S_i \rrbracket(t) \quad \text{and} \quad \mathcal{V}(\mathcal{S}_{|\pi \cup \wp'}, t)(\widehat{p}_i) = \mathbf{True}.$$

Summing up, Eq. (3) holds.

To prove Eq. (4), we notice that there exists  $\widehat{p} \in \wp'$  such that  $\mathcal{V}(\mathcal{S}, t)(\widehat{p}) = \mathbf{False}$ , and hence  $\mathcal{V}(\mathcal{S}_{\pi \cup \wp'}, t) \not\models \phi'_{|\wp'}$ , making  $\llbracket \langle \mathcal{S}_{|\pi \cup \wp'} | \phi \wedge \phi'_{|\wp'} \rangle \rrbracket(t) = \mathbb{F}$ .

Thus Eq. (1) holds.

3. If  $\mathcal{V}(\mathcal{S}, t) \not\models \phi$  and  $\mathcal{V}(\mathcal{S}, t) \models \phi'$ , then this case is similar to the case when  $\mathcal{V}(\mathcal{S}, t) \models \phi$  and  $\mathcal{V}(\mathcal{S}, t) \not\models \phi'$  discussed above in Item 2.
4. If  $\mathcal{V}(\mathcal{S}, t) \not\models \phi$  and  $\mathcal{V}(\mathcal{S}, t) \not\models \phi'$ , then in this case

$$\begin{aligned} \llbracket \langle \mathcal{S} | \phi \vee \phi' \rangle \rrbracket(t) &= \mathbb{F}, \quad \text{and} \\ \forall \wp' \subset \pi', \llbracket \langle \mathcal{S}_{|\pi \cup \wp'} | \phi \wedge \phi'_{|\wp'} \rangle \rrbracket(t) &= \mathbb{F}, \quad \text{and} \quad \forall \wp \subset \pi, \llbracket \langle \mathcal{S}_{|\wp \cup \pi'} | \phi_{|\wp} \wedge \phi' \rangle \rrbracket(t) = \mathbb{F}, \end{aligned}$$

making the Eq. (1) hold.

**Lemma 6.** *Let  $p_1, \dots, p_n$  be parallel positions in  $\mathcal{P}os$ , and  $S_1, \dots, S_n$  be CE-strategies, with  $n \geq 1$ . Let  $\pi = \{\widehat{p}_1, \dots, \widehat{p}_n\}$  and Let  $\mathcal{S} = [ @p_1.S_1, \dots, @p_n.S_n ]$ . Then we have the equivalence*

$$\langle \mathcal{S} | \bigvee \pi \rangle \equiv \left( \bigoplus_{\substack{\wp \subseteq \pi \\ |\wp| = |\pi|}} \langle \mathcal{S}_{|\wp} | \bigwedge \wp \rangle \right) \oplus \dots \oplus \left( \bigoplus_{\substack{\wp \subseteq \pi \\ |\wp| = 0}} \langle \mathcal{S}_{|\wp} | \bigwedge \wp \rangle \right) \quad (5)$$

*Proof.* We recall that

$$\langle \mathcal{S} | \bigvee \pi \rangle(t) = \begin{cases} (\llbracket \eta(@p_n.S_n) \rrbracket \circ \dots \circ \llbracket \eta(@p_1.S_1) \rrbracket)(t) & \text{if } \mathcal{V}(\mathcal{S}, t) \models \bigvee \pi, \\ \mathbb{F} & \text{otherwise.} \end{cases}$$

Out of the valuation  $\mathcal{V}(\mathcal{S}, t)$ , we shall show that there exists a unique  $\wp \subseteq \pi$  such that

$$\llbracket \langle \mathcal{S} | \bigvee \pi \rangle \rrbracket(t) = \llbracket \langle \mathcal{S}_{|\wp} | \bigwedge \wp \rangle \rrbracket(t), \quad (6)$$

and that for all  $\wp' \subseteq \pi$  where  $|\wp'| \geq |\wp|$  and  $\wp' \neq \wp$ , we have that

$$\llbracket \langle \mathcal{S}_{|\wp'} | \bigwedge \wp' \rangle \rrbracket(t) = \mathbb{F}. \quad (7)$$

For this purpose, we define  $\wp$  by

$$\wp \stackrel{def}{=} \{\widehat{p} \in \pi \mid \mathcal{V}(\mathcal{S}, t) = \mathbf{True}\}.$$

Therefore,  $\mathcal{V}(\mathcal{S}, t) \models \bigvee \pi$  iff  $\mathcal{V}(\mathcal{S}_{|\wp}, t) \models \bigwedge \wp$ , and

$$\forall \widehat{p}_i \in \pi, \quad \llbracket \eta(@p_i.S_i) \rrbracket(t) = \begin{cases} \llbracket @p_i.S_i \rrbracket(t) & \text{if } \mathcal{V}(\mathcal{S}, t) \models \bigvee \pi \\ t & \text{otherwise} \end{cases}$$

and

$$\forall \widehat{p}_i \in \wp, \mathcal{V}(\mathcal{S}_{|\wp}, t) \models \bigwedge \wp \quad \text{and} \quad \llbracket \eta(@p_i.S_i) \rrbracket(t) = \llbracket @p_i.S_i \rrbracket(t).$$

Hence Eq. (6) holds. And Eq. (7) follows from the fact that there exists  $\widehat{q} \in \wp'$  such that  $\mathcal{V}(\mathcal{S}, t)(\widehat{q}) = \text{False}$ , thus  $\mathcal{V}(\mathcal{S}_{|\wp'}, t)(\widehat{q}) = \text{False}$  and  $\mathcal{V}(\mathcal{S}_{|\wp'}, t) \not\models \bigwedge \wp'$ .

**Lemma 7.** *Each CE-strategy in which every Boolean formulas is a conjunction of position-variables in  $\widehat{\mathcal{P}os}$ , can be turned into an equivalent CE-strategy in which every Boolean formulas is a conjunction of position-variables in  $\widehat{\mathbb{N}}_\epsilon$ .*

*Proof.* Let  $S$  be CE-strategy strategy. The idea is simple. If there are no Boolean formulas in the CE-strategy, then we rely on the observation that the CE-strategy  $@(ip).S'$  is equivalent to  $@i.(@p.S')$  where  $i \in \mathbb{N}_\epsilon$  and  $p \in \mathcal{P}os$ . Which means that we use the reduction rule

$$@(ip).S' \rightarrow @i.(@p.S') \quad (8)$$

to put the CE-strategy in the canonic form. We generalize the rule (8) to take into account the presence of Boolean formulas as follows. Let

$$\begin{aligned} \mathcal{S} &= \left( \bigsqcup_j @1\widehat{p}_j.S_j^1 \right) \sqcup \dots \sqcup \left( \bigsqcup_j @n\widehat{p}_j.S_j^n \right), \text{ and} \\ \mathcal{S}_1 &= @1.\langle \left( \bigsqcup_j @\widehat{p}_j.S_j^1 \right) \mid \bigwedge_j \widehat{p}_j \rangle, \text{ and} \\ \mathcal{S}_n &= @n.\langle \left( \bigsqcup_j @\widehat{p}_j.S_j^1 \right) \mid \bigwedge_j \widehat{p}_j \rangle \end{aligned}$$

Then we define the reduction rule

$$\langle \mathcal{S} \mid \bigwedge_i \bigwedge_j \widehat{ip}_j \rangle \rightarrow \langle [S_1, \dots, S_n] \mid \bigwedge_i \widehat{i} \rangle.$$

Since all the Boolean formulas are conjunctions of position-variables, then we have

$$\langle \mathcal{S} \mid \bigwedge_i \bigwedge_j \widehat{ip}_j \rangle \equiv \langle [S_1, \dots, S_n] \mid \bigwedge_i \widehat{i} \rangle.$$

## 8.5 Properties of the function $\Psi$

**Lemma 8** ( $\Psi$  preserves the semantics, i.e. Lemma 2). *For any CE-strategy  $S$  in  $\mathcal{C}$  and any term  $t$  in  $\mathcal{T}$ ,*

$$\llbracket S \rrbracket(t) = \Psi(S, t)(t) \quad (9)$$

*Proof.* The proof is by induction on  $\Delta(S)$ , the depth of  $S$ .

**Basic case:**  $\Delta(S) = (0, 0)$ . We distinguish three cases depending on  $S$ .

1. If  $S = \emptyset$ , then this case is trivial.
2. If  $S = @p.\tau$ . This case is trivial since  $\Psi(S, t) \stackrel{def}{=} S$ .

3. If  $S = (u, \tau)$ . In this case

$$\llbracket S \rrbracket(t) = \begin{cases} \tau[t] & \text{if } u \ll t \\ \mathbb{F} & \text{otherwise,} \end{cases}$$

and on the other hand,

$$\Psi(S, t) = \begin{cases} @\epsilon.\tau & \text{if } u \ll t \\ \emptyset & \text{otherwise} \end{cases} \quad \text{hence} \quad \Psi(S, t)(t) = \begin{cases} \tau[t] & \text{if } u \ll t \\ \mathbb{F} & \text{otherwise} \end{cases}$$

That is,  $\llbracket S \rrbracket(t) = \Psi(S, t)(t)$ .

**Induction case:**  $\Delta(S) > (0, 0)$ . We distinguish three cases depending on  $S$ .

1. If  $S$  is a left-choice of the form

$$S = S_1 \oplus \dots \oplus S_n$$

then,

$$\llbracket S \rrbracket(t) = \begin{cases} \llbracket S_k \rrbracket(t) & \text{if } k = \mu i \in [n] \text{ s.t. } \llbracket S_i \rrbracket(t) \neq \mathbb{F} \\ \mathbb{F} & \text{if } \forall i \in [n], \llbracket S_i \rrbracket(t) = \mathbb{F} \end{cases}$$

and

$$\Psi(S_1 \oplus \dots \oplus S_n, t) \stackrel{def}{=} \begin{cases} \Psi(S_k, t) & \text{if } k = \mu i \in [n] \text{ s.t. } \Psi(S_k, t) \neq \emptyset \\ \emptyset, & \text{if } \forall i \in [n], \Psi(S_i, t) = \emptyset \end{cases}$$

Since  $\Psi(S_k, t) = \emptyset$  iff  $\Psi(S_k, t)(t) = \mathbb{F}$ , we get

$$\Psi(S_1 \oplus \dots \oplus S_n, t)(t) \stackrel{def}{=} \begin{cases} \Psi(S_k, t)(t) & \text{if } k = \mu i \in [n] \text{ s.t. } \Psi(S_k, t)(t) \neq \mathbb{F} \\ \mathbb{F}, & \text{if } \forall i \in [n], \Psi(S_i, t) = \mathbb{F} \end{cases}$$

From the induction hypothesis we have that  $\llbracket S_i \rrbracket(t) = \Psi(S_i, t)(t)$  for all  $i \in [n]$ . Hence,  $\llbracket S_1 \oplus \dots \oplus S_n \rrbracket(t) = \Psi(S_1 \oplus \dots \oplus S_n, t)(t)$ .

2. If  $S$  is of the form

$$S = \langle [ @p_1.S_1, \dots, @p_n.S_n, @q_1.\tau_1, \dots, @q_m.\tau_m ] \mid \phi \rangle, \quad n \geq 1, m \geq 0,$$

then let

$$f = \llbracket \eta(@p_n.S_n) \rrbracket \circ \dots \circ \llbracket \eta(@p_1.S_1) \rrbracket \quad \text{and} \quad f' = \llbracket @q_m.\tau_m \rrbracket \circ \dots \circ \llbracket @q_1.\tau_1 \rrbracket$$

On the one hand

$$\begin{aligned} \llbracket S \rrbracket(t) &\stackrel{def}{=} \begin{cases} (f' \circ f)(t) & \text{if } \mathcal{V}(S, t) \models \phi \\ \mathbb{F} & \text{otherwise} \end{cases} \\ &= \begin{cases} (\llbracket @p_n.\eta(S_n) \rrbracket \circ \dots \circ \llbracket \eta(@p_1.S_1) \rrbracket)(t) & \text{if } \mathcal{V}(S, t) \models \phi \\ \mathbb{F} & \text{otherwise} \end{cases} \end{aligned}$$

On the other hand, let

$$\mathcal{L} = [\textcircled{p}_1.\eta(\Psi(S_1, t_{|p_1})), \dots, \textcircled{p}_n.\eta(\Psi(S_n, t_{|p_n}))] \quad \text{and} \quad \mathcal{L}' = [\textcircled{q}_1.\tau_1, \dots, \textcircled{q}_m.\tau_m]$$

and thus

$$\Psi(S, t) \stackrel{def}{=} \begin{cases} \mathcal{L} \sqcup \mathcal{L}' & \text{if } \mathcal{V}(S, t) \models \phi \\ \emptyset & \text{otherwise} \end{cases} \quad \text{hence} \quad \Psi(S, t)(t) = \begin{cases} (\llbracket \mathcal{L}' \rrbracket \circ \llbracket \mathcal{L} \rrbracket)(t) & \text{if } \mathcal{V}(S, t) \models \phi \\ \mathbb{F} & \text{otherwise} \end{cases}$$

It remains to show that, for any term  $t$  in  $\mathcal{T}$ ,

$$f(t) = \llbracket \mathcal{L} \rrbracket(t) \quad \text{and} \quad f'(t) = \llbracket \mathcal{L}' \rrbracket(t).$$

But  $f' = \llbracket \mathcal{L}' \rrbracket$ , and thus it remains to show that

$$\forall i \in [n], \quad \llbracket \textcircled{p}_i.S_i \rrbracket(t) = \llbracket \textcircled{p}_i.\Psi(S_i, t_{|p_i}) \rrbracket(t). \quad (10)$$

However,

$$\llbracket \textcircled{p}_i.S_i \rrbracket(t) = \begin{cases} t[\llbracket S_i \rrbracket(t_{|p_i})]_{p_i} & \text{if } p_i \in \mathcal{Pos}(t) \\ \mathbb{F} & \text{otherwise} \end{cases}$$

and

$$\llbracket \textcircled{p}_i.\Psi(S_i, t_{|p_i}) \rrbracket(t) = \begin{cases} t[\Psi(S_i, t_{|p_i})(t_{|p_i})]_{p_i} & \text{if } p_i \in \mathcal{Pos}(t) \\ \mathbb{F} & \text{otherwise} \end{cases}$$

From the induction hypothesis we have  $\llbracket S_i \rrbracket(t_{|p_i}) = \Psi(S_i, t_{|p_i})(t_{|p_i})$ . Therefore, the Eq. (10) holds.

3. If  $S$  is of the form  $S = \mu X.S(X)$ , then the claims follows from the fact that

$$\llbracket \mu X.S(X) \rrbracket(t) = \llbracket \bigoplus_{i=1, \delta(t)} S^i(\emptyset) \rrbracket(t) \quad \text{and} \quad \Psi(\mu X.S(X), t) = \Psi(\bigoplus_{i=1, \delta(t)} S^i(\emptyset), t),$$

by applying the induction hypothesis since

$$\Delta(\bigoplus_{i=1, \delta(t)} S^i(\emptyset)) < \Delta(\mu X.S(X)),$$

because if  $\Delta(\bigoplus_{i=1, \delta(t)} S^i(\emptyset)) = (n, m)$ , for some  $n, m \in \mathbb{N}$ , then  $\Delta(\mu X.S(X)) = (n+1, m')$ , for some  $m' > m$ .

This ends the proof of Lemma 2.

**Lemma 9 (i.e. Lemma 3).** *The function  $\Psi$  enjoys the following properties.*

- i.) *For any term  $t$  and any elementary CE-strategies  $E_1, E_2$  in  $\mathcal{E}$ , we have that*

$$E = E' \quad \text{iff} \quad \Psi(E, t) = \Psi(E', t).$$

ii.) For any term  $t$  and any CE-strategies  $S_1, S_2$  in  $\mathcal{C}$ , we have that

$$S \equiv S' \quad \text{iff} \quad \Psi(S, t) = \Psi(S', t).$$

*Proof.* We only prove Item ii.), the other item follows immediately from the definition of  $\Psi$ . On the one hand, from the definition of  $\equiv$  we have that

$$S \equiv S' \quad \text{iff} \quad \llbracket S \rrbracket(t) = \llbracket S' \rrbracket(t), \quad \forall t \in \mathcal{T}.$$

However, it follows from Lemma 2 that

$$\llbracket S \rrbracket(t) = \Psi(S, t)(t) \quad \text{and} \quad \llbracket S' \rrbracket(t) = \Psi(S', t)(t).$$

Therefore,

$$\Psi(S, t)(t) = \Psi(S', t)(t), \forall t \in \mathcal{T}.$$

Since, both  $\Psi(S, t)$  and  $\Psi(S', t)$  are elementary CE-strategies, it follows from Item i.) of this Lemma that  $\Psi(S, t) = \Psi(S', t)$ .

## 9 Proofs for section 5

### 9.1 Correctness and Completeness of the unification and combination of CE-strategies.

**Theorem 4 (i.e. Theorem 1).** For every term  $t \in \mathcal{T}$ , for every CE-strategies  $S$  and  $S'$  in  $\mathcal{C}$ , we have that

$$\Psi(S \wedge S', t) = \Psi(S, t) \wedge \Psi(S', t) \tag{11}$$

*Proof.* The proof is by a double induction on  $\Delta(S)$  and  $\Delta(S')$ . We recall that if there are two symmetric cases, we only prove one of them. We make an induction on  $\Delta(S)$ .

**Base case:**  $\Delta(S) = (0, 0)$ . We make an induction on  $\Delta(S')$ .

**Base case:**  $\Delta(S') = (0, 0)$ . We distinguish three cases depending on the structure of  $S$  and  $S'$ .

1. The cases when  $(S, S') = (\emptyset, \emptyset)$  or  $(S, S') = (@i.\tau, @j.\tau')$  are trivial whether  $i = j$  or not.

2. If  $(S, S') = (@i.\tau, (u, \tau'))$ , where  $i \in \mathbb{N}_\epsilon \setminus \{\epsilon\}$ , then in this case

$$S \wedge S' = (u, [@i.\tau, @\epsilon.\tau']) \text{ and}$$

$$\Psi(S \wedge S', t) = \begin{cases} [@i.\tau, @\epsilon.\tau'] & \text{if } u \ll t \\ \emptyset & \text{otherwise.} \end{cases}$$

On the other hand,

$$\Psi(S, t) = \begin{cases} @\epsilon.\tau & \text{if } u \ll t \\ \emptyset & \text{otherwise.} \end{cases} \quad \text{and} \quad \Psi(S', t) = @i.\tau'$$

Hence

$$\begin{aligned} \Psi(S, t) \wedge \Psi(S', t) &= \begin{cases} [@i.\tau, @\epsilon.\tau'] & \text{if } u \ll t \\ \emptyset & \text{otherwise.} \end{cases} \\ &= \Psi(S, t) \wedge \Psi(S', t) \end{aligned}$$

3. If  $S = @\epsilon.\tau$  and  $S' = (u, \tau')$ , then this case is similar to the previous one except that the insertion of the tuples of the contexts  $\tau$  and  $\tau'$  occurs at the root position instead of two different positions. We have that

$$S \wedge S' = (u, \tau' \cdot \tau) \quad \text{and} \quad \Psi(S \wedge S', t) = \begin{cases} @\epsilon.(\tau' \cdot \tau) & \text{if } u \ll t \\ \emptyset & \text{otherwise.} \end{cases}$$

On the other hand,

$$\Psi(S, t) = \begin{cases} @\epsilon.\tau & \text{if } u \ll t \\ \emptyset & \text{otherwise.} \end{cases} \quad \text{and} \quad \Psi(S', t) = @\epsilon.\tau'$$

Hence

$$\begin{aligned} \Psi(S, t) \wedge \Psi(S', t) &= \begin{cases} @\epsilon.(\tau' \cdot \tau) & \text{if } u \ll t \\ \emptyset & \text{otherwise.} \end{cases} \\ &= \Psi(S, t) \wedge \Psi(S', t) \end{aligned}$$

**Induction step:**  $\Delta(S') > (0, 0)$ . We distinguish six cases depending on the structure of  $S$  and  $S'$ .

1. If  $S = (@i, \tau)$  and  $S' = (u', R')$ , where  $i \in \mathbb{N}_\epsilon$ , then in this case

$$S \wedge S' = (u', (@i.\tau) \wedge R') \quad \text{and} \quad \Psi(S \wedge S', t) = \begin{cases} \Psi((@i.\tau) \wedge R', t) & \text{if } u' \ll t \\ \emptyset & \text{otherwise.} \end{cases}$$

Since  $\Delta(R') < \Delta(S')$ , it follows from the induction hypothesis that

$$\begin{aligned} \Psi(S \wedge S', t) &= \begin{cases} \Psi(@i.\tau, t) \wedge \Psi(R', t) & \text{if } u' \ll t \\ \emptyset & \text{otherwise.} \end{cases} \\ &= \begin{cases} @i.\tau \wedge \Psi(R', t) & \text{if } u' \ll t \text{ and } i \in \mathcal{P}os(t) \\ \emptyset & \text{otherwise.} \end{cases} \end{aligned}$$

On the other hand,

$$\Psi(S, t) = \begin{cases} @i.\tau & \text{if } i \in \mathcal{P}os(t) \\ \emptyset & \text{otherwise.} \end{cases} \quad \text{and} \quad \Psi(S', t) = \begin{cases} \Psi(R', t) & \text{if } u' \ll t \\ \emptyset & \text{otherwise} \end{cases}$$

Hence the unification  $\Psi(S, t) \sqcup \Psi(S', t)$  is defined by

$$\begin{aligned} \Psi(S, t) \sqcup \Psi(S', t) &= \begin{cases} @i.\tau \sqcup \Psi(R', t) & \text{if } \Psi(R', t) \text{ and } u' \ll t \\ \emptyset & \text{otherwise} \end{cases} \\ &= \Psi(S, t) \sqcup \Psi(S', t). \end{aligned}$$

2. If  $S = (@i, \tau)$  and  $S' = \langle \bigsqcup_{j \in J} @j.S_j \mid \phi \rangle$ , where  $i \in \mathbb{N}_\epsilon$ , then we only discuss the case when  $i \in J$ , the case when  $i \notin I$  is immediate. In this case, let

$$S = \bigsqcup_{j \in J \setminus \{i\}} @j.S_j \sqcup (@i.\tau \sqcup @i.S_i)$$

and

$$S \sqcup S' = \langle S \mid \phi \rangle, \text{ and}$$

$$\begin{aligned} \Psi(S \sqcup S', t) &= \begin{cases} \bigsqcup_{j \in J \setminus \{i\}} @j.\Psi(S_j, t_{|j}) \sqcup \Psi((@i.\tau \sqcup @i.S_i), t_{|i}) & \text{if } \mathcal{V}(S, t) \models \phi, \\ \emptyset & \text{otherwise} \end{cases} \\ &= \begin{cases} \bigsqcup_{j \in J \setminus \{i\}} @j.\Psi(S_j, t_{|j}) \sqcup (\Psi(@i.\tau, t_{|i}) \sqcup \Psi(@i.S_i, t_{|i})) & \text{if } \mathcal{V}(S, t) \models \phi, \\ \emptyset & \text{otherwise} \end{cases} \end{aligned}$$

Since  $\Delta(S_i) < \Delta(S', t)$ , it follows from the induction hypothesis that

$$\Psi(S \sqcup S', t) = \begin{cases} \bigsqcup_{j \in J \setminus \{i\}} @j.\Psi(S_j, t_{|j}) \sqcup (@i.\tau \sqcup \Psi(@i.S_i, t_{|i})) & \text{if } \mathcal{V}(S, t) \models \phi, \\ \emptyset & \text{otherwise} \end{cases}$$

On the other hand,

$$\Psi(S, t) = \begin{cases} @i.\tau & \text{if } i \in \mathcal{P}os(t), \\ \emptyset & \text{otherwise} \end{cases} \quad \text{and} \quad \Psi(S', t) = \begin{cases} \bigsqcup_{j \in J} @j.\Psi(S_j, t_{|j}) & \text{if } \mathcal{V}(S, t) \models \phi, \\ \emptyset & \text{otherwise} \end{cases}$$

and since  $i \in J$ , the unification of  $\Psi(S, t)$  and  $\Psi(S', t)$  is

$$\begin{aligned} \Psi(S, t) \sqcup \Psi(S', t) &= \\ &= \begin{cases} \bigsqcup_{j \in J \setminus \{i\}} @j.\Psi(S_j, t_{|j}) \sqcup (@i.\tau \sqcup @i.\Psi(S_i, t_{|i})) & \text{if } i \in \mathcal{P}os(t) \text{ and } \mathcal{V}(S, t) \models \phi, \\ \emptyset & \text{otherwise} \end{cases} \end{aligned}$$

Since  $\phi$  is a conjunction of position-variables, and  $i \in J$ , which means  $i \in \text{Dom}(S)$ , then

$$\mathcal{V}(S, t) \models \phi \quad \text{iff} \quad i \in \mathcal{P}os(t) \text{ and } \mathcal{V}(S, t) \models \phi.$$

That leads to  $\Psi(S \sqcup S', t) = \Psi(S, t) \sqcup \Psi(S', t)$ .

3. If  $S = (@i.\tau)$  and  $S' = \mu Z.R(Z)$ , where  $i \in \mathbb{N}_\epsilon$ , then in this case

$$\begin{aligned}
S \wedge S' &= S''(\mu Z.R(Z)), \text{ where } S''(Z) = (@i.\tau) \wedge R(Z), \text{ and} \\
\Psi(S \wedge S', t) &= \Psi(S''(\mu Z.R(Z)), t) \\
&= \Psi\left(S''\left(\bigoplus_{i=0, \delta(t)} R^i(\emptyset)\right), t\right) \\
&= \Psi\left((@i.\tau) \wedge R\left(\bigoplus_{i=0, \delta(t)} R^i(\emptyset)\right), t\right) \\
&= \Psi\left((@i.\tau) \wedge \bigoplus_{i=0, \delta(t)} R^{i+1}(\emptyset), t\right) \\
&= \Psi\left((@i.\tau) \wedge \bigoplus_{i=0, \delta(t)} R^i(\emptyset), t\right)
\end{aligned}$$

If we assume that  $\Delta(\bigoplus_{i=0, \delta(t)} R^i(\emptyset)) = (n, m)$ , for some  $n, m \in \mathbb{N}$ , then  $\Delta(\mu Z.R(Z)) = (n+1, m')$ , for some  $m' \in \mathbb{N}$ . Meaning that  $\Delta(\bigoplus_{i=1, \delta(t)} R^i(\emptyset)) < \Delta(\mu Z.R(Z))$ . Thus it follows from the induction hypothesis that

$$\Psi(S \wedge S', t) = \Psi((@i.\tau), t) \wedge \Psi\left(\bigoplus_{i=0, \delta(t)} R^i(\emptyset), t\right)$$

On the hand,

$$\begin{aligned}
\Psi(S', t) &= \Psi(\mu Z.R, t) \\
&= \Psi\left(\bigoplus_{i=0, \delta(t)} R^i(\emptyset), t\right)
\end{aligned}$$

Hence,

$$\Psi(S \wedge S', t) = \Psi(S, t) \wedge \Psi(S', t).$$

4. If  $S = (u, \tau)$  and  $S' = (u', R')$ , then in this case

$$\begin{aligned}
S \wedge S' &= (u \wedge u', (@\epsilon.\tau) \wedge S') \quad \text{and} \quad \Psi(S \wedge S', t) = \begin{cases} \Psi((@\epsilon.\tau) \wedge S', t) & \text{if } (u \wedge u') \ll t \\ \emptyset, & \text{otherwise.} \end{cases} \\
&= \begin{cases} \Psi(@\epsilon.\tau, t) \wedge \Psi(S', t) & \text{if } (u \wedge u') \ll t \\ \emptyset, & \text{otherwise.} \end{cases}
\end{aligned}$$

On the other hand,

$$\Psi(S, t) = \begin{cases} @\epsilon.\tau & \text{if } u \ll t \\ \emptyset & \text{otherwise} \end{cases} \quad \text{and} \quad \Psi(S', t) = \begin{cases} \Psi(S', t) & \text{if } u' \ll t \\ \emptyset, & \text{otherwise.} \end{cases}$$

Since

$$(u \wedge u') \ll t \quad \text{iff} \quad u \ll t \text{ and } u' \ll t \quad (\text{Lemma 4})$$

We get

$$\Psi(S \wedge S', t) = \Psi(S, t) \wedge \Psi(S', t).$$

5. If  $S = (u, \tau)$  and  $S' = \langle \bigsqcup_{i \in I} @i.S'_i \mid \phi' \rangle$ , then we only prove the case when  $I \subset \mathbb{N}_\epsilon \setminus \{\epsilon\}$ , the case when  $\epsilon \in I$  is similar. We have that

$$\begin{aligned} S \wedge S' &= (u, \langle \bigsqcup_{i \in I} @i.S'_i \sqcup (@\epsilon.\tau) \mid \phi' \rangle), \text{ and} \\ \Psi(S \wedge S', t) &= \begin{cases} \Psi(\langle \bigsqcup_{i \in I} @i.S'_i \sqcup (@\epsilon.\tau) \mid \phi' \rangle, t) & \text{if } u \ll t \\ \emptyset, & \text{otherwise} \end{cases} \\ &= \begin{cases} \bigsqcup_{i \in I} @i.\Psi(S'_i, t_i) \sqcup (@\epsilon.\tau) & \text{if } u \ll t \text{ and } \mathcal{V}(\bigsqcup_{i \in I} @i.\Psi(S'_i), t) \models \phi' \\ \emptyset, & \text{otherwise} \end{cases} \\ &= \Psi(S, t) \wedge \Psi(S', t). \end{aligned}$$

6. If  $S = (u, \tau)$  and  $S' = \mu Z.R(Z)$ , then this case is similar to the case where  $S = @i.\tau$  discussed before.

**Induction step:**  $\Delta(S) > (0, 0)$ . We make an induction on  $\Delta(S')$ .

Base case:  $\Delta(S') = (0, 0)$ . This case is symmetric to the case where  $\Delta(S) = (0, 0)$  and  $\Delta(S') > (0, 0)$  discussed before.

Induction step:  $\Delta(S') > (0, 0)$ . We distinguish four cases.

1. If  $S = (u, R)$  and  $S' = (u', R')$ , then in this case

$$S \wedge S' = (u \wedge u', R \wedge R') \quad \text{and} \quad \Psi(S \wedge S', t) = \begin{cases} \Psi(R \wedge R', t) & \text{if } (u \wedge u') \ll t \\ \emptyset & \text{otherwise} \end{cases}$$

Since

$$(u \wedge u') \ll t \quad \text{iff} \quad u \ll t \text{ and } u' \ll t \quad (\text{Lemma 4})$$

and since  $\Delta(R) < \Delta(S)$  and  $\Delta(R') < \Delta(S')$ , it follows from the induction hypothesis that

$$\Psi(S \wedge S', t) = \begin{cases} \Psi(R, t) \wedge \Psi(R', t) & \text{if } u \ll t \text{ and } u' \ll t \\ \emptyset & \text{otherwise} \end{cases}$$

On the other hand,

$$\Psi(S, t) = \begin{cases} \Psi(R, t) & \text{if } u \ll t \\ \emptyset & \text{otherwise} \end{cases} \quad \text{and} \quad \Psi(S', t) = \begin{cases} \Psi(R', t) & \text{if } u' \ll t \\ \emptyset & \text{otherwise} \end{cases}$$

Therefore  $\Psi(S, t) \wedge \Psi(S', t) = \Psi(S \wedge S', t)$ .

2. If  $S$  and  $S'$  are lists of position delimiters of the form

$$S = \langle \bigsqcup_{i \in \mathcal{I}} @i.S_i \mid \phi \rangle \quad \text{and} \quad S' = \langle \bigsqcup_{j \in \mathcal{J}} @j.S'_j \mid \phi' \rangle$$

where  $\mathcal{I}, \mathcal{J} \subset \mathbb{N}_\epsilon$ , then let

$$\mathcal{S} = \bigsqcup_{i \in \mathcal{I}} @i.S_i \quad \text{and} \quad \mathcal{S}' = \bigsqcup_{j \in \mathcal{J}} @j.S'_j$$

On the one hand we have that

$$\Psi(S, t) = \begin{cases} \bigsqcup_{i \in \mathcal{I}} @i.\eta(\Psi(S_i, t_i)) & \text{if } \mathcal{V}(\mathcal{S}, t) \models \phi \\ \emptyset & \text{otherwise,} \end{cases}$$

and

$$\Psi(S', t) = \begin{cases} \bigsqcup_{j \in \mathcal{J}} @j.\eta(\Psi(S'_j, t_j)) & \text{if } \mathcal{V}(\mathcal{S}', t) \models \phi' \\ \emptyset & \text{otherwise.} \end{cases}$$

Hence, the unification  $\Psi(S, t) \lambda \Psi(S', t)$  is defined by

$$\Psi(S, t) \lambda \Psi(S', t) =$$

$$\begin{cases} \bigsqcup_{i \in \mathcal{I}} @i.\eta(\Psi(S_i, t_i)) \lambda \bigsqcup_{j \in \mathcal{J}} @j.\eta(\Psi(S'_j, t_j)) & \text{if } \mathcal{V}(\mathcal{S}, t) \models \phi \text{ and } \mathcal{V}(\mathcal{S}', t) \models \phi' \\ \emptyset & \text{otherwise.} \end{cases}$$

On the other hand, let

$$\mathcal{S}'' = \bigsqcup_{i \in \mathcal{I} \cap \mathcal{J}} @i.(S_i \lambda S'_i) \sqcup \bigsqcup_{i \in \mathcal{I} \setminus \mathcal{J}} @i.S_i \sqcup \bigsqcup_{i \in \mathcal{J} \setminus \mathcal{I}} @i.S'_i$$

and thus the combination  $S \lambda S'$  is defined by

$$S \lambda S' \stackrel{def}{=} \langle \mathcal{S}'' \mid \phi \wedge \phi' \rangle.$$

To simplify the presentation, let

$$\tilde{\mathcal{S}}'' = \bigsqcup_{i \in \mathcal{I} \cap \mathcal{J}} @i.\eta(\Psi((S_i \lambda S'_i), t)) \sqcup \bigsqcup_{i \in \mathcal{I} \setminus \mathcal{J}} @i.\eta(\Psi(S_i, t)) \sqcup \bigsqcup_{i \in \mathcal{J} \setminus \mathcal{I}} @i.\eta(\Psi(S'_i, t)).$$

Thus  $\Psi(S \lambda S', t)$  can be written as

$$\Psi(S \lambda S', t) = \begin{cases} \tilde{\mathcal{S}}'' & \text{if } \mathcal{S}'' \models \phi \wedge \phi' \\ \emptyset & \text{otherwise.} \end{cases}$$

3.  $\langle \bigsqcup_{i \in \mathcal{I}} @i.S_i \mid \phi \rangle \lambda (u', S') = (u', \langle \bigsqcup_{i \in \mathcal{I}} @i.S_i \mid \phi \lambda S' \rangle)$

4. If  $S = \mu X.S(X)$  and  $S' = \mu X'.S'(X')$ , then we have

$$(\mu X.S(X)) \wedge (\mu X'.S'(X')) \stackrel{def}{=} \mu Z.S''(\mu X.S(X), \mu X'.S'(X'), Z)$$

where  $S''(X, X', X \wedge X') \stackrel{def}{=} S(X) \wedge S'(X')$ .

Let  $t \in \mathcal{T}$  and let  $n = \delta(t)$ . To show that

$$\Psi(\mu X.S(X), t) \wedge \Psi(\mu X'.S'(X'), t) = \Psi(\mu Z.S''(\mu X.S(X), \mu X'.S'(X'), Z), t)$$

it is sufficient to show that

$$\bigoplus_{i \in [n]} \tilde{S}^i(\emptyset) = \bigoplus_{i \in [n]} \bigoplus_{i \in [n]} S^i(\emptyset) \wedge S'^i(\emptyset) \quad (12)$$

We have that for all  $i \geq 1$ ,

$$\begin{aligned} S^i(\emptyset) \wedge S'^i(\emptyset) &\stackrel{def}{=} S(S^{i-1}(\emptyset)) \wedge S'(S'^{i-1}(\emptyset)) \\ &\stackrel{def}{=} S''(S^{i-1}(\emptyset), S'^{i-1}(\emptyset), S^{i-1}(\emptyset) \wedge S'^{i-1}(\emptyset)) \\ &\stackrel{def}{=} \tilde{S}^i(\emptyset) \end{aligned}$$

hence,

$$\begin{aligned} \llbracket \mu X.S(X) \rrbracket \wedge \llbracket \mu X'.S'(X') \rrbracket &\stackrel{def}{=} \left( \bigoplus_{i \in [n]} S^i(\emptyset) \right) \wedge \left( \bigoplus_{i \in [n]} S'^i(\emptyset) \right) \\ &= S'' \left( \bigoplus_{i \in [n-1]} S^i(\emptyset), \bigoplus_{i \in [n-1]} S'^i(\emptyset), \bigoplus_{i \in [n-1]} S^i(\emptyset) \wedge \bigoplus_{i \in [n-1]} S'^i(\emptyset) \right) \\ &= \bigoplus_{i \in [n]} \tilde{S}^i(\emptyset) \\ &= \llbracket \mu X.S(X) \wedge \mu X'.S'(X') \rrbracket \end{aligned}$$

Hence,

$$\begin{aligned} \Psi(\mu X.S(X) \wedge \mu X'.S'(X'), t) &= \Psi \left( \left( \bigoplus_{i \in [n]} S^i(\emptyset) \right) \wedge \left( \bigoplus_{i \in [n]} S'^i(\emptyset) \right), t \right) \\ &= \Psi \left( \bigoplus_{i \in [n]} S^i(\emptyset), t \right) \wedge \Psi \left( \bigoplus_{i \in [n]} S'^i(\emptyset), t \right) \\ &= \Psi(\mu X.S(X), t) \wedge \Psi(\mu X'.S'(X'), t) \end{aligned}$$

5. The cases of  $(\mu X.S(X)) \wedge S'$  and  $S \wedge \mu X'.S'(X')$  are similar to the previous one.

6.  $\bigoplus_{i \in [n]} S_i \wedge \bigoplus_{j \in [m]} S'_j = \bigoplus_{i \in [n]} \bigoplus_{j \in [m]} S_i \wedge S'_j$ . On the one hand we have that

$$\Psi \left( \bigoplus_{i \in [n]} S_i, t \right) \stackrel{def}{=} \bigoplus_{i \in [n]} \Psi(S_i, t) \quad \text{and} \quad \Psi \left( \bigoplus_{j \in [m]} S'_j, t \right) \stackrel{def}{=} \bigoplus_{j \in [m]} \Psi(S'_j, t)$$

and

$$\Psi\left(\bigoplus_{i \in [n]} \bigoplus_{j \in [m]} S_i \wedge S'_j, t\right) \stackrel{def}{=} \bigoplus_{i \in [n]} \bigoplus_{j \in [m]} \Psi(S_i \wedge S'_j, t)$$

And we need to show that

$$\bigoplus_{i \in [n]} \bigoplus_{j \in [m]} \Psi(S_i \wedge S'_j, t) = \bigoplus_{i \in [n]} \Psi(S_i, t) \wedge \bigoplus_{j \in [m]} \Psi(S'_j, t) \quad (13)$$

The proof is by a double induction on  $n$  and  $m$ .

(a)  $n = 1$ . We make an induction on  $m$ .

i.  $m = 1$ . This case is obvious since the equality  $\Psi(S_1, \wedge S'_1, t) = \Psi(S_1, t) \wedge \Psi(S'_1, t)$  follows from the induction “hypothesis”.

ii.  $m > 1$ . In this case we have

$$\begin{aligned} L.Eq(13) &= \bigoplus_{i \in [n]} \bigoplus_{j \in [m]} \Psi(S_i \wedge S'_j, t) \\ &= \bigoplus_{j \in [m]} \Psi(S_1 \wedge S'_j, t) \\ &= \bigoplus_{j \in [m-1]} \Psi(S_1 \wedge S'_j, t) \oplus \Psi(S_1 \wedge S'_m, t) \\ &= \bigoplus_{j \in [m-1]} (\Psi(S_1, t) \wedge \Psi(S'_j, t)) \oplus \Psi(S_1 \wedge S'_m, t) \\ &\hspace{15em} (\text{Induc. on } m) \\ &= \bigoplus_{j \in [m-1]} (\Psi(S_1, t) \wedge \Psi(S'_j, t)) \oplus (\Psi(S_1, t) \wedge \Psi(S'_m, t)) \\ &\hspace{15em} (\text{Induc. hypothesis on } \Delta(S_1), \Delta(S'_m)) \\ &= \Psi(S_1, t) \wedge \bigoplus_{j \in [m-1]} \Psi(S'_j, t) \oplus \Psi(S'_m, t) \\ &\hspace{15em} (\text{Def. of } \wedge) \\ &= \Psi(S_1, t) \wedge \bigoplus_{j \in [m]} \Psi(S'_j, t) \\ &= R.Eq(13) \end{aligned}$$

(b)  $n > 1$ . Again, we make an induction on  $m$ .

i.  $m = 1$ . This case is similar to the case when  $n = 1$  and  $m > 1$  discussed above.

ii.  $m > 1$ . In this case,

$$\begin{aligned}
L.Eq(13) &= \bigoplus_{i \in [n]} \bigoplus_{j \in [m]} \Psi(S_i \wedge S'_j, t) \\
&= \bigoplus_{i \in [n-1]} \bigoplus_{j \in [m]} \Psi(S_i \wedge S'_j, t) \oplus \bigoplus_{j \in [m]} \Psi(S_1 \wedge S'_j, t) \\
&= \bigoplus_{i \in [n-1]} \left( \bigoplus_{j \in [m-1]} \Psi(S_i \wedge S'_j, t) \oplus \Psi(S_i \wedge S'_m, t) \right) \oplus \bigoplus_{j \in [m]} \Psi(S_n \wedge S'_j, t) \\
&= \bigoplus_{i \in [n-1]} \left( \bigoplus_{j \in [m-1]} (\Psi(S_i, t) \wedge \Psi(S'_j, t)) \oplus \Psi(S_i \wedge S'_m, t) \right) \oplus \bigoplus_{j \in [m]} \Psi(S_n \wedge S'_j, t) \\
&\hspace{15em} \text{(Induc. on } m) \\
&= \bigoplus_{i \in [n-1]} \left( \bigoplus_{j \in [m-1]} (\Psi(S_i, t) \wedge \Psi(S'_j, t)) \oplus \Psi(S_i, t) \wedge \Psi(S'_m, t) \right) \oplus \\
&\quad \bigoplus_{j \in [m]} \Psi(S_n, t) \wedge \Psi(S'_j, t) \\
&\hspace{15em} \text{(Induc. Hyp. on } \Delta(S_n), \Delta(S'_j)) \\
&= \bigoplus_{i \in [n-1]} \left( \bigoplus_{j \in [m-1]} \Psi(S_i, t) \wedge (\Psi(S'_j, t) \oplus \Psi(S'_m, t)) \right) \oplus \\
&\quad \bigoplus_{j \in [m]} (\Psi(S_n, t) \wedge \Psi(S'_j, t)) \hspace{5em} \text{(Def. of } \wedge) \\
&= \bigoplus_{i \in [n-1]} (\Psi(S_i, t) \wedge \bigoplus_{j \in [m]} \Psi(S'_j, t)) \oplus (\Psi(S_n, t) \wedge \bigoplus_{j \in [m]} \Psi(S'_j, t)) \\
&\hspace{15em} \text{(Def. of } \wedge) \\
&= \bigoplus_{i \in [n-1]} ((\Psi(S_i, t) \oplus \Psi(S_n, t)) \wedge \bigoplus_{j \in [m]} \Psi(S'_j, t)) \\
&\hspace{15em} \text{(Def. of } \wedge) \\
&= \bigoplus_{i \in [n]} (\Psi(S_i, t) \wedge \bigoplus_{j \in [m]} \Psi(S'_j, t)) \\
&= \bigoplus_{i \in [n]} \bigoplus_{j \in [m]} \Psi(S_i, t) \wedge \Psi(S'_j, t) \\
&= R.Eq(13)
\end{aligned}$$

**Theorem 5 (i.e. Theorem 2).** *For every term  $t \in \mathcal{T}$ , for every CE-strategies  $S$  and  $S'$  in  $\mathcal{C}$ , we have that*

$$\Psi(S \gamma S', t) = \Psi(S, t) \gamma \Psi(S', t). \quad (14)$$

*Proof.*

$$\begin{aligned}
\Psi(S \curlywedge S', t) &= \Psi((S \wedge S') \oplus S \oplus S', t) && \text{(Def. 13 of } \curlywedge \text{)} \\
&= \Psi(S \wedge S', t) \oplus \Psi(S, t) \oplus \Psi(S', t) && \text{(Def. 11 of } \Psi \text{)} \\
&= (\Psi(S, t) \wedge \Psi(S', t)) \oplus \Psi(S, t) \oplus \Psi(S', t) && \text{(Theorem 1)} \\
&= \Psi(S, t) \curlywedge \Psi(S', t) && \text{(Def. 13 of } \curlywedge \text{)}
\end{aligned}$$

**Proposition 3 (i.e. Proposition 2).** *The following hold.*

1. *The set  $\mathcal{E}$  of CE-strategies together with the unification operation  $\wedge$  is a Hamiltonian half-group, that is*
  - (a) *The neutral element of the unification is  $@\epsilon.\square$ . i.e. for every  $S$  in  $\mathcal{C}$ , we have  $(@\epsilon.\square) \wedge S = S \wedge (@\epsilon.\square) = S$ .*
  - (b) *The empty list  $\emptyset$  is the absorbing element, i.e. for every  $S$  in  $\mathcal{C}$ , we have  $\emptyset \wedge S = S \wedge \emptyset = \emptyset$ .*
  - (c) *Every CE-strategy  $S$  is idempotent, i.e.  $S \wedge S = S$ .*
  - (d) *The unification is associative, i.e.  $(S_1 \wedge S_2) \wedge S_3 \equiv S_1 \wedge (S_2 \wedge S_3)$ , for any  $S_1, S_2, S_3$  in  $\mathcal{C}$ .*
2. *The combination of CE-strategies is non commutative.*
3. *For any CE-strategies  $S$  and  $S'$  in  $\mathcal{C}$ , and for any term  $t$  in  $\mathcal{T}$ , we have that*

$$\Psi(S \wedge S', t) = \emptyset \quad \text{iff} \quad \Psi(S, t) = \emptyset \text{ or } \Psi(S', t) = \emptyset.$$

4. *The unification and combination of CE-strategies is a congruence, that is, for any CE-strategies  $S_1, S_2$  and  $S$  in  $\mathcal{C}$ , we have that*

$$\text{If } S_1 \equiv S_2 \quad \text{then} \quad S_1 \wedge S \equiv S_2 \wedge S \quad \text{and} \quad S \wedge S_1 \equiv S \wedge S_2$$

*Besides,*

$$\text{If } S_1 \equiv S_2 \quad \text{then} \quad S_1 \curlywedge S \equiv S_2 \curlywedge S \quad \text{and} \quad S \curlywedge S_1 \equiv S \curlywedge S_2$$

*Proof.* We only prove the last Item. To prove the associativity of the both unification and combination for CE-strategies we rely on the associativity of the unification and combination of elementary CE-strategies (Proposition 1) together with the property of the function  $\Psi$  (Theorems 1 and 2).

Let  $S_1, S_2$  and  $S_3$  be CE-strategies in  $\mathcal{C}$ . It follows from Item *iii.*) of Lemma 3 that in order to prove that

$$S_1 \curlywedge (S_2 \curlywedge S_3) \equiv (S_1 \curlywedge S_2) \curlywedge S_3,$$

it suffices to prove that, for any term  $t \in \mathcal{T}$ , we have that

$$\Psi(S_1 \curlywedge (S_2 \curlywedge S_3), t) = \Psi((S_1 \curlywedge S_2) \curlywedge S_3, t).$$

But this follows from an easy computation:

$$\begin{aligned}
\Psi(S_1 \curlywedge (S_2 \curlywedge S_3), t) &= \Psi(S_1, t) \curlywedge \Psi(S_2 \curlywedge S_3, t) && \text{(Theorem 2)} \\
&= \Psi(S_1, t) \curlywedge (\Psi(S_2, t) \curlywedge \Psi(S_3, t)) && \text{(Theorem 2)} \\
&= (\Psi(S_1, t) \curlywedge \Psi(S_2, t)) \curlywedge \Psi(S_3, t) && \text{(Proposition 1)} \\
&= \Psi(S_1 \curlywedge S_2, t) \curlywedge \Psi(S_3, t) && \text{(Theorem 2)} \\
&= \Psi((S_1 \curlywedge (S_2 \curlywedge S_3)), t) && \text{(Theorem 2)}
\end{aligned}$$

On the one hand, it follows from Theorem 2 that

$$\Psi(S_1 \wedge S, t) = \Psi(S_1, t) \wedge \Psi(S, t).$$

On the other hand, since  $S_1 \equiv S_2$ , it follows from Item *iii.*) of Lemma 3 that

$$\Psi(S_1, t) = \Psi(S_2, t).$$

Hence we get

$$\begin{aligned} \Psi(S_1 \wedge S, t) &= \Psi(S_2, t) \wedge \Psi(S, t) \\ &= \Psi(S_2 \wedge S, t) \end{aligned} \quad (\text{Theorem 2})$$

Again, from Item *iii.*) of Lemma 3, we get

$$S_1 \wedge S \equiv S_2 \wedge S.$$

The proof of the remaining claims is similar.
