HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Exploiting the Phase in Diffusion MRI for Microstructure Recovery: Towards Axonal Tortuosity via Asymmetric Diffusion Processes

Tortuosity via Asymmetric Diffusion Processes

We derive the **Ensemble Average Propagator (EAP)** for the case of straight axons (White Matter tissue elongation) and for undulated axons having **different tortuosity rates** (WM tissue compression). We show that under the hypothesis of having both the **Magnitude and Phase** of the dMRI signal we can **quantify the asymmetry** of the EAP which is related to the rate of tortuosity variation in the compressed axon.

1 Undulated and Tortuous Axons

Tortuous and undulated white matter axons are found in pathological scenarios associated with axonal elongation or compression.

White Matter Tissue

straight

compressed

Models

Axonal compression leads to **asymmetry** in the **Ensemble Average Propagator (EAP)**. What is asymmetry?

2 EAP asymmetry: an example

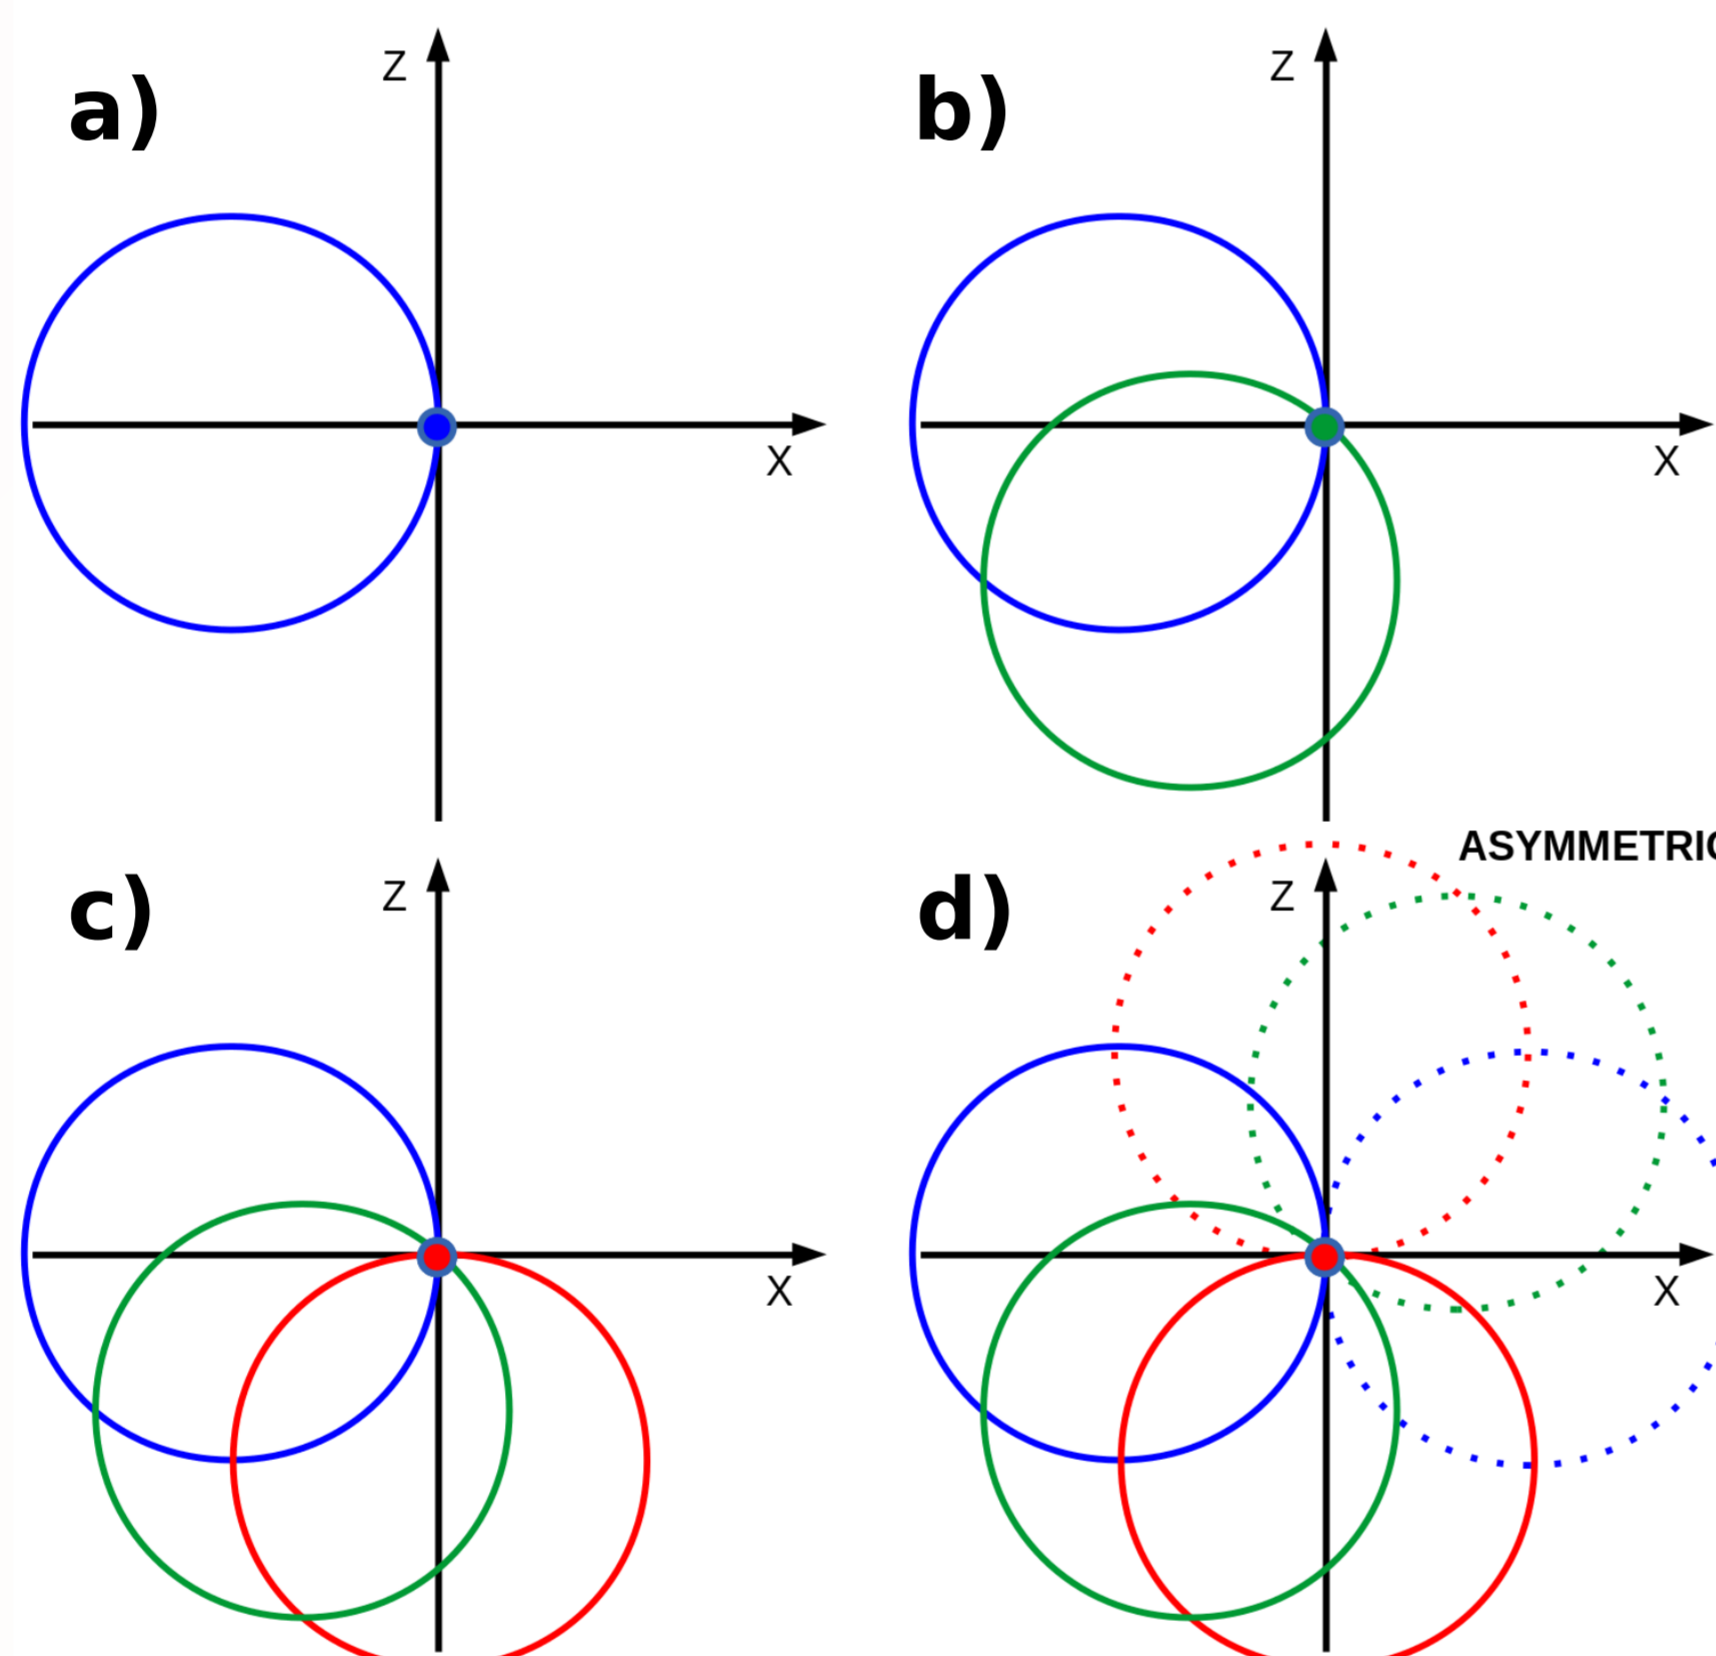

EAP

Based on Özarslan et al.

Spins displacement space

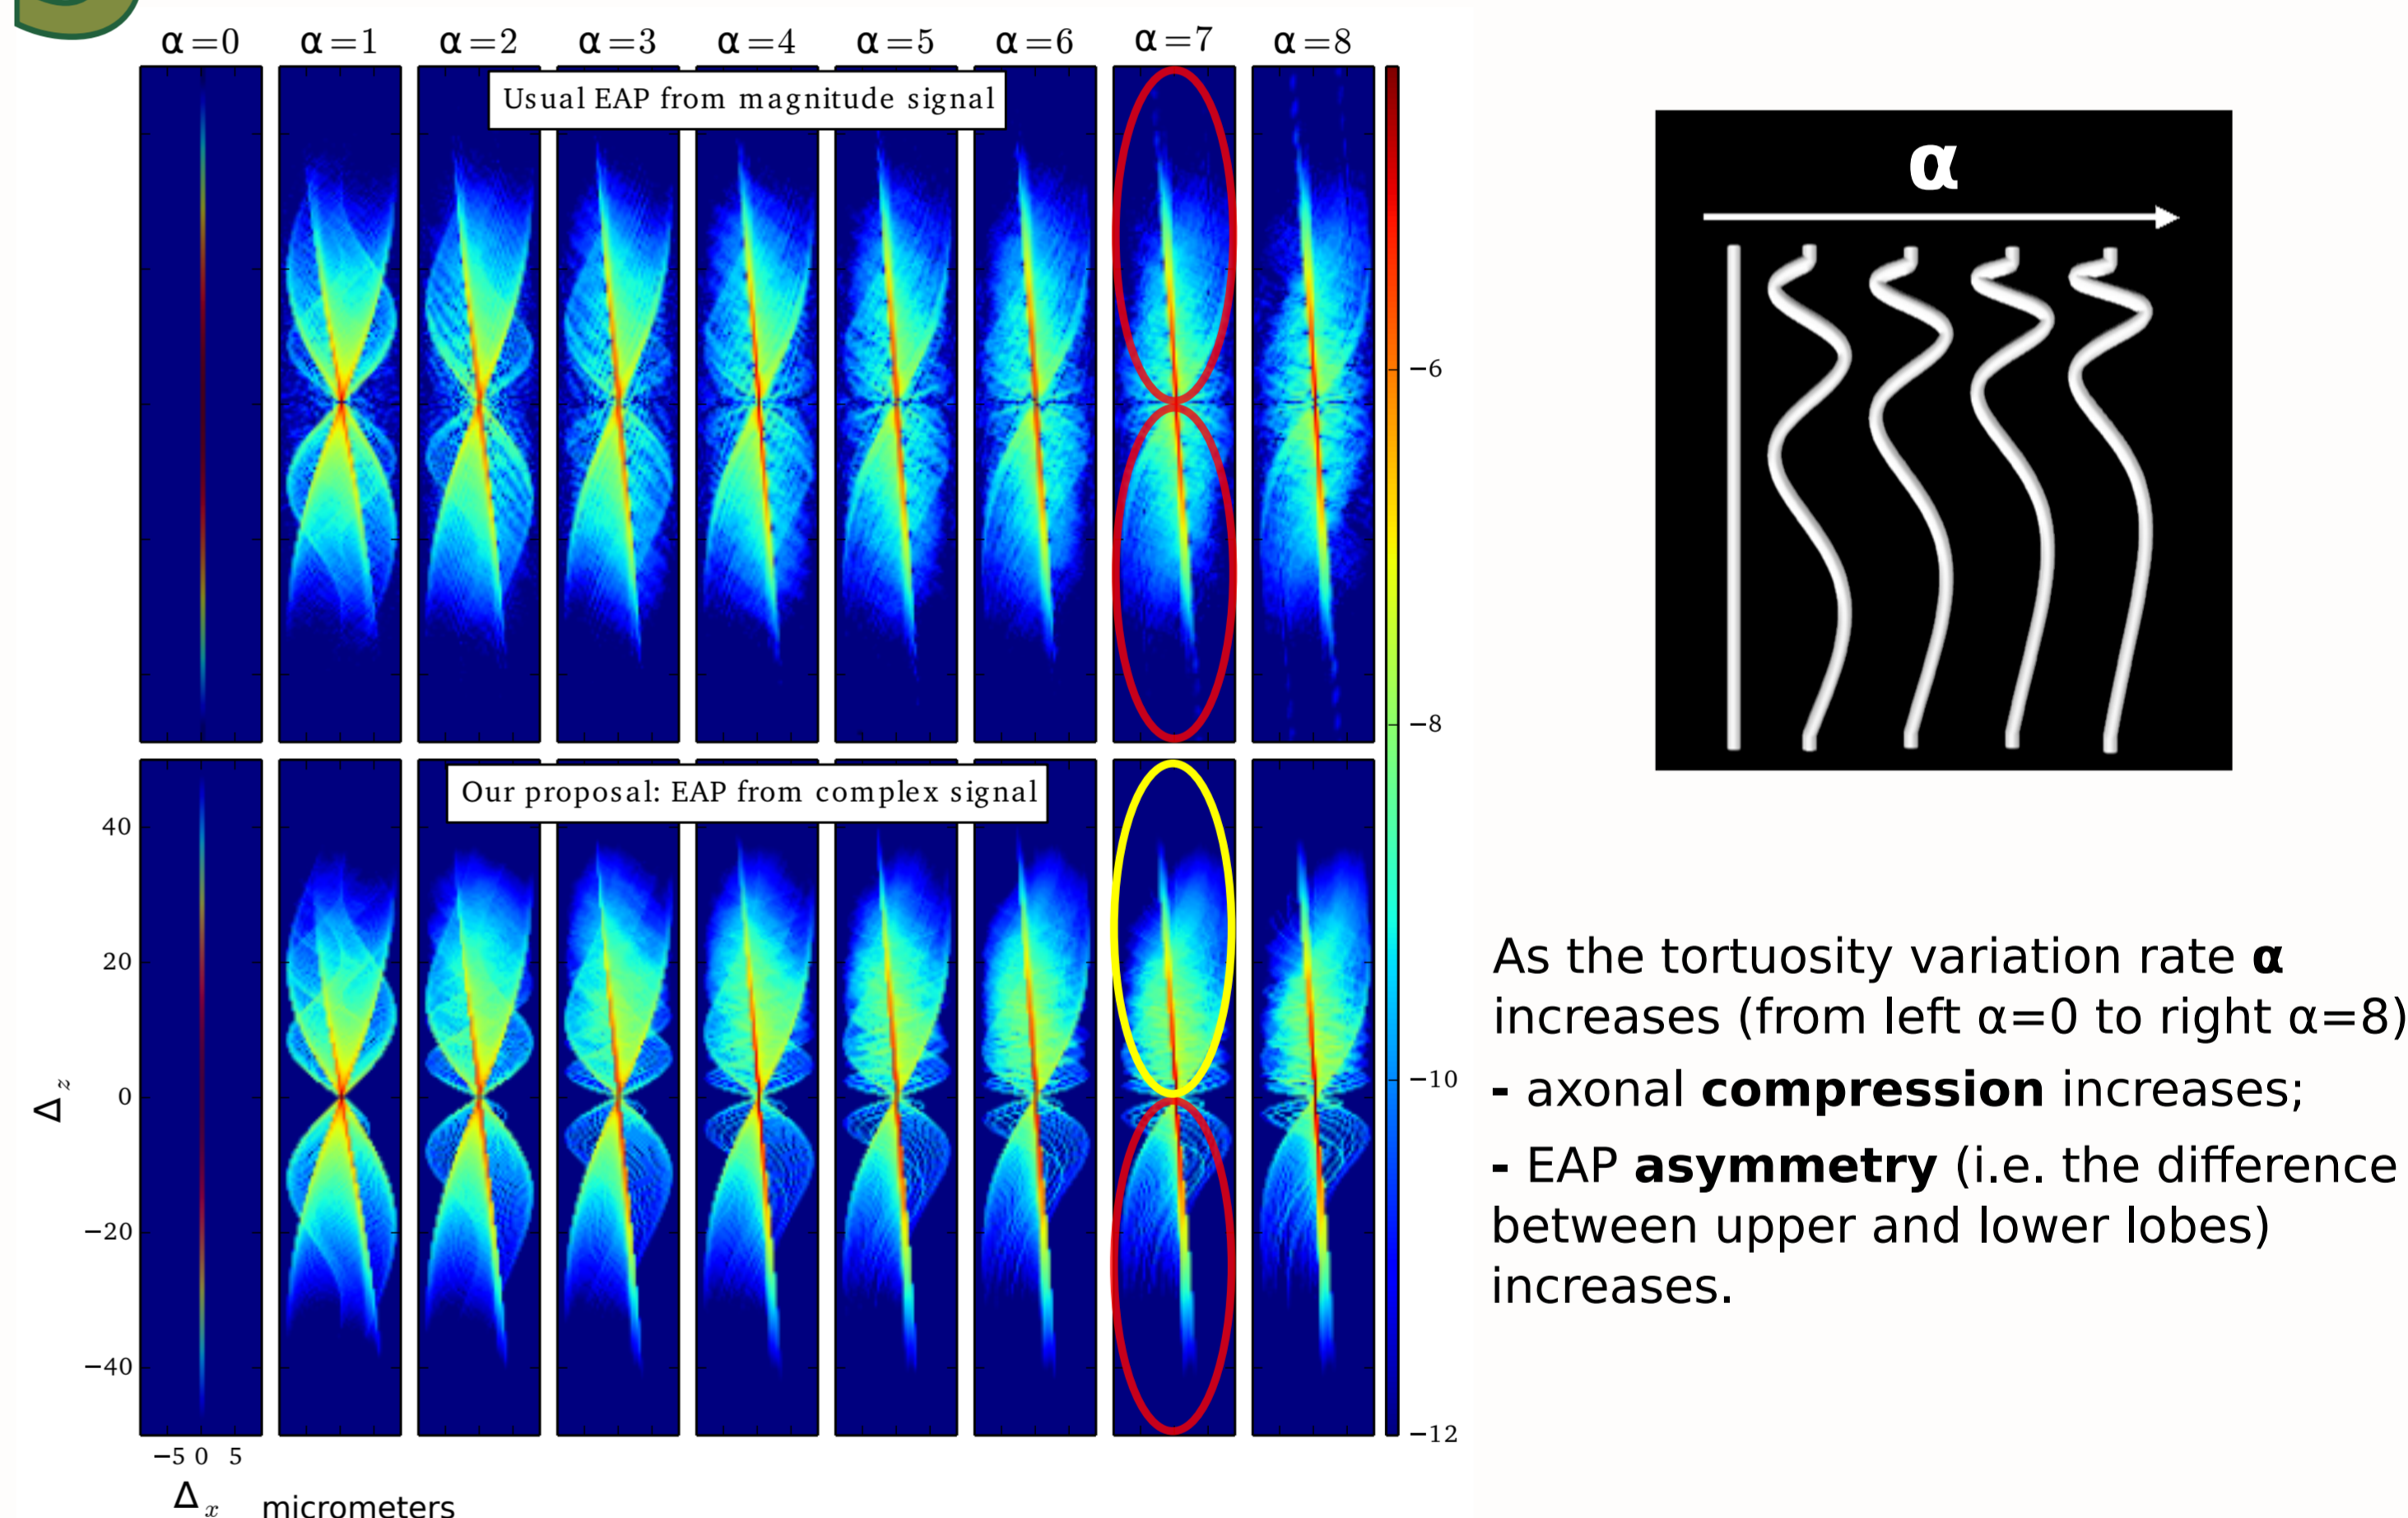

4 EAP asymmetry and PHASE

The asymmetry of the EAP can be appreciated from the complex Diffusion MRI signal. The signal's Phase carries information.

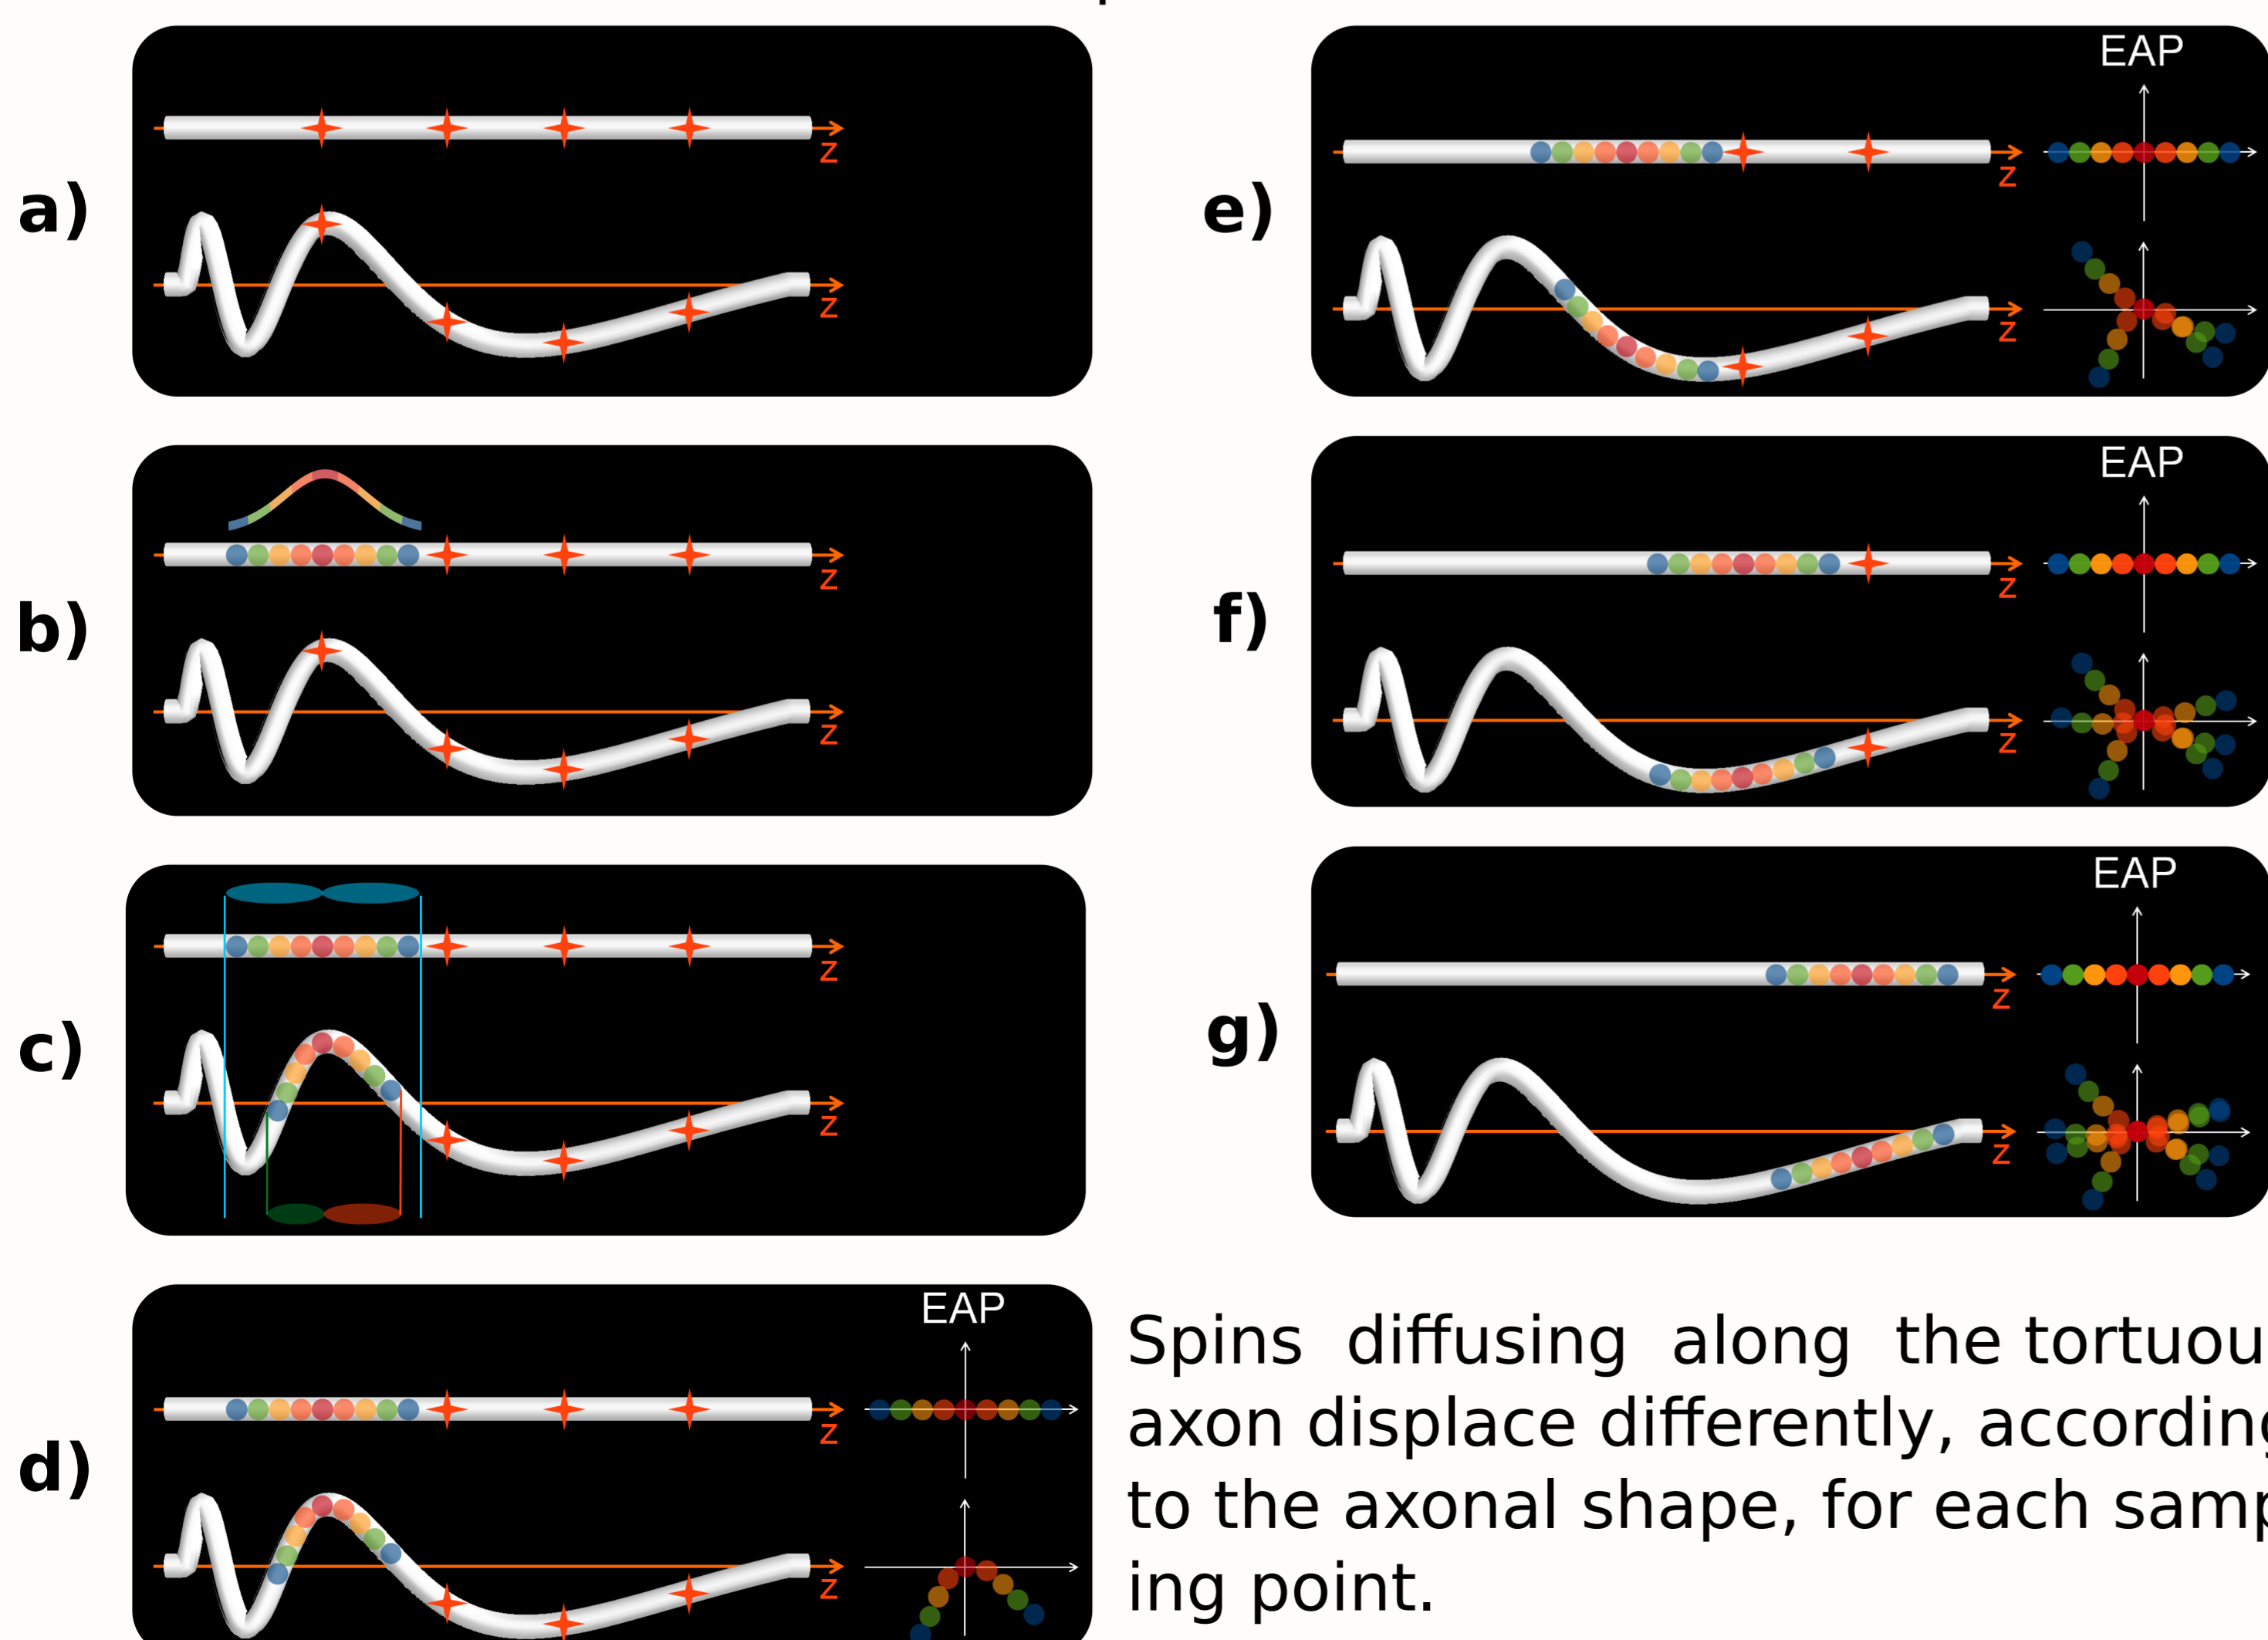

5 Simulated EAP of Tortuous Axons

As the tortuosity variation rate α increases (from left $\alpha=0$ to right $\alpha=8$):
 - axonal **compression** increases;
 - EAP **asymmetry** (i.e. the difference between upper and lower lobes) increases.

3 EAP of Tortuous Axons: derivation

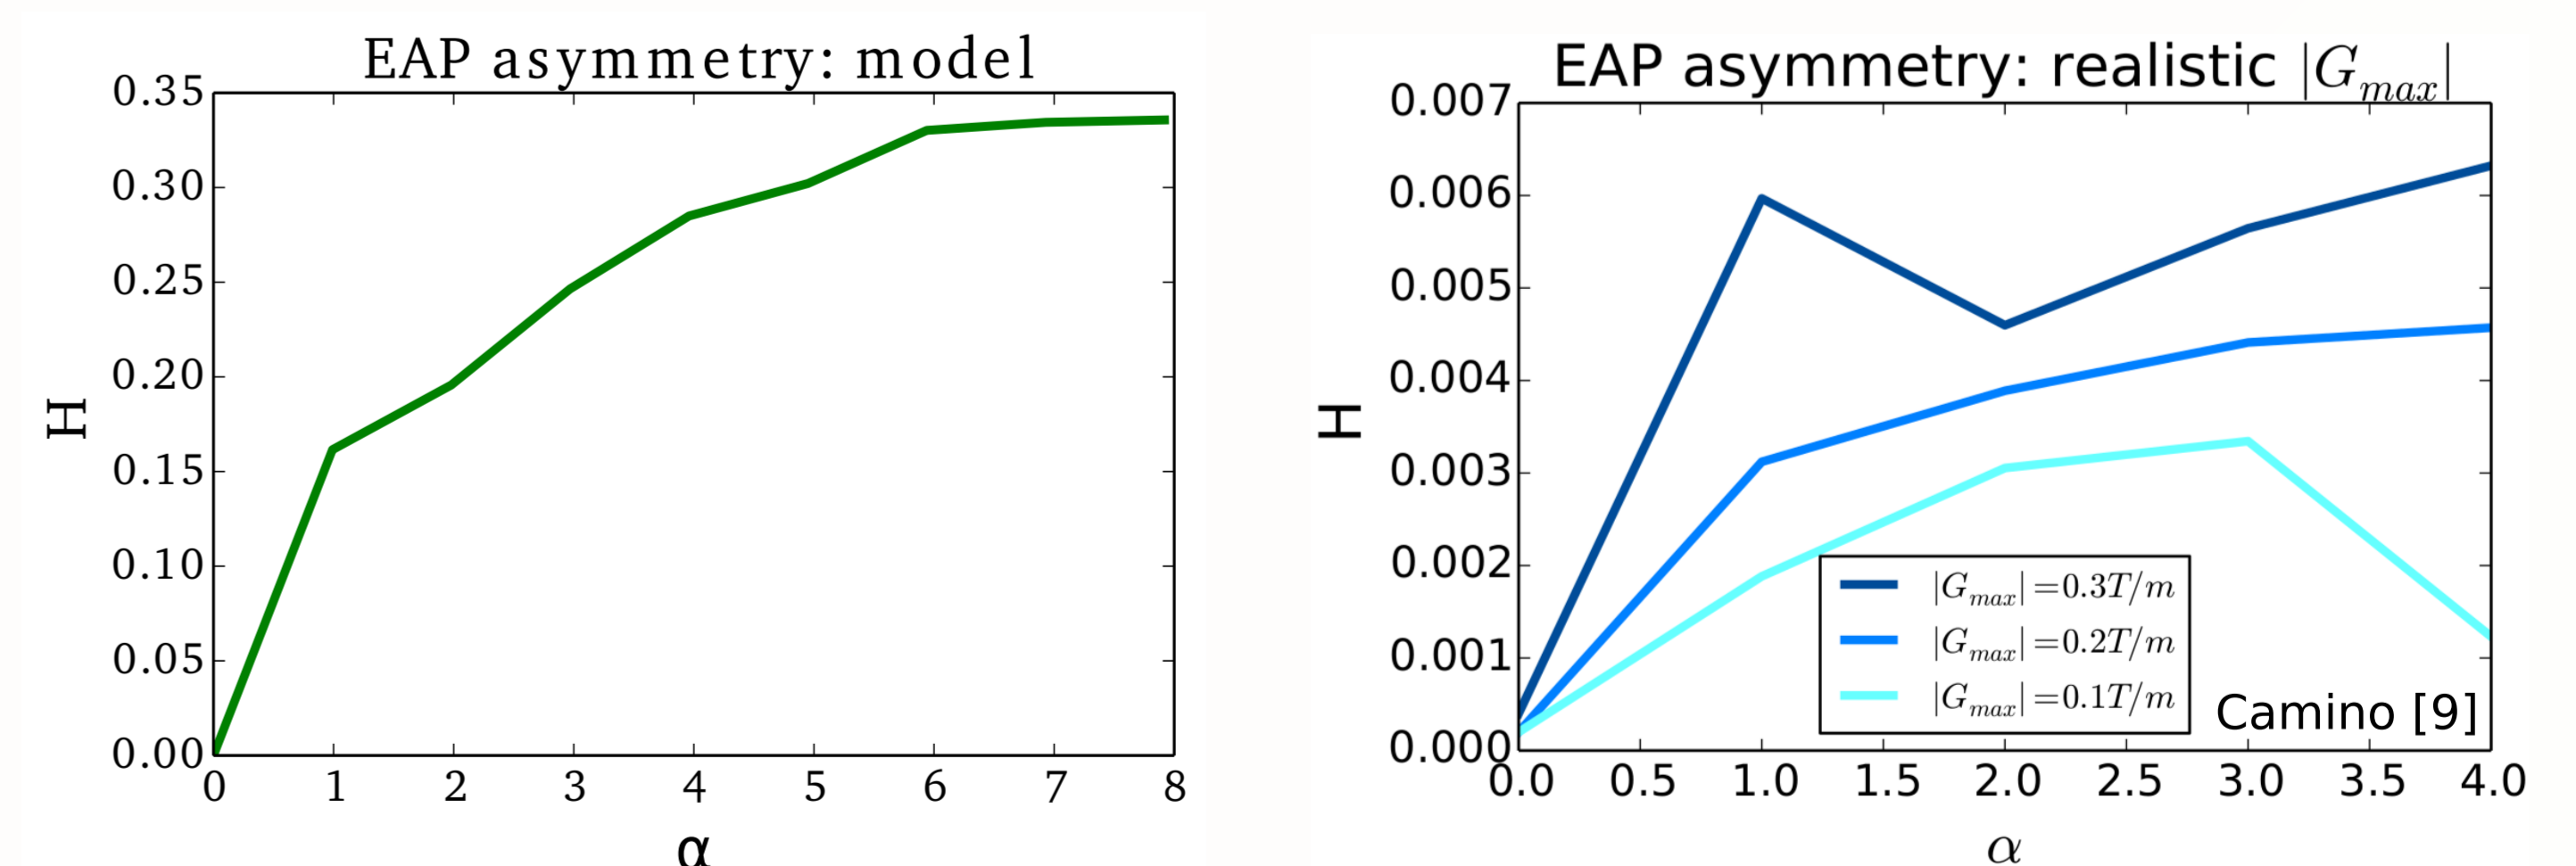

We hypothetically sample a **straight** and a **tortuous** axons in **four sampling points** (stars) in order to obtain an empiric representation of the bidimensional EAP. At each point Gaussian diffusion is assumed.

Spins diffusing along the tortuous axon displace differently, according to the axonal shape, for each sampling point.

6 Asymmetry quantification

As the tortuosity rate α (i.e compression) increases the calculated EAP asymmetry increases. EAP asymmetry might be used as bio-marker for axonal compression.

$$H^2 = \frac{1}{2} \int \left(\sqrt{\text{EAP}(\mathbf{r}|t_d)} - \sqrt{\text{EAP}(-\mathbf{r}|t_d)} \right)^2 d\mathbf{r}$$

The authors express their thanks to the Provence-Alpes-Côte d'Azur (PACA) Regional Council for providing grant and support.
 We thank Nathanaël Foy for the constructive discussions and brainstorming moments.
