#### Abstract

In this paper we focus on the solution of shifted quasiseparable systems and of more general parameter dependent matrix equations with quasiseparable representations. We propose an efficient algorithm exploiting the invariance of the quasiseparable structure under diagonal shifting and inversion. This algorithm is applied to compute various functions of matrices. Numerical experiments show the effectiveness of the approach.

Keywords: Quasiseparable matrices, shifted linear system, QR factorization, matrix function, matrix equation.
2010 MSC: 65F15

## 1 Introduction

In this paper we propose a novel method for computing the solution of shifted quasiseparable systems and of more general parameter dependent linear matrix equations with quasiseparable representations. We show that our approach has also a noticeable potential for effectively solving some large-scale algebraic problems that reduce to evaluating the action of a quasiseparable matrix function to a vector.

Quasiseparable matrices found their application in several branches of applied mathematics and engineering and, therefore, there has been major interest in developing fast algorithms for working with them in the last decade [6, 7, 17, 16]. The quasiseparable structure arises in the discretization of continuous operators due either to the local properties of the discretization schemes and/or the decaying properties of the operator or its finite approximations.

It is a celebrated fact that operations with quasiseparable matrices can be performed in linear time with respect to their size. In particular the QR factorization algorithm presented in [5] computes in linear time a QR decomposition of a quasiseparable matrix $A \in \mathbb{C}^{N \times N}$ of the form $A=V \cdot U$. $R$, where $R$ is upper triangular whereas $U$ and $V$ are banded unitary matrices and $V$ only depends on the generators of the strictly lower triangular part of $A$. This implies that any shifted linear system $A+\sigma I_{N}, \sigma \in \mathbb{C}$, can also be factored as $A+\sigma I_{N}=V \cdot U_{\sigma} \cdot R_{\sigma}$ for suitable $U_{\sigma}$ and $R_{\sigma}$.

Relying upon this fact, in this paper we design an efficient algorithm for solving a sequence of shifted quasiseparable linear systems. The invariance of the factor $V$ can be exploited to halve the overall computational cost. Section 2 illustrates the potential of our approach using motivating examples and applications. In Section 3 we describe the novel algorithm by proving its correctness. Finally, in Section 4 we show the results of numerical experiments which confirm the effectiveness and the robustness of our method.

## 2 Motivating Examples

In this section we describe two motivating examples from applied fields that lead to the solution of several shifted or parameter dependent quasiseparable linear systems.

### 2.1 A Model Problem for Boundary Value ODEs

Consider the non-local boundary value problem in a linear finite dimensional normed space $X=\mathbb{R}^{N}$ :

$$
\begin{gather*}
\frac{d \boldsymbol{v}}{d t}=A \boldsymbol{v}, \quad 0<t<\tau,  \tag{2.1}\\
\frac{1}{\tau} \int_{0}^{\tau} \boldsymbol{v}(t) d t=\boldsymbol{g} \tag{2.2}
\end{gather*}
$$

where $A$ is a linear operator in $\mathbb{R}^{N}$ and $\boldsymbol{g} \in \mathbb{R}^{N}$ is a given vector.
Under the assumption that all the numbers $\mu_{k}=2 \pi i k / \tau, k= \pm 1, \pm 2, \pm 3, \ldots$ are regular points of the operator $A$ the problem (2.1), (2.2) has a unique
solution. Moreover this solution is given by the formula

$$
\begin{equation*}
\boldsymbol{v}(t)=q_{t}(A) \boldsymbol{g}, \quad q_{t}(z)=\frac{\tau z e^{z t}}{e^{z \tau}-1} \tag{2.3}
\end{equation*}
$$

Without loss of generality one can assume that $\tau=2 \pi$.
Expanding the function $q_{t}(z)$ in the Fourier series of $t$ we obtain

$$
q_{t}(z)=1+\sum_{k \in \mathbb{Z} /\{0\}} \frac{z e^{i k t}}{z-i k}, \quad 0<t<2 \pi
$$

We consider the equivalent representation with the real series given by

$$
q_{t}(z)=1+2 \sum_{k=1}^{\infty} z(z \cos k t-k \sin k t)\left(z^{2}+k^{2}\right)^{-1}, \quad 0<t<2 \pi
$$

Using the formula

$$
-\frac{k}{z^{2}+k^{2}}=\frac{z^{2}}{k\left(k^{2}+z^{2}\right)}-\frac{1}{k}
$$

we find that
$q_{t}(z)=1+2 \sum_{k=1}^{\infty} z\left(z \cos k t+\frac{1}{k} z^{2} \sin k t\right)\left(z^{2}+k^{2}\right)^{-1}-2 z \sum_{k=1}^{\infty} \frac{1}{k} \sin k t, \quad 0<t<2 \pi$ and since

$$
2 \sum_{k=1}^{\infty} \frac{1}{k} \sin k t=\pi-t, \quad 0<t<2 \pi
$$

we arrive at the following formula
$q_{t}(z)=1+2 \sum_{k=1}^{\infty}\left(z \cos k t+\frac{1}{k} z^{2} \sin k t\right)\left(z^{2}+k^{2}\right)^{-1}-z(\pi-t), \quad 0<t<2 \pi$.
Thus we obtain the sought expansion of the solution $\boldsymbol{v}(t)$ of the problem (2.1), (2.2):
$v(t)=g-(\pi-t) A g+2 \sum_{k=1}^{\infty}\left(A \cos k t+\frac{1}{k} A^{2} \sin k t\right)\left(A^{2}+k^{2} I_{N}\right)^{-1} A g, \quad 0 \leq t \leq 2 \pi$.

Under the assumptions

$$
\begin{equation*}
\left\|\left(A-i k I_{N}\right)^{-1}\right\| \leq \frac{C}{|k|}, \quad k= \pm 1, \pm 2, \ldots \tag{2.5}
\end{equation*}
$$

using the Abel transform one can check that the series in (2.4) converges uniformly in $t \in[0,2 \pi]$. Hence, by continuity we extend here the formula
(2.4) for the solution on all the segment $[0,2 \pi]$. The rate of convergence of the series in (2.4) is the same as for the series $\sum_{k=1}^{\infty} \frac{1}{k^{2}}$. The last may be improved using standard techniques for series acceleration but by including higher degrees of $A$. Indeed set

$$
C_{k}(t)=A \cos k t+\frac{1}{k} A^{2} \sin k t .
$$

Using the identity

$$
\left(A^{2}+k^{2} I\right)^{-1}=\frac{1}{k^{2}} I-\frac{1}{k^{2}} A^{2}\left(A^{2}+k^{2} I\right)^{-1}
$$

we get
$\sum_{k=1}^{\infty} C_{k}(t)\left(A^{2}+k^{2} I_{N}\right)^{-1} A g=\sum_{k=1}^{\infty} \frac{1}{k^{2}} C_{k}(t) A g-\sum_{k=1}^{\infty} \frac{1}{k^{2}} C_{k}(t)\left(A^{2}+k^{2} I\right)^{-1} A^{3} g$.
The first entry here has the form

$$
\sum_{k=1}^{\infty} \frac{1}{k^{2}} C_{k}(t) A g=\sum_{k=1}^{\infty}\left(\frac{\cos k t}{k^{2}} A^{2} g+\frac{\sin k t}{k^{3}} A^{3} g\right) .
$$

Using the formulas

$$
\sum_{k=1}^{\infty} \frac{\cos k t}{k^{2}}=\frac{\pi^{2}}{6}-\frac{\pi}{2} t+\frac{t^{2}}{4}, \quad \sum_{k=1}^{\infty} \frac{\sin k t}{k^{3}}=\frac{\pi^{2}}{6} t-\frac{\pi}{4} t^{2}+\frac{t^{3}}{12} .
$$

Thus we get
$v(t)=V_{0}(t) g+V_{1}(t) A g+V_{2}(t) A^{2} g+V_{3}(t) A^{3} g-2 \sum_{k=1}^{\infty} \frac{1}{k^{2}} C_{k}(t)\left(A^{2}+k^{2} I\right)^{-1} A^{3} g$.
with

$$
\begin{equation*}
V_{0}(t)=1, V_{1}(t)=t-\pi, V_{2}(t)=\frac{\pi^{2}}{3}-\pi t+\frac{t^{2}}{2}, V_{3}(t)=\frac{\pi^{2}}{3} t-\frac{\pi}{2} t^{2}+\frac{t^{3}}{6} . \tag{2.6}
\end{equation*}
$$

Summing up, our proposal consists in approximating the solution $\boldsymbol{v}(t)$ of the problem (2.1), (2.2) by the finite sum

$$
\begin{equation*}
v_{\ell}(t)=g-(\pi-t) A g+2 \sum_{k=1}^{\ell}\left(A \cos k t+\frac{1}{k} A^{2} \sin k t\right)\left(A^{2}+k^{2} I_{N}\right)^{-1} A g, \quad 0 \leq t \leq 2 \pi, \tag{2.7}
\end{equation*}
$$

or using $\sqrt{2.6}$ by the sum

$$
\begin{gather*}
\hat{v}_{\ell}(t)=\sum_{j=0}^{3} V_{j}(t) A^{j} g \\
-2 \sum_{k=1}^{\ell} \frac{1}{k^{2}}\left(A \cos k t+\frac{1}{k} A^{2} \sin k t\right)\left(A^{2}+k^{2} I_{N}\right)^{-1} A^{3} g, \quad 0 \leq t \leq 2 \pi \tag{2.8}
\end{gather*}
$$

where $\ell$ is suitably chosen by checking the convergence of the expansion.
The computation of $\boldsymbol{v}_{\ell}\left(t_{i}\right) \simeq \boldsymbol{v}\left(t_{i}\right), 0 \leq i \leq M+1$, requires the solution of a possibly large set of the shifted systems of the form

$$
\begin{equation*}
\left(A+\sigma_{i} I_{N}\right) \boldsymbol{x}_{i}=\boldsymbol{y}, \quad i=1, \ldots, \ell \tag{2.9}
\end{equation*}
$$

The same conclusion applies to the problem of computing the function of a quasiseparable matrix whenever the function can be represented as a series of partial fractions. The classes of meromorphic functions admitting such a representation were investigated for instance in [13]. Other partial fraction approximations of certain analytic functions can be found in [11. In the next section we describe an effective algorithm for this task.

A numerical approximation of the solution can be obtained by using the discretization of the boundary value problem on a grid and the subsequent application of the cyclic reduction approach discussed in [1]. In this approach the saving of an approximate quasiseparable structure in recursive LU-based solvers may be used as it was done in the recent papers [2, 4, 9]. The approximate quasiseparable structure of functions of quasiseparable matrices has also been investigated in [12].

### 2.2 Sylvester-type Matrix Equations

As a natural extension of the problem (2.9), the right-hand side $\boldsymbol{y}$ could also depend on the parameter, that is, $\boldsymbol{y}=\boldsymbol{y}(\sigma)$ and $\boldsymbol{y}_{i}=\boldsymbol{y}\left(\sigma_{i}\right), i=$ $1, \ldots, \ell$. This situation is common in many applications such as control theory, structural dynamics and time-dependent PDEs [10]. In this case, the systems to be solved takes the form

$$
A X+X D=Y, \quad A \in \mathbb{R}^{N \times N}, D=\operatorname{diag}\left[\sigma_{1}, \ldots, \sigma_{\ell}\right], Y=\left[\boldsymbol{y}_{1}, \ldots, \boldsymbol{y}_{\ell}\right]
$$

Using the Kronecker product this matrix equation can be rewritten as a bigger linear system $\mathcal{A} \operatorname{vec}(X)=\operatorname{vec}(Y)$, where $\mathcal{A}=I_{\ell} \otimes A+D^{T} \otimes I_{N} \in$ $\mathbb{R}^{N \ell \times N \ell}, \operatorname{vec}(X)=\left[\boldsymbol{x}_{1}^{T}, \ldots, \boldsymbol{x}_{\ell}^{T}\right]^{T}, \operatorname{vec}(Y)=\left[\boldsymbol{y}_{1}^{T}, \ldots, \boldsymbol{y}_{\ell}^{T}\right]^{T}$.

The extension to the case where $D$ is replaced by a lower triangular $\operatorname{matrix} L=\left(l_{i, j}\right) \in \mathbb{R}^{\ell \times \ell}$ is based on the backward substitution technique which amounts to solve

$$
\begin{equation*}
\left(A+l_{i, i} I_{N}\right) \boldsymbol{x}_{i}=\boldsymbol{y}_{i}-\sum_{j=i+1}^{\ell} l_{i, j} \boldsymbol{x}_{j}, \quad i=\ell:-1: 1 \tag{2.10}
\end{equation*}
$$

Such approach has been used in different related contexts where the considered Sylvester equation is occasionally called sparse-dense equation [14]. Then the classical reduction proposed by Bartels and Stewart [3] makes possible to deal with a general matrix $F$ by first computing its Schur decomposition $F=U L U^{H}$ and then solving $A(X U)+(X U) L=Y U$. The
resulting approach is well suited especially when the size of $A$ is large w.r.t. the number of shifts. If $A$ is quasiseparable then 2.10 again reduces to computing a sequence of shifted systems having the same structure in the lower triangular part and the method presented in the next section can be used.

## 3 The basic algorithm

To solve the systems (2.9), 2.10 we rely upon the QR factorization algorithm described in [5] (see also Chapter 20 of [6]). On the first step we compute the factorization

$$
\begin{equation*}
A+\sigma I=V \cdot T_{\sigma} \tag{3.11}
\end{equation*}
$$

with a unitary matrix $V$ and a lower banded, or a block upper triangular, matrix $T_{\sigma}$. It turns out that the matrix $V_{\sigma}$ does not depend on $\sigma$ at all and moreover essential part of the quasiseparable generators of the matrix does not depend on $\sigma$ also. So a relevant part of computations for all the values of $\sigma$ may be performed only once. Thus the problem is reduced to the solution of the set of the systems

$$
\begin{equation*}
T_{\sigma} \boldsymbol{x}_{\sigma}=V^{H} \boldsymbol{y}_{i}, \quad \sigma=\sigma_{i}, i=1, \ldots, \ell \tag{3.12}
\end{equation*}
$$

The inversion of every matrix $T_{\sigma}$ as well as the solution of the corresponding linear system is basically simpler than for the original matrix. We compute the factorization

$$
T_{\sigma}=U_{\sigma} R_{\sigma}
$$

with a block upper triangular unitary matrix $U_{\sigma}$ and upper triangular $R_{\sigma}$ and solve the systems

$$
R_{\sigma} \boldsymbol{x}_{\sigma}=U_{\sigma}^{H} V^{H} \boldsymbol{y}_{i}
$$

Thus we obtain the following algorithm. Recall that a block matrix $A=$ $\left(A_{i, j}\right)_{i, j=1}^{N}, A_{i, j} \in \mathbb{R}^{m_{i} \times m_{j}}$ is said to have lower quasiseparable generators $p(i) \in \mathbb{R}^{m_{i} \times r_{i-1}^{L}}(i=2, \ldots, N), q(j) \in \mathbb{R}^{r_{j}^{L} \times m_{j}}(j=1, \ldots, N-1)$, $a(k) \in \mathbb{R}^{r_{k}^{L} \times r_{k-1}^{L}}(k=2, \ldots, N-1)$ of orders $r_{k}^{L}(k=1, \ldots, N-1)$ and upper quasiseparable generators $g(i) \in \mathbb{R}^{m_{i} \times r_{i}^{U}}(i=1, \ldots, N-1)$, $h(j) \in \mathbb{R}^{r_{j-1}^{U} \times m_{j}}(j=2, \ldots, N), b(k) \in \mathbb{R}^{r_{k-1}^{U} \times r_{k}^{U}} ;(k=2, \ldots, N-1)$ of orders $r_{k}^{U}(k=1, \ldots, N-1)$ if

$$
A_{i, j}=\left\{\begin{array}{c}
p(i) a_{i, j}^{>} q(j) \text { if } 1 \leq j<i \leq N \\
g(i) b_{i, j}^{<} h(j) \text { if } 1 \leq i<j \leq N
\end{array}\right.
$$

where $a_{i, j}^{>}=a(i-1) \cdots a(j+1)$ for $i>j+1$ and $a_{j+1, j}=I_{r_{j}^{L}}$, and, similarly, $b_{i, j}^{<}=b(i+1) \cdots b(j-1)$ for $j>i+1$ and $b_{i, i+1}=I_{r_{i}^{U}}$.

Theorem 3.1. Let $A=\left(A_{i, j}\right)_{i, j=1}^{N}$ be a block matrix with entries of sizes $m_{i} \times m_{j}$, lower quasiseparable generators $p(i)(i=2, \ldots, N), q(j)(j=$ $1, \ldots, N-1), a(k)(k=2, \ldots, N-1)$ of orders $r_{k}^{L}(k=1, \ldots, N-$ 1), upper quasiseparable generators $g(i)(i=1, \ldots, N-1), h(j)(j=$ $2, \ldots, N), b(k)(k=2, \ldots, N-1)$ of orders $r_{k}^{U}(k=1, \ldots, N-1)$ and diagonal entries $d(k)(k=1, \ldots, N)$. Let $\boldsymbol{y}_{i}=\left(y_{i}(k)\right)_{k=1}^{N}$ be a vector column with $m_{k^{-}}$dimensional coordinates $y(k)$ and let $\sigma_{i}, i=1, \ldots, \ell$ be complex numbers. Then the set of solutions $\boldsymbol{x}^{(i)}=\boldsymbol{x}_{\sigma_{i}}, i=1, \ldots, \ell$ of the systems (3.12) is obtained as follows.

1. Set

$$
\begin{gathered}
\rho_{N}=0, \quad \rho_{k-1}=\min \left\{m_{k}+\rho_{k}, r_{k-1}^{L}\right\}, \quad k=N, \ldots, 2, \rho_{0}=0 \\
\rho_{k}^{\prime}=\rho_{k}+r_{k}^{U}, k=1, \ldots, N-1, \quad \nu_{k}=m_{k}+\rho_{k}-\rho_{k-1}, k=1, \ldots, N
\end{gathered}
$$

Compute the quasiseparable representation of the matrix $V$ and the basic elements of the representation of the matrix $T_{\sigma}$ as well as the vector $\boldsymbol{w}_{i}=$ $V^{H} \boldsymbol{y}_{i}$ as follows.
1.1. Using $Q R$ factorization or another algorithm compute the factorization

$$
\begin{equation*}
p(N)=V_{N}\binom{X_{N}}{0_{\nu_{N} \times r_{N-1}^{L}}} \tag{3.13}
\end{equation*}
$$

where $V_{N}$ is a unitary matrix of sizes $m_{N} \times m_{N}, X_{N}$ is a matrix of sizes $\rho_{N-1} \times r_{N-1}^{L}$.

Determine the matrices $p_{V}(N), d_{V}(N)$ of sizes $m_{N} \times \rho_{N-1}, m_{N} \times \nu_{N}$ from the partition

$$
\begin{equation*}
V_{N}=\left(p_{V}(N) \quad d_{V}(N)\right) \tag{3.14}
\end{equation*}
$$

Compute

$$
\begin{gather*}
\binom{h_{T}(N)}{d_{T}(N)}=\binom{h(N)}{V_{N}^{H} d(N)}  \tag{3.15}\\
\binom{c_{N, i}}{w_{i}(N)}=V_{N}^{H} y_{i}(N), \quad 1 \leq i \leq \ell \tag{3.16}
\end{gather*}
$$

with the matrices $h_{T}(N), d_{T}(N), c_{N, i}, w_{i}(N)$ of sizes $\rho_{N-1}^{\prime} \times m_{N}, \nu_{N} \times m_{N}, \rho_{N-1} \times$ $1, \nu_{N} \times 1$ respectively.

Compute

$$
\begin{equation*}
\gamma_{N}=\binom{0_{r_{N}^{U}-1 \times m_{N}}}{p_{V}^{H}(N)} \tag{3.17}
\end{equation*}
$$

1.2. For $k=N-1, \ldots, 2$ perform the following.
1.2.1. Using $Q R$ factorization or another algorithm compute the factorization

$$
\begin{equation*}
\binom{p(k)}{X_{k+1} a(k)}=V_{k}\binom{X_{k}}{0_{\nu_{k} \times r_{k-1}^{L}}} \tag{3.18}
\end{equation*}
$$

where $V_{k}$ is a unitary matrix of sizes $\left(m_{k}+\rho_{k}\right) \times\left(m_{k}+\rho_{k}\right), X_{k}$ is a matrix of sizes $\rho_{k-1} \times r_{k-1}^{L}$.

Determine the matrices $p_{V}(k), q_{V}(k), a_{V}(k), d_{V}(k)$ of sizes $m_{k} \times \rho_{k-1}, \rho_{k} \times$ $\nu_{k}, \rho_{k} \times \rho_{k-1}, m_{k} \times \nu_{k}$ from the partition

$$
V_{k}=\left(\begin{array}{cc}
p_{V}(k) & d_{V}(k)  \tag{3.19}\\
a_{V}(k) & q_{V}(k)
\end{array}\right)
$$

1.2.2. Compute

$$
\left(\begin{array}{cc}
h_{T}(k) & b_{T}(k)  \tag{3.20}\\
d_{T}(k) & g_{T}(k)
\end{array}\right)=\left(\begin{array}{cc}
I_{r_{k-1}^{U}} & 0 \\
0 & V_{k}^{H}
\end{array}\right)\left(\begin{array}{ccc}
h(k) & b(k) & 0 \\
d(k) & g(k) & 0 \\
X_{k+1} q(k) & 0 & I_{\rho_{k}}
\end{array}\right)
$$

with the matrices $h_{T}(k), b_{T}(k), d_{T}(k), g_{T}(k)$ of sizes $\rho_{k-1}^{\prime} \times m_{k}, \rho_{k-1}^{\prime} \times \rho_{k}^{\prime}, \nu_{k} \times$ $m_{k}, \nu_{k} \times \rho_{k}^{\prime}$ respectively.

Compute

$$
\begin{equation*}
\gamma_{k}=\binom{0_{r_{k-1}^{U} \times m_{k}}}{p_{V}^{H}(k)} \tag{3.21}
\end{equation*}
$$

and

$$
\begin{equation*}
\binom{c_{k, i}}{w_{i}(k)}=V_{k}^{H}\binom{y_{i}(k)}{c_{k+1, i}}, \quad 1 \leq i \leq \ell \tag{3.22}
\end{equation*}
$$

with the vector columns $c_{k, i}, w_{i}(k)$ of sizes $\rho_{k-1}, \nu_{k}$ respectively.
1.3. Set $V_{1}=I_{\nu_{1}}$ and

$$
\begin{gather*}
d_{T}(1)=\binom{d(1)}{X_{2} q(1)}, g_{T}(1)=\left(\begin{array}{cc}
g(1) & 0 \\
0 & I_{\rho_{1}}
\end{array}\right), \quad \gamma_{1}=\binom{I_{m_{1}}}{0_{\rho_{1} \times m_{1}}},  \tag{3.23}\\
w_{i}(1)=V_{1}^{H}\binom{y_{i}(1)}{c_{2, i}}, \quad 1 \leq i \leq \ell . \tag{3.24}
\end{gather*}
$$

2. For $i=1, \ldots, \ell$ perform the following:
2.1. Compute the factorization $T_{\sigma_{i}}=U_{\sigma_{i}} R_{\sigma_{i}}$ and the vector $\boldsymbol{v}^{(i)}=\boldsymbol{v}_{\sigma_{i}}=$ $U_{\sigma_{i}}^{H} \boldsymbol{w}_{i}, \boldsymbol{w}_{i}=V^{H} \boldsymbol{y}_{i}$.
2.1.1. Compute the $Q R$ factorization

$$
\begin{equation*}
d_{T}(1)+\sigma_{i} \gamma_{1}=U_{1}^{(i)}\binom{d_{R}^{(i)}(1)}{0_{\rho_{1} \times m_{1}}} \tag{3.25}
\end{equation*}
$$

where $U_{1}^{(i)}$ is a $\nu_{1} \times \nu_{1}$ unitary matrix and $d_{R}^{(i)}(1)$ is an upper triangular $m_{1} \times m_{1}$ matrix.

Compute

$$
\begin{equation*}
\binom{g_{R}^{(i)}(1)}{Y_{1}^{(i)}}=\left(U_{1}^{(i)}\right)^{H} g_{T}(1) \tag{3.26}
\end{equation*}
$$

$$
\begin{equation*}
\binom{v^{(i)}(1)}{\alpha_{1}^{(i)}}=\left(U_{1}^{(i)}\right)^{H} w_{i}(1) \tag{3.27}
\end{equation*}
$$

with the matrices $g_{R}^{(i)}(1), v^{(i)}(1), Y_{1}^{(i)}, \alpha_{1}^{(i)}$ of sizes $m_{1} \times \rho_{1}^{\prime}, m_{1} \times 1, \rho_{1} \times \rho_{1}^{\prime}, \rho_{1} \times$ 1.
2.1.2. For $k=2, \ldots, N-1$ perform the following.

Compute the $Q R$ factorization

$$
\begin{equation*}
\binom{Y_{k-1}^{(i)}\left(h_{T}(k)+\sigma_{i} \gamma_{k}\right)}{d_{T}(k)+\sigma_{i} d_{V}^{H}(k)}=U_{k}^{(i)}\binom{d_{R}^{(i)}(k)}{0_{\rho_{k} \times m_{k}}} \tag{3.28}
\end{equation*}
$$

where $U_{k}^{(i)}$ is an $\left(m_{k}+\rho_{k}\right) \times\left(m_{k}+\rho_{k}\right)$ unitary matrix and $d_{R}^{(i)}(k)$ is an $m_{k} \times m_{k}$ upper triangular matrix.

Compute

$$
\begin{gather*}
\binom{g_{R}^{(i)}(k)}{Y_{k}^{(i)}}=\left(U_{k}^{(i)}\right)^{H}\binom{Y_{k-1}^{(i)} b_{T}(k)}{g_{T}(k)}  \tag{3.29}\\
\binom{v^{(i)}(k)}{\alpha_{k}^{(i)}}=\left(U_{k}^{(i)}\right)^{H}\binom{\alpha_{k-1}^{(i)}}{w_{i}(k)} \tag{3.30}
\end{gather*}
$$

with the matrices $g_{R}^{(i)}(k), v^{(i)}(k), Y_{k}^{(i)}, \alpha_{k}^{(i)}$ of sizes $m_{k} \times \rho_{k}^{\prime}, m_{k} \times 1, \rho_{k} \times \rho_{k}^{\prime}, \rho_{k} \times$ 1.
2.1.3. Compute the $Q R$ factorization

$$
\begin{equation*}
\binom{Y_{N}^{(i)} h_{T}(N)+\sigma_{i} \gamma_{N}}{d_{T}(N)+\sigma_{i} d_{V}^{H}(N)}=U_{N}^{(i)} d_{R}^{(i)}(N) \tag{3.31}
\end{equation*}
$$

where $U_{N}^{(i)}$ is a unitary matrix of sizes $\left(\nu_{N}+\rho_{N-1}\right) \times\left(\nu_{N}+\rho_{N-1}\right)$ and $d_{R}^{(i)}(N)$ is an upper triangular matrix of sizes $m_{N} \times m_{N}$.

Compute

$$
\begin{equation*}
v^{(i)}(N)=\left(U_{N}^{(i)}\right)^{H}\binom{\alpha_{N-1}^{(i)}}{w_{i}(N)} \tag{3.32}
\end{equation*}
$$

2.2. Solve the system $R_{\sigma_{i}} \boldsymbol{x}^{(i)}=\boldsymbol{v}^{(i)}$.
2.2.1. Compute

$$
x^{(i)}(N)=\left(d_{R}^{(i)}(N)\right)^{-1} v^{(i)}(N), \quad \eta_{N-1}^{(i)}=\left(h_{T}(N)+\sigma_{i} \gamma_{N}\right) v^{(i)}(N)
$$

2.2.2. For $k=N-1, \ldots, 2$ compute
$x^{(i)}(k)=\left(d_{R}^{(i)}(k)\right)^{-1}\left(v^{(i)}(k)-g_{R}^{(i)}(k) \eta_{k}^{(i)}\right), \quad \eta_{k-1}^{(i)}=b_{T}(k) \eta_{k}^{(i)}+\left(h_{T}(k)+\sigma_{i} \gamma_{k}\right) x^{(i)}(k)$.
2.2.3. Compute

$$
x^{(i)}(1)=\left(d_{R}^{(i)}(1)\right)^{-1}\left(v^{(i)}(1)-g_{R}^{(i)}(1) \eta_{1}^{(i)}\right)
$$

Proof. The shifted matrix $A+\sigma I_{N}$ has the same lower and upper quasiseparable generators as the matrix $A$ and diagonal entries $d(k)+\sigma I_{m_{k}}(k=$ $1, \ldots, N)$. To compute the factorization (3.11) we apply Theorem 20.5 from [6]. Directly from Theorem 20.5 we obtain the representation of the unitary matrix $V$ in the form

$$
\begin{equation*}
V=\tilde{V}_{N} \tilde{V}_{N-1} \cdots \tilde{V}_{2} \tilde{V}_{1} \tag{3.33}
\end{equation*}
$$

where

$$
\tilde{V}_{1}=V_{1} \oplus I_{\phi_{1}}, \quad \tilde{V}_{k}=I_{\eta_{k}} \oplus V_{k} \oplus I_{\phi_{k}}, k=2, \ldots, N-1, \quad \tilde{V}_{N}=I_{\eta_{N}} \oplus V_{N}
$$

with $\eta_{k}=\sum_{j=1}^{k-1} m_{j}, \phi_{k}=\sum_{j=k+1}^{N}$ and $\left(m_{k}+\rho_{k}\right) \times\left(m_{k}+\rho_{k}\right)$ unitary matrices $V_{k}$, as well as the formulas (3.13), (3.14), (3.18), (3.19), $V_{1}=$ $I_{\nu_{1}}$. Here we see that the matrix $V$ does not depend of $\sigma$. Moreover the representation (3.33) yields the formulas (3.16), (3.22), (3.24) to compute the vectors $\boldsymbol{w}_{i}=V^{H} \boldsymbol{y}_{i}, 1 \leq i \leq \ell$.

Next we apply the corresponding formulas from the same theorem to compute diagonal entries $d_{T}^{\sigma}(k)(k=1, \ldots, N)$ and upper quasiseparable generators $g_{T}^{\sigma}(i)(i=1, \ldots, N-1), h_{T}^{\sigma}(j)(j=2, \ldots, N), b_{T}^{\sigma}(k)(k=$ $2, \ldots, N-1$ ) of the matrix $T_{\sigma}$. Hence, we obtain that

$$
\begin{gathered}
\binom{h_{T}^{\sigma}(N)}{d_{T}^{\sigma}(N)}=\left(\begin{array}{cc}
I_{r_{N-1}^{U}} & 0 \\
0 & V_{N}^{H}
\end{array}\right)\binom{h(N)}{d(N)+\sigma I_{m_{N}}}, \\
\left(\begin{array}{ll}
d_{T}^{\sigma}(1) & g_{T}^{\sigma}(1)
\end{array}\right)=\left(\begin{array}{ccc}
d(1)+\sigma I_{m_{1}} & g(1) & 0 \\
X_{2} q(1) & 0 & I_{\rho_{1}}
\end{array}\right),
\end{gathered}
$$

and for $k=N-1, \ldots, 2$,

$$
\left(\begin{array}{cc}
h_{T}^{\sigma}(k) & b_{T}^{\sigma}(k) \\
d_{T}^{\sigma}(k) & g_{T}^{\sigma}(k)
\end{array}\right)=\left(\begin{array}{cc}
I_{r_{k-1}^{U}} & 0 \\
0 & V_{k}^{H}
\end{array}\right)\left(\begin{array}{ccc}
h(k) & b(k) & 0 \\
d(k)+\sigma I_{m_{k}} & g(k) & 0 \\
X_{k+1} q(k) & 0 & I_{\rho_{k}}
\end{array}\right) .
$$

From here we obtain the formulas

$$
\begin{gather*}
h_{T}^{\sigma}(k)=h_{T}(k)+\sigma \gamma_{k}, k=N, \ldots, 2, \\
d_{T}^{\sigma}(k)=d_{T}(k)+\sigma d_{V}^{*}(k), k=N, \ldots, 2, \quad d_{T}^{\sigma}(1)=d_{T}(1)+\sigma \gamma_{1}, \\
g_{T}^{\sigma}(k)=g_{T}(k), k=1, \ldots, N-1, \quad b_{T}^{\sigma}(k)=b_{T}(k), k=2, \ldots, N-1 \tag{3.34}
\end{gather*}
$$

with $h_{T}(k), d_{T}(k), g_{T}(k), b_{T}(k)$ and $\gamma_{k}$ as in (3.15), (3.17), (3.20), (3.21) and (3.23).

Now by applying Theorem 20.7 from [6] to the matrices $T_{\sigma_{i}}, i=1,2, \ldots, M$ with the generators determined in (3.34) we obtain the formulas (3.25), (3.26), 3.28, 3.29, 3.31) to compute unitary matrices $U_{k}^{(i)}$ and quasiseparable generators of the upper triangular $R_{\sigma_{i}}$ such that $T_{\sigma_{i}}=U_{\sigma_{i}} R_{\sigma_{i}}$, where

$$
\begin{equation*}
U_{\sigma_{i}}=\tilde{U}_{1}^{(i)} \tilde{U}_{2}^{(i)} \cdots \tilde{U}_{N-1}^{(i)} \tilde{U}_{N}^{(i)} \tag{3.35}
\end{equation*}
$$

with
$\tilde{U}_{1}^{(i)}=U_{1}^{(i)} \oplus I_{\phi_{1}}, \quad \tilde{U}_{k}^{(i)}=I_{\eta_{k}} \oplus U_{k}^{(i)} \oplus I_{\phi_{k}}, k=2, \ldots, N-1, \quad \tilde{U}_{N}^{(i)}=I_{\eta_{N}} \oplus U_{N}^{(i)}$.
Moreover the representation (3.35) yields the formulas (3.27), (3.30), 3.32) to compute the vector $\boldsymbol{v}^{(i)}=U_{\sigma_{i}}^{H} \boldsymbol{w}_{i}, 1 \leq i \leq l$.

Finally applying Theorem 13.13 from [6] we obtain Step 2.2 to compute the solutions of the systems $R_{\sigma_{i}} \boldsymbol{x}^{(i)}=\boldsymbol{v}_{(i)}$.

Concerning the complexity of the previous algorithm we observe that under the simplified assumptions of $r_{k}^{L}=r_{k}^{U}=r, m_{i}=m_{j}=m$ and $r \ll m$ the cost of step 1 is of order $\left(6 r^{2} m+2 m^{2}\right)(N m)$ whereas the cost of step 2 can be estimated as $\left(2 m^{2} \ell\right)(N m)$ arithmetic operations. Therefore, the proposed algorithm saves at least half of the overall cost of solving $\ell$ shifted quasiseparable linear systems.

## 4 Numerical Experiments

The proposed fast algorithm has been implemented in MATLAB ${ }^{1}$ All experiments were performed on a MacBookPro equipped with MATLAB R2016b.

Example 4.1. Let us test the computation of functions of quasiseparable matrices via series expansion, as outlined in Section 2. We choose $A$ as the $100 \times 100$ one-dimensional discretized Laplacian with zero boundary conditions, and $g$ as a random vector with entries taken from a uniform distribution over $[0,1]$. Define

$$
v_{e x}=2 \pi A e^{A t}\left(e^{2 \pi A}-I\right)^{-1} g
$$

as exact solution (computed in multiprecision) to the problem (2.1), (2.2). Let $v_{\ell}$ and $\hat{v}_{\ell}$ be the approximate solutions obtained from (2.7) and (2.8), respectively, with $\ell$ expansion terms. Figures 1 and 2 show logarithmic plots of the absolute normwise errors $\left\|v_{e x}-v_{\ell}\right\|_{2}$ and $\left\|v_{e x}-\hat{v}_{\ell}\right\|_{2}$ for $t=\pi / 2$ and $t=\pi / 12$, and values of $\ell$ ranging from 10 to 500. The results clearly confirm that the formulation (2.8) has improved convergence properties with respect to 2.7). Note that the decreasing behavior of the errors is not always monotone.

Example 4.2. This example is taken from [15], Example 3.3. We consider here the matrix $A \in \mathbb{R}^{2500 \times 2500}$ stemming from the centered finite difference discretization of the differential operator $-\Delta u+10 u_{x}$ on the unit square with homogeneous Dirichlet boundary condition. Note that A has (scalar) quasiseparability order 50, but it can also be seen as block 1-quasiseparable with block size 50 .

[^0]

Figure 1: Results for Example 4.1 for $t=\pi / 2$. This is a logarithmic plot of the errors given by the application of formulas (2.7) (blue circles) and (2.8) (red diamonds) for the computation of a matrix function times a vector.

We want to compute the matrix function

$$
A^{\frac{1}{2}} b \approx \sum_{k=1}^{\ell} \kappa_{k}\left(\omega_{k}^{2} I-A\right)^{-1} A b,
$$

where $b$ is the vector of all ones. We apply the rational approximations presented in [11] as method2 and method3 (the latter is designed for the square root function and it is known to have better convergence properties).

Table 1 shows 2 -norm relative errors with respect to the result computed by the MATLAB command $\operatorname{sqrtm(A)*b,~for~several~values~of~} \ell$ (number of terms in the expansion or number of integration nodes). We have tested three approaches to solve the shifted linear systems involved in the expansion: classical backslash solver, fast structured solver with blocks of size 1 and quasiseparability order 50, and fast structured solver with blocks of size 50 and quasiseparability order 1 . For each value of $\ell$, the errors are roughly the same for all three approaches: in particular, the fast algorithms appear to be as accurate as standard solvers.

Example 4.3. The motivation for this example comes from the classical problem of solving the Poisson equation on a rectangular domain with uni-

Figure 2: Results for Example 4.1 for $t=\pi / 12$. This is a logarithmic plot of the errors given by the application of formulas (2.7) (blue circles) and (2.8) (red diamonds) for the computation of a matrix function times a vector. In this example the errors do not decrease monotonically.

Table 1: Relative errors for Example 4.2

| $\ell$ | rel. error (method 2) | rel. error (method 3) |
| :---: | :---: | :---: |
| 6 | $4.58 \mathrm{e}-4$ | $3.25 \mathrm{e}-5$ |
| 8 | $3.03 \mathrm{e}-5$ | $6.77 \mathrm{e}-7$ |
| 10 | $9.67 \mathrm{e}-7$ | $9.90 \mathrm{e}-9$ |
| 12 | $1.55 \mathrm{e}-8$ | $1.16 \mathrm{e}-10$ |
| 14 | $2.06 \mathrm{e}-9$ | $1.56 \mathrm{e}-12$ |
| 16 | $2.25 \mathrm{e}-11$ | $2.16 \mathrm{e}-13$ |
| 18 | $2.29 \mathrm{e}-12$ | $2.09 \mathrm{e}-13$ |
| 20 | $2.44 \mathrm{e}-13$ | $2.14 \mathrm{e}-13$ |

Table 2: Relative errors for Example 4.3 .

|  | $N_{a}$ | 10 | 25 | 50 | 75 | 100 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $N_{b}$ |  |  |  |  |  |  |
| 10 |  | $2.18 \mathrm{e}-15$ | $3.51 \mathrm{e}-15$ | $2.78 \mathrm{e}-15$ | $7.25 \mathrm{e}-15$ | $1.18 \mathrm{e}-14$ |
| 25 |  | $1.80 \mathrm{e}-15$ | $9.66 \mathrm{e}-15$ | $1.34 \mathrm{e}-14$ | $3.48 \mathrm{e}-14$ | $5.74 \mathrm{e}-14$ |
| 50 |  | $9.58 \mathrm{e}-16$ | $1.98 \mathrm{e}-14$ | $2.05 \mathrm{e}-14$ | $9.34 \mathrm{e}-14$ | $2.14 \mathrm{e}-13$ |
| 75 |  | $3.93 \mathrm{e}-15$ | $2.14 \mathrm{e}-14$ | $2.04 \mathrm{e}-14$ | $1.93 \mathrm{e}-13$ | $4.15 \mathrm{e}-13$ |
| 100 |  | $5.55 \mathrm{e}-15$ | $2.30 \mathrm{e}-14$ | $4.58 \mathrm{e}-14$ | $2.11 \mathrm{e}-13$ | $5.61 \mathrm{e}-13$ |

form zero boundary conditions. The equation takes the form

$$
\Delta u(x, y)=f(x, y), \quad \text { with } \quad 0<x<a, 0<y<b
$$

and its finite difference discretization yields a matrix equation

$$
\begin{equation*}
A X+X B=F \quad \text { with } \quad X, F \in \mathbb{R}^{N_{b} \times N_{a}} \tag{4.36}
\end{equation*}
$$

where $N_{a}$ is the number of grid points taken along the $x$ direction and $N_{b}$ is the number of grid points along the $y$ direction. Here $A$ and $B$ are matrices of sizes $N_{b} \times N_{b}$ and $N_{a} \times N_{a}$, respectively, and both are Toeplitz symmetric tridiagonal with nonzero entries $\{-1,2,1\}$. See e.g., [18] for a discussion of this problem.

A widespread approach consists in reformulating the matrix equation (4.36) as a larger linear system of size $N_{a} N_{b} \times N_{a} N_{b}$ via Kronecker products. Here we apply instead the idea outlined in Section 2.2: compute the (well-known) Schur decomposition of $B$, that is, $B=U D U^{H}$, and solve the equation $A(X U)+(X U) D=F U$. Note that, since $D$ is diagonal, this equation can be rewritten as a collection of shifted linear systems, where the right-hand side vector may depend on the shift.

Table 2 shows relative errors on the solution matrix $X$, computed w.r.t. the solution given by a standard solver applied to the Kronecker linear system. Here we take $F$ as the matrix of all ones.

In the next examples we test experimentally the complexity of our algorithm.

Example 4.4. We consider matrices $A_{n} \in \mathbb{R}^{n \times n}$ defined by random quasiseparable generators of order 3. The first column of Table 3 shows the running times of our structured algorithm applied to randomly shifted systems $\left(A_{n}+\sigma_{i} I_{n}\right) \mathbf{x}_{\mathbf{i}}=\mathbf{y}$, for $i=1, \ldots, 50$ and growing values of $n$. The same data are plotted in Figure 3: the growth of the running times looks linear with $n$, as predicted by theoretical complexity estimates.

Table 3: Running times in seconds for Example 4.4.

| system size $n$ | fast algorithm | sequential algorithm | ratio |
| :---: | :---: | :---: | :---: |
| 100 | 0.6016 | 1.2049 | 2.0029 |
| 200 | 0.8473 | 1.6382 | 1.9334 |
| 300 | 1.2291 | 2.4377 | 1.9833 |
| 400 | 1.6639 | 3.2492 | 1.9528 |
| 500 | 2.1976 | 4.0544 | 1.8449 |
| 600 | 2.6654 | 5.1508 | 1.9325 |
| 700 | 2.9765 | 5.8691 | 1.9718 |
| 800 | 3.3367 | 6.5671 | 1.9681 |
| 900 | 3.8411 | 7.6630 | 1.9950 |
| 1000 | 4.2435 | 8.4006 | 1.9796 |

The second column of Table 3 shows timings for the structured algorithm applied sequentially (i.e., without re-using the factorization (3.11) to the same set of shifted systems. The gain obtained by the fast algorithm of Section 3 w.r.t. a sequential structured approach amounts to a factor of about 2, which is consistent with the discussion at the end of Section 3. Experiments with a different number of shifts yield similar results.

Example 4.5. In this example we study the complexity of our algorithm w.r.t. block size (that is, the parameter $m$ at the end of Section 3). We choose $N=2, \ell=2, r_{L}=r_{U}=1$, with random quasiseparable generators, and focus on large values of $m$. Running times, each of them averaged over ten trials, are shown in Table 4. A log-log plot is given in Figure 4, together with a linear fit, which shows that the experimental growth of these running times is consistent with theoretical complexity estimates.

## 5 Conclusion

In this paper we have presented an effective algorithm based on QR decomposition for solving a possibly large number of shifted quasiseparable systems. Two main motivations are the computation of a meromorphic function of a quasiseparable matrix and the solution of linear matrix equations with quasiseparable matrix coefficients. The experiments performed suggest that our algorithm has good numerical properties.

Future work includes the analysis of methods based on the MittagLeffler's theorem for computing meromorphic functions of quasiseparable matrices. Approximate expansions of Mittag-Leffler type can be obtained by using the

Figure 3: Running times for Example 4.4. The linear fit appears to be a good approximation of the actual data. Its equation is $y=0.0042 x+0.071$.

Table 4: Running times in seconds for Example 4.5.

| block size $m$ | running time (sec) |
| :---: | :---: |
| 400 | 0.1481 |
| 800 | 1.0527 |
| 1200 | 3.4238 |
| 1600 | 7.6118 |
| 2000 | 15.2020 |
| 2400 | 26.3695 |
| 2800 | 40.1458 |
| 3200 | 61.2488 |

Figure 4: Log-log plot of running times versus block size $m$ for Example 4.5. The equation of the linear fit is $y=2.9 x-8.4$, which confirms that the complexity of the algorithm grows as $m^{3}$.

Carathéodory-Fejér approximation theory (see [8]). The application of these techniques for computing quasiseparable matrix functions is an ongoing research.
