Abstract

In a recent paper [12], Herbelin developed dPA^{ac}, a calculus in which constructive proofs for the axioms of countable and dependent choices could be derived via the encoding of a proof of countable universal quantification as a stream of its components. However, the property of normalization (and therefore the one of soundness) was only conjectured. The difficulty for the proof of normalization is due to the simultaneous presence of dependent types (for the constructive part of the choice), of control operators (for classical logic), of coinductive objects (to encode functions of type \( N \rightarrow A \) into streams \((a_0, a_1, \ldots)\)) and of lazy evaluation with sharing (for these coinductive objects).

Elaborating on previous works, we introduce in this paper a variant of dPA^{ac} presented as a sequent calculus. On the one hand, we take advantage of a variant of Krivine classical realizability that we developed to prove the normalization of classical call-by-need [21]. On the other hand, we benefit from dL_{\omega}, a classical sequent calculus with dependent types in which type safety is ensured by using delimited continuations together with a syntactic restriction [20]. By combining the techniques developed in these papers, we manage to define a realizability interpretation à la Krivine of our calculus that allows us to prove normalization and soundness.

Keywords Curry-Howard, dependent choice, classical arithmetic, side effects, dependent types, classical realizability, sequent calculus

1 Introduction

1.1 Realizing AC_{\omega} and DC in presence of classical logic

Dependent types are one of the key features of Martin-Löf’s type theory [18], allowing formulas to refer to terms. Notably, the existential quantification rule is defined so that a proof term of type \( \exists x . A : B \) is a pair \((p, t)\) where \( p \)—the witness—is of type \( A \), while \( t \)—the proof—is of type \( B[t/x] \). Dually, the theory enjoys two elimination rules: one with a destructor \( \text{wit} \) to extract the witness, the second one with a constructor \( \text{prf} \) to extract the proof. This allows for a simple and constructive proof of the full axiom of choice [18]:

\[
AC_A := \lambda h . \lambda x . \text{wit}(H x), \lambda x . \text{prf}(H x) (\forall x . \exists y . B(x, y)) \rightarrow \exists f \forall x . B(x, f(x))
\]

This term is nothing more than an implementation of Brouwer-Heyting-Kolomogoroff interpretation of the axiom of choice [13]: given a proof \( H \) of \( \forall x . \exists y . B(x, y) \), it constructs a choice function which simply maps any \( x \) to the witness of \( H x \), while the proof that this function is sound w.r.t. \( B \) returns the corresponding certificate.

Yet, this approach deeply relies on the constructivity of the theory. We present here a continuation of Herbelin’s works [12], who proposed a way of scaling up Martin-Löf’s proof to classical logic.

The first idea is to restrict the dependent types to the fragment of negative-elimination-free proofs (NEF) which, intuitively, only contains constructive proofs behaving as values. The second idea is to represent a countable universal quantification as an infinite conjunction. This allows us to internalize into a formal system (called dPA^{ac}) the realizability approach [2, 10] as a direct proofs-as-programs interpretation.

Informally, let us imagine that given a proof \( \lambda H . \lambda n . \text{wit}(n \text{th} n H_{\omega}) \), we could create the infinite sequence \( H_{\omega} = (H_0, H_1, \ldots) \) and select its \( n^{\text{th}} \)-element with some function \( n \text{th} \). Then, one might wish that:

\[
\lambda H . \lambda n . \text{wit}(n \text{th} n H_{\omega}), \lambda n . \text{prf}(n \text{th} n H_{\omega})
\]

could stand for a proof for \( \text{AC}_{\omega} \). One problem is that even if we were effectively able to build such a term, \( H_{\omega} \) might still contain some classical proofs. Therefore, two copies of \( Hn \) might end up behaving differently according to the contexts in which they are executed, and thus returning two different witnesses (which is known to lead to logical inconsistencies [11]). This problem can be fixed by using a shared version of \( H_{\omega} \), that is to say:

\[
\lambda H . \lambda n . \text{wit}(n \text{th} n H_{\omega}), \lambda n . \text{prf}(n \text{th} n H_{\omega})
\]

In words, the term \( H_{\omega} \) is now shared between all the places which may require some of its components.

It only remains to formalize the intuition of \( H_{\omega} \), which is done by means of a stream \( \text{cof}([n H, f(S(n))]) \) iterated on \( f \) with parameter \( n \), starting with 0:

\[
\text{AC}_{\omega} := \lambda H . \lambda n . \text{wit}(n \text{th} n H_{\omega}), \lambda n . \text{prf}(n \text{th} n H_{\omega})
\]

The stream is, at the level of formulas, an inhabitant of a coinductive type \( \nu n (\exists y . B(n, y)) \times \nu n n \). Since we cannot afford to pre-evaluate each of its components, and we thus have to use a lazy call-by-value evaluation discipline. However, it still might be responsible for some non-terminating reductions, all the more classical proofs may contain backtrack.

1.2 Normalization of dPA^{ac}

In [12], the property of normalization (on which relies the one of consistency) was only conjectured, and the proof sketch that was given turned out to be hard to formalize properly. Our first attempt to prove the normalization of dPA^{ac} was to derive a continuation-passing style translation (CPS), but translations appeared to be hard to obtain for dPA^{ac} as such. In addition to the difficulties caused by control operators and co-fixpoints, dPA^{ac} reduction system is defined in a natural deduction fashion, with contextual rules where the contexts involved can be of arbitrary depth. This kind of rules is indeed difficult to faithfully translate through a CPS.

Rather than directly proving the normalization of dPA^{ac}, we choose to first give an alternative presentation of the system under
the form of a sequent calculus, which we call \(\text{dLPA}^{\omega}\). Indeed, sequent calculus presentations of a calculus usually provides good intermediate steps for CPS translations \([9, 22, 23]\) since they enforce a decomposition of the reduction system into finer-grain rules. To this aim, we first handled separately the difficulties peculiar to the definition of such a calculus: on the one hand, we proved with Herbelin the normalization of a calculus with control operators and lazy evaluation \([21]\); on the other hand, we defined a classical sequent calculus with dependent types \([20]\). By combining the techniques developed in these frameworks, we finally manage to define \(\text{dLPA}^{\omega}\), which we present here and prove to be normalizing.

1.3 Realizability interpretation of classical call-by-need

In the call-by-need evaluation strategy, the substitution of a variable is delayed until knowing whether the argument is needed. To this end, Ariola et al. \([1]\) proposed the \(\hat{\Lambda}^{\omega}[\nu\tau]\)-calculus, a variant of Curien-Herbelin’s \(\lambda\mu\nu\)-calculus \([7]\) in which substitutions are stored in an explicit environment. Thanks to Danvy’s methodology of semantics artifacts \([8]\), which consists in successively refining the reduction system until getting context-free reduction rules\(^1\), they obtained an untyped CPS translation for the \(\hat{\Lambda}^{\omega}[\nu\tau]\)-calculus. By pushing one step further this methodology, we showed with Herbelin how to obtain a realizability interpretation à la Krivine for this framework \([21]\). The main idea, in contrast to usual models of Krivine realizability \([15]\), is that realizers are defined as pairs of a term and a substitution. The adequacy of the interpretation directly provided us with a proof of normalization, and we shall follow the same methodology to prove the normalization of \(\text{dLPA}^{\omega}\).

1.4 A sequent calculus with dependent types

While sequent calculi are naturally tailored to smoothly support CPS interpretations, there was no such presentation of language with dependent types compatible with a CPS. In addition to the problem of safely combining control operators and dependent types \([11]\), the presentation of a dependently typed language under the form of a sequent calculus is a challenge in itself. In \([20]\), we introduced such a system, called \(\text{dLPA}_0\), which is a call-by-value sequent calculus with classical control and dependent types. In comparison with usual type systems, we decorated typing derivations with a list of dependencies to ensure subject reduction. Besides, the soundness of the calculus was justified by means of a CPS translation taking the dependencies into account. The very definition of the translation constrained us to use delimited continuations in the calculus when reducing dependently typed terms. At the same time, this unveiled the need for the syntactic restriction of dependencies to the negative-elimination-free fragment as in \([12]\). Additionally, we showed how to relate our calculus to a similar system by Lepigre \([17]\), whose consistency is proved by means of a realizability interpretation. In the present paper, we use the same techniques, namely a list of dependencies and delimited continuations, to ensure the soundness of \(\text{dLPA}^{\omega}\), and we follow Lepigre’s interpretation of dependent types for the definition of our realizability model.

1.5 Contributions of the paper

The main contributions of this paper can be stated as follows. First, we define \(\text{dLPA}^{\omega}\) (Section 2), a sequent calculus with classical control, dependent types, inductive and coinductive fixpoints and lazy evaluation made available thanks to the presence of stores. This calculus can be seen as a sound combination of \(\text{dLPA}_0\) \([20]\) and the \(\hat{\Lambda}^{\omega}[\nu\tau]\)-calculus \([\text{1, 21}]\) extended with the expressive power of \(\text{dPA}^{\omega}\) \([12]\). Second, we prove the properties of normalization and soundness for \(\text{dLPA}^{\omega}\) thanks to a realizability interpretation à la Krivine, which we obtain by applying Danvy’s methodology of semantic artifacts (Sections 3 and 4). Lastly, \(\text{dLPA}^{\omega}\) incidentally provides us with a direct proofs-as-programs interpretation of classical arithmetic with dependent choice, as sketched in \([12]\).

This paper is partially taken from the Chapter 8 of the author’s PhD thesis \([19]\). For more detailed proofs, we refer the reader to the different appendices.

2 A sequent calculus with dependent types for classical arithmetic

2.1 Syntax

The language of \(\text{dLPA}^{\omega}\) is based on the syntax of \(\text{dLPA}_0\) \([20]\), extended with the expressive power of \(\text{dPA}^{\omega}\) \([12]\) and with explicit stores as in the \(\hat{\Lambda}^{\omega}[\nu\tau]\)-calculus \([1]\). We stick to a stratified presentation of dependent types, that is to say that we syntactically distinguish terms—that represent mathematical objects—from proof terms—that represent mathematical proofs. In particular, types and formulas are separated as well, matching the syntax of \(\text{dPA}^{\omega}\)'s formulas. Types are defined as finite types with the set of natural numbers as the sole ground type, while formulas are inductively built on atomic equalities of terms, by means of conjunctions, disjunctions, first-order quantifications, dependent products and co-inductive types.

The syntax of terms is identical to the one in \(\text{dLPA}_0\), including \(\lambda\)s and \(\lambda\)'s, and applications \(tu\), as well as a recursion operator \(\text{rec}_{x_0}^t\), so that terms represent objects in arithmetic of finite types. As for proof terms (and contexts, commands), they are now defined with all the expressiveness of \(\text{dPA}^{\omega}\). Each constructor in the syntax of formulas is reflected by a constructor in the syntax of proofs and by the dual co-proof (i.e. destructor) in the syntax of evaluation contexts. Amongst other things, the syntax includes pairs \((t, p)\) where \(t\) is a term and \(p\) a proof, which inhabit the dependent sum type \(\exists x^T.A\); dual co-pairs \(\mu\nu x.a.c\) which bind the (term and proof) variables \(x\) and \(a\) in the command \(c\); functions \(\lambda x.p\) inhabiting the type \(\forall x.A\). Together with their dual, stacks \(t.e\) where \(e\) is a context whose type might be dependend in \(t\); functions \(\lambda a.p\) which inhabit the dependent product type \(\Pi a.A\); and, dually, stacks \(q.e\), where \(e\) is a context whose type might be dependend in \(q\); a proof term \(\text{ref}\) which is the proof of atomic equalities \(t = t\) and a destructor \(\mu v.c\) which allows us to type the command \(c\) modulo an equality of terms; operators \(f_1 x t_1[p_1] p_2\) and \(\text{cof} f_1[x t_1[p_1] p_2]\), as in \(\text{dPA}^{\omega}\), for inductive and coinductive reasoning; delimited continuations through proofs \(\mu \nu.\mathfrak{C}\) and the context \(\mathfrak{P}\); a distinguished context \(\mathfrak{L}\) of type \(\perp\), which allows us to reason ex-falso.
From the image, the text appears to be a page discussing a sequent calculus with dependent types for classical arithmetic. It introduces a language of dLPA, which is defined in terms of rules and axioms. The text explains how the language is used to formalize classical arithmetic, including the use of dependent types and the concept of delimited continuations.

The figure 1 provides the language of dLPA, which includes the syntax for closures, commands, proof terms, proof values, terms, and terms values. The language is defined in terms of specific constructs and rules.

The text continues to discuss the reduction system of dLPA, highlighting the difference between inductive and coinductive fixpoints. It also mentions the use of a call-by-value evaluation strategy except for fixpoint processors.

2.2 Reduction rules

The reduction system of dLPA is given in Figure 2. The basic rules are those of the call-by-value λµ-calculus and of dL. The rules for delimited continuations are exactly the same as in dL, except that we have to prevent \( \hat{p} \) from being caught and stored by a proof \( \mu a.c \). We thus distinguish two rules for commands of the shape \( \langle a b, c \rangle \), depending on whether \( \varepsilon \) is the shape of \( e p \) or not. In the former case, we perform the substitution \( e p / a \), which is linear since \( \mu a.c \) is necessarily nef. We should also mention in passing that we abuse the syntax in every other rule, since \( e \) should actually refer to \( e \) or \( e p \) (or the reduction of delimited continuations would be stuck). Elimination rules correspond to commands where the proof is a constructor (say of pairs) applied to values, and where the context is the matching destructor. Call-by-value rules correspond to \( (c) \) rule of Wadler’s sequent calculus \([26]\). The next rules express the fact that (co-)fixpoints are lazily stored, and reduced only if their value is eagerly demanded by a forcing context.

2.3 Typing rules

As often in Martin-Löf’s intensional type theory, formulas are considered up to equational theory on terms. We denote by \( A \equiv B \) the reflexive-transitive-symmetric closure of the relation \( \equiv \) induced by the reduction of terms and nef proofs as follows:

\[
A[t] \equiv A[t'] \quad \text{whenever} \quad t \rightarrow B t' \\
A[p] \equiv A[q] \quad \text{whenever} \quad \forall \alpha \,(A[p\alpha] \rightarrow A[q\alpha])
\]

in addition to the reduction rules for equality and for coinductive formulas:

\[
0 = S(t) \quad \perp \\
S(t) = 0 \quad \perp \\
\text{We work with one-sided sequents where typing contexts are defined by:}
\]

\[
\Gamma, \Delta ::= x \mid \Gamma, \Delta, t : T \mid \Gamma, \Delta, a : A \mid \Gamma, \alpha : A^\mu \mid \Gamma, \hat{p} : A^\mu.
\]

using the notation \( \alpha : A^\mu \) for an assumption of the refutation of \( A \). This allows us to mix hypotheses over terms, proofs and contexts while keeping track of the order in which they are added (which is necessary because of the dependencies). We assume that a variable occurs at most once in a typing context.

We define nine syntactic kinds of typing judgments: six in regular mode, that we write \( \Gamma \vdash^r J \), and three more for the dependent mode, that we write \( \Gamma \vdash^d J : \sigma \). In each case, \( \sigma \) is a list of dependencies—we explain the presence of a list of dependencies in

---

5See [20] for further details.
6To highlight the duality between inductive and coinductive fixpoints, we evaluate both in a lazy way. Even though this is not indispensable for inductive fixpoints, we find this approach more natural in that we can treat both in a similar way in the small-step reduction system and thus through the realizability interpretation.
7Our so-called stores somewhat behave like lazy explicit substitutions or mutable environments. See [21] for a discussion on this point.
The substitution on formulas according to a list of dependencies and not only a variable.

\[ (\lambda a. p) \triangleright (\mu \Phi . q) \triangleright \langle (\mu \Phi . (q) \triangleright \mu a . (p) \triangleright q) \rangle \]

Elimination rules

\[ \langle V_{V} \rangle \triangleright (\mu \Phi . (q) \triangleright \mu a . (p) \triangleright q) \rangle \]

\[ \langle V_{V} \rangle \triangleright (\mu \Phi . (q) \triangleright \mu a . (p) \triangleright q) \rangle \]

Lookup

\[ \langle V_{V} \rangle \triangleright (\mu \Phi . (q) \triangleright \mu a . (p) \triangleright q) \rangle \]

Terms

\[ (\mu \Phi . (q) \triangleright \mu a . (p) \triangleright q) \rangle \]

Delimited continuations

\[ \langle (\mu \Phi . (q) \triangleright \mu a . (p) \triangleright q) \rangle \]

Call-by-value

\[ (\mu \Phi . (q) \triangleright \mu a . (p) \triangleright q) \rangle \]

Laziness

\[ (\mu \Phi . (q) \triangleright \mu a . (p) \triangleright q) \rangle \]

Each case thereafter—, which are defined from the following grammar:

\[ \sigma ::= \varepsilon \mid \sigma [p/q] \]

The substitution on formulas according to a list of dependencies \( \sigma \) is defined by:

\[ \varepsilon (A) \triangleq \{ A \} \]

\[ \sigma (p/q) (A) \triangleq \begin{cases} \sigma (A/p) & \text{if } q \in \text{NEF} \\ \sigma (A) & \text{otherwise} \end{cases} \]

Because the language of proof terms include constructors for pairs, injections, etc., the notation \( A[q/p] \) does not refer to usual substitutions properly speaking: \( p \) can be a pattern (for instance \( (a_{1}, a_{2}) \)) and not only a variable.

We shall attract the reader’s attention to the fact that all typing judgments include a list of dependencies. Indeed, as in the A\( \text{[ter]} \) calculus, when a proof or a context is caught by a binder, say \( V \) and \( \mu a \), the substitution \( [V/a] \) is not performed but rather put in the store: \( \tau [a := V] \). Now, consider for instance the reduction of a dependent function \( \lambda a . p \) (of type \( \Pi a : A . B \)) applied to a stack \( V \cdot e \):

\[ (\lambda a. p) \cdot V \cdot e \cdot \tau \rightarrow (\mu \Phi . (V) \triangleright \mu a . (p) \triangleright q) \cdot e \cdot \tau \]

\[ \triangleright (\mu \Phi . (q) \triangleright \mu a . (p) \triangleright q) \rangle \cdot (a := V) \rightarrow (p \cdot e) \cdot \tau [a := V] \]

\[ \tau [a := V] \]

Since \( p \) still contains the variable \( a \), whence his type is still \( B[a] \), whereas the type of \( e \) is \( B[V] \). We thus need to compensate the missing substitution\( ^{8} \).

We are mostly left with two choices. Either we mimic the substitution in the type system, which would amount to the following typing rule:

\[ \Gamma, \Gamma' \vdash \tau (c) \quad \Gamma \vdash : \Gamma' \quad \Gamma' \vdash \tau \]

\[ \Gamma \vdash c \tau \]

where:

\[ C_{1} \quad ::= \langle (l \mid p) \rangle \mid \langle (l \mid p) \rangle \] (\( \text{NEF} \))

\[ (c) \quad ::= \langle (l \mid p) \rangle \mid \langle (l \mid p) \rangle \] (\( \text{NEF} \))

\[ T [ ] \quad ::= C_{1} \mid T [ l ] \cup T [ r (l \mid p) \rangle \] (\( \text{NEF} \))

Or we type stores in the spirit of the \( T_{A}[l \mid r, \rho, e] \) calculus, and we carry along the derivations all the bindings liable to be used in types, which constitutes again a list of dependencies.

The former solution has the advantage of solving the problem before typing the command, but it has the flaw of performing computations which would not occur in the reduction system. For instance, the substitution \( \tau (c) \rangle \) could duplicate co-foxpoints (and their typing derivations), which would never happen in the calculus. That is the reason why we favor the other solution, which is closer to the calculus in our opinion. Yet, it has the drawback that it forces us to carry a list of dependencies even in regular mode. Since this list is fixed (it does not evolve in the derivation except

\[ \text{We refer the reader to} \ [20] \text{for detailed explanations on this rule.} \]

\[ ^{8} \text{The reader is referred to} \ [20] \text{for detailed explanation on this rule.} \]

\[ \text{Étienne Miquey} \]
when stores occur), we differentiate the denotation of regular typing judgments, written \( \Gamma \vdash \sigma \), from the one of judgments in dependent mode, which we write \( \Gamma \vdash_d \sigma \), to highlight that \( \sigma \) grows along derivations. The type system we obtain is given in Figure 3.

### 2.4 Subject reduction

We shall now prove that typing is preserved along reduction. As for the \( \Delta \Gamma \) calculus, the proof is simplified by the fact that substitutions are not performed (except for terms), which keeps us from proving the safety of the corresponding substitutions. Yet, we first need to prove some technical lemmas about dependencies. To this aim, we define a relation \( \sigma \Rightarrow \sigma' \) between lists of dependencies, which expresses the fact that any typing derivation obtained with \( \sigma \) could be obtained as well with \( \sigma' \):

\[
\sigma \Rightarrow \sigma' \iff \forall A, B : \sigma(A) = \sigma(B) \Rightarrow \sigma'(A) = \sigma'(B) \quad \text{(for any } A, B)\]

### Proposition 2.1 (Dependencies weakening).

If \( \sigma, \sigma' \) are two lists of dependencies such that \( \sigma \Rightarrow \sigma' \), then any derivation using \( \sigma \) can be done using \( \sigma' \) instead. In other words, the following rules are admissible:

\[
\frac{\Gamma \vdash \sigma \Gamma' \vdash' \tau : (\Gamma'; \sigma')} {\Gamma \vdash \sigma' \Gamma' \vdash' \tau : (\Gamma'; \sigma')} \quad \text{(w)}
\]

We can prove the safety of reduction with respect to typing:

### Theorem 2.2 (Subject reduction).

For any context \( \Gamma \) and any closures \( \sigma \) and \( \sigma' \) such that \( \sigma \vdash \sigma' \), we have:

1. If \( \Gamma \vdash \sigma \) then \( \Gamma \vdash \sigma' \).
2. If \( \Gamma \vdash_d \sigma \) then \( \Gamma \vdash_d \sigma' \).

Proof. The proof follows the usual proof of subject reduction, by induction on the reduction \( \sigma \vdash \sigma' \). See Appendix A. \( \square \)
2.5 Natural deduction as macros

We can recover the usual proof terms for elimination rules in natural deduction systems, and in particular the ones from dPA$\omega$, by defining them as macros in our language. The definitions are straightforward, using delimited continuations for let ... in and the constructors over new proofs which might be dependently typed:

\[
\begin{align*}
\text{let } p = q & \Rightarrow p \triangleq \mu \alpha.p.(p\beta.a.a.|\alpha\beta) \\
\text{split } p & \Rightarrow (a_1, a_2) \triangleq \mu \beta.(a_1, a_2).|\beta a a | \alpha \beta a a | \gamma \alpha \beta a a \\
\text{case } p & \Rightarrow (a, x) \triangleq \mu \delta.(\delta a x).|\alpha \beta a a | \gamma \beta a a \\
\text{dest } p & \Rightarrow (a, x) \triangleq \mu \delta.(\delta a x).|\alpha \beta a a | \gamma \beta a a \\
\text{prf } & \Rightarrow \mu \psi.(\psi a x).|\beta a a |
\end{align*}
\]

where $\alpha_\beta = \psi$ if $p$ is a new and $\alpha_\beta = \alpha$ otherwise.

It is then straightforward to check that the macros match the expected typing rules:

**Proposition 2.3** (Natural deduction). The typing rules from dPA$\omega$, given in Figure 4, are admissible.

One can even check that the reduction rules in dLPA$\omega$ for these proofs almost mimic the ones of dPA$\omega$. To be more precise, the rules of dLPA$\omega$ do not allow to simulate each rule of dPA$\omega$, due to the head-reduction strategy amongst other things. Nonetheless, up to a few details the reduction of a command in dLPA$\omega$ follows one particular reduction path of the corresponding proof in dPA$\omega$, or in other words, one reduction strategy.

The main result is that using the macros, the same proof terms are suitable for countable and dependent choice [12]. We do not state it here, but following the approach of [12], we could also extend dLPA$\omega$ to obtain a proof for the axiom of bar induction.

**Theorem 2.4** (Countable choice [12]). We have:

\[
\begin{align*}
\text{AC}_\mathbb{N} & := \lambda h.\text{let } a = \text{cofix} \lambda_n.(Hn,b(S(n))) \\
& \Rightarrow \text{in } (\lambda n.\text{w}it(nth a), \lambda n.\text{prf}(nth a)) \\
& \Rightarrow \forall x \exists y.\exists z. P(x, y) \Rightarrow \exists f^\exists \exists \forall x P(x, f(x))
\end{align*}
\]

where $\text{nth } a := \pi_1(\text{fix}_1\lambda c.a | \pi_2(c))$.

**Theorem 2.5** (Dependent choice [12]). We have:

\[
\begin{align*}
\text{DC} & := \lambda h.\lambda x.\text{let } a = (x_0, \text{cofix} \lambda_n.(d_n)) | \text{six} \\
& \Rightarrow \text{in } (\lambda n.\text{w}it(nth a), \text{refl}, \lambda n.\pi_1(\text{prf}(\text{prf}(nth a)))) \\
& \Rightarrow \forall x^\exists \exists y.\exists z.\exists \bar{f}^{\exists \exists} \forall x^\exists P(x, f(x))
\end{align*}
\]

where $d_n := \text{dest } Hn$ as $(y, c)$ in $(y, (c, b))$ and $\text{nth } a := \text{fix}_1\lambda x_1.d[a | (\text{wit}(\text{prf } d), \pi_2(\text{prf } (d)))].$

3 Small-step calculus

As for the $\lambda[\lambda x.\cdot]_\mathbb{N}$-calculus [21, 22], we follow here Danvy’s methodology of semantic artifacts [1, 8] to obtain a realizability interpretation. We first decompose the reduction system of dLPA$\omega$ into small-step reduction rules, that we denote by $\rightarrow_s$. This requires a refinement and an extension of the syntax, that we shall now present. To keep us from boring the reader stiff with new (huge) tables for the syntax, typing rules and so forth, we will introduce them step by step. We hope it will help the reader to convince herself of the necessity and of the somewhat natality of these extensions.

3.1 Values

First of all, we need to refine the syntax to distinguish between strong and weak values in the syntax of proof terms. As in the $\lambda[\lambda x.\cdot]_\mathbb{N}$-calculus, this refinement is induced by the computational behavior of the calculus: weak values are the ones which are stored by $\mu$ binders, but which are not values enough to be eliminated in front of a forcing context, that is to say variables. Indeed, if we observe the reduction system, we see that in front of a forcing context $f$, a variable leads a search through the store for a “stronger” value, which could incidentally provoke the evaluation of some fix-points. On the other hand, strong values are the ones which can be reduced in front of the matching forcing context, that is to say functions, $\text{refl}$, pairs of values, injections or dependent pairs:

**Weak values** $V := a | v$

**Strong values** $v := i(V) | (V, V) | (V, V) | \lambda x.\mu_\pi \cdot a_\pi | \text{refl}$

This allows us to distinguish commands of the shape $(\pi f)\pi$, where the forcing context (and next the strong value) are examined to determine whether the command reduces or not; from commands of the shape $(\lambda f)\pi$ where the focus is put on the variable $a$, which leads to a lookup for the associated proof in the store.

3.2 Terms

Next, we need to explicit the reduction of terms. To this purpose, we include a machinery to evaluate terms in a way which resembles the evaluation of proofs. In particular, we define new commands which we write $(t|\pi)$ where $t$ is a term and $\pi$ is a context for terms (or co-term). Co-terms are either of the shape $\mu x.c$ or stacks of the shape $u \cdot \pi$. These constructions are the usual ones of the $\lambda\mu$-calculus (which are also the ones for proofs). We also extend the definitions of commands with delimited continuations to include the corresponding commands for terms:

**Commands** $c ::= (p|e) | (t|\pi)$

**Co-terms** $\pi ::= t \cdot \pi | \mu x.c$
We give typing rules for these new constructions, which are the usual rules for typing contexts in the λµ∐-calculus:

$$
\begin{align*}
\Gamma, t : T & \vdash \Gamma \vdash \pi : (T \to U \to \bot) \\
\Gamma, t : T & \vdash \Gamma \vdash \mu \pi, c : T \to U \to \bot \\
\Gamma, t : T & \vdash \Gamma \vdash \mu \pi, c : T \to U \to \bot
\end{align*}
$$

It is worth noting that the syntax as well as the typing and reduction rules for terms now match exactly the ones for proofs. In other words, with these definitions, we could abandon the stratified presentation without any trouble, since reduction rules for terms will naturally collapse to the ones for proofs.

3.3 Co-delimited continuations

Finally, in order to maintain typability when reducing dependent pairs of the strong existential type, we need to add what we call special reduction rules. Indeed, consider such a pair of type \(\exists t. T.A\), the standard way of reducing it would be a rule like:

$$
\langle \langle t, p \rangle | e \rangle \cdot \tau \rightsquigarrow \langle \langle t \| \mu \pi \cdot \langle \langle \psi \| \mu \alpha, \langle \langle x, a \rangle | e \rangle \rangle \rangle \rangle \cdot \tau
$$

but such a rule does not satisfy subject reduction. Consider indeed a typing derivation for the left-hand side command, when typing the pair \(t, p\), \(p\) is of type \(A[t]\). On the command on the right-hand side, the variable \(a\) will then also be of type \(A[t]\), while it should be of type \(A[x]\) for the pair \(x, a\) to be typed. We thus need to compensate this mismatching of types, by reducing \(t\) within a context where \(a\) is not linked to \(p\) but to a co-reset \(\psi\) (dual to reset \(\mu\)), whose type can be changed from \(A[x]\) to \(A[t]\) thanks to a list of dependencies:

$$
\langle \langle t, p \rangle | e \rangle \cdot \tau \rightsquigarrow \langle \langle t \| \mu \pi \cdot \langle \langle \psi \| \mu \alpha, \langle \langle x, a \rangle | e \rangle \rangle \rangle \rangle \cdot \tau
$$

We thus equip the language with new contexts \(\mu \mu \cdot \mu \alpha\), which we call co-shifts and where \(\mu \alpha\) is a command whose last cut is of the shape \(\langle \langle \psi \| \mu \alpha \rangle \rangle\). This corresponds formally to the following syntactic sets, which are dual to the ones introduced for delimited continuations:

**Contexts**

\[
\begin{align*}
e & ::= \cdots | \mu \mu \cdot \mu \alpha, c_{\mu}\n\end{align*}
\]

**Co-delimited continuations**

\[
\begin{align*}
c_{\mu} & ::= \langle \langle \psi \| e_{\mu} \rangle \rangle | \langle \langle t \| \pi_{\mu} \rangle \rangle | \langle \langle \psi \| e \rangle \rangle \\
\end{align*}
\]

**NEF**

\[
\begin{align*}
e_N & ::= \cdots | \mu \mu \cdot \mu \alpha, c_{\mu}
\end{align*}
\]

This might seem to be a heavy addition to the language, but we insist on the fact that these artifacts are merely the dual constructions of delimited continuations introduced in \(d\)L\(_B\), with a very similar intuition. In particular, it might be helpful for the reader to think of the fact that we introduced delimited continuations for type safety of the evaluation of dependent products in \(\Pi A. B\) (which naturally extends to the case \(\forall X.T.A\)). Therefore, to maintain type safety of dependent sums in \(\exists X.A\), we need to introduce the dual constructions of co-delimited continuations. We also give

\[\text{typing rules to these constructions, which are dual to the typing rules for delimited-continuations:}\]

\[
\begin{align*}
\Gamma, \mu \psi : A + \mu \psi, c_{\mu} : \sigma & \vdash \Gamma, \mu \psi, c_{\mu} : A \to \sigma \\
\Gamma, \mu \psi, c_{\mu} : \sigma & \vdash \Gamma, \mu \psi, c_{\mu} : A \to \sigma
\end{align*}
\]

Note that we also need to extend the definition of list of dependencies to include bindings of the shape \(\langle \langle x, a \rangle | e \rangle\) for terms, and that we have to give the corresponding typing rules to type commands of terms in dependent mode:

\[
\begin{align*}
\Gamma, t : T & \vdash \Pi e_{\mu} : T \to \sigma | e_{\mu} | \langle \langle \psi \| \mu \alpha, \langle \langle x, a \rangle | e \rangle \rangle | \langle \langle \psi \| \mu \alpha, \langle \langle x, a \rangle | e \rangle \rangle | \langle \langle \psi \| \mu \alpha, \langle \langle x, a \rangle | e \rangle \rangle
\end{align*}
\]

The small-step reduction system is given in Appendix C. The rules are written \(\cdot \rightsquigarrow \cdot\) where the annotation \(\cdot, p\) on commands are indices (i.e. \(c, p, e, V, f, t, \pi, V_i\)) indicating which part of the command is in control. As in the \(\lambda[\mu \tau \exists \sigma]\)-calculus, we observe an alternation of steps descending from \(p\) to \(f\) for proofs and from \(t\) to \(V_i\) for terms. The descent for proofs can be in two main phases. During the first phase, from \(p\) to \(e\) we observe the call-by-value process, which extracts values from proofs, opening recursively the constructors and computing values. In the second phase, the core computation takes place from \(V_i\) to \(f\), with the destruction of constructors and the application of function to their arguments. The laziness corresponds precisely to a skip of the first phase, waiting to possibly reach the second phase before actually going through the first one.

Here again, reduction is safe with respect to the type system:

**Proposition 3.1 (Subject reduction).** The small-step reduction rules satisfy subject reduction.

**Proof.** The proof is again an induction on \(\cdot \rightsquigarrow \cdot\), see Appendix C. \(\Box\)

It is also direct to check that the small-step reduction system simulates the big-step one, and in particular that it preserves the normalization:

**Proposition 3.2.** If a closure \(\cdot\) normalizes for the reduction \(\rightsquigarrow\), then it normalizes for \(\to\).

**Proof.** By contraposition, see Appendix C. \(\Box\)

4 A realizability interpretation of \(d\)LPA

We shall now present the realizability interpretation of \(d\)LPA, which will finally give us a proof of its normalization. Here again, the interpretation combines ideas of the interpretations for the \(\lambda[\mu \tau \exists \sigma]\)-calculus [21] and for \(\mu\)L\(_B\) through the embedding in Lepigre’s calculus [17, 20]. Namely, as for the \(\lambda[\mu \tau \exists \sigma]\)-calculus, formulas will be interpreted by sets of proofs-in-store of the shape \(p(\tau)\), and the orthogonality will be defined between proofs-in-store \(p(\tau)\) and contexts-in-store \(e(\tau)\) such that the stores \(\tau\) and \(\tau'\) are compatible.

We recall the main definitions necessary to the realizability interpretation:

**Definition 4.1 (Proofs-in-store).** We call closed proof-in-store (resp. closed context-in-store, closed term-in-store, etc) the combination of a proof \(p\) (resp. context \(e\), term \(t\), etc) with a closed store \(\tau\) such that \(\text{FV}(p) \subseteq \text{dom}(\tau)\). We use the notation \((p(\tau))\) to denote such
a pair. In addition, we denote by $\Lambda_p$ (resp. $\Lambda_c$, etc.) the set of all proofs and by $\Lambda_{p, c}$ (resp. $\Lambda_{p, c}$, etc.) the set of all proofs-in-store.

We denote the sets of closed closures by $C_0$, and we identify $(c|\tau)$ with the closure $c\tau$ when $c$ is closed in $\tau$.

We now recall the notion of compatible stores [21], which allows us to define an orthogonality relation between proofs- and contexts-in-store.

**Definition 4.2 (Compatible stores and union).** Let $\tau$ and $\tau'$ be stores, we say that:

- they are independent and note $\tau \nparallel \tau'$ if $\mathrm{dom}(\tau) \cap \mathrm{dom}(\tau') = \emptyset$.
- they are compatible and note $\tau \parallel \tau'$ if for all variables $a$ (resp. co-variables $\alpha$) present in both stores: $a \in \mathrm{dom}(\tau) \cap \mathrm{dom}(\tau')$; the corresponding proofs (resp. contexts) in $\tau$ and $\tau'$ coincide.

- $\tau'$ is an extension of $\tau$ and we write $\tau \preceq \tau'$ whenever $\tau \parallel \tau'$ and $\mathrm{dom}(\tau) \subseteq \mathrm{dom}(\tau')$.

- $\tau \parallel \tau'$ is the compatible union of compatible closed stores $\tau$ and $\tau'$. It is defined as $\tau \parallel \tau' \triangleq \text{join}(\tau, \tau')$, which itself given by:

  \[
  \text{join}(\sigma_0(a \Rightarrow p_0) \tau_0, \sigma_0(a \Rightarrow p_0) \tau'_0) \triangleq \text{join}(\sigma_0(a \Rightarrow p_0) \tau_0) \tau'_0 \tau_0 \triangleq \text{join}(\sigma_0(a \Rightarrow p_0) \tau_0) \tau_0 \tau_0
  \]

  where $\sigma_0 \#_p\tau'_0$.

The next lemma (which follows from the previous definition) states the main property we will use about union of compatible stores.

**Lemma 4.3.** If $\tau$ and $\tau'$ are two compatible stores, then $\tau \preceq \tau$ and $\tau' \preceq \tau$. Besides, if $\tau$ is of the form $\sigma_0[\alpha \Rightarrow \tau_0|\tau_1]$, then $\tau \parallel \tau'$ is of the form $\sigma_0[\alpha \Rightarrow \tau_0|\tau_1]$ with $\tau_0 \preceq \tau_0$ and $\tau_1 \preceq \tau_1$.

We can now define the notion of pole, which has to satisfy an extra condition due to the presence of delimited continuations.

**Definition 4.4 (Pole).** A subset $\perp \subseteq C_0$ is said to be saturated or closed by anti-reduction whenever for all $(c|\tau), (c'|\tau') \in C_0$, we have:

\[
(c|\tau' \in \perp) \land (c|\tau \rightarrow c'|\tau') \Rightarrow (c|\tau \in \perp)
\]

It is said to be closed by store extension if whenever $c|\tau$ is in $\perp$, for any store $\tau'$ extending $\tau$, $c|\tau'$ is also in $\perp$.

\[
(c|\tau \in \perp) \land (\tau \parallel \tau') \Rightarrow (c|\tau' \in \perp)
\]

It is said to be closed under delimited continuations if whenever $c(e|\hat{\psi})\tau$ (resp. $c(V|\hat{\psi})\tau$) is in $\perp$, then $(\mu\hat{\psi}, c|\psi)(\tau)$ (resp. $(V|\mu\hat{\psi}, c|\tau)$) belongs to $\perp$:

\[
(c(e|\hat{\psi})\tau \in \perp) \Rightarrow (\mu\hat{\psi}, c|\psi)(\tau) \in \perp)
\]

\[
(c(V|\hat{\psi})\tau \in \perp) \Rightarrow (V|\mu\hat{\psi}, c|\tau) \tau \in \perp)
\]

A pole is defined as any subset of $C_0$ that is closed by anti-reduction, by store extension and under delimited continuations.

We verify that the set of normalizing command is indeed a pole.

**Proposition 4.5.** The set $\perp = \{c|\tau \in C_0 : c|\tau \text{ normalizes} \}$ is a pole.

We finally recall the definition of the orthogonality relation w.r.t. a pole, which is identical to the one for the $\Lambda_{\{t\tau \cdot \tau\}}$-calculus:

**Definition 4.6 (Orthogonality).** Given a pole $\perp$, we say that a proof-in-store $(\rho|\tau)$ is orthogonal to a context-in-store $(e|\tau')$ and write $(\rho|\tau) \perp (e|\tau')$ if $\tau$ and $\tau'$ are compatible and $(\rho|\tau) \tau \tau' \in \perp$.

The orthogonality between terms and co-terms is defined identically.

We are now equipped to define the realizability interpretation of $\lambda\text{DA}^{DA}$. Firstly, in order to simplify the treatment of coinductive formulas, we extend the language of formulas with second-order variables $X, Y, \ldots$ and we replace $\forall^*_X A$ by $\forall^*_X A(x/y) = 0$.

The typing rule for co-axiom operators then becomes:

\[
\frac{\Gamma \vdash \tau : T \quad \Gamma, x : T, b : \forall^*_Y X(y) \vdash \sigma : a \quad X \notin \text{FV}(\Gamma)}{\Gamma \vdash \text{cofix}_{b}\lambda^T_{\alpha} \rightarrow \tau^T_{\alpha} A} \quad \text{(cofix)}
\]

where $X$ has to be positive in $A$.

Secondly, as in the interpretation of $\lambda\text{DA}$ through Lepigre’s calculus, we introduce two new predicates, $p \in A$ for nef proofs and $t \in T$ for terms. This allows us to decompose the dependent products and sums into:

\[
\forall^*_X A \triangleq \forall^*_Y (x : T \rightarrow A) \quad \Pi^*_X A \triangleq \exists^*_X (x : T \rightarrow A)\]

\[
\Pi^*_X A \triangleq \forall^*_X (A(a : a \rightarrow B)(a \notin \text{FV}(B))) \quad \exists^*_X A \triangleq \exists^*_X (A : T \rightarrow A) \quad (\text{otw.})
\]

This corresponds to the language of formulas and types defined by:

**Types**

\[
T, U ::= \forall T \mid T \rightarrow U \mid t \in T
\]

**Formulas**

\[
A, B ::= \top \mid \bot \mid X(t) \mid t = u \mid A \land B \mid A \lor B \mid \forall X, A \mid \exists X, A \mid \forall^*_X A \mid a \in A
\]

and to the following inference rules:

\[
\frac{\Gamma \vdash \sigma : a \notin \text{FV}(\Gamma)}{\Gamma \vdash \sigma : a \notin \text{FV}(\Gamma)} \quad (\forall^*_T)
\]

\[
\frac{\Gamma, \tau \vdash \sigma : A[q/a] \quad \Gamma \vdash \sigma : (\forall^*_A) \neg B}{\Gamma \vdash \sigma : (\forall^*_A) \neg B} \quad (\forall^*_T)
\]

\[
\frac{\Gamma \vdash \sigma : A(t/x)}{\Gamma \vdash \sigma : A(t/x)} \quad (\exists^*_T)
\]

\[
\frac{\Gamma \vdash \sigma : A \quad \Gamma \vdash \sigma : (\exists^*_A) \neg B}{\Gamma \vdash \sigma : (\exists^*_A) \neg B} \quad (\exists^*_T)
\]

\[
\frac{\Gamma \vdash \sigma : p \in A \quad \Gamma \vdash \sigma : (\forall^*_A) \neg B}{\Gamma \vdash \sigma : (\forall^*_A) \neg B} \quad (\forall^*_T)
\]

\[
\frac{\Gamma \vdash \sigma : (A \rightarrow \tau)}{\Gamma \vdash \sigma : (A \rightarrow \tau)} \quad (\forall^*_T)
\]

\[
\frac{\Gamma \vdash \sigma : X(t) \mid t \in T}{\Gamma \vdash \sigma : X(t) \mid t \in T} \quad (\forall^*_T)
\]

These rules are exactly the same as in Lepigre’s calculus [17] up to our stratified presentation in a sequent calculus fashion, and modulo our syntactic restriction to nef proofs instead of his semantical restriction. It is a straightforward verification to check that the typability is maintained through the decomposition of dependent products and sums.

Another similarity with Lepigre’s realizability model is that truth/falsity values will be closed under observational equivalence of proofs and terms. To this purpose, for each store $\tau$ we introduce the relation $\equiv_{\forall^*_\tau}$, which we define as the reflexive-transitive-symmetric closure of the relation $\forall^*_\tau$:

\[
\forall^*_\tau \parallel \tau \quad \forall^*_\tau \parallel \tau \quad \forall^*_\tau \parallel \tau \quad \forall^*_\tau \parallel \tau \quad \forall^*_\tau \parallel \tau
\]

All this being settled, it only remains to determine how to interpret coinductive formulas. While it would be natural to try to interpret them by fixpoints in the semantics, this poses difficulties for the proof of adequacy. We discuss this matter in Appendix E,
A sequent calculus with dependent types for classical arithmetic

but as for now, we will give a simpler interpretation. We stick to the intuition that since \texttt{cofix} operators are lazily evaluated, they actually are realizers of every finite approximation of the (possibly infinite) coinductive formula. Consider for instance the case of a stream:

\[
\text{str}^\infty_\text{px} \triangleq \text{cofix}(\text{px}, b(S(x)))
\]

of type \(v^0_{\text{px}} A(x) \land X(S(x))\). Such stream will produce on demand any tuple (\(p(x), (p_1, p_2, \ldots)\)) where \(\Box\) denotes the fact that it could be any term, in particular \(\text{str}^\infty_\text{px}\). Therefore, \(\text{str}^\infty_\text{px}\) should be a successful defender of the formula

\[
(A(0) \land (A(1) \land \ldots (A(n) \land T) \ldots)
\]

Since \texttt{cofix} operators only reduce when they are bound to a variable in front of a forcing context, it suggests interpreting the coinductive formula \(v^0_{\text{px}} A(x) \land X(S(x))\) at level \(f\) as the union of all the opponents to a finite approximation. 10

To this end, given a coinductive formula \(v^0_{\text{px}} A\) where \(X\) is positive in \(A\), we define its finite approximations by:

\[
F^n_{f, A} \triangleq \top
\]

Since \(X\) is positive in \(A\), we have for any integer \(n\) and any term \(t\) that \(\| F^n_{f, A} \|_f \subseteq \| F^n_{f, \top} \|_f\). We can finally define the interpretation of coinductive formulas by:

\[
\| v^0_{\text{px}} A \|_f \equiv \bigcup_{n \in \mathbb{N}} \| F^n_{f, A(x)} \|_f
\]

The realizability interpretation of closed formulas and types is defined in Figure 5 by induction on the structure of formulas at level \(f\), and by orthogonality at levels \(V, e, p\). When \(S\) is a subset of \(\mathcal{P}(\Lambda_f^\top)\) (resp. \(\mathcal{P}(\Lambda_f^\bot), \mathcal{P}(\Lambda_f^\circlearrowleft)\), we use the notation \(S^\top_f\) (resp. \(S^\bot_f, S^\circlearrowleft\)) to denote its orthogonal set restricted to \(\Lambda_f^\top\):

\[
S^\top_f \equiv \{ (f, \tau) \land (p, \tau') \land (S, \tau) \land \tau' \Rightarrow (p, f) \land \tau' \in \mathbb{N} \}
\]

At level \(f\), closed formulas are interpreted by sets of strong forcing contexts-in-store \((f, \tau)\). As explained earlier, these sets are besides closed under the relation \(\equiv\) along their component \(\tau\), we thus denote them by \(\mathcal{P}(\Lambda_f^\top)\). Second-order variables \(X, Y, \ldots\) are then interpreted by functions from the set of terms \(\Lambda_t\) to \(\mathcal{P}(\Lambda_f^\top)\). and as is usual in Krivine realizability [15], for each such function \(F\) we add a predicate symbol \(\exists\) in the language.

We shall now prove the adequacy of the interpretation with respect to the type system. To this end, we need to recall a few definitions and lemmas. Since stores only contain proof terms, we need to define valuations for term variables in order to close formulas. These valuations are defined by the usual grammar:

\[
\rho := e \mid \rho[x \mapsto V] \mid \rho[	au \mapsto F]
\]

where:

- \(e \in \mathbb{S}\) (resp. \(e, V, \text{etc.}\) denotes \(p, \tau) \in S\) (resp. \(e, V, \text{etc.}\), etc.),
- \(F \) is a function from \(A_t\) to \(\mathcal{P}(\Lambda_f^\top)\).

\[\text{Definition 4.7.}\] Given a closed store \(\tau\), a valuation \(\rho\) and a fixed pole \(\rho\), we say that the pair \((\tau, \rho)\) realizes \(\Gamma\), which we write \(\tau)\), if:

1. for any \((a : A) \in \Gamma\), \((a, \tau) \in [A_\rho]_V\),
2. for any \((\alpha : A^\bot_\rho) \in \Gamma\), \((\alpha, \tau) \in [A_\rho]_V\),
3. for any \([a, \rho) \in [\sigma, \rho) \in \rho\) for any \((x : T) \in \Gamma\), \(x \in \text{dom}(\rho)\) and \((\rho(x), \tau) \in [T_\rho]_V\).

We can check that the interpretation is indeed defined up to the relations \(\equiv\).

\[\text{Proposition 4.8.}\] For any store \(\tau\) and any valuation \(\rho\), the component along \(\tau\) of the truth and falsity values defined in Figure 5 are closed under the relation \(\equiv\):

1. if \((f, \tau) \in [A_\rho]_f\) and \(A_\rho \equiv B_\rho\), then \((f, \tau) \in [B_\rho]_f\),
2. if \((V, \tau) \in [A_\rho]_V\) and \(A_\rho \equiv B_\rho\), then \((V, \tau) \in [B_\rho]_V\).

The same applies with \([A_\rho, B_\rho]_\circlearrowleft\), etc.

We can now prove the main property of our interpretation:

\[\text{Proposition 4.9 (Adequacy).}\] The typing rules are adequate with respect to the realizability interpretation, i.e. typed proofs (resp. values, terms, contexts, etc.) belong to the corresponding truth values.

Proof. By induction on typing derivations such as given in the system extended for the small-step reduction. See Appendix D. \(\Box\)

\[\text{10\textit{See Appendix E for a discussion on this point.}}\]
We can finally deduce that dLPAω is normalizing and sound.

**Theorem 4.10** (Normalization). If $\Gamma \vdash^\omega c$, then $c$ is normalizable.

**Proof.** Direct consequence of Propositions 4.5 and 4.9. □

**Theorem 4.11** (Consistency). $\forall \delta \in \mathrm{dLPA}^\omega \; p : \bot$

**Proof.** Assume there is such a proof $p$, by adequacy $(p|r)$ is in $|\bot|_p$ for any pole. Yet, the set $\bot \triangleq \emptyset$ is a valid pole, and with this pole, $|\bot|_p = \emptyset$, which is absurd. □

5 Conclusion and perspectives

**Conclusion** At the end of the day, we met our main objective, namely proving the soundness and the normalization of a language which includes proof terms for dependent and countable choice in a classical setting. This language, which we called dLPAω, provides us with the same computational features as dPAω but in a sequent calculus fashion. These computational features allow dLPAω to internalize the realizability approach of [2, 10] as a direct proofs-as-programs interpretation: both proof terms for countable and dependent choices furnish a lazy witness for the ideal choice function which is evaluated on demand. This interpretation is in line with the slogan that with new programming principles—here the lazy evaluation and the co-inductive objects—come new reasoning principles—here the axioms ACω and DC.

Interestingly, in our search for a proof of normalization for dLPAω, we developed novel tools to study these side effects and dependent types in presence of classical logic. On the one hand, we set out in [20] the difficulties related to the definition of a sequent calculus with dependent types. On the other hand, building on [21], we developed a variant of Krivine realizability adapted to a lazy calculus where delayed substitutions are stored in an explicit environment. The sound combination of both frameworks led us to the definition of dLPAω together with its realizability interpretation.

**Krivine’s interpretations of dependent choice** The computational content we give to the axiom of dependent choice is pretty different of Krivine’s usual realize of the same [14]. Indeed, our proof uses dependent types to get witnesses of existential formulas, and we represent choice functions through the lazily evaluated stream of their values. In turn, Krivine realizes a statement which is logically equivalent to the axiom of dependent choice thanks to the instruction quote, which injectively associates a natural number to each closed $\lambda c$-term. In a more recent work [16], Krivine proposes a realizability model which has a bar-recursor and where the axiom of dependent choice is realized using the bar-recursion. This realizability model satisfies the continuum hypothesis and many more properties, in particular the real numbers have the same properties as in the ground model. However, the very structure of this model, where $A$ is of cardinal $\aleph_1$ (in particular infinite streams of integer are terms), makes it incompatible with quote.

It is clear that the three approaches are different in terms of programming languages. Nonetheless, it could be interesting to compare them from the point of view of the realizability models they give rise to. In particular, our analysis of the interpretation of co-inductive formulas may suggest that the interest of lazy co-fixpoints is precisely to approximate the limit situation where $A$ has infinite objects.

**Reduction of the consistency of classical arithmetic in finite types with dependent choice to the consistency of second-order arithmetic** The standard approach to the computational content of classical dependent choice in the classical arithmetic in finite types is via realizability as initiated by Spector [25] in the context of Gödel’s functional interpretation, and later adapted to the context of modified realizability by Berardi et al [2]. The aforementioned works of Krivine [14, 16] in the different settings of PA2 and ZFω also give realizers of dependent choice. In all these approaches, the correctness of the realizer, which implies consistency of the system, is itself justified by a use at the meta-level of a principle classically equivalent to dependent choice (dependent choice itself in [14], bar induction or update induction [3] in the case of [2, 25]).

Our approach is here different, since we directly interpret proofs of dependent choice in classical arithmetic computationally. Besides, the structure of our realizability interpretation for dLPAω suggests the definition of a typed CPS to an extension of system Fω, but it is not clear whether its consistency is itself conservative or not over system F. Ultimately, we would be interested in a computational reduction of the consistency of dPAω or dLPAω to the one of PA2, that is to the consistency of second-order arithmetic. While it is well-known that DC is conservative over second-order arithmetic with full comprehension (see [24, Theorem VII.6.20]), it would nevertheless be very interesting to have such a direct computational reduction. The converse direction has been recently studied by Valentin Blot, who presented in [4] a translation of System F into a simply-typed total language with a variant of bar recursion.

Since most of the proofs contain typing derivations, we switch to a one column format to ease their display.

A Subject reduction (Proofs of Section 2.4)

We detail here the proof of subject reduction for \( d\text{LPA}^{\omega} \). Recall that we define the relation \( \sigma \Rightarrow \sigma' \) between lists of dependencies by:

\[
\sigma \Rightarrow \sigma' \triangleq \sigma(A) = \sigma(B) \Rightarrow \sigma'(A) = \sigma'(B)
\]

(for any \( A, B \))

We first show that the cases which we encounter in the proof of subject reduction satisfy this relation:

**Lemma A.1** (Dependencies implication). The following holds for any \( \sigma, \sigma', \sigma'' \):

1. \( \sigma\sigma'' \Rightarrow \sigma\sigma'\sigma' \)
2. \( \sigma[(a_1, a_2)](V_1, V_2)] \Rightarrow \sigma[a_1|V_1|a_2|V_2] \)
3. \( \sigma[i(a)]i_2(V) \Rightarrow \sigma[i(V)] \)
4. \( \sigma([x, a]|(t, V)) \Rightarrow \sigma(a|V)\{x|t\} \)
5. \( \sigma\{\{p_1, p_2\}\} \Rightarrow \sigma\{a_1|p_1|a_2|p_2\}\{\{a_1, a_2\}\} \)
6. \( \sigma\{i(p)\} \Rightarrow \sigma\{a|p\}\{i(a)\} \)
7. \( \sigma\{\{t, p\}\} \Rightarrow \sigma\{a|p\}\{\{t, a\}\} \)

where the fourth item abuse the definition of list of dependencies to include a substitution of terms.

**Proof.** All the properties are trivial from the definition of the substitution \( \sigma(A) \).

We can now prove that the relation \( \Rightarrow \) indeed matches the expected intuition:

**Proposition 2.1** (Dependencies weakening). If \( \sigma, \sigma' \) are two dependencies list such that \( \sigma \Rightarrow \sigma' \), then any derivation using \( \sigma \) can be one using \( \sigma' \) instead. In other words, the following rules are admissible:

\[
\begin{align*}
\Gamma \vdash \sigma \, f & \quad \frac{}{\Gamma \vdash \sigma' \, f} \quad (\omega) \\
\Gamma \vdash \sigma \, f & \quad \frac{}{\Gamma \vdash \sigma' \, f} \quad (\omega' d)
\end{align*}
\]

**Proof.** Simple induction on the typing derivations. The rules (\( \Phi \)) and (Cut) where the list of dependencies is used exactly match the definition of \( \Rightarrow \). Every other case is direct using the first item of Lemma A.1.

In addition to the previous proposition, we need the following extra lemma to simplify the proof of subject reduction, which we will use when concatenating two stores:

**Lemma A.2.** The following rule is admissible:

\[
\begin{align*}
\Gamma \vdash \sigma \, \tau_0 : (\rho_0, \sigma_0) & \quad \frac{}{\Gamma, \rho_0 \vdash \sigma \, \tau_1 : (\rho_1, \sigma_1)} \\
\Gamma \vdash \sigma & \quad \frac{}{\Gamma \vdash \sigma} \quad (\tau')
\end{align*}
\]

**Proof.** By induction on the structure of \( \tau_1 \).

Finally, we need to prove that substitutions of terms are safe with respect to typing (recall that substitutions of proofs are handled through the typing rules for stores):

**Lemma A.3.** [Safe term substitution] If \( \Gamma \vdash \sigma \, t : T \) then for any conclusion \( J \) for typing proofs, contexts, terms, etc; the following holds:

1. If \( \Gamma, x : T, \Gamma' \vdash J \) then \( \Gamma, \Gamma'[t/x] \vdash [\tau[t/x]] \, J[t/x] \).
2. If \( \Gamma, x : T, \Gamma' \vdash J; \sigma \) then \( \Gamma, \Gamma'[t/x] \vdash J[t/x] ; \sigma[t/x] \).

**Proof.** By induction on typing rules.

We are now equipped to prove the expected property:

**Theorem 2.2.** For any context \( \Gamma \) and any closures \( c\tau \) and \( c'\tau' \) such that \( c\tau \rightarrow c'\tau' \), we have:

1. If \( \Gamma \vdash c\tau \) then \( \Gamma \vdash c'\tau' \).
2. If \( \Gamma \vdash d\tau; \varepsilon \) then \( \Gamma \vdash d'\tau'; \varepsilon \).

**Proof.** The proof follows the usual proof of subject reduction, by induction on the typing derivation and the reduction \( c\tau \rightarrow c'\tau' \). Since there is no substitution but for terms (proof terms and contexts being stored), there is no need for auxiliary lemmas about the safety of substitution. We sketch it by examining all the rules from Figure 3 from top to bottom.

- The cases for reductions of \( \lambda \) are identical to the cases proven in the previous chapter for \( d\text{LPA}^{\omega} \).
- The rules for reducing \( \mu \) and \( \bar{\mu} \) are almost the same except that elements are stored, which makes it even easier. For instance in the case of \( \bar{\mu} \), the reduction rule is:

\[
(V \bar{\mu}a; c\tau_1) \rightarrow c\tau_0[a := V] \tau_1
\]
A sequent calculus with dependent types for classical arithmetic

A typing derivation in regular mode for the command on the left-hand side is of the shape:

\[
\begin{align*}
\Pi_c & \quad \frac{\Gamma_0, a : A, \Gamma_1 \vdash \sigma_0 \sigma_1 \tau_1 : (\Gamma_1 ; \sigma_1)}{\Gamma, \Gamma_0, a : A \vdash \tau_1} \quad (l) \\
\Pi_v & \quad \frac{\Gamma_0 \vdash \sigma_0 V : A}{\Gamma, \Gamma_0 \vdash (V \mid \mu_a.c\tau_1) \tau_0} \quad (CvT) \\
\end{align*}
\]

Thus we can type the command on the right-hand side:

\[
\begin{align*}
\Pi_c & \quad \frac{\Gamma_0, a : A, \Gamma_1 \vdash \sigma_0 (a[V]) \sigma_1 \tau_1 : (\Gamma_1 ; \sigma_1)}{\Gamma, \Gamma_0, a : A, \Gamma_1 \vdash \sigma_0 (a[V]) \sigma_1 \tau_1} \quad (w) \\
\Pi_v & \quad \frac{\Gamma \vdash \sigma_0 \sigma_0 (a[V]) : \Gamma}{\Gamma, \Gamma_0 \vdash \Pi} \quad (p) \\
\end{align*}
\]

As for the dependent mode, the binding \( \{ a[p] \} \) within the list of dependencies is compensated when typing the store as shown in the last derivation.

- Similarly, elimination rules for contexts \( \mu[a_1.c_1|a_2.c_2].\mu(a_1.c_2).c, \mu(x,a).c \) or \( \mu^v.c \) are easy to check, using Lemma A.1 and the rule \( \tau_p \) in dependent mode to prove the safety with respect to dependencies.
- The cases for delimited continuations are identical to the corresponding cases for \( dL_{\text{f_0}} \).
- The cases for the so-called “call-by-value” rules opening constructors are straightforward, using again Lemma A.1 in dependent mode to prove the consistency with respect to the list of dependencies.
- The cases for the lazy rules are trivial.
- The first case in the “lookup” section is trivial. The three lefts correspond to the usual unfolding of inductive and co-inductive fixpoints. We only sketch the latter in regular mode. The reduction rule is:

\[
\begin{align*}
(a[l])\tau_0[a := \text{cofix}_{_b} p][t/x][b' /b][\mu_a.(a[l])\tau_1] & \rightarrow (p[t/x][b' /b][\mu_a.(a[l])\tau_1])\tau_0[b' := \lambda y.\text{cofix}_{_b} p]\n\end{align*}
\]

The crucial part of the derivation for the left-hand side command is the derivation for the cofix in the store:

\[
\begin{align*}
\Pi_n & \quad \frac{\Gamma \vdash \sigma_0 t : T}{\Gamma, \Gamma_0, t : T \rightarrow \text{Nat}, x : T, b : \forall y. t . f (y) = 0 \vdash \sigma_0 p : A} \quad (\text{cofix}) \\
\Pi_p & \quad \frac{\Gamma \vdash \sigma_0 \text{cofix}_{_b} p [t] : v'_f x A}{\Gamma, \Gamma_0 \vdash \Pi} \quad (p) \\
\end{align*}
\]

Then, using this derivation, we can type the store of the right-hand side command:

\[
\begin{align*}
\Pi_n & \quad \frac{\Gamma, \Gamma_0, y : T \vdash \sigma_0 y : T}{\Gamma, \Gamma_0, y : T \rightarrow \text{Nat}, x : T, b : \forall y. t . f (y) = 0 \vdash \sigma_0 p : A} \quad (\text{cofix}) \\
\Pi_p & \quad \frac{\Gamma, \Gamma_0, y : T \vdash \sigma_0 \text{cofix}_{_b} p [t] : v'_f x A}{\Gamma, \Gamma_0, y : T \vdash \Pi} \quad (p) \\
\end{align*}
\]

It only remains to type (we avoid the rest of the derivation, which is less interesting) the proof \( p[t/x] \) with this new store to ensure that the reduction is safe (since the variable \( a \) will still be of type \( v'_f x A \) when typing the rest of the command):

\[
\begin{align*}
\Pi_p & \quad \frac{\Gamma, \Gamma_0, b : \forall y. v'_f x A \vdash p[t/x] : A[t/x][v'_f x A] f(y) = 0]}{\Gamma, \Gamma_0, b : \forall y. v'_f x A \vdash p[t/x] : v'_f x A} \quad (\varepsilon r) \\
\end{align*}
\]

- The cases for reductions of terms are easy. Since terms are reduced in place within proofs, the only things to check is that the reduction of \( \text{wit} \) preserves types (which is trivial) and that the \( \beta \)-reduction verifies the subject reduction (which is a well-known fact). \( \square \)
B Natural deduction as macros (Proofs of Section 2.5)

We give here two examples of typing rules for the macros subst \( pq \) and \( \text{prf } pq \) (in natural deduction) that are admissible in dLPA\(^\omega \). Recall that we have the following typing rules in dLPA\(^\omega \):

\[
\Gamma, x : T, a : A \vdash \sigma c \\
\Gamma \vdash \mu(x, a) : (\exists x : T, A) \underline{\sigma}
\]

\[
\Gamma \vdash p : A, \Gamma \vdash e : A[u/t] \\
\Gamma \vdash \mu \cdot (p[e]) : (t = u) \underline{\sigma}
\]

and that we defined \( \text{prf } p \) and subst \( pq \) as syntactic sugar:

\[
\text{prf } p \triangleq \mu \Phi. (\mu \tilde{\Phi}(p[n(x, a), a[\tilde{\Phi}]])) \\
\text{subst } pq \triangleq \mu \alpha. (p[n(x, a), a[\tilde{\Phi}]]).
\]

Observe that \( \text{prf } p \) is now only definable if \( p \) is a \text{NEF} proof term. For any \( p \in \text{NEF} \) and any variables \( a, \alpha \), we can prove the admissibility of the \( \text{(prf)\text{-rule}} \):

\[
\Gamma \vdash p : \exists x : T, A | \Delta \\
\Gamma \vdash \mu \Phi. (p[n(x, a), a[\tilde{\Phi}]] : \exists x : T, A) \vdash \Delta, \alpha \vdash A \vdash \alpha(n(x, a)[\tilde{\Phi}]) \vdash \Delta | \Delta | \alpha \vdash B[u] | \Delta
\]

Similarly, we can prove that the \( \text{(subst)\text{-rule}} \) is admissible:

\[
\Gamma \vdash p : t = u | \Delta \\
\Gamma \vdash \mu \cdot (p[q[a]]) : (t = u) \vdash \Delta, \alpha \vdash B[u] \vdash \Delta | \Delta | \alpha \vdash B[u] | \Delta \vdash \Delta | \Delta | \alpha \vdash B[u] | \Delta
\]

**Theorem 2.4** (Countable choice [12]). We have:

\[AC_\square := \lambda H. \lambda a : (\text{cofix } x^0_a)((Hn, b(S(n)))]
\]

\[
\text{in}(\lambda n. \text{wit}(\text{nth}_n a), \lambda n. \text{prf}(\text{nth}_n a)) \quad : \forall x^\square \exists y^T \text{P}(x, y) \rightarrow \exists f^\square \forall x^\square \text{P}(f, s(n)))
\]

where \( \text{nth}_n a := \pi_1(\text{fix}_x^a, c[a \mid \pi_2(c)]) \).

**Proof.** The complete typing derivation of the proof term for \( AC_\square \) from Herbelin’s paper [12] is given in Figure 6. \( \square \)

**Theorem 2.5** (Dependent choice [12]). We have:

\[DC := \lambda H. \lambda x_0, \lambda \text{let } a = (x_0, \text{cofix } x^0_{\text{nth}_n a}) \text{if six}
\]

\[
\text{in}(\lambda n. \text{wit}(\text{nth}_n a), (\text{refl}, \lambda n. \text{prf}(\text{nth}_n a))) \quad : \forall x^\square \exists y^T \text{P}(x, y) \rightarrow \forall x^\square \exists f^\square \forall x^\square, y^T \text{P}(f, s(n)))
\]

where \( \text{nth}_n a := \pi_1(\text{fix}_x^a, c[a \mid (\text{wit } \text{prf } d), \pi_2(\text{prf } (\text{prf } d))] \).

**Proof.** Left to the reader. \( \square \)
A sequent calculus with dependent types for classical arithmetic

Notations:
- $\text{nth}_p \triangleq \pi_1(\text{fix}_x^p[p | \pi_2(s)])$
- $A^m_n \triangleq \forall x. \pi_n(A(x) \land f(S(x)) = 0)$
- $\text{str}_{n}^{m, H} \triangleq \text{cofix}_{n}^{l, m}([Hn, b(S(n))])$
- $A(x) \triangleq \exists y^o.P(x, y)$

Typing derivation for $\text{nth}$ ($\Pi_{\text{nth}}$):

$\begin{array}{c}
\Gamma \vdash \text{n} : \mathbb{N} \triangleright \text{n} : \mathbb{N} \quad (\text{Ax}_x) \\
\Gamma \vdash a : A^0_n \triangleright a : A^0_n \quad (\text{Ax}_x) \\
\Gamma \vdash m : \mathbb{N}, s : A^m_n \triangleright s : A(m) \land A^S_n \quad (\text{Ax}_r) \\
\end{array}$

Typing derivation for $\text{str}_{n}^{m}$ ($\Pi_{\text{str}_{n}^{m}}$):

$\begin{array}{c}
\Gamma \vdash P(x, y) \triangleright H : \forall x^o \exists y^o.P(x, y) \\
\Gamma \vdash \text{nth}_n \triangleright 0 : \mathbb{N} \\
\Gamma \vdash H : \forall x^o \exists y^o.P(x, y), n : \mathbb{N}, b : \forall x^N.f(z) = 0 \triangleright (Hn, b(S(n))) : \exists y^o.P(n, y) \land f(S(n)) = 0 \\
\Gamma \vdash H : \forall x^o \exists y^o.P(x, y) \triangleright \text{str}_{n}^{m} \triangleright H : A^0_n \quad (\text{Ax}_r) \\
\end{array}$

Typing derivation for $AC_{\exists}$:

$\begin{array}{c}
\Gamma \vdash \Pi_{\text{nth}} \\
\Gamma \vdash a : A^0_n, n : \mathbb{N} \triangleright \text{n} \triangleright \text{n} \triangleright a : A(n) \quad (\text{def}) \\
\Gamma \vdash a : A^0_n, n : \mathbb{N} \triangleright \text{n} \triangleright \text{n} \triangleright a : \exists y^o.P(n, y) \quad (\text{wit}) \\
\Gamma \vdash a : A^0_n, n : \mathbb{N} \triangleright \text{n} \triangleright \text{n} \triangleright a : T \quad (\text{wit}) \\
\Gamma \vdash a : A^0_n, \lambda n. \text{wit}(n(a)) : \text{n} \rightarrow T \\
\Gamma \vdash H : \forall x^o \exists y^o.P(x, y) \triangleright \text{let} a = \text{str}_{n}^{m} \triangleright H \in (\lambda n. \text{wit}(n(a)), \lambda n. \text{prf}(n(a)) : \exists f^N \rightarrow T. \forall x^o. P(x, f(x))$ \\
\end{array}$

Figure 6. Proof of the axiom of countable choice in dLPA$^o$
C Small-step reduction rules (Proofs of Section 3)

We give in Figure 7 the full reduction system based on small-step reduction rules which are described in Section 3. We detail thereafter the proofs of the two properties of the small-step reduction system.

Proposition 3.1 (Subject Reduction). The small-step reduction rules satisfy subject reduction.

Proof. The proof is again a tedious induction on the reduction \( \leadsto_s \). There is almost nothing new in comparison with the cases for the big-step reduction rules: the cases for reduction of terms are straightforward, as well as the administrative reductions changing the focus on a command. We only give the case for the reduction of pairs \( (t, p) \). The reduction rule is:

\[
(\langle t, p \rangle) \tau \leadsto_s (p)\mu^\top. (t)\mu_\xi. (\mu^\top\mu_\xi. (\langle (x, a) \| e \rangle))\| p \tau
\]

Consider a typing derivation for the command on the left-hand side, which is of the shape (we omit the rule \( (l) \) and the store for conciseness):

\[
\Pi_T \\
\Pi_P \\
\Pi_e \\
\Pi_e \\
\Pi_e
\]

Then we can type the command on the right-hand side with the following derivation:

\[
\Pi_{(x, a)} \\
\Pi_e \\
\Pi_e \\
\Pi_e
\]

where \( \Pi_{(x, a)} \) is as expected.

\[ \square \]

Proposition 3.2. If a closure \( ct \) normalizes for the reduction \( \leadsto_s \), then it normalizes for \( \rightarrow \).

Proof. By contraposition, one proves that if a command \( ct \) produces an infinite number of steps for the reduction \( \rightarrow \), then it does not normalize for \( \leadsto_s \) either. This is proved by showing by induction on the reduction \( \rightarrow \) that each step, except for the contextual reduction of terms, is reflected in at least one for the reduction \( \leadsto_s \). The rules for term reductions require a separate treatment, which is really not interesting at this point. We claim that the reduction of terms, which are usual simply-typed \( \lambda \)-terms, is known to be normalizing anyway and does not deserve that we spend another page proving it in this particular setting.

\[ \square \]
A sequent calculus with dependent types for classical arithmetic

**Commands**

\[(p|e)_{c\tau} \rightsquigarrow_s (p|e)_{p\tau}\]

\[(t|\pi)_{c\tau} \rightsquigarrow_s (t|\pi)_{p\tau}\]

**Delimited continuations**

(for any \(t, o\))

\[\langle \mu \psi.c\tau\rangle_{p\tau} \rightsquigarrow_s \langle \mu \psi.c\tau\rangle_{p\tau}\]

\[\langle \mu \psi.(p|\psi)\rangle_{p\tau} \rightsquigarrow_s \langle p|\psi\rangle_{p\tau}\]

(for any \(t, o\))

\[\langle V\mu \psi.c\tau\rangle_{c\tau} \rightsquigarrow_s \langle V\mu \psi.c\tau\rangle_{c\tau}\]

\[\langle V\|\rho |\psi\|e\rangle_{c\tau} \rightsquigarrow_s \langle V\|\rho |\psi\|e\rangle_{c\tau}\]

**Proofs**

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

\[\langle a\|f\|e\rangle_{\tau}[a := e]\]

\[\langle a\|f\|e\rangle_{\tau}[a := e]\]

\[\langle a\|f\|e\rangle_{\tau}[a := e]\]

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

**Values**

\[(\lambda x.p[t \cdot e]_{\tau}\rangle_{\tau} \rightsquigarrow_s \langle \mu \psi.(\lambda x.p[t \cdot e])_{\tau}\rangle_{\tau}\]

\[\langle a\|f\|e\rangle_{\tau}[a := e]\]

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

**Forcing contexts**

\[\langle \lambda x.p[t \cdot e]_{\tau}\rangle_{\tau} \rightsquigarrow_s \langle \mu \psi.(\lambda x.p[t \cdot e])_{\tau}\rangle_{\tau}\]

\[\langle a\|f\|e\rangle_{\tau}[a := e]\]

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

\(\langle a\|f\|e\rangle_{\tau}[a := e]\)

**Terms**

\[\langle t\|u\|\pi\rangle_{\tau} \rightsquigarrow_s \langle \mu \psi.(\lambda x.p[x, x]_{\pi})_{\tau}\]

\[\langle t\|u\|\pi\rangle_{\tau} \rightsquigarrow_s \langle \mu \psi.(\lambda x.p[x, x]_{\pi})_{\tau}\]

\[\langle t\|u\|\pi\rangle_{\tau} \rightsquigarrow_s \langle \mu \psi.(\lambda x.p[x, x]_{\pi})_{\tau}\]

\[\langle t\|u\|\pi\rangle_{\tau} \rightsquigarrow_s \langle \mu \psi.(\lambda x.p[x, x]_{\pi})_{\tau}\]

\[\langle t\|u\|\pi\rangle_{\tau} \rightsquigarrow_s \langle \mu \psi.(\lambda x.p[x, x]_{\pi})_{\tau}\]

\[\langle t\|u\|\pi\rangle_{\tau} \rightsquigarrow_s \langle \mu \psi.(\lambda x.p[x, x]_{\pi})_{\tau}\]

\[\langle t\|u\|\pi\rangle_{\tau} \rightsquigarrow_s \langle \mu \psi.(\lambda x.p[x, x]_{\pi})_{\tau}\]

**Figure 7.** Small-step reduction rules
D Realizability interpretation (Proofs of Section 4)

We give here the different proofs relative to the realizability interpretation of dLPA⁺.

First, we verify that the set of normalizing closures is indeed a pole:

**Proposition 4.5.** The set \( \parallel \parallel \parallel \parallel = \{ \pi \in \mathcal{C}_0 : \pi \text{ normalizes} \} \) is a pole.

**Proof.** The first two conditions are already verified for the \( \lambda_{\text{lur}*} \)-calculus [21]. The third one is straightforward, since if a closure \( (\mu \Phi, c/\epsilon)\pi \) is not normalizing, it is easy to verify that \( c/\epsilon/\Phi \) is not normalizing either. Roughly, there is only two possible reduction steps for a command \( \mu \Phi, c/\epsilon \rightarrow \tau \), either it reduces to \( \mu \Phi, c/\epsilon \rightarrow \tau \), in which case \( c/\epsilon/\Phi \rightarrow \tau \) also reduces to a closure which is almost \( (\epsilon' \pi')(e/\Phi) \); or \( \epsilon \) is of the shape \( (\rho/\Phi) \) and it reduces to \( c(e/\Phi) \tau \). In both cases, if \( (\mu \Phi, c/\epsilon)\pi \) can reduce, so can \( c(e/\Phi) \tau \). The same reasoning allows us to show that if \( c((V/\Phi) \tau \) normalizes, then so does \( (V/\Phi, c)\tau \) for any value \( V \). \( \square \)

We recall two key properties of the interpretation, whose proofs are similar to the proofs for the corresponding statements in the \( \lambda_{\text{lur}*} \)-calculus [21]:

**Lemma D.1** (Store weakening). Let \( \tau \) and \( \tau' \) be two stores such that \( \tau \prec \tau' \), let \( \Gamma \) be a typing context, let \( \parallel \) be a pole and \( \rho \) a valuation. The following statements hold:

1. \( \tau \tau' = \tau' \)
2. If \( (p|\tau)_\rho \in |A|_p \), for some closed proof-in-store \( (p|\tau) \) and formula \( A \), then \( (p|\tau')_\rho \in |A|_p \). The same holds for each level \( e, E, f, t, \pi, V \) of the interpretation.
3. If \( (\tau, \rho) \parallel \Gamma \) then \( (\tau', \rho) \parallel \Gamma \).

**Proposition D.2** (Monotonicity). For any closed formula \( A \), any type \( T \) and any given pole \( \parallel \), we have the following inclusions:

\[ |A|_V \subseteq |A|_p \quad |A|_f \subseteq |A|_e \quad |T|_V \subseteq |T|_t \]

Truth and falsity values are defined up to observational equivalence:

**Lemma 4.8.** For any store \( \tau \) and any valuation \( \rho \), the component along \( \tau \) of the truth and falsity values defined in Figure 5 are closed under the relation \( \equiv : \)

1. If \( (f|\tau)_\rho \in |A|_p \) and \( A_\rho \equiv \tau B_\rho \), then \( (f|\tau)_\rho \in |B|_p \).
2. If \( (V_\pi|\tau)_\rho \in |A|_p |V_\pi | \), and \( A_\rho \equiv \tau B_\rho \), then \( (V_\pi|\tau)_\rho \in |B|_p |V_\pi | \).

The same applies with \( |A|_p |P_\rho |, |A|_e |P_\rho |, \) etc.

**Proof.** By induction on the structure of \( A_\rho \) and the different levels of interpretation. The different base cases \( (p \in A_\rho, t \in T, t = u) \) are direct since their components along \( \tau \) are defined modulo \( \equiv : \), the other cases are trivial inductions. \( \square \)

We can now give the complete proof of adequacy of the typing rules with respect to the realizability interpretation, defined in Figure 5.

**Proposition 4.9.** The typing rules are adequate with respect to the realizability interpretation. In other words, if \( \Gamma \) is a typing context, \( \parallel \) a pole, \( \rho \) a valuation and \( \tau \) a store such that \( (\tau, \rho) \parallel \Gamma, \sigma \), then the following hold:

1. If \( v \) is a strong value such that \( \Gamma \vdash ^{\sigma} v : A \) or \( \Gamma \vdash _d v : A; \sigma \), then \( (v|\tau)_\rho \in |A|_V \).
2. If \( f \) is a forcing context such that \( \Gamma \vdash ^{\sigma} f : A^\mu \) or \( \Gamma \vdash _d f : A^\mu; \sigma \), then \( (f|\tau)_\rho \in |A|_f \).
3. If \( V \) is a weak value such that \( \Gamma \vdash ^{\sigma} V : A \) or \( \Gamma \vdash _d V : A; \sigma \), then \( (V|\tau)_\rho \in |A|_V \).
4. If \( e \) is a context such that \( \Gamma \vdash _d e : A^\mu \) or \( \Gamma \vdash _d e : A^\mu; \sigma \), then \( (e|\tau)_\rho \in |A|_e \).
5. If \( p \) is a proof term such that \( \Gamma \vdash ^{\sigma} p : A \) or \( \Gamma \vdash _d p : A; \sigma \), then \( (p|\tau)_\rho \in |A|_p \).
6. If \( V_\pi \) is a term value such that \( \Gamma \vdash ^{\sigma} V_\pi : T \), then \( (V_\pi|\tau)_\rho \in |T|_V \).
7. If \( \pi \) is a term context such that \( \Gamma \vdash ^{\sigma} \pi : T \), then \( (\pi|\tau)_\rho \in |T|_\pi \).
8. If \( t \) is a term such that \( \Gamma \vdash ^{\sigma} t : T \), then \( (t|\tau)_\rho \in |T|_t \).
9. If \( \tau' \) is a store such that \( \Gamma \vdash ^{\sigma} \tau' : (\tau')' \) or \( \Gamma \vdash _d \tau' : (\tau')'; \sigma \), then \( (\tau'|\rho) \parallel (\Gamma, \Gamma'; \sigma') \).
10. If \( c \) is a command such that \( \Gamma \vdash ^{\sigma} c : \sigma \) or \( \Gamma \vdash _d c : \sigma ; \sigma \), then \( (c|\tau)_\rho \in \parallel \).
11. If \( c\tau' \) is a closure such that \( \Gamma \vdash _d c\tau' : \tau' \) or \( \Gamma \vdash _d c\tau' : \tau'; \sigma \), then \( (c\tau'|\rho) \in \parallel \).

**Proof.** The proof is done by induction on the typing derivation such as given in the system extended with the small-step reduction \( \rightarrow_s \). Most of the cases correspond to the proof of adequacy for the interpretation of the \( \lambda_{\text{lur}*} \)-calculus, so that we only give the most interesting cases. To lighten the notations, we omit the annotation by the valuation \( \rho \) whenever it is possible.
A sequent calculus with dependent types for classical arithmetic

- **Case** ($\exists \tau_\mathcal{F}$). We recall the typing rule through the decomposition of dependent sums:

\[
\Gamma \vdash \sigma t : u \in T \quad \Gamma \vdash \sigma p : A[u/x]
\]

\[
\Gamma \vdash \sigma (t, p) : (u \in T \land A[u])
\]

By induction hypothesis, we obtain that \(t(\tau) \in [u \in T]_\mu\) and \(p(\tau) \in [A[u]]_\mu\). Consider thus any context-in-store \((e|\sigma') \in [u \in T \land A[u]]_\mu\) such that \(\tau\) and \(\tau'\) are compatible, and let us denote by \(\tau_0\) the union \(\tau \cup \tau'\). We have:

\[
\langle (t, p)|\sigma \rangle_{\mu \alpha} \sim_{\tau_0} \langle \mu \Phi.\langle t, \mu x.\langle (x, a)|\sigma' \rangle \rangle \rangle_{\mu \alpha} p \tau_0
\]

so that by anti-reduction, we need to show that \(\mu \Phi.\langle t, \mu x.\langle (x, a)|\sigma' \rangle \rangle \rangle_{\mu \alpha} p \tau_0\) is in the same store as \(p\). By closure under delimited continuations, to show that \(\langle V|\mu x.\langle V|\mu a.\langle (x, a)|\sigma' \rangle \rangle \rangle_{\mu \alpha} p \tau_0\) is in the store, it is enough to show that the closure \(\langle V|\mu x.\langle V|\mu a.\langle (x, a)|\sigma' \rangle \rangle \rangle_{\mu \alpha} p \tau_0\) is in \([u \in T]|\mu\). Thus, it suffices to show that the coterm-in-store \(\langle V|\mu x.\langle V|\mu a.\langle (x, a)|\sigma' \rangle \rangle \rangle_{\mu \alpha} p \tau_0\) is in the store, that this closure is finally in the pole.

- **Case** ($\exists \tau_\mathcal{F}$). These cases are direct consequences of Proposition 4.8 since if \(A, B\) are two formulas such that \(A \equiv B\), in particular \(A \equiv_{\tau} B\) and thus \([A]|\mu = [B]|\mu\).

- **Case** ($\exists \tau_\mathcal{F}$). The case for \(\exists \tau_\mathcal{F}\) is trivial, while it is trivial to show that \(\mu x.\langle (x, a)|\sigma' \rangle \rangle_{\mu \alpha} p \tau_0\) is in \([t|\mu]\) if \(p(\tau) \in [A[t]]_\mu\) and \(e(\tau) \in [A[u]]_\mu\).

- **Case** ($\forall \tau_\mathcal{F}$). This case is standard in a call-by-value language with value restriction. We recall the typing rule:

\[
\Gamma \vdash \sigma u : A \quad x \notin FV(\Gamma) \\
\Gamma \vdash \sigma u : \forall x. A
\]

\[(\forall \tau_\mathcal{F})\]

The induction hypothesis gives that \((\forall \tau)|\rho\) is in \([A]|\mu\) for any valuation \(\rho(x) \mapsto t\). Then for any \(t\), we have \((\forall \tau)|\rho\) in \([A]|\mu\) if \(\exists \tau \in \Gamma\) and \((\forall \tau)|\rho\) is in \([A[u]]_\mu\), so that \((\forall \tau)|\rho\) belongs to \([\forall x. A]|\mu\). Therefore if \(f(t)|\tau_0\) belongs to \([\forall x. A]|\mu\), then \(\forall x. A\) belongs to \([\forall x. A]|\mu\). We have by definition that \((\forall \tau)|\rho\) is in \([A]|\mu\).

- **Case** ($\forall \tau_\mathcal{F}$). We recall the typing rule:

\[
\Gamma \vdash \sigma t : \mathbb{N} \quad \Gamma \vdash \sigma p_0 : A[0/x] \\
\Gamma \vdash \sigma x : T, a : A \quad \frac{\Gamma \vdash \sigma p_0 : A[S(x)/x]}{\Gamma \vdash \sigma \text{fix}_{A[t]}[p_0, p_S]} : A[t/x]
\]

\[(\forall \tau_\mathcal{F})\]

We want to show that \((\text{fix}_{A[t]}[p_0, p_S])|\tau_0\) is in \([A]|\mu\). Let us then consider \((e|\sigma')\) such that \(\tau\) and \(\tau'\) are compatible, and let us denote by \(\tau_0\) the union \(\tau \cup \tau'\). By induction hypothesis, we have \(1 < \tau \in [\mathbb{N}]_\mu\) and we have:

\[
\langle \text{fix}_{A[t]}[p_0, p_S]|\rho\rangle \sim_{\tau_0} \langle \mu \Phi.\langle t, \mu x.\langle (x, a)|\sigma' \rangle \rangle |\rho\rangle \sim_{\tau_0} \langle \text{fix}_{A[t]}[p_0, p_S]|\rho\rangle \sim_{\tau_0}
\]

so that by anti-reduction and closure under delimited continuations, it is enough to show that the coterm-in-store \(\mu x.\langle x, a|\sigma' \rangle \rangle_{\mu \alpha} p \tau_0\) is in \([t]|\mu\). Let us then consider \((V|\tau_0_\mathcal{F})\) such that \(\tau_0\) and \(\tau_0'\) are compatible, and let us denote by \(\tau_0|\rho\) the union \(\tau_0 \cup \tau_0'\). By definition, \(V_\mathcal{F} = S^n(0)\) for some \(n \in [\mathbb{N}]_\mu\) and \(t \equiv_{\tau_0} S^n(0)\), and we have:

\[
\langle S^n(0)|\mu y.\langle a|\sigma' \rangle |a := \text{fix}_{A[t]}[p_0, p_S]\rangle |a := \text{fix}_{A[t]}[p_0, p_S]\rangle |a := \text{fix}_{A[t]}[p_0, p_S]\rangle |a := \text{fix}_{A[t]}[p_0, p_S]\rangle
\]

We conclude by showing induction on the natural numbers for any \(n \in [\mathbb{N}]_\mu\), the value-in-store \((a|\rho) : \text{fix}_{A[t]}[p_0, p_S]|\rho\rangle\) is in \([A]|\mu\). Let us consider \((f|\tau_0)\) such that the store \(\tau(\sigma) = \text{fix}_{A[t]}[p_0, p_S]|\rho\rangle\) and \(\tau'_0\) are compatible, and let us denote by \(\tau_0'\) their union.

- If \(n = 0\), we have:

\[
\langle f|\tau_0 \rangle |a := \text{fix}_{A[t]}[p_0, p_S]|\rho\rangle |a := \text{fix}_{A[t]}[p_0, p_S]|\rho\rangle |a := \text{fix}_{A[t]}[p_0, p_S]|\rho\rangle |a := \text{fix}_{A[t]}[p_0, p_S]|\rho\rangle
\]

We conclude by anti-reduction and the induction hypothesis for \(p_0\), since it is easy to show that \(\mu y.\langle a|\sigma' \rangle |a := \text{fix}_{A[t]}[p_0, p_S]\rangle\) is in \([A]|\mu\).

- If \(n = S(m)\), we have:

\[
\langle f|\tau_0 |a := \text{fix}_{A[t]}[p_0, p_S]|\rho\rangle |a := \text{fix}_{A[t]}[p_0, p_S]|\rho\rangle |a := \text{fix}_{A[t]}[p_0, p_S]|\rho\rangle |a := \text{fix}_{A[t]}[p_0, p_S]|\rho\rangle
\]

Since we have by induction that \((b'|\tau_1 |b' := \text{fix}_{A[t]}[p_0, p_S]|\rho\rangle)\) is in \([A]|\mu\), we can conclude by anti-reduction, using the induction hypothesis for \(p_S\) and the fact that \(\mu y.\langle a|\sigma' \rangle |a := \text{fix}_{A[t]}[p_0, p_S]\rangle\) belongs to \([A]|\mu\).

9Recall that any term \(t\) of type \(T\) can be given the type \(t \in T\).
Theorem 4.11 (Consistency)

We assume there is such a proof \( \pi \) and deduce by induction hypothesis for \( F^n_{\Lambda_\pi} \), which is absurd.

We recall the typing rule:

\[
\Gamma \vdash t : T \quad \Gamma, x : T, b : \forall y T(x(y)) \vdash \sigma \quad p : A \quad X \text{ positive in } A \quad X \not\in \text{FV}(\Gamma)
\]

\[
\Gamma \vdash \sigma \quad \text{cofix}_{b_\pi}^i[p] : \forall x . X
\]

We want to show that \( (\text{cofix}_{b_\pi}^i[p])\ell \in \forall x . X[A_\pi] \), let us then consider \( (e|\tau') \in \forall x . X[A_\pi] \) such that \( \tau \) and \( \tau' \) are compatible, and let us denote by \( \tau_0 \) the union \( \overline{\tau \tau'} \). By induction hypothesis, we have \( t \in T\tau_0 \) and we have:

\[
(\text{cofix}_{b_\pi}^i[p])\ell \tau_0 \vdash_s (\mu \Phi. (e|\tau)|\mu \Phi|a \vdash \text{cofix}_{b_\pi}^i[p])[\ell] \rho_0
\]

so that by anti-reduction and closure under delimited continuations, it is enough to show that the coterm-in-store \( (\mu y. (a|\ell)[a \vdash \text{cofix}_{b_\pi}^i[p]])\tau_0 \) is in \( t \in \mathbb{N} \). Let us then consider \( (V_t|\tau'_0) \in T|V_t \) such that \( \tau_0 \) and \( \tau'_0 \) are compatible, and let us denote by \( \tau_2 \) the union \( \overline{\tau_0 \tau'_0} \). We have:

\[
(V_t|\mu y. (a|\ell)[a \vdash \text{cofix}_{b_\pi}^i[p]])\tau_2 \vdash_s (a|\ell)\tau_1[a \vdash \text{cofix}_{b_\pi}^i[p]]
\]

It suffices to show now that the value-in-store \( (a|\tau_1[a \vdash \text{cofix}_{b_\pi}^i[p]]) \) is in \( \forall x . X[A_\pi] \). By definition, we have:

\[
|\forall x . X[A_\pi]|V = (\bigcup_{n \in \mathbb{N}} |F_{A_\pi, V}|^{\mu} V) = \bigcap_{n \in \mathbb{N}} |F_{A_\pi, V}|^{\mu} V = \bigcap_{n \in \mathbb{N}} |F_{A_\pi, V}|^n V
\]

We conclude by showing by induction on the natural numbers that for any \( n \in \mathbb{N} \) and any \( V_t \), the value-in-store \( (a|\tau_1[a \vdash \text{cofix}_{b_\pi}^i[p]]) \) is in \( |F_{A_\pi, V}|^n V \).

The case \( n = 0 \) is trivial since \( |F_{A_\pi, V}|^0 V = |\top| V = A_\pi \). Let then be an integer and any \( V_t \) be a term value. Let us consider \( (f|\tau'_1) \in |F_{A_\pi, V}|^n V \) such that \( \tau_1[a \vdash \text{cofix}_{b_\pi}^i[p]] \) and \( \tau'_1 \) are compatible, and let us denote by \( \tau_2[a \vdash \text{cofix}_{b_\pi}^i[p]] \tau'_2 \) their union. By definition, we have:

\[
(a|f)\tau_2[a \vdash \text{cofix}_{b_\pi}^i[p]]\tau'_2 \vdash_s (p|V_t/x)[b'/b]|\mu a. (a|f)\tau_2[b' := \lambda y. \text{cofix}_{b_\pi}^i[p]]
\]

It is straightforward to check, using the induction hypothesis for \( n \), that \( (b'|\tau_2[b' := \lambda y. \text{cofix}_{b_\pi}^i[p]]) \) is in \( |\forall y. y \in T \rightarrow F^n_{A_\pi, y}| V \). Thus we deduce by induction hypothesis for \( p \), denoting by \( S \) the function \( t \mapsto |F_{A_\pi}|^n f \), that:

\[
(p|V_t/x)[b'/b]|\tau_2[b' := \lambda y. \text{cofix}_{b_\pi}^i[p]] \in |A| V_t/x[S/X] p = |A| V_t/x[F^n_{A_\pi, y}/X(y)] p = |F^n_{A_\pi, V}|^n p
\]

It only remains to show that \( (\mu a. (a|f)\tau_2)\tau'_2 \) is in \( |F^n_{A_\pi, V}|^n \), which is trivial from the hypothesis for \( f \).

\[ \Box \]

**Theorem 4.11 (Consistency).** \( \forall \mu \pi \mu x . p : \bot \)

**Proof.** Assume there is such a proof \( \pi \), by adequacy \( (p|\ell) \) is in \( \bot \) for any pole. Yet, the set \( \bot : \emptyset \) is a valid pole, and with this pole, \( \bot \pi = \emptyset \), which is absurd.  

\[ \Box \]
E  About the interpretation of coinductive formulas

While our realizability interpretation gives us a proof of normalization and soundness for dLPA, it has two aspects that we should discuss. First, regarding the small-step reduction system, one could have expected the lowest level of interpretation to be \( \nu \) instead of \( f \). Moreover, if we observe our definition, we notice that most of the cases of \( \| \cdot \|_v \) are in fact defined by orthogonality to a subset of strong values. Indeed, except for coinductive formulas, we could indeed have defined instead an interpretation \( \| \cdot \|_v \) of formulas at level \( v \) and then the interpretation \( \| \cdot \|_f \) by orthogonality:

\[
\begin{align*}
|\bot|_v & \triangleq \emptyset \\
|t = u|_v & \triangleq \begin{cases} 
\text{ref1} & \text{if } t \equiv u \\
\emptyset & \text{otherwise}
\end{cases} \\
|p \in A|_v & \triangleq \{ (\nu|\tau) \in |A|_v : \nu \equiv_{\tau} p \} \\
|T \rightarrow B|_v & \triangleq \{ \lambda x.\rho|\tau : \forall \nu|\tau', \nu \circ \tau' \land (\nu|\tau') \in |T|_v \Rightarrow (\rho|V/x|\tau') \in |B|_p \} \\
|A \rightarrow B|_v & \triangleq \{ \lambda a.\rho|\tau : \forall \nu|\tau', \nu \circ \tau' \land (\nu|\tau') \in |A|_v \Rightarrow (\rho|\tau\tau'|a \equiv V) \in |B|_p \} \\
|T \land A|_v & \triangleq \{ ((\nu|V),\nu|\tau) : (\nu|\tau) \in |T|_v \land (\nu|\tau) \in |A|_v \} \\
|A_1 \land A_2|_v & \triangleq \{ ((\nu|V_1),\nu|\tau_1), (\nu|V_2),\nu|\tau_2) : (\nu|\tau_1) \in |A_1|_v \land (\nu|\tau_2) \in |A_2|_v \} \\
|A_1 \lor A_2|_v & \triangleq \{ ((\nu|V_1),\nu|\tau_1) \lor ((\nu|V_2),\nu|\tau_2) : (\nu|\tau_1) \in |A_1|_v \lor (\nu|\tau_2) \in |A_2|_v \} \\
|\exists x. A|_v & \triangleq \bigcup_{t \in A} |A[t/x]|_v \\
|\forall x. A|_v & \triangleq \bigcap_{t \in A} |A[t/x]|_v \\
|\forall a. A|_v & \triangleq \bigcap_{p \in A} |A[p/x]|_v \\
|A|_f & \triangleq \{ (f|\tau) : \forall \nu|\tau', \nu \circ \tau' \land (\nu|\tau') \in |A|_v \Rightarrow (\nu|\tau') \cup (F|\tau) \}
\end{align*}
\]

If this definition is somewhat more natural, it poses the problem of defining coinductive formulas. Indeed, there is a priori no strong value in the orthogonal of \( \| f \|_v \), which is:

\[
\| f \|_v^\mathbb{D} = (\bigcup_{n \in \mathbb{N}} \| F^n_{A,x} \|_v^\mathbb{D}) = \bigcap_{n \in \mathbb{N}} (\| F^n_{A,x} \|_v^\mathbb{D})
\]

For instance, consider again the case of a stream of type \( v_0 = x \cdot \mathbb{N} \land f(S(x)) = 0 \), a strong value in the intersection should be in every \( |A(0) \land (A(1) \land \ldots (A(n) \land \tau) \ldots) \|_v \), which is not possible due to the finiteness of terms. Thus, the definition \( \| f \|_v \triangleq \bigcap_{n \in \mathbb{N}} \| F^n_{A,x} \|_v \) would give \( \| f \|_v = \emptyset = |\bot|_v \).

Interestingly, and this is the second aspect that we shall discuss here, we could have defined instead the truth value of coinductive formulas directly by:

\[
|f_1|_v \triangleq |A[t/x]|_v \land f(y) = 0
\]

Let us sketch the proof that such a definition is well-founded. We consider the language of formulas without coinductive formulas and extended with formulas of the shape \( X(t) \) where \( X, Y, \ldots \) are parameters. At level \( v \), closed formulas are interpreted by sets of strong values-in-store \( (\nu|\tau) \), and as we already observed, these sets are beside closed under the relation \( \equiv_{\tau} \) along their component \( \tau \). If \( A(x) \) is a formula whose only free variable is \( x \), the function which associates to each term \( t \) the set \( |A(t)|_v \) is thus a function from \( A \) to \( \mathcal{P}(\Lambda^*_v) \), let us denote the set of these functions by \( \mathcal{L} \).

**Proposition E.1.** The set \( \mathcal{L} \) is a complete lattice with respect to the order \( \leq_{\mathcal{L}} \) defined by:

\[
F \leq_{\mathcal{L}} G \iff \forall t \in A, F(t) \subseteq G(t)
\]

**Proof.** Trivial since the order on functions is defined pointwise and the co-domain \( \mathcal{P}(\Lambda^*_v) \) is itself a complete lattice. \( \square \)

We define valuations, which we write \( \rho \), as functions mapping each parameter \( X \) to a function \( \rho(X) \in \mathcal{L} \). We then define the interpretations \( |A|_v^\mathbb{D}, |A|_v^\mathbb{F}, \ldots \) of formulas with parameters exactly as above with the additional rule:

\[
|X(t)|_v^\mathbb{D} = \{ (\nu|\tau) \in \rho(X(t)) \}
\]

Let us fix a formula \( A \) which has one free variable \( x \) and a parameter \( X \) such that sub-formulas of the shape \( X t \) only occur in positive positions in \( A \).

**Lemma E.2.** Let \( B(x) \) be a formula without parameters whose only free variable is \( x \), and let \( \rho \) be a valuation which maps \( X \) to the function \( t \mapsto |B(t)|_v \). Then \( |A|_v^\mathbb{D} = |A|_v^\mathbb{F} = |A|_v^\mathbb{F} \).
Proof. By induction on the structure of $A$, all cases are trivial, and this is true for the basic case $A \equiv (t)$:

$$|X(t)|^U = \rho(X(t)) = |B(t)|^U$$

Let us now define $\varphi_A$ as the following function:

$$\varphi_A : \begin{cases} \mathcal{L} & \rightarrow \mathcal{L} \\ F & \mapsto t \mapsto [A[t/x]|_{\mathcal{L}}^{[X \rightarrow \mathcal{F}]} \end{cases}$$

Proposition E.3. The function $\varphi_A$ is monotone.

Proof. By induction on the structure of $A$, where $X$ can only occur in positive positions. The case $|X(t)|^U$ is trivial, and it is easy to check that truth values are monotonic with respect to the interpretation of formulas in positive positions, while falsity values are anti-monotonic.

We can thus apply Knaster-Tarski theorem to $\varphi_A$, and we denote by $\operatorname{gfp}(\varphi_A)$ its greatest fixed point. We can now define:

$$|v^F_{X,A} |^U \triangleq \operatorname{gfp}(\varphi_A)(t)$$

This definition satisfies the expected equality:

Proposition E.4. We have:

$$|v^F_{X,A} |^U = |A[t/x]|_{\mathcal{L}}^{v^U_{X,A}[X/y]|_{\mathcal{L}}}$$

Proof. Observe first that by definition, the formula $B(z) = |v^F_{X,A} |^U$ satisfies the hypotheses of Lemma E.2. Then we can deduce:

$$|v^F_{X,A} |^U = \operatorname{gfp}(\varphi_A)(t) = \varphi_A(\operatorname{gfp}(\varphi_A))(t) = |A[t/x]|_{\mathcal{L}}^{G[\operatorname{gfp}(\varphi_A)]} = |A[t/x]|_{\mathcal{L}}^{v^U_{X,A}[X/y]|_{\mathcal{L}}}$$

Back to the original language, it only remains to define $|v^F_{X,A} |^U$, as the set $|v^F_{X,A}[X/y]/f(y) = 0]|_{\mathcal{L}}$, that we just defined. This concludes our proof that the interpretation of coinductive formulas through the equation in Proposition E.4 is well-founded.

We could also have done the same reasoning with the interpretation from the previous section, by defining $\mathcal{L}$ as the set of functions from $\Lambda$ to $\mathcal{P}(\Lambda^*_x)$. The function $\varphi_A$, which is again monotonic, is then:

$$\varphi_A : \begin{cases} \mathcal{L} & \rightarrow \mathcal{L} \\ F & \mapsto t \mapsto [A[t/x]|_{\mathcal{L}}^{[X \rightarrow \mathcal{F}]} \end{cases}$$

We recognize here the definition of the formula $F^A_{X,F}$. Defining $f^0$ as the function $t \mapsto \| \top \|_f$ and $f^{n+1} \equiv \varphi_A(f^n)(t)$ we have:

$$\forall n \in \mathbb{N}, \| F^A_{X,F} \|_f = f^n(t) = \varphi_A(f^n)(t)$$

However, in both cases (defining primitively the interpretation at level $\mathcal{L}$ or $f$), this definition does not allow us to prove the adequacy of the (cofixfix) rule. In the case of an interpretation defined at level $\mathcal{L}$, the best that we can do is to show that for any $n \in \mathbb{N}$, $f^n$ is a post-fixedpoint since for any term $t$, we have:

$$f^n(t) = \| F^A_{X,F} \|_f \subseteq \| F^A_{X,F} \|_f = f^{n+1}(t) = \varphi_A(f^n)(t)$$

With $\| v^F_{X,A} \|_f$ defined as the greatest fixedpoint of $\varphi_A$, for any term $t$ and any $n \in \mathbb{N}$ we have the inclusion $f^n(t) \subseteq \operatorname{gfp}(\varphi_A)(t) = \| v^F_{X,A} \|_f$ and thus:

$$\bigcup_{n \in \mathbb{N}} \| F^A_{X,F} \|_f = \bigcup_{n \in \mathbb{N}} f^n(t) \subseteq \| v^F_{X,A} \|_f$$

By orthogonality, we get:

$$\| v^F_{X,A} \|_f \subseteq \bigcap_{n \in \mathbb{N}} \| F^A_{X,F} \|_f$$

and thus our proof of adequacy from the last section is not enough to conclude that $\operatorname{cofix} f^n t \in v^F_{X,A}[p]$. For this, we would need to prove that the inclusion is an equality. An alternative to this would be to show that the function $t \mapsto \bigcup_{n \in \mathbb{N}} \| F^A_{X,F} \|_f$ is a fixedpoint for $\varphi_A$. In that case, we could stick to this definition and happily conclude that it satisfies the equation:

$$\| v^F_{X,A} \|_f = \| A[t/x]|_{\mathcal{L}}^{v^U_{X,A}[X/y]|_{\mathcal{L}}}$$

This would be the case if the function $\varphi_A$ was Scott-continuous on $\mathcal{L}$ (which is a dcpo), since we could then apply Kleene fixed-point theorem\(^{20}\) to prove that $t \mapsto \bigcup_{n \in \mathbb{N}} \| F^A_{X,F} \|_f$ is the stationary limit of $\varphi_A^n(f_0)$. However, $\varphi_A$ is not Scott-continuous\(^{21}\) (the definition of falsity values involves double-orthogonal sets which do not preserve suprema), and this does not apply.

\(^{19}\)To be honest, we should rather say that we could not manage to find a proof, and that we would welcome any suggestion from insightful readers.

\(^{20}\)In fact, Cousot and Cousot proved a constructive version of Kleene fixed-point theorem which states that without any continuity requirement, the transfinite sequence $(\varphi_A^n(f_0))_{n \in \mathbb{N}}$ is stationary \([6]\). Yet, we doubt that the gain of the desired equality is worth a transfinite definition of the realizability interpretation.

\(^{21}\)In fact, this is nonetheless a good news about our interpretation. Indeed, it is well-known that the more “regular” a model is, the less interesting it is. For instance, Streicher showed that the realizability model induced by Scott domains (using it as a realizability structure) was not only a forcing model by also equivalent to the ground model.
