#### Abstract

One of the main concerns in management and economic planning is to sell the right product to the right customer for the right price. Companies in retail and manufacturing employ pricing strategies to maximize their revenues. The Rank Pricing Problem aims at maximizing the revenue of a company by setting the prices of their products, taking into account the customers' preferences and the amount of money they are willing to pay. In this paper, we model the problem as a non linear bilevel program with multiple independent followers and also present a straightforward non linear single level formulation bearing in mind the aim of the problem. Two different linearizations of the models are carried out and two families of valid inequalities are obtained which, embedded in the formulations by implementing a branch-and-cut algorithm, allow us to tighten the upper bound given by the linear relaxation of the models. We also study the polyhedral structure of the models, taking advantage of the fact that a subset of their constraints constitutes a special case of the Set Packing Problem, and characterize all the clique facets. Besides, we develop a preprocessing procedure to reduce the size of the instances. Finally, we show the efficiency of the formulations, the branch-and-cut algorithms and the preprocessing through an extensive computational study.

Keywords: Bilevel Programming, Rank Pricing Problem, Set Packing, Integer Programming

## 1 Introduction

Over the last few decades, the broad development of information and communication technologies has led to extensive changes in society. The impact of the new technologies and globalization has originated different consumer trends and strong competition in the market. This has forced companies to adapt their marketing strategies in order to fit customer's preferences. In this context, many retail and manufacturing companies have opted for the use of pricing strategies designed to increase their revenue, also motivated by the rising amount of data available from surveys and web pages.

Pricing optimization problems aim at determining the prices of a series of products in order to maximize the revenue of a company. Setting a low price can lead to a loss of income if clients were willing to pay a higher price, but it can also make a product available to a greater amount of customers; on the contrary, a high price can generate greater revenue, but clients may not purchase it if it is too high. Therefore, a pricing problem is formulated as a bilevel program, in other words, has a hierarchical structure with a first optimization problem given by the company, which aims at maximizing its profit, and part of the constraints that force the solution to be optimal to another optimization problem, which is minimizing the customers' purchasing cost.

Bilevel Programming (BP) problems were introduced in 1973 by Bracken and McGill in [2] as mathematical programs with optimization problems in constraints, and their hierarchical structure appears in a wide variety of problems related to management, economic planning and engineering, among others. According to [8], price setting problems stated using bilevel programming fit multiple applications in sectors such as networks (an overview can be found in [13]), the trucking industry and in the context of air traffic management, to cite but a few. An equivalent problem in Game Theory is known as the Stackelberg game ([12]). In this two-player game, one of the players (known as the leader) plays first and decides his best strategy taking into account that the second player (or follower) will react to his movement optimally, knowing the leader's choice.

Customers whose purchasing decision is modelled by means of a budget and who intend to buy at most one product amongst the several they are interested in are called unit-demand customers. These customers will be able to purchase a product provided that its price is at most their budget. Unit-demand customers as stated here were introduced by Guruswami et al. [7], where they show that the single item pricing problem with unlimited supply is not only NP-complete, but APX-hard, and they focus on approximation algorithms.

Regarding pricing problems with unlimited supply and unit-demand customers, Rusmevichientong et al. are the first to propose in [11] min-buying and max-buying objectives, as well as a rank-buying objective. In the first two cases, the customer buys the product with lowest or highest price not exceeding his budget, respectively, whereas in the rankbuying objective the client purchases the product that ranks highest among the ones he can afford. In this case, the authors represent a customer by its budget and an ordered list of recommended products. They show that these problems are NP-complete in the strong sense and introduce new constraints on the ordering of prices (Price Ladder arises naturally, for example, when selling two different versions of a product) and a heuristic approximation algorithm together with performance bounds. In another variant of the models, the customers have different budgets associated to each of the products of their interest. Such is the case of Aggarwal et al. [1], who take up the work of Rusmevichientong et al. and present approximation algorithms for all three models, particularly a polynomial-time approximation scheme for both the model with rank-buying objective including Price Ladder and the model with max-buying objective, and a logarithmic approximation for any of them. Ulterior works include near-tight hardness results for the min-buying, the max-buying and some versions of the rank-buying models given by Briest and Krysta [3]. They also prove that the the problem with rank-buying objective, Price Ladder and consistent budgets, i.e., constraints in order to guarantee that customers assign non-smaller budgets to their higher-ranked products, is strongly NP-hard, even if
each customer has at most two non-zero budgets. In the following, we will study the problem with unit-demand customers with a positive budget, a rank-buying objective as customers' selection rule and unlimited supply, without assuming Price Ladder. We have called this problem the Rank Pricing Problem (RPP) and, to the best of our knowledge, no exact models have been proposed in the literature to tackle it so far.

In this paper, we present a non linear bilevel formulation and also a non linear single level formulation for the RPP. We linearize the formulations by means of two types of auxiliary variables and derive new valid inequalities. These inequalities are separated and included into the models through the development of a branch-and-cut algorithm. We also take advantage of the fact that some of its constraints constitute a special case of the Set Packing Problem and other properties of the problem in order to strengthen the formulations. We develop some preprocessing techniques to be applied to the instances before solving them. Finally, we present the results of our computational analysis, in which we compare the formulations and show that the results obtained reduce the computational effort when obtaining optimal solutions.

The remainder of the paper is organized as follows. Section 2 is devoted to a bilevel formulation for the RPP; in Section 3, the RPP is formulated straightforwardly as a single level non linear model; Section 4 includes two linearizations that apply to both models and the development of other valid inequalities to strengthen its linear relaxation through the implementation of a branch-and-cut algorithm; in Section 5 some families of clique inequalities associated to a subset of constraints are studied attending to the formulation; Section 6 includes some preprocessing results; Section 7 is devoted to testing the performance of the models by means of a computational study; and Section 8 constitutes a conclusion of the paper.

## 2 Bilevel formulation

Let $K=\{1, \ldots,|K|\}$ denote the set of customers and $I=\{1, \ldots,|I|\}$ the set of products. Each customer $k \in K$ is represented by a positive budget, a subset of products $S^{k} \subseteq I$ he is interested in and a preference for each product of this subset $s_{i}^{k} \in I, i \in S^{k}$, where $s_{i}^{k}>s_{j}^{k}$ if customer $k$ prefers product $i$ over product $j$. We will also assume that for each customer all preferences are strict, so that he never likes two products the same. As budgets can be equal for different customers, let $B=\left\{b^{1}, \ldots, b^{M}\right\}, M \leq|K|$, denote the set of different budgets, where $b^{1}<b^{2}<\cdots<b^{M}$. To describe the budget of customer $k$, we define a function $\sigma: K \rightarrow\{1, \ldots, M\}$ such that $\sigma(k)=\ell$ if the budget of customer $k$ is $b^{\ell}$. We will say that a customer $k$ is richer than customers $k_{1}, \ldots, k_{m}$ if $\sigma(k)>\sigma\left(k_{r}\right)$ $\forall r \in\{1, \ldots, m\}$, and the richest customers will be those whose budget is $b^{M}$. Without loss of generality, we will suppose that for any product $i \in I$ there exists $k \in K$ such that $i \in S^{k}$, and also $S^{k} \neq \emptyset \forall k \in K$. Since it will be useful in following sections, we will set $b^{0}=0$.

Thus, the RPP aims at establishing the prices of a set of products sold by a company so as to maximize its revenue, which will be the sum of the prices of all items sold, taking into account that customers will purchase their most preferred one among the ones they can afford (if any).

Let us now introduce continuous variables $p_{i}, i \in I$ representing the leader variables, i.e., the prices of the products; and binary variables $x_{i}^{k}, k \in K, i \in S^{k}$, for every customer's purchase decision, that is, $x_{i}^{k}=1$ if and only if customer $k$ buys product $i$. The formulation of the bilevel problem is

$$
\begin{align*}
\left(\mathrm{BNL}^{p}\right) & \max _{p}  \tag{1a}\\
& \sum_{k \in K} \sum_{i \in S^{k}} p_{i} x_{i}^{k}  \tag{1b}\\
\text { s.t. } & p_{i} \geq 0, \quad \forall i \in I,
\end{align*}
$$

where $\forall k \in K, x^{k}$ is an optimal solution of

$$
\begin{align*}
\max _{x^{k}} & \sum_{i \in S^{k}} s_{i}^{k} x_{i}^{k}  \tag{1c}\\
\text { s.t. } & \sum_{i \in S^{k}} x_{i}^{k} \leq 1  \tag{1d}\\
& \sum_{i \in S^{k}} p_{i} x_{i}^{k} \leq b^{\sigma(k)}  \tag{1e}\\
& x_{i}^{k} \in\{0,1\}, \quad \forall i \in S^{k}, \tag{1f}
\end{align*}
$$

where constraint (1d) forces customer $k$ to buy one product or none and (1e) establishes that customer $k$ will only buy a product if he can afford it. ( $\mathrm{BNL}^{p}$ ) is a non linear bilevel problem with multiple independent followers ([4]).

The fact, already observed by Rusmevichientong et al. in [11], that an optimal solution of ( $\mathrm{BNL}^{p}$ ) exists such that $p_{i} \in B \forall i \in I$, suggests us to define new binary variables $v_{i}^{\ell}$, $i \in I, \ell \in\{1, \ldots, M\}$ representing the prices of products, that is, $v_{i}^{\ell}=1$ if and only if product $i$ has price $b^{\ell}$. By definition of $v$-variables, the price of product $i$ can be expressed as $p_{i}=\sum_{\ell=1}^{M} b^{\ell} v_{i}^{\ell}$. We can now reformulate the problem replacing $p_{i}$ variables by $v_{i}^{\ell}$ variables, adding the following constraints in order to ensure products have at most one price

$$
\sum_{\ell=1}^{M} v_{i}^{\ell} \leq 1, \quad \forall i \in I
$$

and replacing constraints (1e) of the lower level by

$$
\begin{equation*}
x_{i}^{k} \leq \sum_{\ell=1}^{\sigma(k)} v_{i}^{\ell}, \quad \forall k \in K, i \in S^{k} . \tag{2}
\end{equation*}
$$

Establishing strictly different values for the preferences $s_{i}^{k}$ guarantees that the lower level problem has a unique optimal solution for each customer. Besides, the fact that the matrix corresponding to the feasible set of each lower level problem is totally unimodular enables us to relax the integrality constraints (1f), according to [14, Propositions 3.2 and 3.3]. The lower level problems can be further simplified taking into account that once the leader variables $v_{i}^{\ell}$ are known, a subset of variables is determined. If we consider the subset $I(k)=\left\{i \in S^{k}: \sum_{\ell=1}^{\sigma(k)} v_{i}^{\ell}=1\right\}$, variables $\left\{x_{i}^{k}, k \in K, i \in S^{k} \backslash I(k)\right\}$ are automatically settled to 0 since customer $k$ cannot afford to buy these products. Hence, constraints (2)
can be eliminated and the lower level problem can be formulated as

$$
\begin{array}{ll}
\max _{x^{k}} & \sum_{i \in I(k)} s_{i}^{k} x_{i}^{k} \\
\text { s.t. } & \sum_{i \in I(k)} x_{i}^{k} \leq 1 \\
& x_{i}^{k} \geq 0, \quad i \in I(k) .
\end{array}
$$

For each customer $k$, the dual problem of the lower level problem is

$$
\begin{array}{ll}
\min _{u^{k}} & u^{k} \\
\text { s.t. } & u^{k} \geq s_{i}^{k}, \quad i \in I(k) \\
& u^{k} \geq 0 .
\end{array}
$$

By duality theory, $x^{k}$ and $u^{k}$ are optimal solutions to the primal and dual problems, respectively, if and only if

$$
\begin{aligned}
\sum_{i \in I(k)} s_{i}^{k} x_{i}^{k} & =u^{k} \\
\sum_{i \in I(k)} x_{i}^{k} & \leq 1 \\
u^{k} & \geq s_{i}^{k} \quad \forall i \in I(k) \\
x_{i}^{k}, u^{k} & \geq 0
\end{aligned}
$$

Thus, the resultant formulation after substitution of $u^{k}$ and using the definition of $I(k)$ is

$$
\begin{align*}
\left(\mathrm{BNL}^{v}\right) \quad \max _{v, x} & \sum_{k \in K} \sum_{i \in S^{k}}\left(\sum_{\ell=1}^{M} b^{\ell} v_{i}^{\ell}\right) x_{i}^{k}  \tag{3a}\\
\text { s.t. } & \sum_{i \in S^{k}} x_{i}^{k} \leq 1, \quad \forall k \in K  \tag{3b}\\
& \sum_{\ell=1}^{M} v_{i}^{\ell} \leq 1, \quad \forall i \in I  \tag{3c}\\
& \sum_{j \in S^{k}} s_{j}^{k} x_{j}^{k} \geq s_{i}^{k} \sum_{\ell=1}^{\sigma(k)} v_{i}^{\ell}, \quad \forall k \in K, i \in S^{k}  \tag{3d}\\
& x_{i}^{k} \leq \sum_{\ell=1}^{\sigma(k)} v_{i}^{\ell}, \quad \forall k \in K, i \in S^{k}  \tag{3e}\\
& v_{i}^{\ell}, x_{i}^{k} \in\{0,1\}, \quad \forall k \in K, i \in S^{k}, \ell \in\{1, \ldots, M\} . \tag{3f}
\end{align*}
$$

## 3 Single level formulations

In this section, we formulate the problem straightforwardly as a single level optimization problem. First of all, we introduce some definitions.

Definition 3.1. Let $k \in K$ be a customer and $i, j \in S^{k}$ two products. It is said that $i$ is $k$-better than $j$ if customer $k$ prefers product $i$ over product $j$, and it is denoted $i>_{k} j$. The set of products $k$-better than $i$ is denoted by $B(k, i)=\left\{j \in S^{k}: j>_{k} i\right\}$.

Definition 3.2. Let $k \in K$ be a customer and $i, j \in S^{k}$ two products. It is said that $i$ is $k$-worse than $j$ if customer $k$ prefers product $j$ over product $i$, and it is denoted $i<_{k} j$. The set of products $k$-worse than $i$ is denoted by $\overline{B(k, i)}=\left\{j \in S^{k}: j<_{k} i\right\}$.

Since preferences are strict, for any given products $i, j \in S^{k}$, it follows $i>_{k} j$ or $i<_{k} j$. It is also worth noticing that a customer $k$ buys product $i$ if and only if $i \in S^{k}$, its price is below the customer budget and all the products more preferred than $i$ have a price higher than his budget. In terms of the binary variables $x_{i}^{k}, v_{i}^{\ell}$ previously defined:

$$
x_{i}^{k}=1 \quad \Leftrightarrow \quad \sum_{\ell=1}^{\sigma(k)} v_{i}^{\ell}=1 \text { and } \sum_{\ell=1}^{\sigma(k)} v_{j}^{\ell}=0 \forall j \in B(k, i) .
$$

Using this notation and decision variables $x_{i}^{k}, v_{i}^{\ell}$, a single level non linear formulation is

$$
\begin{align*}
\text { (SLNL) } \max _{v, x} & \sum_{k \in K} \sum_{i \in S^{k}}\left(\sum_{\ell=1}^{M} b^{\ell} v_{i}^{\ell}\right) x_{i}^{k}  \tag{4a}\\
\text { s.t. } & \sum_{i \in S^{k}} x_{i}^{k} \leq 1, \quad \forall k \in K  \tag{4b}\\
& \sum_{\ell=1}^{M} v_{i}^{\ell} \leq 1, \quad \forall i \in I  \tag{4c}\\
& x_{i}^{k}+\sum_{\ell=1}^{\sigma(k)} v_{j}^{\ell} \leq 1, \quad \forall k \in K, i \in S^{k}, j \in B(k, i)  \tag{4d}\\
& x_{i}^{k}+\sum_{\ell=\sigma(k)+1}^{M} v_{i}^{\ell} \leq 1, \quad \forall k \in K, i \in S^{k}  \tag{4e}\\
& v_{i}^{\ell}, x_{i}^{k} \in\{0,1\}, \quad \forall k \in K, i \in S^{k}, \ell \in\{1, \ldots, M\}, \tag{4f}
\end{align*}
$$

where constraints (3e) have been replaced by (4e) using constraints (4c). Constraints (4d), also called preference constraints, are given by the previous reasoning and can be strengthened by means of the following result:

Proposition 3.3. The following constraints

$$
\begin{equation*}
\sum_{j \in \overline{B(k, i)}} x_{j}^{k}+\sum_{\ell=1}^{\sigma(k)} v_{i}^{\ell} \leq 1, \quad \forall k \in K, i \in S^{k}: \overline{B(k, i)} \neq \emptyset \tag{5}
\end{equation*}
$$

are valid for (SLNL) and dominate constraints (4d).

Proof. First of all, we shall prove the validity of (5). We have $\sum_{j \in \overline{B(k, i)}} x_{j}^{k} \leq \sum_{j \in I} x_{j}^{k} \leq 1$ using (4b) and $\sum_{\ell=1}^{\sigma(k)} v_{i}^{\ell} \leq \sum_{\ell=1}^{M} v_{i}^{\ell} \leq 1$ because of (4c). Furthermore, provided that product $i$ is within $k$ 's budget, i.e., if $\sum_{\ell=1}^{\sigma(k)} v_{i}^{\ell}=1$, then customer $k$ will not buy any product $k$-worse for him than $i$, so $\sum_{j \in \overline{B(k, i)}} x_{j}^{k}=0$, so (5) are valid.

If we change the notation of (5) and write $\sum_{i^{\prime} \in \overline{B(k, j)}} x_{i^{\prime}}^{k}+\sum_{\ell=1}^{\sigma(k)} v_{j}^{\ell} \leq 1, \forall k \in K$, $j \in S^{k}: \overline{B(k, j)} \neq \emptyset$, and taking into account that when $j$ is $k$-better than $i \in S^{k}$ then $i$ is $k$-worse than $j$, we obtain

$$
x_{i}^{k}+\sum_{\ell=1}^{\sigma(k)} v_{j}^{\ell} \leq \sum_{i^{\prime} \in \bar{B}(k, j)} x_{i^{\prime}}^{k}+\sum_{\ell=1}^{\sigma(k)} v_{j}^{\ell} \leq 1 .
$$

Therefore, we have proved that (5) are stronger than (4d).

## 4 Linearizing and strengthening formulations

Formulations ( $\mathrm{BNL}^{v}$ ) and (SLNL) are non linear because of the objective functions (3a) and (4a). Since both objective functions are the same, from now on we refer to (4a). In order to linearize it, one approach consists in introducing variables $z^{k}, k \in K$, representing the profit obtained from customer $k$. Thus, the objective (4a) can be replaced by

$$
\max _{v, x, z} \sum_{k \in K} z^{k}
$$

and the following constraints need to be added to the formulation

$$
\begin{align*}
& z^{k} \leq \sum_{\ell=1}^{M} b^{\ell} v_{i}^{\ell}+b^{\sigma(k)}\left(1-x_{i}^{k}\right), \quad \forall k \in K, i \in S^{k}  \tag{6a}\\
& z^{k} \leq b^{\sigma(k)} \sum_{i \in S^{k}} x_{i}^{k}, \quad \forall k \in K, \tag{6b}
\end{align*}
$$

where constraints (6a) ensure that if customer $k$ buys product $i, z^{k}=\sum_{\ell=1}^{M} b^{\ell} v_{i}^{\ell}$ and (6b) guarantee $z^{k} \leq 0$ if customer $k$ does not make any purchase. Constraints (6a) can be strengthened taking into account that customer $k$ buys at most one item, and he only buys a product below his budget, obtaining

$$
\begin{equation*}
z^{k} \leq \sum_{\ell=1}^{\sigma(k)} b^{\ell} v_{i}^{\ell}+b^{\sigma(k)} \sum_{j \in S^{k}: j \neq i} x_{j}^{k}, \quad \forall k \in K, i \in S^{k} . \tag{7}
\end{equation*}
$$

Notice that $\sum_{j \in S^{k}: j \neq i} x_{j}^{k}$ is less than $\left(1-x_{i}^{k}\right)$ and the first summation in (7) has less terms than in (6a), making constraints (7) stronger than (6a).

Therefore, we can reformulate problem (SLNL) obtaining a linear model as follows:

$$
\begin{align*}
\left(\mathrm{SLL}_{1}\right) \quad \max _{\mathrm{v}, \mathrm{x}, \mathrm{Z}} & \sum_{k \in K} z^{k}  \tag{8a}\\
\text { s.t. } & \sum_{i \in S^{k}} x_{i}^{k} \leq 1, \quad \forall k \in K  \tag{8b}\\
& \sum_{\ell=1}^{M} v_{i}^{\ell} \leq 1, \quad \forall i \in I  \tag{8c}\\
& \sum_{j \in \overline{B(k, i)}} x_{j}^{k}+\sum_{\ell=1}^{\sigma(k)} v_{i}^{\ell} \leq 1, \quad \forall k \in K, i \in S^{k}: \overline{B(k, i)} \neq \emptyset  \tag{8d}\\
& x_{i}^{k}+\sum_{\ell=\sigma(k)+1}^{M} v_{i}^{\ell} \leq 1, \quad \forall k \in K, i \in S^{k}  \tag{8e}\\
& z^{k} \leq \sum_{\ell=1}^{\sigma(k)} b^{\ell} v_{i}^{\ell}+b^{\sigma(k)} \quad \sum_{j \in S^{k}: j \neq i} x_{j}^{k}, \quad \forall k \in K, i \in S^{k}  \tag{8f}\\
& z^{k} \leq b^{\sigma(k)} \sum_{i \in S^{k}} x_{i}^{k}, \quad \forall k \in K  \tag{8g}\\
& v_{i}^{\ell}, x_{i}^{k} \in\{0,1\}, z^{k} \geq 0 \quad \forall k \in K, i \in S^{k}, \ell \in\{1, \ldots, M\} . \tag{8h}
\end{align*}
$$

An alternative to deal with the nonlinearity of the objective function (4a) is to introduce variables $z_{i}^{k}, k \in K, i \in S^{k}$, representing the profit obtained from customer $k$ when he buys product $i$. With these variables, the objective is

$$
\max _{v, x, z} \sum_{k \in K} \sum_{i \in S^{k}} z_{i}^{k}
$$

and the following constraints ought to be added to the model:

$$
\begin{aligned}
& z_{i}^{k} \leq \sum_{\ell=1}^{\sigma(k)} b^{\ell} v_{i}^{\ell}, \quad \forall k \in K, i \in S^{k} \\
& z_{i}^{k} \leq b^{\sigma(k)} x_{i}^{k}, \quad \forall k \in K, i \in S^{k} .
\end{aligned}
$$

Thus, the resulting model is

$$
\begin{align*}
\left(\mathrm{SLL}_{2}\right) \quad \max _{\mathrm{v}, \mathrm{x}, \mathrm{Z}} & \sum_{k \in K} \sum_{i \in S^{k}} z_{i}^{k}  \tag{9a}\\
\text { s.t. } & \sum_{i \in S^{k}} x_{i}^{k} \leq 1, \quad \forall k \in K  \tag{9b}\\
& \sum_{\ell=1}^{M} v_{i}^{\ell} \leq 1, \quad \forall i \in I  \tag{9c}\\
& \sum_{j \in \overline{B(k, i)}} x_{j}^{k}+\sum_{\ell=1}^{\sigma(k)} v_{i}^{\ell} \leq 1, \quad \forall k \in K, i \in S^{k}: \overline{B(k, i)} \neq \emptyset  \tag{9d}\\
& x_{i}^{k}+\sum_{\ell=\sigma(k)+1}^{M} v_{i}^{\ell} \leq 1, \quad \forall k \in K, i \in S^{k}  \tag{9e}\\
& z_{i}^{k} \leq \sum_{\ell=1}^{\sigma(k)} b^{\ell} v_{i}^{\ell}, \quad \forall k \in K, i \in S^{k}  \tag{9f}\\
& z_{i}^{k} \leq b^{\sigma(k)} x_{i}^{k}, \quad \forall k \in K, i \in S^{k}  \tag{9~g}\\
& v_{i}^{\ell}, x_{i}^{k} \in\{0,1\}, z_{i}^{k} \geq 0 \quad \forall k \in K, i \in S^{k}, \ell \in\{1, \ldots, M\} . \tag{9h}
\end{align*}
$$

In the formulations $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$, the values of the $z$-variables associated to an assignment of prices to products ( $v$-variables) and products to clients ( $x$-variables) are obtained, respectively, by means of constraints ( 8 f ) $-(8 \mathrm{~g}$ ) and ( 9 f$)-(9 \mathrm{~g})$. Although these constraints suffice to obtain the desired values of the $z$-variables, they suffer from a great weakness when using the corresponding linear relaxations for solving the problem. Given the shape of the objective function, such weakness is directly transmitted to the upper bounds in the branch-and-bound method. Furthermore, in (8f) (resp. (9f)), a bound for $z$ is obtained exclusively from the $v$-variables, and in ( 8 g ) (resp. ( 9 g )), from the $x$-variables. These two issues invite to the development of stronger constraints which, by means of the reduction of the values of the $z$-variables obtained in the optimal solution of the linear relaxation of the pertinent formulation, produce a smaller optimal value, i.e., tighter upper bounds to be used in the branch-and-cut solution procedure.

In what follows, two families of valid inequalities for $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$ are presented. As will be shown in the computational study, they produce the desired improvement in the bounds, and they have the particularity of relating the $z$-variables with both the $x$ and the $v$-variables at a time.

Proposition 4.1. The following inequalities are valid for $\left(\mathrm{SLL}_{1}\right)$ :

$$
\begin{equation*}
z^{k} \leq \sum_{i \in S^{k}}\left(b^{r_{i}^{k}} x_{i}^{k}+\sum_{\ell=r_{i}^{k}+1}^{\sigma(k)}\left(b^{\ell}-b^{r_{i}^{k}}\right) v_{i}^{\ell}+\sum_{\ell \in Q_{i}^{k}}\left(b^{\ell}-b^{r_{i}^{k}}\right)\left(x_{i}^{k}+v_{i}^{\ell}-1\right)\right) \tag{10}
\end{equation*}
$$

$\forall k \in K$, integers $r_{i}^{k} \in\{0, \ldots, \sigma(k)\} \forall i \in S^{k}$ and subsets $Q_{i}^{k} \subseteq\left\{1, \ldots, r_{i}^{k}-1\right\} \forall i \in S^{k}$.
Proof. Notice that in the case $r_{i}^{k}=0$, set $Q_{i}^{k}$ must be empty. We aim at proving that constraints (10) are valid for $\left(\mathrm{SLL}_{1}\right)$. Let us assume $x_{i_{0}}^{k}=1$ for some $i_{0} \in S^{k}$, and prove
that the sum of the addends corresponding to product $i_{0}$ in the right hand side of the constraint is greater than or equal to its price. Thus, such sum is

$$
\begin{equation*}
b^{r_{i_{0}}^{k}}+\sum_{\ell=r_{i_{0}}^{k}+1}^{\sigma(k)}\left(b^{\ell}-b^{r_{i_{0}}^{k}}\right) v_{i_{0}}^{\ell}+\sum_{\ell \in Q_{i_{0}}^{k}}\left(b^{\ell}-b^{r_{i_{0}}^{k}}\right) v_{i_{0}}^{\ell}, \tag{11}
\end{equation*}
$$

and we know that $v_{i_{0}}^{\ell_{0}}=1$ for some $\ell_{0} \leq \sigma(k)$. If $\ell_{0}>r_{i_{0}}^{k}$, then $v_{i_{0}}^{\ell}=0 \forall \ell \in Q_{i_{0}}^{k}$ and we get $b^{r_{i_{0}}^{k}}+\left(b^{\ell_{0}}-b^{r_{i_{0}}^{k}}\right)=b^{\ell_{0}}$, which is exactly the price of $i_{0}$. On the other hand, if $\ell_{0} \leq r_{i_{0}}^{k}$ we have $v_{i_{0}}^{\ell}=0 \forall \ell: r_{i_{0}}^{k}<\ell \leq \sigma(k)$, and therefore (11) becomes

$$
b^{r_{i_{0}}^{k}}+\sum_{\ell \in Q_{i_{0}}^{k}}\left(b^{\ell}-b^{r_{i_{0}}^{k}}\right) v_{i_{0}}^{\ell} .
$$

If $\ell_{0} \notin Q_{i_{0}}^{k}$, we obtain $b^{r_{i_{0}}^{k}}$, which is greater than or equal to $b^{\ell_{0}}$ because $r_{i_{0}}^{k} \geq \ell_{0}$; otherwise, if $\ell_{0} \in Q_{i_{0}}^{k}$, then the term becomes $b^{r i_{0}}+\left(b^{\ell_{0}}-b^{r_{i_{0}}}\right)=b^{\ell_{0}}$.

Now, let us suppose $x_{i_{0}}^{k}=0$ for $i_{0} \in S^{k}$. Then the addends corresponding to product $i_{0}$ become

$$
\sum_{\ell=r_{i_{0}}^{k}+1}^{\sigma(k)}\left(b^{\ell}-b^{r_{i_{0}}^{k}}\right) v_{i_{0}}^{\ell}+\sum_{\ell \in Q_{i_{0}}^{k}}\left(b^{\ell}-b^{r_{i_{0}}^{k}}\right)\left(v_{i_{0}}^{\ell}-1\right) .
$$

Since $\left(b^{\ell}-b^{r_{i_{0}}^{k}}\right)>0$ for $\ell: r_{i_{0}}^{k}<\ell \leq \sigma(k)$ and $\left(b^{\ell}-b^{r_{i_{0}}^{k}}\right)<0$ for $\ell \in Q_{i_{0}}^{k}$, then the sum is greater than or equal to zero.

Therefore, if $x_{i}^{k}=0 \forall i \in S^{k}, z^{k}$ will be upperly bounded by a sum of non-negative values. Otherwise, since, at any feasible solution, at most one $x$-variable can take value 1 for a fixed customer $k$, say $x_{i_{0}}^{k}$, the upper bound will be obtained as the sum of the term corresponding to product $i_{0}$, which has been proved to be greater than or equal to the price assigned to $i_{0}$, plus some non-negative addends.

Remark 4.2. The family of inequalities (10) contains all of the previous upper bound constraints on $z^{k}$ of ( $\mathrm{SLL}_{1}$ ). Constraints (8f) are obtained by, given a customer $k \in K$ and a product $i \in S^{k}$, setting $r_{i}^{k}=0, r_{j}^{k}=\sigma(k) \forall j \in S^{k} \backslash\{i\}$ and $Q_{j}^{k}=\emptyset \forall j \in S^{k}$ in (10); constraints $(8 \mathrm{~g})$, by, given a customer $k \in K$, setting $r_{i}^{k}=\sigma(k)$ and $Q_{i}^{k}=\emptyset \forall i \in S^{k}$.

Proposition 4.3. The inequalities of the following family are valid for $\left(\mathrm{SLL}_{2}\right)$ :

$$
\begin{equation*}
z_{i}^{k} \leq b^{r_{i}^{k}} x_{i}^{k}+\sum_{\ell=r_{i}^{k}+1}^{\sigma(k)}\left(b^{\ell}-b^{r_{i}^{k}}\right) v_{i}^{\ell}+\sum_{\ell \in Q_{i}^{k}}\left(b^{\ell}-b^{r_{i}^{k}}\right)\left(x_{i}^{k}+v_{i}^{\ell}-1\right), \tag{12}
\end{equation*}
$$

$\forall k \in K, i \in S^{k}$, any integer $r_{i}^{k} \in\{0, \ldots, \sigma(k)\}$ and any subset $Q_{i}^{k} \subseteq\left\{1, \ldots, r_{i}^{k}-1\right\}$.
Proof. First assume that $x_{i}^{k}=1$. This implies $v_{i}^{\ell_{0}}=1$ for some $\ell_{0} \leq \sigma(k)$. If $\ell_{0} \leq r_{i}^{k}$, then $v_{i}^{\ell}=0 \forall \ell: r_{i}^{k}<\ell \leq \sigma(k)$ and (12) becomes $z_{i}^{k} \leq b_{i}^{r_{i}^{k}}+\sum_{\ell \in Q_{i}^{k}}\left(b^{\ell}-b_{i}^{r_{i}^{k}}\right) v_{i}^{\ell}$. If $\ell_{0} \in Q_{i}^{k}$, then the right hand side of the constraint is $b^{r_{i}^{k}}+\left(b^{\ell_{0}}-b^{r_{i}^{k}}\right)=b^{\ell_{0}}$, which is valid as it is the exact price of product $i$; otherwise, the right hand side of the constraint is $b^{r_{i}^{k}}$,
valid since $b_{i}^{r_{i}^{k}} \geq b^{\ell_{0}}$. If $\ell_{0}>r_{i}^{k}$, then $v_{i}^{\ell}=0 \forall \ell \in Q_{i}^{k}$ and the inequality we obtain is $z_{i}^{k} \leq b^{r_{i}^{k}}+\left(b^{\ell_{0}}-b^{r_{i}^{k}}\right)$, also valid.

On the other hand, if we assume $x_{i}^{k}=0$, then the inequality holds trivially because its right hand side is non negative and $z_{i}^{k}=0$.

Remark 4.4. The family of inequalities (12) contains all of the previous upper bound constraints on $z_{i}^{k}$ of ( $\mathrm{SLL}_{2}$ ): constraints (9f) are obtained by setting $r_{i}^{k}=0$ and $Q_{i}^{k}=\emptyset$ $\forall k \in K, i \in S^{k}$, whereas constraints (9g) appear as a result of setting $r_{i}^{k}=\sigma(k), Q_{i}^{k}=\emptyset$ $\forall k, i \in S^{k}$.

The number of inequalities of Propositions 4.1 and 4.3 increases exponentially as the number of customers and products grows. However, these inequalities can be efficiently separated and added dynamically to formulations $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$, respectively, in a branch-and-cut mode. Thus, regarding the family of valid inequalities (10), and given a fractional optimal solution of the linear relaxation of $\left(\mathrm{SLL}_{1}\right),\left(\bar{v}_{i}^{\ell}, \bar{x}_{i}^{k}, \bar{z}^{k}\right)$, our aim is to find, for each $k \in K$, integers $r_{i}^{k}$ and subsets $Q_{i}^{k} \forall i \in S^{k}$ such that the upper bound given by the right hand side of the resultant constraint of the family is as tight as possible. As the sum given by the right hand side of (10) can be decomposed by products and given that $\bar{z}$ is fixed, our problem reduces to

$$
\begin{equation*}
\min _{\substack{r \in\{0, \ldots,(k)\} \\ Q \subseteq\{1, \ldots, r-1\}}} b^{r} \bar{x}_{i}^{k}+\sum_{\ell=r+1}^{\sigma(k)}\left(b^{\ell}-b^{r}\right) \bar{v}_{i}^{\ell}+\sum_{\ell \in Q}\left(b^{\ell}-b^{r}\right)\left(\bar{x}_{i}^{k}+\bar{v}_{i}^{\ell}-1\right), \tag{13}
\end{equation*}
$$

where $(k, i) \in K \times S^{k}$ is fixed, and we have denoted $r_{i}^{k}$ as $r$ and $Q_{i}^{k}$ as $Q$ so as to simplify notation. It is worth noticing that this pair $(r, Q)$ also minimizes the right hand side of the corresponding constraint of family (12) when given an optimal fractional solution of the linear relaxation of $\left(\mathrm{SLL}_{2}\right),\left(\bar{v}_{i}^{\ell}, \bar{x}_{i}^{k}, \bar{z}_{i}^{k}\right)$, and fixed $(k, i) \in K \times S^{k}$. Thus, finding a pair $(r, Q)$ that minimizes (13) for a given customer $k$ and product $i$ not only leads to the development of an efficient separation algorithm for the set of valid inequalities (10), but also for the set (12).

The fact that $\left(b^{\ell}-b^{r}\right) \leq 0 \forall \ell \leq r$ implies that, for a given $r, Q^{r}:=\{\ell \in\{1, \ldots, r-1\}$ : $\left.\bar{x}_{i}^{k}+\bar{v}_{i}^{\ell}>1\right\}$ minimizes (13). Therefore, if $W(r)$ is the value of the sum (13) when $Q=Q^{r}$, our problem consists in minimizing $W(r)$ for $r \in\{0, \ldots, \sigma(k)\}$.

To do so, we shall study the variation of $W(r)$ as $r$ increases. Given that $Q^{r+1}=$ $Q^{r} \cup\{r\}$ if $\bar{x}_{i}^{k}+\bar{v}_{i}^{r}>1, Q^{r+1}=Q^{r}$ otherwise, for $r<\sigma(k)$ we get

$$
\begin{align*}
W(r+1)-W(r)= & \left(b^{r+1} \bar{x}_{i}^{k}+\sum_{\ell=r+2}^{\sigma(k)}\left(b^{\ell}-b^{r+1}\right) \bar{v}_{i}^{\ell}+\sum_{\ell \in Q^{r+1}}\left(b^{\ell}-b^{r+1}\right)\left(\bar{x}_{i}^{k}+\bar{v}_{i}^{\ell}-1\right)\right) \\
& -\left(b^{r} \bar{x}_{i}^{k}+\sum_{\ell=r+1}^{\sigma(k)}\left(b^{\ell}-b^{r}\right) \bar{v}_{i}^{\ell}+\sum_{\ell \in Q^{r}}\left(b^{\ell}-b^{r}\right)\left(\bar{x}_{i}^{k}+\bar{v}_{i}^{\ell}-1\right)\right) \\
= & \left(b^{r+1}-b^{r}\right) \bar{x}_{i}^{k}+\sum_{\ell=r+2}^{\sigma(k)}\left(b^{r}-b^{r+1}\right) \bar{v}_{i}^{\ell}-\left(b^{r+1}-b^{r}\right) \bar{v}_{i}^{r+1} \\
& +\sum_{\ell \in Q^{r+1}}\left(b^{r}-b^{r+1}\right)\left(\bar{x}_{i}^{k}+\bar{v}_{i}^{\ell}-1\right) \\
= & \left(b^{r+1}-b^{r}\right)\left(\bar{x}_{i}^{k}-\sum_{\ell=r+1}^{\sigma(k)} \bar{v}_{i}^{\ell}+\sum_{\ell \in Q^{r+1}}\left(1-\bar{x}_{i}^{k}-\bar{v}_{i}^{\ell}\right)\right) . \tag{14}
\end{align*}
$$

First of all, we are going to prove that, when $r$ increases from 0 to $\sigma(k), W(r)$ first decreases and then increases. We can achieve that by proving that $W(r)-W(r-1) \geq$ $0 \Rightarrow W(r+1)-W(r) \geq 0$. Since $b^{r+1}-b^{r}>0 \forall r<\sigma(k)$, it follows from (14) that $W(r+$ 1) $-W(r) \geq 0 \Leftrightarrow \bar{x}_{i}^{k}-\sum_{\ell=r+1}^{\sigma(k)} \bar{v}_{i}^{\ell}+\sum_{\ell \in Q^{r+1}}\left(1-\bar{x}_{i}^{k}-\bar{v}_{i}^{\ell}\right) \geq 0 \forall r<\sigma(k)$, and therefore demonstrating the above is equivalent to proving $\bar{x}_{i}^{k}-\sum_{\ell=r+1}^{\sigma(k)} \bar{v}_{i}^{\ell}+\sum_{\ell \in Q^{r+1}}\left(1-\bar{x}_{i}^{k}-\bar{v}_{i}^{\ell}\right)-$ $\left(\bar{x}_{i}^{k}-\sum_{\ell=r}^{\sigma(k)} \bar{v}_{i}^{\ell}+\sum_{\ell \in Q^{r}}\left(1-\bar{x}_{i}^{k}-\bar{v}_{i}^{\ell}\right)\right) \geq 0$. But we have

$$
\begin{aligned}
& \bar{x}_{i}^{k}-\sum_{\ell=r+1}^{\sigma(k)} \bar{v}_{i}^{\ell}+\sum_{\ell \in Q^{r+1}}\left(1-\bar{x}_{i}^{k}-\bar{v}_{i}^{\ell}\right)-\left(\bar{x}_{i}^{k}-\sum_{\ell=r}^{\sigma(k)} \bar{v}_{i}^{\ell}+\sum_{\ell \in Q^{r}}\left(1-\bar{x}_{i}^{k}-\bar{v}_{i}^{\ell}\right)\right) \\
&= \bar{v}_{i}^{r}+\min \left\{0,1-\bar{x}_{i}^{k}-\bar{v}_{i}^{r}\right\}=\min \left\{\bar{v}_{i}^{r}, 1-\bar{x}_{i}^{k}\right\} \geq 0 .
\end{aligned}
$$

Hence, $W(r)$ reaches its minimum value for the smallest $r$ such that $W(r)-W(r-1) \leq$ 0 and $W(r+1)-W(r)>0$.

Furthermore, noticing in (14) that $\sum_{\ell \in Q^{r+1}}\left(1-\bar{x}_{i}^{k}-\bar{v}_{i}^{\ell}\right) \leq 0 \forall r$ allows us to deduce that $W(r)-W(r-1) \leq 0$ provided that $\bar{x}_{i}^{k}-\sum_{\ell=r}^{\sigma(k)} \bar{v}_{i}^{\ell} \leq 0$, i.e., if $r$ is such that $\bar{x}_{i}^{k} \leq \sum_{\ell=r}^{\sigma(k)} \bar{v}_{i}^{\ell}$. This fact saves us having to compute the whole sum (14) in order to know if $W(r)-W(r-1) \leq 0$ whenever $\bar{x}_{i}^{k} \leq \sum_{\ell=r}^{\sigma(k)} \bar{v}_{i}^{\ell}$.

Now that we have found a separation for valid inequalities (10), the next step consists in defining a procedure to incorporate these inequalities into formulation ( $\mathrm{SLL}_{1}$ ) dynamically in a branch-and-cut framework where the starting subproblem of every child node is the final formulation of the parent node with the corresponding branching $x$ - or $v$-variable fixed to either zero or one. A scheme of this procedure is depicted in Algorithm 1, and these inequalities are only added into the formulation provided that the node depth in the branching tree is less than or equal to 4 . The termination criteria is that the optimal value of the linear relaxation of that node does not improve in the last iteration. Both the algorithm and the branch-and-cut procedure used to include dynamically inequalities (12) into model ( $\mathrm{SLL}_{2}$ ) are analogous to these ones.

```
Algorithm 1 Separation of inequalities (10)
    Let \(\left(\bar{x}_{i}^{k}, \bar{v}_{i}^{\ell}, \bar{z}^{k}\right)\) be an optimal fractional solution of the linear relaxation of \(\left(\mathrm{SLL}_{1}\right)\).
    For every customer \(k \in K\) do
```

        Step 1. For every product \(i \in S^{k}\) do
            Step 1.1. Set \(r_{i}^{k}=0\).
            Step 1.2. If \(r_{i}^{k}<\sigma(k)\) and \(\sum_{\ell=1}^{k} \bar{v}_{i}^{\ell} \leq \bar{x}_{i}^{k}\), update \(r_{i}^{k}:=r_{i}^{k}+1\) and go to Step
                    1.2.
                            Otherwise, go to Step 1.3.
    Step 1.3. If $r_{i}^{k}<\sigma(k)$ and $W\left(r_{i}^{k}+1\right)-W\left(r_{i}^{k}\right) \leq 0$, update $r_{i}^{k}:=r_{i}^{k}+1$ and go
to Step 1.3.
Otherwise, go to Step 2.
Step 2. Set $Q_{i}^{k}:=\left\{\ell \in\left\{1, \ldots, r_{i}^{k}-1\right\}: \bar{x}_{i}^{k}+\bar{v}_{i}^{\ell}>1\right\} \forall i \in S^{k}$.

Step 3. Incorporate constraint

$$
\bar{z}^{k} \leq \sum_{i \in S^{k}}\left(b^{r_{i}^{k}} \bar{x}_{i}^{k}+\sum_{\ell=r_{i}^{k}+1}^{\sigma(k)}\left(b^{\ell}-b^{r_{i}^{k}}\right) \bar{v}_{i}^{\ell}+\sum_{\ell \in Q_{i}^{k}}\left(b^{\ell}-b^{r_{i}^{k}}\right)\left(\bar{x}_{i}^{k}+\bar{v}_{i}^{\ell}-1\right)\right)
$$

to the formulation if and only if it is violated.

## 5 Polyhedral analysis of the set packing subproblem

In this section, we are going to analyze the subproblem of model ( $\mathrm{SLL}_{1}$ ) (resp. model $\left.\left(\mathrm{SLL}_{2}\right)\right)$ associated to $x$ - and $v$-variables and constraints (8b)-(8e) (resp. constraints (9b)(9e)), given that it constitutes a special case of a Set Packing Problem (SPP). Since this subproblem is the same for both models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$, in the rest of the section we shall refer to the subproblem of model $\left(\mathrm{SLL}_{1}\right)$.

An SPP is a problem in the form of

$$
\max \left\{c t: A t \leq \mathbf{1}_{w}, t \in\{0,1\}^{u}\right\},
$$

where $c \in \mathbb{R}^{u}, A \in\{0,1\}^{w \times u}$ and $\mathbf{1}_{w}$ is a $w$-vector of ones.
The polyhedral structure of the SPP has been widely studied in the literature. The interested reader is referred to [10], where the basis of this section is presented, and to [5], where further results are presented and the main papers on the topic are referenced. In the following paragraphs we briefly expose the notation and results necessary to tackle the section. For details, the reader may consult [9].

Associated with each instance of an SPP, let the intersection graph be $G=(V, E)$, where each node in the set $V$ is associated to a variable of the problem and $\left(v_{i}, v_{j}\right) \in E$ if and only if $a_{k i}+a_{k j}=2$ in some row of $A$. The neighborhood of a node $v$ is the set of nodes adjacent to $v$. A non empty subset of pairwise non adjacent nodes in $G$ is known as a packing, and the problem of obtaining an optimal solution of an SPP is equivalent to that of obtaining a packing of maximum cardinality on its intersection
graph. A complete graph is that in which all the nodes are pairwise adjacent, and a clique in $G$ is a maximal complete subgraph. The incidence vector of a subset $V^{\prime} \subset V$ is a binary vector $\left(t_{1}, \ldots, t_{|V|}\right)$ where $t_{j}=1$ if and only if the $j^{t h}$ node of $V$ belongs to $V^{\prime}$, for $j \in\{1, \ldots,|V|\}$.

Let $P(G)$ be the convex hull of the incidence vectors of all the packings of the intersection graph $G$, i.e., the convex hull of all the feasible solutions of SPP. A valid inequality for $P(G)$ is a facet of $P(G)$ if and only if it is satisfied as an equality by $|V|$ linearly independent points of $P(G)$. Since facets are not dominated by any other valid inequality, one way of confirming that our formulation (or part of it) is tight consists in proving that its constraints are facet-defining. And, as stated in [10], an inequality in the form $\sum_{v \in V^{\prime}} x_{v} \leq 1$, where $V^{\prime} \subset V$, is a facet for $P(G)$ if and only if the subgraph induced by $V^{\prime}$ is a clique in $G$. Clique facets are particularly interesting because they can always provide a valid formulation, they are simple to obtain since they have coefficients equal to zero or one and the right hand side equal to one, and its addition to a problem generally provides better results (when trying to solve it) than the addition of other types of facets which are more complex, such as lifted odd holes.

### 5.1 Set packing subproblem of ( $\mathrm{SLL}_{1}$ )

In order to apply the SPP properties to our problem, we begin by identifying the intersection graph GSLL associated to the previously defined subproblem of formulation ( $\mathrm{SLL}_{1}$ ). The large amount of edges of this graph makes drawing it impractical, so we will follow a different approach in order to describe the intersection graph based on the following proposition.

Proposition 5.1. Given the intersection graph GSLL associated to the subgraph of $\left(\mathrm{SLL}_{1}\right)$ :
(1) Two nodes $x_{i}^{k}, x_{j}^{k}, i \neq j$, are adjacent $\forall i, j \in S^{k}$.
(2) Two nodes $x_{i}^{k}, x_{i}^{k^{\prime}}, k \neq k^{\prime}$, are never adjacent.
(3) Two nodes $x_{i}^{k}, x_{j}^{k^{\prime}}, k \neq k^{\prime}, i \neq j$, are adjacent if and only if $\sigma(k) \geq \sigma\left(k^{\prime}\right)$ and $j \in B(k, i)$ (or, equivalently, $i \in \overline{B(k, j)}$ ).
(4) Two nodes $x_{i}^{k}, v_{i}^{\ell}$, are adjacent if and only if $\ell>\sigma(k)$.
(5) Two nodes $x_{i}^{k}, v_{j}^{\ell}, i \neq j$ are adjacent if and only if $\ell \leq \sigma(k)$ and $j \in B(k, i)$.
(6) Two nodes $v_{i}^{\ell}, v_{i}^{\ell^{\prime}}, \ell \neq \ell^{\prime}$, are adjacent $\forall \ell, \ell^{\prime}$.
(7) Two nodes $v_{i}^{\ell}, v_{j}^{\ell^{\prime}}, i \neq j$, are never adjacent.

Proof.
(1) A customer $k$ purchases at most one product.
(2) The fact that a customer $k$ purchases a product $i$ does not imply that another customer can not afford it (that depends on $i$ 's price), and therefore does not allow us to determine whether another customer is going to buy it or not.
(3) Let us suppose $x_{i}^{k}=1$, i.e., customer $k$ purchases product $i$. That implies $k$ is not able to afford any product $j$ that is $k$-better than $i$, and therefore no customer $k^{\prime}$ with $\sigma\left(k^{\prime}\right) \leq \sigma(k)$ will be able to afford it either, hence $x_{j}^{k^{\prime}}=0$. However, the fact that $k$ purchases product $i$ does not allow us to infer which products will not be purchased by other customers $k^{\prime}$ richer that $k$ or which customers will not purchase a product $j \in \overline{B(k, i)} \cup\{i\}$.
(4) If $x_{i}^{k}=1, k$ can afford product $i$, so there must exist $\ell_{0} \leq \sigma(k)$ such that $v_{i}^{\ell_{0}}=1$. Since product $i$ can have one price at most, it follows $v_{i}^{\ell}=0 \forall \ell>\sigma(k)$.
(5) Let us suppose $x_{i}^{k}=1$, i.e., customer $k$ purchases product $i$. That implies $k$ is not able to afford any product $j$ that is $k$-better than $i$, i.e., $v_{j}^{\ell}=0 \forall j \in B(k, i)$, $\forall \ell \leq \sigma(k)$. However, it does not provide any insight into the prices of products $j \in \overline{B(k, i)}$.
(6) A product $i$ can have at most one price.
(7) Knowing the price of a product does not provide any insight into the price of the rest.

Having identified the intersection graph GSLL, the next subsection focuses on characterizing all its cliques.

### 5.2 Characterization of all the cliques in the intersection graph

We first include a lemma that will be useful when characterizing all the cliques.
Lemma 5.2. Any clique in GSLL which contains nodes $v_{i}^{\ell_{1}}, v_{i}^{\ell_{2}}$ with $\ell_{1}<\ell_{2}$, contains $v_{i}^{\ell}$ $\forall \ell$ such that $\ell_{1}<\ell<\ell_{2}$.

Proof. Let $\left(V^{\prime}, E^{\prime}\right)$ be a clique in GSLL and suppose $v_{i}^{\ell_{1}}, v_{i}^{\ell_{2}} \in V^{\prime}$, for $\ell_{1}<\ell_{2}$.
Let us suppose that there exists $k \in K$ with $x_{i}^{k} \in V^{\prime}$. Then, $x_{i}^{k}$ is adjacent to $v_{i}^{\ell_{1}}$, and thus for Prop. 5.1(4) it follows $\sigma(k)<\ell_{1}$. Therefore, for every $\ell>\ell_{1}>\sigma(k)$, the same result implies $x_{i}^{k}$ is adjacent to $v_{i}^{\ell}$.

Now let us suppose that there exist $k \in K$ and $j \in S^{k}, j \neq i$, with $x_{j}^{k} \in V^{\prime}$. By hypothesis we have $x_{j}^{k}$ adjacent to $v_{i}^{\ell_{2}}$, which for Proposition 5.1(5) implies $i \in B(k, j)$ and $\sigma(k) \geq \ell_{2}$. Thus, for every $\ell<\ell_{2} \leq \sigma(k)$, it follows from the same result that $x_{j}^{k}$ is adjacent to $v_{i}^{\ell}$.

Finally, we know from Proposition 5.1(6) and (7) that $v_{j}^{\ell}$ adjacent to $v_{i}^{\ell_{1}} \Leftrightarrow j=i$, hence $v_{i}^{\ell}$ is adjacent to $v_{i}^{\ell^{\prime}} \forall \ell \neq \ell^{\prime}$ and $v_{j}^{\ell} \notin V^{\prime}$ for $j \neq i$.

All in all, we have proven that for $\ell$ such that $\ell_{1}<\ell<\ell_{2}$, any variable $x_{j}^{k}$ or $v_{i}^{\ell^{\prime}} \in V^{\prime}$ is adjacent to $v_{i}^{\ell}$. Thus, the statement follows.

Before proving the main results of this section, we introduce some sets that generalize $B(k, i)$.

Definition 5.3. Let $k$ be a customer and $P \subseteq S^{k}$ a subset of products in which $k$ is interested. Then we define $B(k, P)$ as the set $\left\{i \in \frac{\left.S^{k}: i>_{k} j \forall j \in P\right\} \text { of products that }}{B(k, P)}\right.$ are preferred by $k$ to all the products in $P$. Similarly $\overline{B(k, P)}:=\left\{i \in S^{k}: i<_{k} j \forall j \in P\right\}$. In the special case when $P=\emptyset$ we define $B(k, \emptyset):=I$ and $\overline{B(k, \emptyset)}:=I$.

Now we can state the two main results in this section. Note that, in order to keep a consistent notation, a set $\left\{k_{2}, \ldots, k_{n}\right\}$ is defined in Theorem 5.4 that will be extended to $\left\{k_{1}, \ldots, k_{n}\right\}$ in Theorem 5.5.

Theorem 5.4. Given a set of customers $\left\{k_{2}, \ldots, k_{n}\right\}$, $n \geq 2$, with $\sigma\left(k_{2}\right) \leq \cdots \leq \sigma\left(k_{n}\right)$, and non empty pairwise disjoint sets of products $P^{k_{q}} \subseteq S^{k_{q}}, q=2, \ldots, n$, such that
$P^{k_{q}} \subseteq\left(\bigcap_{\substack{r=2: \\ \sigma\left(k_{r}\right)<\sigma\left(k_{q}\right)}}^{q-1} \overline{B\left(k_{q}, P^{k_{r}}\right)}\right) \bigcap\left(\bigcap_{\substack{r=2: \\ \sigma\left(k_{r}\right)=\sigma\left(k_{q}\right)}}^{q-1}\left(\overline{B\left(k_{q}, P^{k_{r}}\right)} \cup B\left(k_{r}, P^{k_{r}}\right)\right)\right) \forall q \in\{3, \ldots, n\}$,
the following inequalities are valid for $\left(\mathrm{SLL}_{1}\right)$ :

$$
\begin{equation*}
\sum_{q=2}^{n} \sum_{j \in P^{k_{q}}} x_{j}^{k_{q}} \leq 1 \tag{15}
\end{equation*}
$$

Valid inequalities (15) are facets for the subproblem of $\left(\mathrm{SLL}_{1}\right)$ if and only if $\nexists\left(k_{0}, i_{0}\right) \in$ $K \times S^{k_{0}}$ satisfying

1. $i_{0} \in B\left(k_{q}, P^{k_{q}}\right) \forall q \in\{2, \ldots, n\}: \sigma\left(k_{q}\right) \geq \sigma\left(k_{0}\right)$,
2. $i_{0} \in \overline{B\left(k_{0}, P^{k_{q}}\right)} \forall q \in\{2, \ldots, n\}: \sigma\left(k_{q}\right) \leq \sigma\left(k_{0}\right)$,
and $\left|\bigcup_{\substack{q=2: \\ \sigma\left(k_{q}\right)=\sigma\left(k_{2}\right)}}^{n} P^{k_{q}}\right| \geq 2$. Furthermore, all the clique facets for the subproblem of $\left(\mathrm{SLL}_{1}\right)$ containing only $x$-variables are in family (15).

Proof. Let GSLL $=\left(V_{G}, E_{G}\right)$ be the intersection graph of the subproblem of $\left(\mathrm{SLL}_{1}\right)$ associated to $x$ - and $v$-variables and constraints (8b)-(8e), and let $Q=\left(V^{\prime}, E^{\prime}\right)$ be a clique of GSLL containing only $x$-variables.

Let $k_{2}$ be a customer with minimum budget in the clique and a subset of products $P^{k_{2}} \subseteq S^{k_{2}}$ such that $x_{j}^{k_{2}} \in V^{\prime} \forall j \in P^{k_{2}}$ (taking into account that, by Proposition 5.1(1), $x_{i}^{k_{2}}$ is adjacent to $\left.x_{j}^{k_{2}} \forall i \neq j\right)$.

Provided that there exist customers $k_{q}, \forall q \in\{3, \ldots, n\}$ such that $\sigma\left(k_{2}\right) \leq \sigma\left(k_{3}\right) \leq$ $\cdots \leq \sigma\left(k_{n}\right)$ and sets of products $P^{k_{q}} \subseteq S^{k_{q}}, P^{k_{q}} \neq \emptyset \forall q \in\{3, \ldots, n\}$, such that $x_{j}^{k_{q}} \in V^{\prime}$ $\forall j \in P^{k_{q}}$, then by Proposition $5.1(2) P^{k_{2}}, \ldots, P^{k_{n}}$ are pairwise disjoint, and verify the following conditions:

$$
P^{k_{q}} \subseteq \bigcap_{\substack{r=2 \\ \sigma\left(k_{r}\right)<\sigma\left(k_{q}\right)}}^{q-1} \overline{B\left(k_{q}, P^{k_{r}}\right)}, \quad \forall q \in\{3, \ldots, n\} .
$$

Otherwise, there exist $k_{r}$ with $\sigma\left(k_{r}\right)<\sigma\left(k_{q}\right)$ and products $i \in P^{k_{r}}, j \in P^{k_{q}}$ such that $x_{i}^{k_{r}}, x_{j}^{k_{q}} \in V^{\prime}$ but $j \notin \overline{B\left(k_{q}, i\right)}$, and by Proposition 5.1(3) this implies $x_{i}^{k_{r}}$, $x_{j}^{k_{q}}$ are not neighbors in the intersection graph. Therefore, $V^{\prime}$ does not induce a complete graph.

$$
P^{k_{q}} \subseteq \bigcap_{\substack{r=2 \\ \sigma\left(k_{r}\right)=\sigma\left(k_{q}\right)}}^{q-1}\left(\overline{B\left(k_{q}, P^{k_{r}}\right)} \cup B\left(k_{r}, P^{k_{r}}\right)\right), \quad \forall q \in\{3, \ldots, n\}
$$

Otherwise, there exist $k_{r}$ with $\sigma\left(k_{r}\right)=\sigma\left(k_{q}\right)$ and products $i \in P^{k_{r}}, j \in P^{k_{q}}$ such that $x_{i}^{k_{r}}, x_{j}^{k_{q}} \in V^{\prime}$ but Proposition 5.1(3) does not hold for $k=k_{r}, k^{\prime}=k_{q}$ or for $k=k_{q}, k^{\prime}=k_{r}$, and hence $V^{\prime}$ does not induce a complete graph.

Therefore, the above conditions guarantee that the nodes corresponding with the $x$ variables in an inequality in the form of (15) induce a complete graph, so the family of inequalities (15) is valid.

In addition, if there exist $\left(k_{0}, i_{0}\right) \in K \times S^{k_{0}}$ meeting the conditions of the statement, then $x_{i_{0}}^{k_{0}}$ is adjacent in the intersection graph to every other node in $V^{\prime}$ by Proposition $5.1(3)$ and conditions 1 and/or 2, and therefore the complete subgraph is not maximal.

On the other hand, if $\left|\bigcup_{\substack{q=2 ; \\ \sigma\left(k_{q}\right)=\sigma\left(k_{2}\right)}}^{n} P^{k_{q}}\right| \geq 2$ holds, no $v$-variable can be adjacent in the intersection graph to all nodes in $V^{\prime}$. Otherwise, $P^{k_{2}}=\{i\}$ and either $n=2$ or $\sigma\left(k_{2}\right)<\sigma\left(k_{3}\right)$, and hence variable $v_{i}^{\sigma\left(k_{2}\right)+1}$ would be adjacent to every node in $V^{\prime}$ and the complete subgraph would not be maximal.

Theorem 5.5. Given a nonempty set $L=\left\{\ell_{1}, \ldots, \ell_{p}\right\} \subseteq\{1, \ldots, M\}$, a product $i \in I$ and

- if $\ell_{1}>1$, a customer $k_{1}$ such that $\sigma\left(k_{1}\right)=\ell_{1}-1, i \in S^{k_{1}}$, and a set $P^{k_{1}}=\{i\}$; otherwise, $P^{k_{1}}=\emptyset$;
- if $\ell_{p}<M$, customers $k_{2}, \ldots, k_{n}, n \geq 2$, such that $\ell_{p}=\sigma\left(k_{2}\right) \leq \cdots \leq \sigma\left(k_{n}\right)$ ( $n=1$ otherwise) and non empty pairwise disjoint sets of products $P^{k_{q}} \subseteq S^{k_{q}} \backslash\{i\}$, $q=2, \ldots, n$ such that $P^{k_{2}} \subseteq \overline{B\left(k_{2}, i\right)}$ and

$$
P^{k_{q}} \subseteq\left(\bigcap_{\substack{r=1: \\ \sigma\left(k_{r}\right)<\sigma\left(k_{q}\right)}}^{q-1} \overline{B\left(k_{q}, P^{k_{r}}\right)}\right) \bigcap\left(\bigcap_{\substack{r=1: \\ \sigma\left(k_{r}\right)=\sigma\left(k_{q}\right)}}^{q-1}\left(\overline{B\left(k_{q}, P^{k_{r}}\right)} \cup B\left(k_{r}, P^{k_{r}}\right)\right)\right)
$$

$\forall q \in\{3, \ldots, n\}$,
the following inequalities are valid for $\left(\mathrm{SLL}_{1}\right)$ :

$$
\begin{equation*}
\sum_{\ell \in L} v_{i}^{\ell}+\sum_{q=1}^{n} \sum_{j \in P^{k_{q}}} x_{j}^{k_{q}} \leq 1 . \tag{16}
\end{equation*}
$$

Valid inequalities (16) are facets for the previously defined subproblem of $\left(\mathrm{SLL}_{1}\right)$ if and only if $\nexists\left(k_{0}, i_{0}\right) \in K \times\left(S^{k_{0}} \backslash\{i\}\right): \sigma\left(k_{0}\right) \geq \ell_{p}$ satisfying

1. $i_{0} \in B\left(k_{q}, P^{k_{q}}\right) \forall q \in\{1, \ldots, n\}: \sigma\left(k_{q}\right) \geq \sigma\left(k_{0}\right)$,
2. $i_{0} \in \overline{B\left(k_{0}, P^{k_{q}}\right)} \forall q \in\{1, \ldots, n\}: \sigma\left(k_{q}\right) \leq \sigma\left(k_{0}\right)$.

Furthermore, all the clique facets for the subproblem of $\left(\mathrm{SLL}_{1}\right)$ containing $v$-variables are in family (16).

Proof. Let GSLL $=\left(V_{G}, E_{G}\right)$ be the intersection graph of the previously defined subproblem of $\left(\mathrm{SLL}_{1}\right)$ and let $Q=\left(V^{\prime}, E^{\prime}\right)$ be a clique of GSLL containing $v$-variables. Taking into account Proposition 5.1(7), all $v$-variables in the same clique must share the subindex, and by Lemma 5.2, all $v$-variables in the same clique must have consecutive superindices. We represent with $L=\left\{\ell_{1}, \ldots, \ell_{p}\right\}$ this set of consecutive superindices and with $i$ the common subindex. We thus distinguish several cases depending on $L$ :

1. $L=\{1, \ldots, M\}$.

Then by Proposition 5.1(5) we know that a node $x_{j}^{k}$ in the neighborhood of $v_{i}^{1}, \ldots, v_{i}^{M}$ must satisfy $\sigma(k)=M$ and $j \in \overline{B(k, i)}$. However, the richest customers always purchase their most preferred product, and therefore we have removed all these $x$-nodes from the intersection graph, i.e., $P^{k_{2}}=\cdots=P^{k_{n}}=\emptyset$.
Since Proposition 5.1(4) does not either provide any node adjacent to $v_{i}^{\ell} \forall \ell$, we obtain $P^{k_{1}}=\emptyset$ and thus the set of nodes $\left\{v_{i}^{\ell}: \ell \in\{1, \ldots, M\}\right\}$ induces a maximal complete subgraph in GSLL.
2. $L=\left\{\ell_{1}, \ldots, M\right\}$ for some $\ell_{1}>1$.

As $v_{i}^{\ell} \notin V^{\prime} \forall \ell \in\left\{1, \ldots, \ell_{1}-1\right\}$, a node adjacent to $v_{i}^{\ell}$ for $\ell \geq \ell_{1}$ but not to $v_{i}^{\ell_{1}-1}$ must belong to the clique. Applying Lemma 5.2 and Proposition 5.1, we know this node corresponds with an $x$-variable, i.e., there exists a node $x_{j}^{k} \in V^{\prime}$ for some customer $k$ and product $j$. As in the previous case, Proposition 5.1(5) does not provide any node adjacent to $v_{i}^{M}$, thus $P^{k_{2}}=\cdots=P^{k_{n}}=\emptyset$. Therefore, node $x_{j}^{k}$ must be adjacent to $v_{i}^{\ell}$ for $\ell \geq \ell_{1}$ by Proposition 5.1(4), so $j=i$ and $k=k_{1}$ for a customer $k_{1}: \sigma\left(k_{1}\right)<\ell_{1}$ and $P^{k_{1}}=\{i\}$. Since $x_{i}^{k_{1}}$ is not adjacent to $v_{i}^{\ell_{1}-1}$, also by Proposition 5.1(4) $\sigma\left(k_{1}\right) \geq \ell_{1}-1$, and hence $\sigma\left(k_{1}\right)=\ell_{1}-1$.
If we suppose there exists another node $x_{j}^{k} \in V^{\prime}$, then $x_{j}^{k}$ must be adjacent to $v_{i}^{\ell}$ $\forall \ell \geq \ell_{1}$ by Proposition 5.1(4), and therefore $j=i$. However, $x_{i}^{k}$ and $x_{i}^{k_{1}}$ are not adjacent for any customer $k \neq k_{1}$ by (2), so the set $\left\{v_{i}^{\ell}: \ell \geq \ell_{1}\right\} \cup\left\{x_{i}^{k_{1}}\right\}$ induces a clique in GSLL.
3. $L=\left\{1, \ldots, \ell_{p}\right\}$ for some $\ell_{p}<M$.

Since $v_{i}^{\ell} \notin V^{\prime} \forall \ell>\ell_{p}$, applying Lemma 5.2 and Proposition 5.1 there must exist a node $x_{i_{0}}^{k} \in V^{\prime}$ such that $x_{i_{0}}^{k}$ is adjacent to $v_{i}^{\ell_{p}}$ but not to $v_{i}^{\ell_{p}+1}$. Proposition 5.1(4) does not provide any node adjacent to $v_{i}^{1}$, hence $P^{k_{1}}=\emptyset$ and $x_{i_{0}}^{k}$ has to be adjacent to $v_{i}^{\ell}, \ell \leq \ell_{p}$, by Proposition 5.1(5). Hence, there exists a customer $k_{2}: \sigma\left(k_{2}\right) \geq \ell_{p}$ and a subset of products $P^{k_{2}} \subseteq \overline{B\left(k_{2}, i\right)}$ such that $i_{0} \in P^{k_{2}}$ and $x_{j}^{k_{2}} \in V^{\prime} \forall j \in P^{k_{2}}$ (taking into account that, by Proposition 5.1(1), $x_{j}^{k_{2}}$ is adjacent to $x_{j^{\prime}}^{k_{2}} \forall j \neq j^{\prime}$ ). Since $x_{i_{0}}^{k_{2}}$ is not adjacent to $v_{i}^{\ell_{p}+1}$, it follows $\sigma\left(k_{2}\right)=\ell_{p}$.
Provided that there exist customers $k_{q}, \forall q \in\{3, \ldots, n\}$ such that $\sigma\left(k_{2}\right) \leq \sigma\left(k_{3}\right) \leq$ $\cdots \leq \sigma\left(k_{n}\right)$ and sets of products $P^{k_{q}} \subseteq S^{k_{q}}, P^{k_{q}} \neq \emptyset \forall q \in\{3, \ldots, n\}$, such that $x_{j}^{k_{q}} \in V^{\prime} \forall j \in P^{k_{q}}$, then by Proposition $5.1(2) P^{k_{1}}, \ldots, P^{k_{n}}$ are pairwise disjoint. Moreover, $P^{k_{q}} \subseteq S^{k_{q}} \backslash\{i\} \forall q \in\{3, \ldots, n\}$; otherwise, $x_{i}^{k_{q}} \in V^{\prime}$ for some $k_{q}: \sigma\left(k_{q}\right) \geq$ $\ell_{p}$ and is not adjacent to $v_{i}^{\ell_{p}}$ (Proposition 5.1(4)), thus $V^{\prime}$ does not induce a complete graph.
Applying arguments analogous to those of Theorem 5.4, the rest of the conditions stated above must hold.
4. $L=\left\{\ell_{1}, \ldots, \ell_{p}\right\}$ for some $\ell_{1}>1, \ell_{p}<M$.

Applying arguments analogous to those of the previous items, we can conclude that there exist customers $k_{1} \in K: \sigma\left(k_{1}\right)=\ell_{1}-1, i \in S^{k_{1}}$ such that $P^{k_{1}}=\{i\}$ and $k_{2} \in K: \sigma\left(k_{2}\right)=\ell_{p}$ with $P^{k_{2}} \subseteq \overline{B\left(k_{2}, i\right)}, P^{k_{2}} \neq \emptyset$. The rest of the conditions also hold applying a reasoning analogous to that of Theorem 5.4.

Now that we have established the different shapes that clique facets can adopt, we are able to determine whether constraints (8b)-(8e) always define clique facets in the corresponding subproblem of ( $\mathrm{SLL}_{1}$ ). Thus, we can conclude that constraints (8c) and (8e) always define clique facets by applying cases 1 and 2 of the proof of Theorem 5.5, respectively. By Theorem 5.4, and given that $B\left(k, S^{k}\right)=\emptyset \forall k$, we know a valid inequality from the family (8b) will be a clique if and only if $\left|S^{k}\right| \geq 2$ and $\nexists\left(k_{0}, i_{0}\right) \in K \times S^{k_{0}}$ satisfying $\sigma\left(k_{0}\right) \geq \sigma(k)$ and $i_{0} \in \overline{B\left(k_{0}, S^{k}\right)}$. As for constraints (8d), they do not necessarily define clique facets either but, like in the former case, they define clique facets in most cases.

Even though the valid inequalities given by Theorems 5.4 and 5.5 are facet defining on the subproblem of $\left(\mathrm{SLL}_{1}\right)$ associated to $x$ - and $v$-variables and constraints (8b)-(8e), they might not define facets on the polyhedra which is obtained once we consider also $z$-variables and their corresponding constraints of model ( $\mathrm{SLL}_{1}$ ). Nevertheless, they are still strong valid inequalities and, as such, make the extended formulation ( $\mathrm{SLL}_{1}$ ) stronger in turn. As we have previously stated, the same applies to model ( $\mathrm{SLL}_{2}$ ). Additionally, we have incorporated some of these valid inequalities into models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$, but they do not significantly improve their performance, given that the original models are already tight since they contain mainly inequalities which are facet defining in the corresponding subproblems, as we have been able to prove through this section. Therefore, in the computational study of Section 7 we will test the performance of both models without any additional clique facet of their subproblems.

## 6 Preprocessing

In this section, our aim is to fix $x$ - and $v$-variables to zero in order to reduce the size of the RPP instances before solving them.

Let us begin by recursively defining a function $u: K \rightarrow I$ as follows:

1. If $\sigma(k)=M$, then $u(k)=i$ if and only if $i \in S^{k}$ and $B(k, i)=\emptyset$.
2. If $\sigma(k) \neq M$ and $\exists i \in S^{k}$ such that $\forall k^{\prime}: \sigma\left(k^{\prime}\right)>\sigma(k), u\left(k^{\prime}\right) \neq i$, then $u(k)=i$ if and only if $i \in S^{k}, \nexists k^{\prime}$ with $\sigma\left(k^{\prime}\right)>\sigma(k)$ such that $u\left(k^{\prime}\right)=i$ and $\forall j \in B(k, i) \cap S^{k}$, $\exists k^{\prime}, \sigma\left(k^{\prime}\right)>\sigma(k)$, such that $u\left(k^{\prime}\right)=j$.
3. If $\sigma(k) \neq M$ and $\forall i \in S^{k}, \exists k^{\prime}$ with $\sigma\left(k^{\prime}\right)>\sigma(k)$ and $u\left(k^{\prime}\right)=i$, then $u(k)=i$ if and only if $i \in S^{k}$ and $\overline{B(k, i)}=\emptyset$.

Function $u$ assigns, to the richest customers, their most preferred product; and to the rest of the customers, their most preferred product among the ones which have not been previously assigned to any richer customer (or their least preferred one if all of them have already been assigned).

Based on the definition of $u$, we are going to establish a partition of the set of customers. Thus, let $C_{r}, r \in\{1,2,3\}$, be such that $k \in C_{r} \Leftrightarrow u(k)$ has been defined for $k$ making use of item $r$ of the definition of $u$. It is clear that $\cup_{r \in\{1,2,3\}} C_{r}=K$, but given this definition it is possible that both $C_{2}$ and $C_{3}$ are empty or $C_{3}$ is. If $C_{2}=C_{3}=\emptyset$, then $\sigma(k)=M \forall k \in K$, and the problem becomes trivial: it suffices to establish $v_{i}^{M}=1$ $\forall i \in I$, every customer will purchase his most preferred item and the objective value will be the sum of every client's budget, i.e., $b^{M}|K|$. If $C_{1} \neq \emptyset \neq C_{2}$ and $C_{3}=\emptyset$, then we will see in Corollary 6.7 that an optimal solution can be found by inspection.

The following result shows the usefulness of this function when fixing $x$-variables to zero:

Proposition 6.1. There exist optimal solutions $(\tilde{v}, \tilde{x})$ of ( $\left.\mathrm{BNL}^{v}\right)$ and (SLNL) such that $\tilde{x}_{i}^{k}=0 \forall k \in K, \forall i \in \overline{B(k, u(k))}$.

Proof. Suppose we have an optimal solution $(\hat{v}, \hat{x})$ which does not satisfy the statement conditions. By slightly modifying $(\hat{v}, \hat{x})$, we aim at building another solution $(\tilde{v}, \tilde{x})$, with the same objective value, which does satisfy them.

Let us proceed by induction on $k$. First consider $k_{0}$ such that $\sigma\left(k_{0}\right)=M$, i.e., one of the richest customers. Then we know $k_{0}$ is able to afford every product he is interested in, and therefore in every optimal solution he will purchase his most preferred product. Therefore, $\hat{x}_{i}^{k_{0}}=0$ must hold for all $k_{0}$ such that $\sigma\left(k_{0}\right)=M$ and $i \in \overline{B\left(k_{0}, u\left(k_{0}\right)\right)}$.

Since $(\hat{v}, \hat{x})$ does not satisfy the statement conditions, there will exist $k_{0} \in K$ such that $\sigma\left(k_{0}\right)=\ell_{0}<M$ and $\forall k$ such that $\sigma(k)>\ell_{0} \hat{x}_{i}^{k}=0 \forall i \in \overline{B(k, u(k))}$ but $\hat{x}_{i_{0}}^{k_{0}}=1$ for a product $i_{0} \in \overline{B\left(k_{0}, u\left(k_{0}\right)\right)}$. It is clear that $k_{0} \in C_{2}$. The fact that $k_{0}$ buys product $i_{0}$ implies he can not afford product $u\left(k_{0}\right)$, i.e., $\sum_{\ell=1}^{\ell_{0}} \hat{v}_{u\left(k_{0}\right)}^{\ell}=0$ and $\hat{x}_{u\left(k_{0}\right)}^{k_{0}}=0$. We are going to show that $\hat{x}_{u\left(k_{0}\right)}^{k}=0 \forall k$, that is to say, that product $u\left(k_{0}\right)$ has not been sold
in the considered optimal solution. On the one hand, it is clear that $\hat{x}_{u\left(k_{0}\right)}^{k}=0$ for all $k$ such that $\sigma(k) \leq \sigma\left(k_{0}\right)$ because these customers cannot afford it either. On the other hand, let us prove that for all $k$ such that $\sigma(k)>\sigma\left(k_{0}\right)$, it holds $u\left(k_{0}\right) \in \overline{B(k, u(k))}$ or $u\left(k_{0}\right) \notin S^{k}$. First of all, we know $u\left(k_{0}\right) \neq u(k) \forall k: \sigma(k)>\sigma\left(k_{0}\right)$ because $k_{0} \in C_{2}$. Besides, let us suppose $u\left(k_{0}\right) \in B\left(k_{1}, u\left(k_{1}\right)\right)$ for $k_{1}: \sigma\left(k_{1}\right)>\sigma\left(k_{0}\right)$. If $\sigma\left(k_{1}\right)=M$, we have $B\left(k_{1}, u\left(k_{1}\right)\right)=\emptyset$, hence $M>\sigma\left(k_{1}\right)>\sigma\left(k_{0}\right)$ and $k_{1} \in C_{2} \cup C_{3}$. But then, by definition of $u, u\left(k_{0}\right) \in B\left(k_{1}, u\left(k_{1}\right)\right) \Rightarrow$ there exists $k_{2}: \sigma\left(k_{2}\right)>\sigma\left(k_{1}\right)$ and $u\left(k_{2}\right)=u\left(k_{0}\right)$, which is a contradiction with $k_{0} \in C_{2}$. Therefore, we have proved that customers with budget greater than $k_{0}$ do not purchase product $u\left(k_{0}\right)$ because they buy others that prefer more, and customers $k$ such that $\sigma(k) \leq \sigma\left(k_{0}\right)$ cannot afford product $u\left(k_{0}\right)$. Hence, $u\left(k_{0}\right)$ is not sold in this optimal solution.

Let us consider now a price vector $\tilde{v}$ defined by $\tilde{v}_{i}^{\ell}=\hat{v}_{i}^{\ell} \forall \ell, \forall i \neq u\left(k_{0}\right)$ and $\tilde{v}_{u\left(k_{0}\right)}^{\ell_{0}}=1$, $\tilde{v}_{u\left(k_{0}\right)}^{\ell}=0 \forall \ell \neq \ell_{0}$. If prices are settled this way, customers $k$ such that $\sigma(k)<\ell_{0}$ can afford the same products as before, so they purchase the same item; customers $k$ with $\sigma(k)=\ell_{0}$ are now able to afford product $u\left(k_{0}\right)$, but if they purchase it (because they prefer it over the one they were buying in the previous solution) they spend their whole budget, therefore the revenue does not decrease; and customers $k$ with $\sigma(k)>\ell_{0}$ were already buying a product more preferable than $u\left(k_{0}\right)$ in the previous solution, so they buy the same as previously. Thus, $\tilde{x}_{i}^{k}=\hat{x}_{i}^{k} \forall k: \sigma(k) \neq \ell_{0}, \forall i \in S^{k} ; \tilde{x}_{i}^{k}=\hat{x}_{i}^{k} \forall k: \sigma(k)=\ell_{0}$ and $u_{k_{0}} \in \overline{B(k, j)}$ for $j: \hat{x}_{j}^{k}=1, \forall i \in S^{k}$; and $\tilde{x}_{u\left(k_{0}\right)}^{k}=1, \tilde{x}_{i}^{k}=0 \forall k: \sigma(k)=\ell_{0}$ and $u\left(k_{0}\right) \in B(k, j)$ for $j: \hat{x}_{j}^{k}=1$, and $\forall i \neq u\left(k_{0}\right)$.

Therefore, through $\tilde{v}$ we have built a feasible solution $(\tilde{v}, \tilde{x})$ with the same objective value as the one given by solution $(\hat{v}, \hat{x})$ and such that $\tilde{x}_{i}^{k_{0}}=0 \forall i \in \overline{B\left(k_{0}, u\left(k_{0}\right)\right)}$. Proceeding by induction on $k$, we deduce that we can obtain an optimal solution satisfying the statement conditions.

Remark 6.2. Besides being useful when fixing variables to zero, the proof of Proposition 6.1 derives an optimal solution ( $\tilde{v}, \tilde{x}$ ) from another solution ( $\hat{v}, \hat{x}$ ) which satisfies $\sum_{i \in S^{k}} s_{i}^{k} \tilde{x}_{i}^{k} \geq \sum_{i \in S^{k}} s_{i}^{k} \hat{x}_{i}^{k} \forall k \in K$, that is, it allows us to obtain an optimal solution in which customers either buy the same product or buy another one they prefer more. It is also remarkable that there may be more than one optimal solution satisfying Proposition 6.1.

Function $u$ also lets us conclude that some products will not be sold in any optimal solution that satisfies Proposition 6.1:

Corollary 6.3. Let $(\tilde{v}, \tilde{x})$ be an optimal solution of $\left(\mathrm{BNL}^{v}\right)$ or (SLNL) satisfying Proposition 6.1. Then for every product $i \in I$ such that $u^{-1}(i)=\emptyset$, it follows $\tilde{x}_{i}^{k}=0$ for every client $k \in K$ with $i \in S^{k}$, i.e., product $i$ is not sold.

Proof. Let us consider an optimal solution ( $\tilde{v}, \tilde{x}$ ) which meets the requirements given by Proposition 6.1, and a customer $k$ and a product $i$ such that $\hat{x}_{i}^{k}=1$. Then $u(k)=i$ or $i \in B(k, u(k))$, and in the last case by definition of $u$ there exists a customer $k^{\prime}$ with $\sigma\left(k^{\prime}\right)>\sigma(k)$ and $u\left(k^{\prime}\right)=i$.

Remark 6.4. Corollary 6.3 allows us to eliminate $x_{i}^{k} \forall k$ and $v_{i}^{\ell} \forall \ell$ for all products $i$ we know will not be sold, thus reducing the size of the problem. Furthermore, after this
procedure, and by definition of $u$, we will always obtain instances of the problem with $|I| \leq|K|$. However, there might still remain products which will not be sold in one or more optimal solutions.

The following result, whose proof we omit for the sake of brevity, is useful to fix $v$-variables to zero, reducing the size of the problem.

Proposition 6.5. There exists an optimal solution ( $\tilde{v}, \tilde{x})$ of ( $\left.\mathrm{BNL}^{v}\right)$ or (SLNL) such that $\forall i, \ell: \nexists k$ with $\sigma(k)=\ell$ and $i \in S^{k}$, it follows $v_{i}^{\ell}=0$.

Remark 6.6. Although optimal solutions satisfying Proposition 6.1 do not necessarily satisfy Proposition 6.5, there exist optimal solutions satisfying both propositions. Furthermore, we can assume that if a variable $x_{i}^{k}$ can be fixed to zero in an optimal solution ( $\hat{v}, \hat{x}$ ) according to Proposition 6.1, then $i$ no longer belongs to the list of products of interest of customer $k$, i.e., $i \notin S^{k}$, thus fixing more $v$-variables to zero when applying Proposition 6.5 .

By recursively building function $u$ and using the previous results, $x_{i}^{k}$-variables with $i \in \overline{B(k, u(k))}$ can be removed from all formulations based on $v$ - and $x$-variables. This will imply that $x_{u(k)}^{k}=1$ for all richest customers $k$ and their preferred products $u(k)$ such that $B(k, u(k))=\emptyset$. Variables in the conditions of Proposition 6.5 can also be removed. In some cases, as shown in the following result, an optimal solution to the problem can be directly obtained from the preprocessing phase:
Corollary 6.7. If for all customers $k \in K$ with $\sigma(k)<M$ an $i \in S^{k}$ exists such that $\forall k^{\prime}: \sigma\left(k^{\prime}\right)>\sigma(k), u\left(k^{\prime}\right) \neq i$, that is, if $C_{3}=\emptyset$, an optimal solution can be derived by inspection.

Proof. Let $(\tilde{v}, \tilde{x})$ be defined as follows: for all $k \in K, \tilde{x}_{u(k)}^{k}=1, \tilde{x}_{i}^{k}=0 \forall i \neq u(k)$ and $\tilde{v}_{u(k)}^{\sigma(k)}=1, \tilde{v}_{u(k)}^{\ell}=0 \forall \ell \neq \sigma(k)$; for all $i: u^{-1}(i)=\emptyset, \tilde{v}_{i}^{M}=1, \tilde{v}_{i}^{\ell}=0 \forall \ell \neq M$. We are going to show that solution $(\tilde{v}, \tilde{x})$ is optimal.

First of all, we know by hypothesis that $u(k)=u\left(k^{\prime}\right) \Rightarrow \sigma(k)=\sigma\left(k^{\prime}\right)$, and therefore $\tilde{v}$ is well defined. Moreover, $\tilde{x}$ is also well defined because for all $k \in K, i \in B(k, u(k))$ there exists $k^{\prime}: \sigma\left(k^{\prime}\right)>\sigma(k)$ with $u\left(k^{\prime}\right)=i$, and thus $\tilde{v}_{i}^{\sigma\left(k^{\prime}\right)}=1$ and $k$ cannot afford product $i$. Finally, since in this solution all customers $k$ are purchasing a product for their whole budget $\sigma(k)$, then the objective value is equal to the sum of the budgets of every customer (which is an upper bound), and therefore ( $\tilde{v}, \tilde{x}$ ) is optimal.
Corollary 6.8. If $|K| \leq|I|$ and $S^{k}=I \forall k \in K$, then an optimal solution can be derived by inspection.

Proof. It suffices to notice that Corollary 6.7 can by applied.

## 7 Computational results

A computational experiment was carried out in order to compare the different models and check the performance of the valid inequalities proposed in Section 4 and the preprocessing

Figure 1: Percentage of instances solved with a time limit by models $\left(\mathrm{BL}_{1}\right),\left(\mathrm{BL}_{2}\right),\left(\mathrm{SLL}_{1}\right)$, $\left(\mathrm{SLL}_{2}\right)$ and $\left(\mathrm{SLL}_{1}\right),\left(\mathrm{SLL}_{2}\right)$ with the branch-and-cut procedure

Figure 2: Percentage of solved instances depending on the number of nodes explored in the branching tree by models $\left(\mathrm{BL}_{1}\right),\left(\mathrm{BL}_{2}\right),\left(\mathrm{SLL}_{1}\right),\left(\mathrm{SLL}_{2}\right)$ and $\left(\mathrm{SLL}_{1}\right),\left(\mathrm{SLL}_{2}\right)$ with the branch-and-cut procedure

Figure 3: In the ordinate axis it is represented, for models $\left(\mathrm{BL}_{1}\right)$, $\left(\mathrm{BL}_{2}\right)$, $\left(\mathrm{SLL}_{1}\right),\left(\mathrm{SLL}_{2}\right)$ and $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$ with the branch-and-cut procedure, the percentage of instances with a duality gap less than or equal to that of the axis of abscissas
techniques described in Section 6. The commercial IP solver used through all the testing was Xpress mosel version 4.0.3, on a computer Dell PowerEdge T110 II Server (Intel Xeon E3-1270, 3.40 GHz ) with 16 GB of RAM.

The reader can find all the results of the computational experiment detailed in the tables grouped in the appendix. In the rest of this section, the more relevant information of those tables will be summarized by means of several figures.

To begin with, we performed a first computational study to compare models ( $\mathrm{BNL}^{v}$ ) and (SLNL). Thus, we tested the performance of the linearization of these models by means of $z^{k}$ - and $z_{i}^{k}$-variables, as well as both linearizations of model (SLNL) including the branch-and-cut algorithm described in Section 4.

In this first experiment, the instances include $|K|=30$ customers whose budgets have been generated independent and uniformly at random, sets of products of sizes $|I|=5$, $|I|=15$ and $|I|=25$, and lists of products of interest of sizes the $10,25,50,75$ and 100 percent of $|I|$, rounded up. The items included in the lists of products of interest and their order have also been selected independent and uniformly at random, and the number of products of interest is the same for every customer in all the instances. We generated ten instances for each combination of the three mentioned parameters, 150 in total. The values of $s_{i}^{k}$ can be chosen in different but equivalent ways. For the computational study, we have fixed $s_{i}^{k}=|I|-n+1$ if $i$ is the $n$-th most preferred product for customer $k$, $\forall k \in K, i \in S^{k}$.

So as to be able to compare the duality gaps and times of resolution provided by these models, we disabled automatic cuts and switched Xpress presolve settings off. The
time limit for each instance and model was fixed to 600 seconds. The only preprocessing applied to the instances consisted in setting $x_{i}^{k}=1$ for every richest customer $k$ and for every product $i \in S^{k}$ such that $B(k, i)=\emptyset$. In order to check the usefulness of the valid inequalities proposed for formulations $\left(\mathrm{SLL}_{1}\right)$ and ( $\mathrm{SLL}_{2}$ ) in Section 4, we also implemented a branch-and-cut algorithm following the separation procedure explained in that section. Thus, in every node of the branching tree, a fractional solution $(\bar{v}, \bar{x}, \bar{z})$ was obtained after solving the linear relaxation of the corresponding subproblem, and, provided that the depth of this node in the tree was 4 or less, we checked for valid inequalities (10) or (12), respectively, and re-optimized the subproblem until no more valid inequalities were violated or the linear relaxation bound was no further improved.

Figures 1, 2 and 3 illustrate the results obtained, and refer to Table 1 of the appendix. As described in Section 4, models $\left(\mathrm{BL}_{1}\right)$ and $\left(\mathrm{SLL}_{1}\right)$ (resp. $\left(\mathrm{BL}_{2}\right)$ and $\left(\mathrm{SLL}_{2}\right)$ ) are the linearizations of models ( $\mathrm{BNL}^{v}$ ) and (SLNL) by means of $z^{k}$-variables (resp. $z_{i}^{k}$-variables). Models $\left(\mathrm{BL}_{1}\right),\left(\mathrm{BL}_{2}\right),\left(\mathrm{SLL}_{1}\right),\left(\mathrm{SLL}_{2}\right)$, as well as models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$ with the corresponding branch-and-cut algorithms, appear in the legend of the figures, respectively, as BL1, BL2, SLL1, SLL2, SLL1+VI and SLL2+VI. Figure 1 shows the percentage of instances solved within a given time limit; the cumulated percentage of solved instances depending on the number of nodes explored in the branching tree is shown in Figure 2, where the axis of abscissas has been represented using a logarithmic scale; and Figure 3 shows the percentage of instances which have a duality gap less than or equal to that of the $x$-axis. For models $\left(\mathrm{BL}_{1}\right),\left(\mathrm{BL}_{2}\right),\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$, this duality gap is the result of dividing by the optimal value of the instance (OPT) the difference between the upper bound provided by the linear relaxation (UB) and the optimal value, LRGap $=100 \frac{\mathrm{UB}-\mathrm{OPT}}{\mathrm{OPT}} \%$. In the case of models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$ with the corresponding branch-and-cut algorithms, it is represented the duality gap that results when dividing by the optimal value the difference between the upper bound of the linear relaxation after the cuts in the root node (UBC) and the optimal value, RGap $=100 \frac{\mathrm{UBC}-\mathrm{OPT}}{\mathrm{OPT}} \%$.

As we can see in Figure 1, models $\left(\mathrm{BL}_{1}\right)$ and $\left(\mathrm{BL}_{2}\right)$ were only able to solve around the 65 and the 70 percent, respectively, of the instances proposed within a time limit of 600 seconds. For its part, models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$ solved all the instances in 300 seconds, and this time is further improved to only a few seconds when adding the branch-and-cut procedure. In fact, we can see how the lines SLL1+VI and SLL2+VI of Figure 1 are very close to each other and reach $100 \%$ almost immediately. In Figure 2 we can observe that models $\left(\mathrm{SLL}_{1}\right),\left(\mathrm{BL}_{1}\right)$ and $\left(\mathrm{BL}_{2}\right)$ reached the million of nodes explored in the branching tree in some of the instances, and this amount decreases in two orders of magnitude for model $\left(\mathrm{SLL}_{2}\right)$. As for models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$ with the branch-and-cut algorithm, they solved the totality of the instances exploring on average less than 10 nodes, highly improving the performance of the other four models. And Figure 3 shows that models $\left(\mathrm{BL}_{1}\right)$ and $\left(\mathrm{BL}_{2}\right)$ reached duality gaps of more than 30 percent in some instances. The maximum gap reached by model $\left(\mathrm{SLL}_{1}\right)$ is of around 20 percent, and this gap was halved when using model ( $\mathrm{SLL}_{2}$ ) and divided by eight when adding the cuts in the root node in models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$, illustrating how these cuts have a significant importance in the reduction of the duality gaps.

The results represented in Figures 1, 2 and 3 show that, whilst the linearization of ( $\mathrm{BNL}^{v}$ ) using $z^{k}$ variables provides slightly better results in terms of time and nodes than the one using $z_{i}^{k}$, the opposite occurs when comparing both linearizations of formulation

Figure 4: Average time needed to solve instances with $|K|=30$ by models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$, with and without the preprocessing techniques (ten instances averaged per size)
(SLNL), since model $\left(\mathrm{SLL}_{2}\right)$ performs clearly better than $\left(\mathrm{SLL}_{1}\right)$ in terms of both the number of nodes explored in the branching tree and the duality gaps. The introduction of the branch-and-cut algorithm into the models leads to a considerable improvement in both models.

With the aim of testing the performance of the preprocessing proposed in Section 6, we ran the same instances after fixing $x$ - and $v$-variables to zero by applying Propositions 6.1 and 6.5 , respectively, with the six previous models. The results are detailed in Table 2 in the appendix, where it can be appreciated the great improvement provided by the preprocessing. The results provided by the two best previous models, $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$, both with the branch-and-cut procedure, are represented in Figures 4 and 5.

Figure 4 shows the average time (in seconds, using a logarithmic scale) needed to optimally solve the ten instances previously created for each number of products $(|I|=5$, $|I|=15$ and $|I|=25$ ) and each size of the list of products of interest of every customer $\left(\left|S^{k}\right|=\lceil 0.1|I|\rceil,\left|S^{k}\right|=\lceil 0.25|I|\rceil,\left|S^{k}\right|=\lceil 0.5|I|\rceil,\left|S^{k}\right|=\lceil 0.75|I|\rceil\right.$ and $\left.\left|S^{k}\right|=|I|\right)$. The size of the set of products is included after the letter $i$ in the notation of the instances, and the number of products of interest of every customer appears after the letter s. Regarding the instances, it is noticeable from the results of Figure 4 that the difficulty to solve them increases when the number of products in which every customer is interested grows. It is also remarkable that the preprocessing techniques are more efficient in the reduction of the times when the number of products increases: for the instances with 25 products and complete list of products of interest, fixing $x$ - and $v$-variables to zero according to Propositions 6.1 and 6.5 leads to a reduction in the average resolution times of two and one orders of magnitude for models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$, respectively. This is due to the fact that instances with more products (with respect to the number of customers) lead

Figure 5: Average duality gaps of the linear relaxation, LRGap, for instances with $|K|=$ 30 by models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$, with and without the preprocessing techniques (ten instances averaged per size)
to the fixing of a greater number of $x$-variables, which results in the elimination of more $v$-variables, thus considerably reducing the size of the problem. Finally, we can observe that the average resolution times for the preprocessed instances (light grey and black bars) never exceed five seconds.

The average duality gaps of the linear relaxation LRGap, calculated dividing by the optimal value of the instance the difference between the linear relaxation bound and the optimal value, are represented in Figure 5. The greatest duality gaps are reached when the size of the set of products is small, which may be because these instances have a smaller optimal value. It is noticeable the improvement of the gaps when adding the preprocessing to the model $\left(\mathrm{SLL}_{1}\right)$, regardless of the number of products and the size of the list of products of interest. Probably due to the small size of the instances, the preprocessing applied to model $\left(\mathrm{SLL}_{2}\right)$ with the branch-and-cut algorithm does not result in any reduction on the duality gaps. However, as it will be stated in the second computational study, the preprocessing techniques applied to $\left(\mathrm{SLL}_{2}\right)$ improve the results when the instances have a bigger size.

Regarding the number of nodes explored in the branching tree, in the majority of the instances only one node is explored, and the average number does not exceed six nodes. Furthermore, the average duality gaps are reduced to zero in all cases after the cuts in the root node.

Considering the results of the first computational experiment, we decided to create instances of bigger and more varied sizes and discard the models derived from ( $\mathrm{BNL}^{v}$ ), as well as extending the time limit for each instance and model to 1200 seconds. In order to
create the instances of our second computational study, we designed a model based on the Characteristics Model proposed by Fernandes et al. in [6]. This model has an economic interpretation, and focuses on the idea that each product has a profile of characteristics, and each customer is interested in several of them. In this way, a product will be more preferred by a client than another provided that more of its characteristics, or the most important ones, are among the ones he desires.

Let $C$ be the set of characteristics, o the number of options for any characteristic and $p$ the number of options in which a customer is interested for any characteristic. The characteristics of every product $i$ are represented by means of a vector of options $E^{i}=\left(e_{c}^{i}\right)$, $c \in C$, whose entries are in the set $\{1,2, \ldots, o\}$, chosen independent and uniformly at random. The set of characteristics in which a customer $k$ is interested is represented by a matrix $A_{|C| \times o}^{k}=\left(a_{c v}^{k}\right)$ where, for every row, $p$ positions are set independent and uniformly at random to 1 (the ones in which $k$ is interested) and $o-p$ positions to 0 . The relevance of each characteristic $c$ is determined by its weight $w(c)$, so that $w(c)>w\left(c^{\prime}\right)$ if characteristic $c$ is considered (for every customer) more important than $c^{\prime}$. In this way, the score each customer $k$ gives to a product $i$ is defined as the sum of the weights of the characteristics of $i$ in which $k$ is interested, i.e., score ${ }_{i}^{k}:=\sum_{c \in C} w(c) a_{c c_{c}^{i}}^{k}$. The preferences of a customer are based on the score he has given to each product, since customer $k$ will prefer product $i$ over product $j$ if and only if score ${ }_{i}^{k}>\operatorname{score}_{j}^{k}$. Each customer is interested in $s \in\{1, \ldots,|I|\}$ products; therefore, if $s<|I|$, the set of products of interest of every customer will only include the $s$ products with the greatest scores for each of them.

The instances for the computational experiment were created fixing the number of options of each characteristic as $o=8$; the number of options preferred by each customer as $p=7$; the number of characteristics as $|C|=50|I|$; and the budgets of the customers are integers randomly selected between 1 and $2|K|$. With the aim of testing the performance of the models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$ with the branch-and-cut procedure, with and without preprocessing, using instances of different sizes and densities, we created instances of $|K|=50,|K|=100$ and $|K|=150$ customers and $0.1|K|, 0.5|K|$ and $|K|$ products. We created 10 instances of each size, 360 in total. And once the customers (including their budgets and scores for each product) and products were randomly created following the previously described procedure, we created four different instances by modifying $s$, that is, including lists of products of interest of 1 product, the 20 percent, half of the products and all of them. The lists of products of interest have equal size $s=\left|S^{k}\right|$ for all the customers in all the instances.

Figures 6, 7 and 8 illustrate the results obtained. We have included a detailed description of the results in which these figures are based in Tables 3 and 4 of the appendix for the interested reader.

Figure 6 shows the percentage of instances solved within a given time limit. In this figure we can observe how model $\left(\mathrm{SLL}_{1}\right)$ performed clearly worse than the rest of the models, not reaching the $60 \%$ of solved instances. Models $\left(\mathrm{SLL}_{2}\right)$ and $\left(\mathrm{SLL}_{1}\right)$ and ( $\mathrm{SLL}_{2}$ ) with the preprocessing techniques had a similar behaviour, the three of them solving more than the $80 \%$ of instances in less than 1200 seconds. Model $\left(\mathrm{SLL}_{2}\right)$ with the preprocessing techniques offered the best results, reaching the $89 \%$. We can also notice that model $\left(\mathrm{SLL}_{1}\right)$ with the preprocessing outperformed model $\left(\mathrm{SLL}_{2}\right)$ without it at the beginning, but it performed worse after approximately 800 seconds.

Figure 6: Percentage of instances solved with a time limit by models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$, with and without the preprocessing techniques detailed in Section 6

Figure 7: Percentage of solved instances depending on their size. Instances with $|K|=100$ are shown in the graphic of the left hand side, and instances with $|K|=150$, in the graphic of the right hand side. The size of the set of products is included after the letter $i$ in the notation of the instances, and the number of products of interest of every customer appears after the letter $s$

Figure 8: Average duality gaps for models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$ with the preprocessing techniques. Instances with $|K|=100$ are shown in the graphic of the left hand side, and instances with $|K|=150$, in the graphic of the right hand side

In Figure 7 it is represented the percentage of instances solved attending to their size. The graphic of the left hand size shows the instances with $|K|=100$, and the graphic of the right hand side, the instances with $|K|=150$, given that models $\left(\mathrm{SLL}_{1}\right)$ with the preprocessing techniques and $\left(\mathrm{SLL}_{2}\right)$ with and without the preprocessing techniques solved all the instances of 50 customers. The size of the set of products $(|I|)$ is indicated by the number that follows letter $i$ in the notation of the instances; the size of the set of products in which a customer is interested $\left(\left|S^{k}\right|\right)$, by the number after the letter $s$. As we had previously noted in the first computational study, the difficulty of the instances grows when the size of $S^{k}$ increases. In particular, instances with complete list of products of interest are the most difficult ones, and none of them was solved in less than 1200 seconds for $|K|=150$ and 15 and 75 products. For the instances with the same number of customers and products, the preprocessing makes a great improvement. This is specially noticeable when $|K|=|I|=\left|S^{k}\right|=150$, where adding the preprocessing led to the resolution of all the instances, taking into account that none of them had been solved without it.

Figure 8 shows the duality gaps for both models with the preprocessing techniques. The LRGap is calculated dividing by the objective value of the best solution found by any of the models (OV) the difference between the upper bound of the linear relaxation and the value of this best solution, $100 \frac{\mathrm{UB}-\mathrm{OV}}{\mathrm{OV}} \%$, and the RGap, as the division by the objective value of the best solution found of the difference between the upper bound of the linear relaxation after the cuts in the root node and the value of this best solution, $100 \frac{\mathrm{UBC}-\mathrm{OV}}{\mathrm{OV}} \%$. The notation used to express the size of the instances is the same as the notation of Figure 7. It can be observed how, even though there were sizes of instances for which the average LRGap was smaller for model $\left(\mathrm{SLL}_{1}\right)$ than for $\left(\mathrm{SLL}_{2}\right)$, the cuts in
the root node were more effective in the reduction of the upper bound for model ( $\mathrm{SLL}_{2}$ ) regardless of the case, since the RGap is smaller in this model. In most cases, the reduction of the duality gap by the branch-and-cut procedure was crucial in the resolution of the instances. It is also remarkable that, for $|K|=|I|$, the LRGap did not reach the $3 \%$, and the inclusion of the cuts reduced it to zero.

## 8 Conclusions

We have studied the Rank Pricing Problem, proposing two exact formulations for the first time in the literature, and two different linearizations. We have also carried out a characterisation of all the families of clique inequalities of a subproblem of both linearizations which constitutes a special case of the SPP, and as a result we have been able to determine which of them are part of our model. In order to improve the bound provided by the linear relaxation of the models, we have derived some families of valid inequalities by making an in-depth analysis of its structure and developed a separation procedure to embed them into the formulations. Some preprocessing techniques have also been applied so as to reduce the size of the instances before solving them. The different models and results have been tested through the development of a branch-and-cut algorithm and by means of a computational experiment which shows how these techniques lead to the resolution of instances of greater size with reduced running times and duality gaps.

A challenging future line of research consists in generalizing the RPP by considering limited supply. Adding capacity constraints on product supply would require the development of new formulations, since a decision must be taken about how to allocate the available units of each product to the customers. In particular, the development of models which provide an envy-free solution, i.e., a solution in which no customer can afford any other product more preferable for him than his own, or not, would lead to different solution strategies.

Table 3: Results obtained for model $\left(\mathrm{SLL}_{1}\right)$ with the branch-and-cut algorithm, without and with the preprocessing described in Section 6, for instances of 50,100 and 150 customers (10 instances averaged per line). The table includes the number of customers of the instance $(|K|)$, the number of products $(|I|)$ and the number of products in which every customer is interested $\left(\left|S^{k}\right|\right)$ and, in the model which includes preprocessing, it also shows the average percentage of $x$ - and $v$-variables fixed to zero during the preprocessing ( $\% \mathrm{~K}$ ) and ( $\% \mathrm{~V}$ ), respectively). For each model, the table shows the average number of cuts in the branching tree (Cuts), the number of nodes of the branching tree (Nodes), the average duality gap of the linear relaxation (LRGap), the average duality gap of the linear relaxation after the cuts in the root node (RGap), the execution time in seconds taking into account that the time limit was settled to 1200 seconds ( $\mathrm{t}(\mathrm{s})$ ) and the number of instances solved within that time period (Sol)

Table 4: Results obtained for model ( $\mathrm{SLL}_{2}$ ) with the branch-and-cut algorithm, without and with the preprocessing described in Section 6, for instances of 50,100 and 150 customers (10 instances averaged per line). The table includes the number of customers of the instance $(|K|)$, the number of products $(|I|)$ and the number of products in which every customer is interested $\left(\left|S^{k}\right|\right)$ and, in the model which includes preprocessing, it also shows the average percentage of $x$ - and $v$-variables fixed to zero during the preprocessing $((\% \mathrm{X})$ and $(\% \mathrm{~V})$, respectively). For each model, the table shows the average number of cuts in the branching tree (Cuts), the number of nodes of the branching tree (Nodes), the average duality gap of the linear relaxation (LRGap), the average duality gap of the linear relaxation after the cuts in the root node (RGap), the execution time in seconds taking into account that the time limit was settled to 1200 seconds ( $\mathrm{t}(\mathrm{s}$ )) and the number of instances solved within that time period (Sol)

[^0]:    Table 1: Results of the first computational study without the preprocessing techniques. Comparison of models $\left(\mathrm{BL}_{1}\right)$ and $\left(\mathrm{BL}_{2}\right)$ with models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$, as well as models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$ including the branch-and-cut method (10 instances averaged per line). All instances have $|K|=30$ customers, and the table shows the number of products $(|I|)$ and the number of products in which every customer is interested $\left(\left|S^{k}\right|\right)$. Depending on the model, it also includes the number of cuts in the branching tree (Cuts), the number of nodes of the branching tree (Nodes), the duality gap of the linear relaxation (LRGap), the duality gap of the linear relaxation after the cuts in the root node (RGap), the execution time in seconds taking into account that the time limit was settled to 600 seconds ( $\mathrm{t}(\mathrm{s}$ )), and the number of instances solved within that time period for the models for which not every instance was solved (Sol)

[^1]:    Table 2: Results of the first computational study with the preprocessing techniques. Comparison of models ( $\mathrm{BL}_{1}$ ) and $\left(\mathrm{BL}_{2}\right)$ with models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$, as well as models $\left(\mathrm{SLL}_{1}\right)$ and $\left(\mathrm{SLL}_{2}\right)$ including the branch-and-cut method, applying the preprocessing described in Section 6 to all the instances (10 instances averaged per line). All instances have $|K|=30$ customers, and the table shows the number of products $(|I|)$, the number of products in which every customer is interested $\left(\left|S^{k}\right|\right)$ and the average percentage of $x$ and $v$-variables fixed to zero during the preprocessing $((\% \mathrm{X})$ and $(\% \mathrm{~V})$, respectively). Depending on the model, it also includes the number of cuts in the branching tree (Cuts), the number of nodes of the branching tree (Nodes), the duality gap of the linear relaxation (LRGap), the duality gap of the linear relaxation after the cuts in the root node (RGap) and the average time needed to optimally solve the instances ( $\mathrm{t}(\mathrm{s})$ )
