Submitted on 16 May 2018

HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

NoSQL databases

- Principle category of Big Data Storage
- Overcome the scalability issues of SQL DBs
- Almost Cloud-friend systems
- Different architectures and data-models

MongoDB

- A document-based NoSQL database (JSON documents)
- It uses sharding for distributing data
- Different tools for easy-deployment and migration (Ex. mongorestore, mongodump)
- Simple to use and fit well with various kinds of apps.

Querying data

- NoSQL flexibility: store data; think how to use after!
- No schema ⇒ not only one way to guery the data

frequent need to create indexes on demand, on large-scale data!

Querying data

- NoSQL flexibility: store data; think how to use after!
- No schema ⇒ not only one way to query the data

frequent need to create indexes on demand, on large-scale data!

Problem statement

 MongoDB takes unjustified amount of time for making indexes on a pre-existed data

this problem could affect other NoSQL databases!

Benchmarking?

- ⇒ Tools such as *Yahoo! Cloud Serving Benchmarks* (*YCSB*) could:
 - report high level metrics (Ex. throughput, latency, ...)
 - reduce the effort for comparing different systems

But

- could not reflect the complexity of production-like data ©
- are not suitable for explaining performance issues ②

Research objectives

- Identifying the performance issue(s) of MongoDB while indexing data
- Introducing new experimental tools for explaining the causes of performance issue(s)

Datasets

Dataset type	(min, avrg, max) in Kb	N. of data units	Size (Gb)
SDU_1	(1, 3, 6)	20,000,000 docs	71

■ Every doc x (int, date, 2 x string[min, max], array[1..4] x string[min, max])

MongoDB's storage engine: Wiredtiger

- The default storage engine for persistent data.
- _id_s for holding the collection's records
- collection is a separate file
- Btree data structure on disks
- Contiguous allocation on disk, but unspanned
- Default page size is 4 KB

 ${
m FIGURE}$ — a) Spanned & b) Unspanned allocation

Experimental setup

- Experiments are performed on Grid'5000 testbed Machines x 2 CPUs Intel Xeon E5-2630 v3, 8 cores/CPU, 128GB RAM, 2x558GB HDD, 10Gbps ethernet
- Ubuntu 14.04, Linux 4.9.13, MongoDB v3.4
- wiredTiger cache = 2Gb, replicas are disabled, sharding key is _id_s
- Considering only hash sharding in this talk \Rightarrow load balancing

Dynamic tracing with eBPF

extended Berkeley Packet Filter (eBPF)

- Connect to all Linux data sources : (Kprobes, Uprobes, tracepoints, ...)
- Almost no overhead (4 ns per syscall) [A. Starovoitov]
- In-kernel verifier, JIT-compilation, mapping (kernel-userspace exchange)
- Processing, tracing, filtering inside Linux kernel.
- Suitable to work with system in-production & real data.

BPF compiler collection (BCC)

- Like-standard frontend project for eBPF tools
- No more byte code! ⇒ write your BPF code in restricted C
- Write your frontend code using Python or Lua
- Towards script-driven tracing

Dynamic tracing with eBPF, our tool

An eBPF tool is built to evaluate the I/O patterns

- I/O access are no longer considered as black boxes!
- A generic tool, works on VFS layer
- It traces all I/O read requests
- It reports all files offsets, req. latencies & data size
- Could filter the results by file

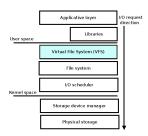

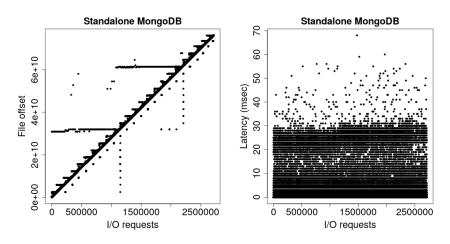

FIGURE – Linux abstracted I/O

Tracing impact on our experiments

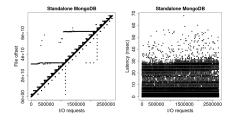

- Overhead cost is lower than 0.8% of execution time in all Experiments. ②
- Basically, it depends on the number issued I/O requests.

Experiments : eBPF results with SDU₁

 $\ensuremath{\mathrm{I/O}}$ access pattern and latency on standalone config.

Experiments : eBPF results with SDU1

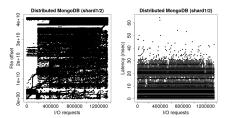

I/O access pattern and latency on standalone config.

Experiments : eBPF results with SDU1

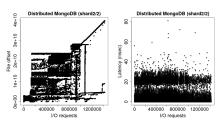

I/O access pattern and latency on standalone config.

- ⇒ Acceptable access pattern on standalone
- ⇒ Almost random access on shards!
- ⇒ Data distribution is poorly done

First shard results in two-shards config (50.9% of data)

Second shard results in two-shards config (49.1% of data)

The exact issue

■ Mismatch between the scanning table vs data stored on disk

MongoDB integrated tools?

- \blacksquare RepairDatabase \Rightarrow verifying the coherence of data. \odot
- Rebuilding the _id index \Rightarrow consider the pre-existed ordering. \odot

MongoDB integrated tools?

- \blacksquare RepairDatabase \Rightarrow verifying the coherence of data. \odot
- \blacksquare Rebuilding the _id index \Rightarrow consider the pre-existed ordering. \odot

Our ad-hoc solution

recreating the _id index regarding how the data is stored on disk.

MongoDB integrated tools?

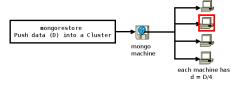

- \blacksquare RepairDatabase \Rightarrow verifying the coherence of data. \circledcirc
- \blacksquare Rebuilding the _id index \Rightarrow consider the pre-existed ordering. \odot

Our ad-hoc solution

recreating the _id index regarding how the data is stored on disk.

The worst case example!

- Data on one shard in a four conf. experiment (1/4 out of data)
- indexing time: Doubling the indexing time of the whole data on standalone config (3000 sec).
- indexing time after : six time faster! (about 500 sec)

MongoDB integrated tools?

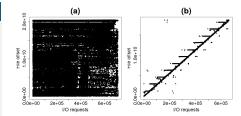

- RepairDatabase ⇒ verifying the coherence of data. ②
- Rebuilding the _id index ⇒ consider the pre-existed ordering. ②

Our ad-hoc solution

recreating the _id index regarding how the data is stored on disk.

The worst case example!

- Data on one shard in a four conf. experiment (1/4 out of data)
- indexing time: Doubling the indexing time of the whole data on standalone config (3000 sec).
- indexing time after : six time faster! (about 500 sec)

 $\label{eq:Figure} Figure - I/O \mbox{ access pattern a) before \& b) after applying \\ \mbox{ the solution}$

Conclusion

Conclusion

- A performance study on MongoDB I/O access pattern is done
- A generic tool for testing I/O access patterns is introduced
- An ad hoc solution is proposed to correct MongoDB I/O access patterns
- We showed how a trivial data management issue could affect the performance
- We demonstrated how it is worthy to use dynamic tracing to go beyond benchmarking results

Future works

- Including other solutions like Cassandra in those tests.
- Trying to enrich eBPF tools which explain specific issues.
