HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Bridging Brain Structure and Function by Correlating Structural Connectivity and Cortico-Cortical Transmission

1 INTRODUCTION

Elucidating the structure-function relationship of the brain is one of the main open questions in neuroscience.

The capabilities of *diffusion MRI-based* (dMRI) techniques to quantify the connectivity strength between brain areas, namely structural connectivity, in combination with modalities such as *electrocorticography* (ECoG) to quantify brain function have enabled advances in this field.

In this project, **we aim to establish a relationship** between:

- > dMRI structural connectivity measures,
- > direct measures of electrical properties of the human brain cortex obtained with ECoG,
- > response elicited by direct electrostimulation of the brain (DES).

2 STRUCTURAL CONNECTIVITY

The dMRI scans are acquired prior to the surgery, in order to extract structural connectivity indices through probabilistic tractography.

The acquisition protocol is optimized for maximum accuracy of MAPL model under the constraint of 25-minutes scanning time. It contains 99 diffusion weighted images and 6 b=0 images as illustrated in Figure 1.

Figure 1: Illustration of the multishell dMRI acquisition protocol.

Figure 2: Visualization of Patient's #2 Arcuate Fasciculus and Superior Longitudinal Fasciculus III.

3 FUNCTIONAL CONNECTIVITY

Following the classical procedure of awake craniotomy, a **brain cartography** is performed using DES (low-intensity current, bipolar electrode) to identify the functional cortical sites for sensory-motor, language, visual and cognitive functions.

To obtain **intrasurgical cortico-cortical electrical measures**, the ECoG electrodes are positioned on the cortical terminations of the designated bundles previously identified by dMRI and DES.

The electrical signal is recorded spontaneously and after DES of the cortex.

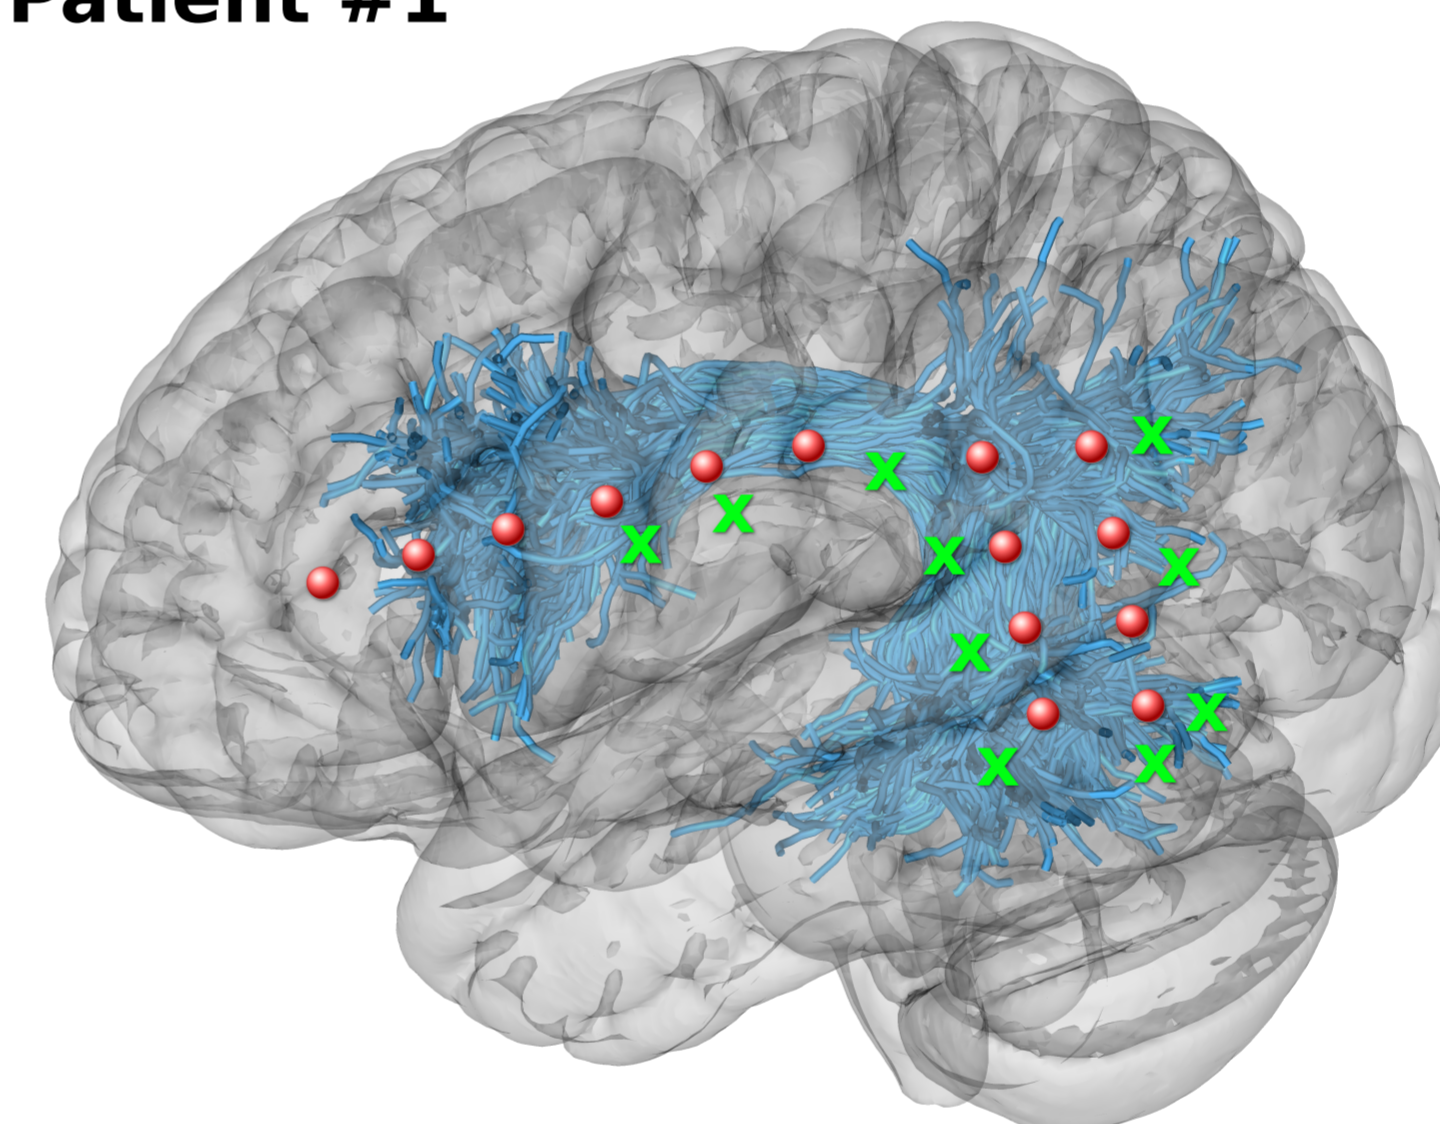

Figure 3: Awake craniotomies of two patients diagnosed with the brain tumor. The ECoG electrodes are placed on the cortical terminations of Arcuate Fasciculus and Superior Longitudinal Fasciculus III. Stimulation points are marked S0-S9.

4 EXPERIMENTS

Patient #1

Stimulation parameters:

- > 3.5mA current
- > bipolar, biphasic
- > 5Hz frequency
- > 4s length

Figure 5: Sample ECoG recordings. The evoked potential propagates from the stimulation site nearest to the electrode e1 (red plot).

Patient #2

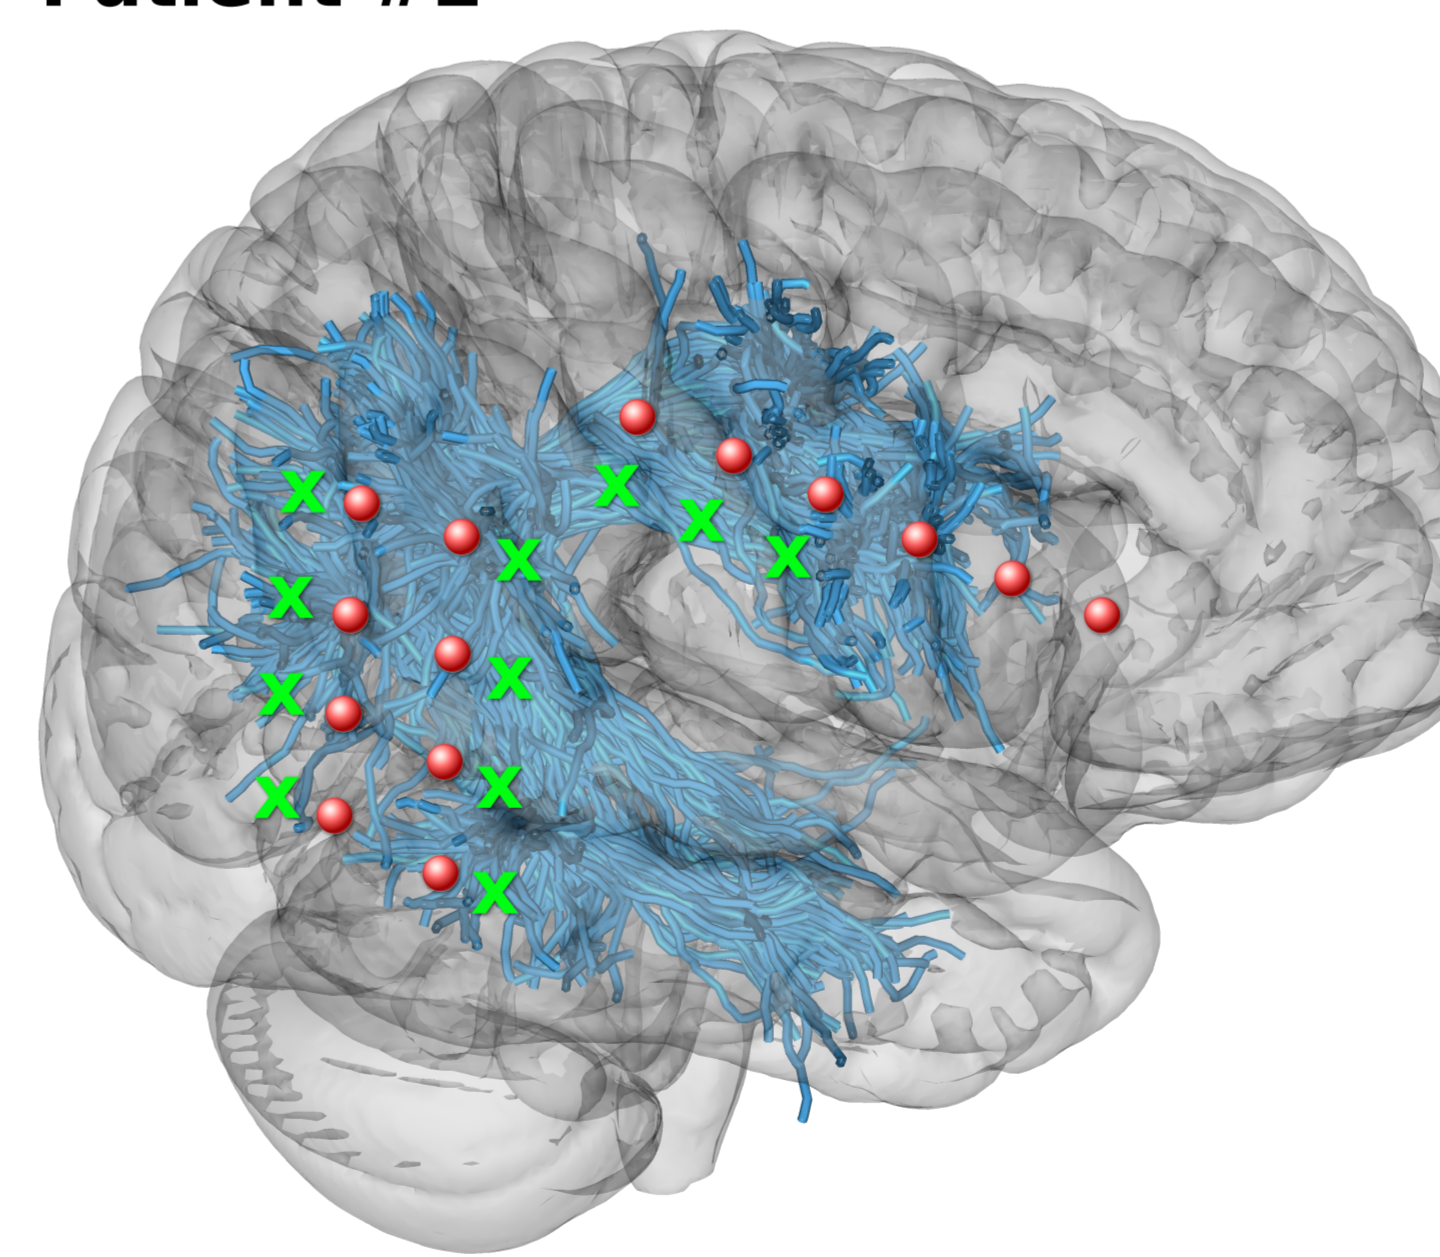

Figure 4: Tractography-based Arcuate Fasciculus and Superior Longitudinal Fasciculus III (marked as blue streamlines), ECoG electrode placements (red circles), and stimulation points (green crosses).

5 CONCLUSIONS

The results of this multi-modal approach combining structure and function explorations of the brain should:

- > help to **elucidate the relationship between non-invasive (dMRI) structural connectivity measures and cortico-cortical transmission properties** (delays, transfer functions),
- > help in **understanding the organization of the brain for cognitive functions** as well as **neurosurgical planning** for resection of brain tumors and drug-resistant epilepsy.
