HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Transformation of a copula using the associated co-copula

Stéphane Girard

Univ. Grenoble Alpes, Inria, CNRS, Grenoble INP, LJK, 38000 Grenoble, France

Abstract

We investigate the properties of a new transformation of copulas based on the co-copula and an univariate function. It is shown that several families in the copula literature can be interpreted as particular outputs of this transformation. Symmetry, association, ordering and dependence properties of the resulting copula are established.

Keywords: Copula, co-copula.

AMS 2000 subject classification: 62H05.

1 Introduction

Let \mathcal{C} be the set of all bivariate copulas. For all function $f : [0, 1] \rightarrow [0, 1]$, $C \in \mathcal{C}$ and $(u, v) \in [0, 1]^2$, introduce the following transformation of a bivariate copula:

$$T(f, C)(u, v) = C(u, v)f(C^*(u, v)), \quad (1)$$

where C^* is the co-copula associated with C , *i.e.*

$$C^*(u, v) = u + v - C(u, v) = \mathbb{P}(U \leq u \cup V \leq v),$$

the random pair (U, V) being distributed from the copula $C(u, v) = \mathbb{P}(U \leq u \cap V \leq v)$. Let us stress that $T(f, C)$ may not be a copula for any function f and copula C . We thus shall investigate conditions on f such that $T(f, C)$ is a copula for any copula C : In the following, a function f is said to be admissible if and only if $T(f, C) \in \mathcal{C}$ for all $C \in \mathcal{C}$.

Several particular cases of this transformation have been investigated in the copula literature. Four parametric models for f combined with arbitrary copulas C have been considered in [5, 7] while, conversely, [6, 9] and [1], Paragraph 5.1, considered an arbitrary function with a specific copula, see Section 2 for details. In this work, we study the transformation in its full generality: Both the function f and the copula C may be arbitrary.

A number of recent works are dedicated to the transformation of copulas: [8, 10, 13, 15, 18]. We also refer to [4, 14] who focused on Archimedean copulas. The usual motivation is that, starting from a simple parametric family, the transformation may lead to a new copula with increased flexibility.

The goal of Section 2 is to characterize the set of admissible functions and to provide some examples. The symmetry and ordering properties of the transformed copula are established in

Section 3 and Section 4 respectively. The dependence aspects are studied in Section 5: The consequences of the transformation on tail dependence, association measures and dependence properties are exhibited.

2 Admissible functions

In Subsection 2.1, we establish necessary and sufficient conditions on a function f to be admissible *i.e.* so that $T(f, C)$ is still a copula whatever the starting copula C . Then, some properties of admissible functions are derived in Subsection 2.2.

2.1 Necessary and sufficient conditions

For all $(u, v) \in [0, 1]^2$, let $W(u, v) = \max(u + v - 1, 0)$ and $M(u, v) = \min(u, v)$ be the two Fréchet-Hoeffding bounds. Let also introduce $\Pi(u, v) = uv$ the independence copula. Remark that the property $W(u, v) \leq C(u, v) \leq M(u, v)$ for all $C \in \mathcal{C}$ (see for instance (2.2.5) in [16]) entails $0 \leq u + v - C(u, v) \leq 1$ and therefore the transformed copula (1) is well-defined for all $(u, v) \in [0, 1]^2$ and $f : [0, 1] \rightarrow [0, 1]$.

Our first result provides necessary and sufficient conditions so that the margins of $T(f, C)$ are uniform. Its proof is straightforward.

Lemma 1 (Boundary conditions)

- (i) For all function f , one has $T(f, C)(u, 0) = T(f, C)(0, u) = 0$ for all $u \in [0, 1]$.
- (ii) A necessary and sufficient condition for $T(f, C)(u, 1) = T(f, C)(1, u) = u$ for all $u \in [0, 1]$ is $f(1) = 1$.

The second step is to investigate the effect of the mapping $T(f, \cdot)$ on quasi-copulas. Recall that, from [16, Definition 6.2.1], a quasi-copula satisfies the same boundary, increasing and Lipschitz properties as do copulas but is not necessarily 2-increasing.

Proposition 1 (Transformation of quasi-copula) *If C is a quasi-copula, f is positive, increasing, 1-Lipschitzian and $f(1) = 1$ then $T(f, C)$ is a quasi-copula.*

Proof. Let us consider the expansion:

$$\begin{aligned} T(f, C)(u + h, v) - T(f, C)(u, v) &= \Delta_1(u, v, h) + \Delta_2(u, v, h), \\ \Delta_1(u, v, h) &= (C(u + h, v) - C(u, v))f(u + h + v - C(u + h, v)), \\ \Delta_2(u, v, h) &= C(u, v)(f(u + h + v - C(u + h, v)) - f(u + v - C(u, v))). \end{aligned}$$

Since f is positive, increasing and $f(1) = 1$, it follows that $0 \leq f(t) \leq 1$ for all $t \in [0, 1]$ and thus

$$0 \leq \Delta_1(u, v, h) \leq C(u + h, v) - C(u, v). \quad (2)$$

Moreover, C is a quasi-copula implies that $C(\cdot, v)$ is increasing and 1-Lipschitzian, so that

$$(u + h + v - C(u + h, v)) - (u + v - C(u, v)) = h + C(u, v) - C(u + h, v) \geq 0.$$

Therefore, in view of the Lipschitz and increasing properties of f ,

$$0 \leq f(u+h+v-C(u+h,v)) - f(u+v-C(u,v)) \leq h + C(u,v) - C(u+h,v),$$

which entails

$$0 \leq \Delta_2(u,v,h) \leq h - C(u+h,v) + C(u,v). \quad (3)$$

Collecting (2) and (3) yields $0 \leq T(f,C)(u+h,v) - T(f,C)(u,v) \leq h$ i.e. $T(f,C(\cdot,v))$ is increasing and 1-Lipschitzian. The proof that $T(f,C)(u,\cdot)$ is increasing and 1-Lipschitzian is similar. Finally, from Lemma 1, the boundary conditions are fulfilled and therefore $T(f,C)$ is a quasi-copula. \blacksquare

Let us consider \mathcal{D} the set of increasing functions f such that $f(1) = 1$ and I_d/f is increasing where I_d denotes the identity function. The effect of the mapping $T(f,\cdot)$ on the Fréchet-Hoeffding lower and upper bounds is illustrated in the next lemma:

Lemma 2 (Fréchet-Hoeffding bounds)

(i) If $f(1) = 1$ then $T(f,W) = W$.

(ii) For all function $f : [0,1] \rightarrow [0,1]$, $T(f,M) = C_f$ where

$$C_f(u,v) = \min(u,v)f(\max(u,v)), \quad (u,v) \in [0,1]^2. \quad (4)$$

Moreover, from [6], $C_f \in \mathcal{C}$ if and only if $f \in \mathcal{D}$.

It appears that, provided $f(1) = 1$, the Fréchet-Hoeffding lower bound W is a fixed point of $T(f,\cdot)$. Besides, the new class of symmetric bivariate copulas (4) introduced in [6], can be interpreted as the transformation of the Fréchet-Hoeffding upper bound M by the mapping $T(f,\cdot)$. As a straightforward consequence of Lemma 2(ii), we thus have:

Proposition 2 (Necessary condition) *If f is admissible then $f \in \mathcal{D}$.*

The necessary condition $f \in \mathcal{D}$ may not be sufficient to ensure that $T(f,\cdot)$ preserves the 2-increasing property. We thus introduce $\mathcal{F} \subset \mathcal{D}$ the set of increasing, twice differentiable functions f such that $f(1) = 1$, I_d/f is increasing and $f'' \geq 0$.

Proposition 3 (Sufficient conditions) *If $f \in \mathcal{F}$ then f is admissible.*

Proof. The proof follows the same lines as the one of [7, Proposition 2.2]. Let us first assume that C is an absolutely continuous copula with continuous partial derivatives denoted by $D_1C := \partial C/\partial u$, $D_2C := \partial C/\partial v$ and $D_{12}C := \partial^2 C/\partial u\partial v$. Let $f \in \mathcal{F}$. Then, I_d/f is increasing implies $f(t) - tf'(t) \geq 0$ for all $t \in [0,1]$ and therefore $f'(1) \leq 1$. Now, $f'' > 0$ implies that f' is increasing so that $f'(t) \leq f'(1) \leq 1$ for all $t \in [0,1]$. This proves that f is 1-Lipschitzian and, from Proposition 1, $T(f,C)$ is a quasi-copula. To check the 2-increasing property, consider the density:

$$\begin{aligned} D_{12}T(f,C) &= C D_1C^* D_2C^* f''(C^*) \\ &+ f'(C^*) [(1 - D_1C^*)D_2C^* + (1 - D_2C^*)D_1C^*] \\ &+ D_{12}C [f(C^*) - Cf'(C^*)]. \end{aligned}$$

This expansion can be rewritten equivalently as

$$D_{12}T(f, C) = C D_1 C^* D_2 C^* f''(C^*) + D_{12}C (C^* - C) f'(C^*) \quad (5)$$

$$+ f'(C^*) [(1 - D_1 C^*) D_2 C^* + (1 - D_2 C^*) D_1 C^*] \quad (6)$$

$$+ D_{12}C [f(C^*) - C^* f'(C^*)]. \quad (7)$$

Recall that $0 \leq D_1 C^* \leq 1$ and $0 \leq D_2 C^* \leq 1$ from [16, Theorem 2.2.7]. It is thus clear that (6) is non-negative because f is increasing. Besides, $f(C^*) - C^* f'(C^*) \geq 0$ since I_d/f is increasing and thus (7) is non-negative. Finally, $C^*(u, v) - C(u, v) = u + v - 2C(u, v) \geq 0$ for all $(u, v) \in [0, 1]^2$ in view of $C(u, v) \leq M(u, v) \leq (u + v)/2$. Assuming $f'' \geq 0$ implies that (5) is also non-negative. As a first conclusion, if C is an absolutely continuous copula with continuous partial derivatives, then $T(f, C)$ is a copula.

Second, let us consider the case of an arbitrary copula in \mathcal{C} and recall that copulas with continuous partial derivatives are dense in \mathcal{C} with respect to the L_∞ norm. It is easily seen that $T(f, \cdot)$ is continuous with respect to the L_∞ norm. Therefore, by density, $T(f, C)$ is a copula for any $C \in \mathcal{C}$. ■

2.2 First properties

The next result exhibits some properties of admissible functions. First, the identity is the only admissible function vanishing at the origin. Second, $I_d \in \mathcal{F}$ and the stability of \mathcal{F} with respect to composition entail that \mathcal{F} is a sub-monoid of the set of functions defined on the unit interval. Besides, the stability of \mathcal{F} with respect to convex combinations shows that \mathcal{F} is a convex set. Third, any admissible function is either constant or strictly increasing in a neighbourhood of 1. This property will reveal useful in Section 4.

Lemma 3 (Properties of admissible functions)

(i) If $f \in \mathcal{F}$ then $t \leq f(t) \leq 1$ and $0 \leq f'(t) \leq 1$ for all $t \in [0, 1]$.

(ii) If $f \in \mathcal{F}$ and $f(0) = 0$, then $f = I_d$.

(iii) Let $(f, g) \in \mathcal{F}^2$ and $p \in [0, 1]$. Then, $f \circ g \in \mathcal{F}$ and $pf + (1 - p)g \in \mathcal{F}$.

(iv) Let $f \in \mathcal{F}$. Then, either $f \equiv 1$ or there exists $x_0 \in (0, 1)$ such that f is strictly increasing on $[x_0, 1]$.

Proof. (i) The property $t \leq f(t)$ is a consequence of I_d/f is increasing and $f(1) = 1$ while $f(t) \leq 1$ is implied by f is increasing and $f(1) = 1$. The properties of f' have been established in the proof of Proposition 3.

(ii) Let $f \in \mathcal{F}$. From [3, Theorem 5], $f'' \geq 0$ and $f(0) = 0$ imply that f is star-shaped *i.e.* f/I_d is increasing. Taking account of $f \in \mathcal{F}$ leads to $f = cI_d$ where $c \in \mathbb{R}$. Since $f(1) = 1$, we obtain $c = 1$ and the conclusion follows.

(iii) Let $(f, g) \in \mathcal{F}^2$. Remarking that $I_d/f \circ g = (I_d/f) \times (f/f \circ g)$, it is clear that $f \circ g \in \mathcal{F}$. The proof of $pf + (1 - p)g \in \mathcal{F}$ for all $p \in [0, 1]$ is straightforward.

(iv) Let $f \in \mathcal{F}$. First, if f is constant then, necessarily $f \equiv 1$ in view of the condition $f(1) = 1$.

Second, if f is not constant, assume that, for all $x_0 \in (0, 1)$, there exists $x_0 < x_1 < x_2$ such that $f(x_0) < f(x_1) = f(x_2)$. Let $p \in (0, 1)$ such that $px_0 + (1-p)x_2 = x_1$. The convexity property $f(px_0 + (1-p)x_2) \leq pf(x_0) + (1-p)f(x_2)$ can be rewritten as $f(x_1) \leq pf(x_0) + (1-p)f(x_1)$ or equivalently $f(x_1) \leq f(x_0)$. This contradicts the assumption $f(x_0) < f(x_1)$. As a conclusion, there exists $x_0 \in (0, 1)$ such that, for all $x_0 < x_1 < x_2$, $f(x_0) < f(x_1) < f(x_2)$. The result is proved. \blacksquare

Several particular cases of the mapping (1) have been addressed in the literature, restricting on particular parametric forms for f :

$$\begin{aligned} f_\lambda^{(1)}(x) &= 1/(1 + \lambda - \lambda x), \lambda \in [0, 1], \\ f_\lambda^{(2)}(x) &= 1 - \lambda + \lambda x, \lambda \in [0, 1], \\ f_\lambda^{(3)}(x) &= \exp(\lambda(x - 1)), \lambda \in \mathbb{R}, \\ f_{\lambda, \theta}^{(4)}(x) &= (1 + \lambda - \lambda x)^\theta, \theta \in \mathbb{R}, \lambda \in [0, 1], \end{aligned}$$

for all $x \in [0, 1]$. In [7], it is proved that $f_\lambda^{(1)}$ is admissible while, in [5, Theorem 3.1], it is established that $f_\lambda^{(2)}$ is admissible. It is also clear that $f_\lambda^{(1)} \in \mathcal{F}$ and $f_\lambda^{(2)} \in \mathcal{F}$ which provides an unified proof of the previous results. The next lemma answers some open questions of [5] and extends the result of [7] since $f_\lambda^{(1)} = f_{\lambda, -1}^{(4)}$.

Lemma 4 (Examples)

- (i) $f_\lambda^{(3)}$ is admissible if and only if $\lambda \in [0, 1]$. Besides, $f_\lambda^{(3)}$ gives rise to the transformed copula introduced in [5], eq. (17).
- (ii) $f_{\lambda, \theta}^{(4)}$ is admissible if and only if $\lambda \in [0, 1]$ and $-1/\lambda \leq \theta \leq 0$. Besides, $f_{\lambda, \theta}^{(4)}$ gives rise to a particular case of the transformed copula introduced in [5], eq. (18).

Proof. (i) It is clear that $f_\lambda^{(3)} \in \mathcal{D}$ if and only if $\lambda \in [0, 1]$. Besides, $(f_\lambda^{(3)})'' \geq 0$ for all $\lambda \in \mathbb{R}$ and thus Proposition 2 and Proposition 3 conclude the proof.

(ii) It is clear that $f_{\lambda, \theta}^{(4)} \in \mathcal{D}$ if and only if $\lambda \in [0, 1]$ and $-1/\lambda \leq \theta \leq 0$. Besides, $(f_{\lambda, \theta}^{(4)})'' \geq 0$ for all $\lambda \in [0, 1]$, $\theta \leq 0$ and thus Proposition 2 and Proposition 3 conclude the proof. \blacksquare

New admissible functions can then be proposed by combining Lemma 3(iii) and Lemma 4. For instance, the function defined for all $x \in [0, 1]$ by $f_{\lambda, \theta}^{(5)}(x) := (f_\lambda^{(3)} \circ f_{1, \theta}^{(4)})(x) = \exp(\lambda((2-x)^\theta - 1))$ is admissible for all $\lambda \in [0, 1]$ and $\theta \in [-1, 0]$. The graph of this function is depicted on Figure 1.

3 Symmetry properties

Let (X, Y) be a random pair. X and Y are said to be exchangeable if (X, Y) and (Y, X) are identically distributed, see for instance [16], Section 2.7. From [16, Theorem 2.7.4], a necessary and sufficient condition for exchangeability is that X and Y are identically distributed and that their associated copula C is symmetric *i.e.* $C(u, v) = C(v, u)$ for all $(u, v) \in [0, 1]$. The following result is straightforward:

Proposition 4 (Symmetry) *Let $C \in \mathcal{C}$ and $f \in \mathcal{F}$. If C is symmetric then $T(f, C)$ is symmetric.*

Let $(a, b) \in \mathbb{R}^2$. (X, Y) is said to be radially symmetric about (a, b) if $(X-a, Y-b)$ and $(a-X, b-Y)$ are identically distributed. Assume that X is symmetric about a and Y is symmetric about b . Then, from [16, Theorem 2.7.3], a necessary and sufficient condition for radial symmetry is that

$$C(u, v) = u + v - 1 + C(1 - u, 1 - v) \text{ for all } (u, v) \in [0, 1]^2. \quad (8)$$

A copula satisfying (8) is said to be radially symmetric. The next result generalizes [5, Theorem 3.9].

Proposition 5 (Radial symmetry) *Let $f \in \mathcal{F}$. The copula $T(f, C)$ is radially symmetric for all radially symmetric copula C if and only if $f = f_\lambda^{(2)}$.*

Proof. From (8), $T(f, C)$ is radially symmetric if and only if, for all $(u, v) \in [0, 1]^2$:

$$u + v - 1 + C(1 - u, 1 - v)f(2 - u - v - C(1 - u, 1 - v)) = C(u, v)f(u + v - C(u, v)).$$

Since C also satisfies (8), the previous equation is equivalent to

$$u + v - 1 + (C(u, v) - u - v + 1)f(1 - C(u, v)) = C(u, v)f(u + v - C(u, v)).$$

Letting $W_0(u, v) = u + v - 1$, the previous equation can be rewritten as

$$W_0(u, v) + (C(u, v) - W_0(u, v))f(1 - C(u, v)) - C(u, v)f(W_0(u, v) - C(u, v) + 1) = 0,$$

or, equivalently, with $\Delta := f - I_d$:

$$\frac{\Delta(1 - (C - W_0)(u, v))}{(C - W_0)(u, v)} = \frac{\Delta(1 - C(u, v))}{C(u, v)}.$$

Finally, introducing $\Psi(\cdot) := \Delta(1 - \cdot)/I_d(\cdot)$, we end up with the functional equation

$$\Psi((C - W_0)(u, v)) = \Psi(C(u, v)) \text{ for all } C \in \mathcal{C} \text{ and } (u, v) \in [0, 1]^2.$$

Necessarily, Ψ is a constant, say λ , and therefore $f(t) = (1 - \lambda)t + \lambda$. Besides, $f \in \mathcal{F}$ implies $\lambda \in [0, 1]$ and the result follows. \blacksquare

4 Ordering properties

Let us recall the definition of concordance ordering, see [12], Section 2.2.1 for further details. Let $(C_1, C_2) \in \mathcal{C}^2$. Then, C_1 is more concordant than C_2 , written $C_1 \prec C_2$, if $C_1(u, v) \leq C_2(u, v)$ for all $(u, v) \in [0, 1]$.

Proposition 6 (Ordering)

- (i) For all $C \in \mathcal{C}$ and $(f_1, f_2) \in \mathcal{F}^2$, $f_1 \leq f_2$ implies $T(f_1, C) \prec T(f_2, C)$.
- (ii) For all $f \in \mathcal{F}$, the mapping $T(f, \cdot)$ is increasing with respect to concordance ordering, i.e. $C_1 \prec C_2$ implies $T(f, C_1) \prec T(f, C_2)$.
- (iii) $CC^* \prec T(f, C) \prec C$ for all $C \in \mathcal{C}$.

Proof. (i) is straightforward.

(ii) Let $\Psi_a(x) := xf(a-x)$ for $a > 0$ and $x \in [0, a/2]$. Under the assumption $f \in \mathcal{F}$, the first derivative Ψ'_a is such that:

$$\Psi'_a(x) = f(a-x) - xf'(a-x) \geq (a-2x)f'(a-x) \geq 0$$

in view of $yf'(y) \leq f(y)$ for $y \geq 0$ which is a consequence of I_d/f increasing. Thus $C_1 \prec C_2$ implies $C_1(u, v) \leq C_2(u, v) \leq \min(u, v) \leq (u+v)/2$ for all $(u, v) \in [0, 1]^2$ and consequently, $\Psi_{u+v}(C_1(u, v)) \leq \Psi_{u+v}(C_2(u, v))$ which can be rewritten as

$$C_1(u, v)f(u+v-C_1(u, v)) \leq C_2(u, v)f(u+v-C_2(u, v))$$

and the conclusion follows.

(iii) From Lemma 3(i), $f \in \mathcal{F}$ implies $t \leq f(t) \leq 1$ for all $t \in [0, 1]$ and thus Proposition 6(i) yields $T(I_d, C) = CC^* \prec T(f, C) \prec T(1, C) = C$. \blacksquare

Let us now investigate what happens when the transformation $T(f, \cdot)$ is iterated. To this end, let $f \in \mathcal{F}$, $C \in \mathcal{C}$ and consider the following sequence of transformed copulas:

$$C_0 := C, C_{k+1} = T(f, C_k) \text{ for all } k \geq 0.$$

The next proposition shows that the iterations converge to the fixed point of $T(f, \cdot)$, which is W the Fréchet-Hoeffding lower bound.

Proposition 7 (Convergence of iterations) *Let $C \in \mathcal{C}$ and suppose $f \in \mathcal{F}$ is not identically equal to 1. Then $C_k \rightarrow W$ pointwisely as $k \rightarrow \infty$.*

Proof. Let $(u, v) \in [0, 1]^2$. Clearly $C_k(u, v) \geq W(u, v)$ and, from Proposition 6(iii), $C_{k+1}(u, v) \leq C_k(u, v)$ for all $k \geq 0$. The sequence $(C_k(u, v))_{k \geq 1}$ is thus decreasing and lower bounded. As a consequence, this sequence converges to one of the solutions $x = x(u, v)$ of the equation $xf(u+v-x) = x$. Two cases arise: $x(u, v) = 0$ or $f(u+v-x) = 1$. From Lemma 3(iv), $f(u+v-x) = 1$ implies $u+v-x = 1$ i.e. $x(u, v) = u+v-1$. Conversely, $x(\cdot, \cdot)$ should be a copula since \mathcal{C} is a closed subset of bivariate functions. Then, $x(\cdot, \cdot)$ should be positive and continuous to define a copula and therefore $x(u, v) = \max(u+v-1, 0)$. \blacksquare

The convergence of the sequence (C_k) to W is illustrated on Figure 2 on the simple case where $C = \Pi$ and $f = I_d$. The contour plots associated with the densities of C_1, C_2, C_3 and C_4 are depicted. As expected, the contour plots are getting closer to lines with slope -1 as the iterations increase.

5 Dependence

Paragraph 5.1 illustrates how the tail dependence coefficients of the copula are modified by the mapping. Some bounds are provided on the measures of association (Spearman's Rho and Kendall's Tau) of the transformed copula in Paragraph 5.2. Finally, it is shown in Paragraph 5.3 that the mapping preserves dependence properties such as Negative Quadrant Dependence property, Left Tail Increasing property and Stochastic Decreasing property.

5.1 Measures of tail dependence

The tail dependence coefficients are defined as the conditional probabilities that a random vector associated with a copula C belongs to lower or upper tail orthants given that a univariate margin takes extreme values [19]:

$$\begin{aligned}\lambda_{LL}(C) &= \lim_{u \rightarrow 0} \frac{C(u, u)}{u}, & \lambda_{UL}(C) &= 1 - \lim_{u \rightarrow 0} \frac{C(1-u, u)}{u}, \\ \lambda_{LU}(C) &= 1 - \lim_{u \rightarrow 0} \frac{C(u, 1-u)}{u}, & \lambda_{UU}(C) &= 2 - \lim_{u \rightarrow 1} \frac{C(u, u) - 1}{u - 1}.\end{aligned}$$

The next proposition establishes that λ_{UL} and λ_{LU} are left invariant by the mapping while λ_{LL} and λ_{UU} may be decreased, depending on $f(0)$ and $f'(1)$ respectively.

Proposition 8 (Tail dependence coefficients) *Let $C \in \mathcal{C}$, $f \in \mathcal{F}$. Then,*

$$\begin{aligned}\lambda_{LL}(T(f, C)) &= \lambda_{LL}(C)f(0), \\ \lambda_{UL}(T(f, C)) &= \lambda_{UL}(C), \\ \lambda_{LU}(T(f, C)) &= \lambda_{LU}(C), \\ \lambda_{UU}(T(f, C)) &= \lambda_{UU}(C)(1 - f'(1)).\end{aligned}$$

Proof. First,

$$\lambda_{LL}(T(f, C)) = \lim_{u \rightarrow 0} \frac{T(f, C)(u, u)}{u} = \lim_{u \rightarrow 0} \frac{C(u, u)}{u} f(2u - C(u, u)) = \lambda_{LL}(C)f(0).$$

Similarly,

$$1 - \lambda_{UL}(T(f, C)) = \lim_{u \rightarrow 0} \frac{T(f, C)(1-u, u)}{u} = \lim_{u \rightarrow 0} \frac{C(1-u, u)}{u} f(1 - C(1-u, u)) = (1 - \lambda_{UL}(C))f(1),$$

and recalling that $f(1) = 1$ gives the result. The calculation of $\lambda_{LU}(T(f, C))$ follows the same lines. Finally, let us consider $\lambda_{UU}(T(f, C))$. A first order Taylor expansion yields

$$f(2u - C(u, u)) = 1 + (2u - C(u, u) - 1)f'(1) + o(u - 1)$$

when $u \rightarrow 1$ and therefore

$$\begin{aligned}\frac{T(f, C)(u, u) - 1}{u - 1} &= \frac{C(u, u)f(2u - C(u, u) - 1)}{u - 1} \\ &= \frac{C(u, u) - 1}{u - 1} + C(u, u)f'(1)\frac{2u - C(u, u) - 1}{u - 1} + o(1).\end{aligned}$$

Taking the limit as $u \rightarrow 1$ yields

$$2 - \lambda_{UU}(T(f, C)) = 2 - \lambda_{UU}(C) + f'(1)\lambda_{UU}(C),$$

and the result follows. ■

5.2 Measures of association

Several measures of association between the components of a random pair (X, Y) can be considered: the normalized volume [17], Kendall's Tau [16], Paragraph 5.1.1, Gini's gamma [11], Blomqvist's medial correlation coefficient [16], Paragraph 5.1.4, Spearman's footrule [11] and Spearman's Rho [16], Paragraph 5.1.2. All these measures are invariant to strictly increasing functions.

The medial correlation coefficient, introduced by Blomqvist [2], is defined as

$$\beta = \mathbb{P}((X - \tilde{x})(Y - \tilde{y}) > 0) - \mathbb{P}((X - \tilde{x})(Y - \tilde{y}) < 0)$$

where \tilde{x} and \tilde{y} are the medians on the random variables X and Y respectively. In case of continuous random variables, β depends only on the associated copula: $\beta = \beta(C) = 4C(1/2, 1/2) - 1$, see [16], equation (5.1.27). The next result shows how the medial correlation coefficient is modified by the mapping $T(\cdot, f)$.

Proposition 9 (Medial correlation coefficient) *Let $C \in \mathcal{C}$, $f \in \mathcal{F}$. Then,*

$$\beta(T(f, C)) = (\beta(C) + 1)f((3 - \beta(C))/4) - 1.$$

The proof is straightforward. Kendall's Tau and Spearman's Rho can be interpreted as probabilities of concordance minus probabilities of discordance of two random pairs: Kendall's Tau is the probability of concordance minus the probability of discordance of two identically distributed random pairs (X_1, Y_1) and (X_2, Y_2) . Spearman's Rho is the probability of concordance minus the probability of discordance of two pairs (X_1, Y_1) and (X_2, Y_2) with respective copulas C and Π . In case of continuous random variables, both of them can be rewritten in terms of copulas, for instance:

$$\rho = \rho(C) = 12 \int_0^1 \int_0^1 C(u, v) dudv - 3.$$

Note that ρ coincides with the correlation coefficient between the uniform marginal distributions. Obtaining a result similar to Proposition 9 for Spearman's Rho or Kendall's Tau seems a difficult task. It is however clear that the following (sharp) bounds hold.

Proposition 10 (Spearman's Rho and Kendall's Tau)

(i) *Let $C \in \mathcal{C}$. For all $f \in \mathcal{F}$:*

$$\rho(CC^*) \leq \rho(T(f, C)) \leq \rho(C) \text{ and } \tau(CC^*) \leq \tau(T(f, C)) \leq \tau(C).$$

(ii) *Let $f \in \mathcal{F}$. For all $C \in \mathcal{C}$:*

$$-1 \leq \rho(T(f, C)) \leq 12 \int_0^1 x^2 f(x) dx - 3 \text{ and } -1 \leq \tau(T(f, C)) \leq 4 \int_0^1 x f^2(x) dx - 1.$$

Proof. (i) is a consequence of Proposition 6(iii).

(ii) In view of Proposition 6(ii) and Lemma 2, $W = T(f, W) \prec T(f, C) \prec T(f, M) = C_f$. As a consequence, $-1 = \rho(W) \leq \rho(T(f, C)) \leq \rho(C_f) = 12 \int_0^1 x^2 f(x) dx - 3$ from [6, Proposition 3.4]. The proof is similar for Kendall's τ . ■

5.3 Dependence properties

Let (X, Y) be a pair of random variables with continuous margins and associated copula C .

- X and Y are said to be Negatively Quadrant Dependent (NQD) if

$$\mathbb{P}(X \leq x, Y \leq y) \leq \mathbb{P}(X \leq x)\mathbb{P}(Y \leq y) \text{ for all } (x, y).$$

Since this property can be characterized by the copula property $C \prec \Pi$, see for instance [16], Paragraph 5.2.1, we shall write for short that C is NQD.

- X and Y are said to be Left Tail Increasing (LTI) if $\mathbb{P}(X \leq x|Y \leq y)$ is a nondecreasing function of y for all x , and $\mathbb{P}(Y \leq y|X \leq x)$ is a nondecreasing function of x for all y . From [16, Theorem 5.2.5], this property can be characterized by the copula properties

$$\begin{aligned} C(u, v)/u &\text{ is nondecreasing in } u \text{ for all } v \in [0, 1], \\ C(u, v)/v &\text{ is nondecreasing in } v \text{ for all } u \in [0, 1], \end{aligned} \tag{9}$$

and we shall thus write that C is LTI.

- X and Y are said to be Stochastically Decreasing (SD) if $\mathbb{P}(X > x|Y = y)$ is a nonincreasing function of y for all x , and $\mathbb{P}(Y > y|X = x)$ is a nonincreasing function of x for all y . From [16, Corollary 5.2.11], this property can be characterized by the copula properties

$$\begin{aligned} C(u, v) &\text{ is a convex function of } u \text{ for all } v \in [0, 1], \\ C(u, v) &\text{ is a convex function of } v \text{ for all } u \in [0, 1], \end{aligned} \tag{10}$$

and we shall thus write that C is SD.

The three properties NQD, LTI and SD are preserved by the mapping.

Proposition 11 (Dependence properties) *Let $f \in \mathcal{F}$ and $C \in \mathcal{C}$.*

(i) *If C is NQD then $T(f, C)$ is NQD.*

(ii) *If C is LTI then $T(f, C)$ is LTI.*

(iii) *If C is SD then $T(f, C)$ is SD.*

Proof. (i) Proposition 6(ii,iii) show that $C \prec \Pi$ implies $T(f, C) \prec T(f, \Pi) \prec \Pi$. The result is proved.

(ii) Let $(u, v) \in [0, 1]^2$. Our goal is to prove that $T(f, C)(u, v)/u$ is nondecreasing in u for all v , the study of $T(f, C)(u, v)/v$ being similar:

$$\begin{aligned} u^2 \frac{\partial T(f, C)(u, v)/u}{\partial u} &= uD_1T(f, C)(u, v) - T(f, C)(u, v) \\ &= f(C^*(u, v)) (uD_1C(u, v) - C(u, v)) \end{aligned} \tag{11}$$

$$+ uC(u, v)f'(C^*(u, v)) (1 - D_1C(u, v)). \tag{12}$$

From (9), it follows that (11) is nonnegative. Besides, [16, Theorem 2.2.7] entails that (12) is nonnegative and the result is proved.

(iii) Let $(u, v) \in [0, 1]^2$. Our goal is to prove that $T(f, C)(\cdot, v)$ is a convex function for all v , the study of $T(f, C)(u, \cdot)$ being similar:

$$D_{11}T(f, C) = D_{11}C[f(C^*) - Cf'(C^*)] \quad (13)$$

$$+ 2D_1Cf'(C^*)(1 - D_1C) \quad (14)$$

$$+ Cf''(C^*)(1 - D_1C)^2. \quad (15)$$

From (10), it follows that $D_{11}C$ is nonnegative. Besides, $f(C^*) - Cf'(C^*) \geq (C^* - C)f'(C^*)$ as already seen in the proof of Proposition 3 and

$$(C^* - C)(u, v) = u + v - 2C(u, v) \geq u + v - 2\min(u, v) = \max(u, v) - \min(u, v) \geq 0.$$

It follows that (13) is nonnegative. Besides, [16, Theorem 2.2.7] entails that (14) is nonnegative. Finally, (15) is nonnegative since $f \in \mathcal{F}$, and the result is proved. ■
