\begin{abstract}
We consider a variant of the well-known, NP-complete problem of minimum cut linear arrangement for directed acyclic graphs. In this variant, we are given a directed acyclic graph and we are asked to find a topological ordering such that the maximum number of cut edges at any point in this ordering is minimum. In our variant, the vertices and edges have weights, and the aim is to minimize the maximum weight of cut edges in addition to the weight of the last vertex before the cut. There is a known, polynomial time algorithm [Liu, SIAM J. Algebra. Discr., 1987] for the cases where the input graph is a rooted tree. We focus on the instances where the input graph is a directed series-parallel graph, and propose a polynomial time algorithm, thus expanding the class of graphs for which a polynomial time algorithm is known. Directed acyclic graphs are used to model scientific applications where the vertices correspond to the tasks of a given application and the edges represent the dependencies between the tasks. In such models, the problem we address reads as minimizing the peak memory requirement in an execution of the application. Our work, combined with Liu’s work on rooted trees addresses this practical problem in two important classes of applications.

\textbf{Keywords:} series-parallel graphs, scheduling, peak memory minimization.
\end{abstract}

\section{Introduction}

A layout or a linear arrangement of a graph $G$ is a total ordering of the vertices of $G$. In layout problems, the aim is to optimize a certain objective function. There are a number of very well-known layout problems which are surveyed by Díaz et al. [5, 21]. Among those problems \textsc{CutWidth} or the minimum cut linear arrangement (MCLA) is of immediate interest. Consider a
graph on \( n \) vertices and a layout. Consider a cut at \( i \), where the first \( i \) vertices in the layout are on the left part and the remaining vertices are on the right part. The number of edges whose end points straddle the cut at \( i \) is called the width of the cut. The \textsc{CutWidth} problem asks for a layout in which the maximum width of a cut at positions 1 to \( n - 1 \) is the minimum. This paper addresses a variant of the \textsc{CutWidth} problem in which the vertices and edges have weights, and the aim is to minimize the maximum value of a cut at position \( i \) for \( i = 1, \ldots, n \), where the \textit{value of a cut} at \( i \) is now defined as the sum of the weight of the vertex \( v \) at position \( i \), of the weights of all edges whose one end point is either \( v \) or ordered before \( v \) and whose other end point is \( v \) or ordered after \( v \). We address this problem for the well-known class of series-parallel graphs (a formal definition is given in Section 2 for completeness), and propose a polynomial time algorithm.

The \textsc{CutWidth} problem is \text{NP}-complete both in undirected graphs [10] and directed graphs [28], and solved efficiently for graphs with small treewidth [26] and small cutwidth [25]—see the survey and its addendum [5, 21] for a more thorough view of the known results. Leighton and Rao [15] discuss approximation algorithms for the \textsc{CutWidth} problem, which can be improved by using the heuristics by Arora et al. [1]. Yannakakis [29] presents a polynomial time algorithm for the \textsc{CutWidth} problem on trees (general trees) without weights; the weighted version remains \text{NP}-complete [19]. A historical source of interest in the \textsc{CutWidth} problem for graphs with unit weight edges (no vertex weights) is the pebble game of Sethi and Ullman [24], which is \text{PSPACE} complete [11], and polynomial time solvable for rooted trees [23].

The variant of the \textsc{CutWidth} problem studied in this paper is first addressed by Liu [18] for the class of rooted trees. Liu discusses how the problem at hand corresponds to minimizing the peak memory in the context of a certain sparse direct solver [17]. For the sake of fidelity to Liu’s original work, we use the term “peak memory” for defining the objective in our layout problem. Our main contribution in this paper is thus to expand the family of graph classes for which peak-memory problem can be solved in polynomial time.

Our results are of theoretical nature, yet we have been motivated by the practical problem of reducing the memory consumption of applications which are modeled as task graphs [22]. In these graphs, vertices represent tasks and edges represent the dependencies between tasks. Each task consumes one or more \textit{input file/data}, and produces one or more \textit{output file/data}. To be executed, a task also requires an \textit{execution file/data}. As the size of the data to be processed increases, minimizing the peak memory of an application arises as an important objective, as the memory traffic is often the bottleneck. Consider the execution of a task graph on a single compute resource, i.e., a single processor and a single memory hierarchy. An execution of the application is defined by a traversal of the graph, that is, a schedule of the vertices which respects the dependencies (or topological order). The peak memory of a traversal is the maximum amount of memory needed to store application files/data at any given time throughout the application execution. The graphs with vertex and edges weights, and the definition of the value of a cut given above express the objec-
tive of minimizing the peak memory as a graph layout problem. Peak memory minimization problem has been addressed for applications whose task graphs are rooted trees [13, 14, 16, 18]. This work aspires to be helpful in scheduling applications whose task graphs are series parallel [3, 9, 20], as theoretical understanding of the underlying layout problem is needed to reduce the peak memory in a parallel execution environment (see for example a previous study [8]).

This paper is organized as follows. We present the problem formally in Section 2. We then describe the existing optimal algorithm for trees in Section 3, since this algorithm forms the basis of our proposed algorithms. In the same section, we present the principle of our algorithms on a subclass of SP-graphs. Then, Section 4 presents the proposed algorithm for general SP-graphs as well as the new notion on min-cut optimality needed to prove its correctness. Some of the arguments in our proofs are very lengthy and involved. For the sake of readability, the most demanding proofs are detailed in Appendix.

2. Peak memory minimization: Model and objective

We define the problem in general directed acyclic graphs (DAGs) with vertex and edge weights modeling applications. In this model, a DAG $G = (V, E, w_n, w_e)$ contains a vertex for each task of the application and a directed edge $(p, q)$ between two vertices if the task corresponding to the vertex $q$ needs a data produced by the task corresponding to the vertex $p$. Each task in the graph may have several input data, some execution data (or program), and several output data. We denote by $w_e(p, q) \geq 0$ the weight of edge $(p, q)$ which represents the size of the data produced by task $p$ for task $q$, and by $w_n(p) \geq 0$ the weight of a vertex $p$ which is the size of the execution data of task $p$.

During the execution of a task (vertex) $p$, the memory must contain its input data, the execution data, and its output data. The memory needed for executing $p$ is thus:

$$\left(\sum_{(r, p) \in E} w_e(r, p)\right) + w_n(p) + \left(\sum_{(p, q) \in E} w_e(p, q)\right).$$

After $p$ has been processed, its input and execution data are discarded, while its output data are kept in memory until they are consumed at the end of the execution of the corresponding tasks. For example, in the graph depicted in Figure 1a, if task $A$ is processed first, 8 units of memory are needed for its processing, but only 4 remains in the memory after its completion. If task $C$ is processed right after task $A$, 7 units of memory are needed during its processing (4 to store the data produced by $A$ for $B$, and 3 for the execution and output data of $C$).

While processing the task graph, memory consumption changes as data are created and deleted. Our objective is to minimize the peak memory, i.e., the maximum amount of memory used in the graph traversal.

More formally, we define a schedule of the graph as a total order (layout) $\pi$ on the vertices, denoted with $\leq_{\pi}$, such that $p \leq_{\pi} q$ means that vertex $p$ is...
ordered before vertex $q$. The precedence constraints of the task graphs impose that this is a topological order: we have $p \preceq \pi q$ for any edge $(p, q) \in E$. We use the notation $\max^\pi$ (resp. $\min^\pi$) to express the maximum (resp. minimum) according to the order $\pi$: $\min^\pi G$ is, for instance, the first vertex scheduled by $\pi$. When considering a subset $X$ of vertices, we denote by $\pi[X]$ the order $\pi$ restricted to this subset. A schedule is also represented as a list of vertices: $\pi = \langle 1, 2, 3 \rangle$ denotes that $1 \preceq \pi 2 \preceq \pi 3$.

We define $\mu(p, \pi)$ as the memory required during the execution of a vertex $p \in V$ under the schedule $\pi$ as

$$\mu(p, \pi) = w_n(p) + \sum_{q \preceq \pi p \preceq \pi r} \{w_e(q, r) : (q, r) \in E\}.$$ 

Note that the edges $(q, r)$ such that $q \preceq \pi p \preceq \pi r$ correspond to the data that have been created but not yet consumed while $p$ is being processed. The objective is to find a schedule $\pi$ for a graph $G$ that minimizes the peak memory, defined as

$$\mu(\pi) = \max_{p \in V} \mu(p, \pi).$$

Given a directed graph $G = (V, E, w_n, w_e)$, we define the reverse graph $\bar{G} = (V, \bar{E}, w_n, w_e)$ where the orientation of all edges is changed: $\bar{E} = \{(j, i), (i, j) \in E\}$. Note that vertex and edge weights are kept unchanged. Given a schedule $\pi$ of $G$, we may build the reverse schedule $\bar{\pi}$ such that $q \preceq \bar{\pi} p$ whenever $p \preceq \pi q$. It is straightforward to check that both schedules have the same peak memory on their respective graph: $\mu_G(\pi) = \mu_{\bar{G}}(\bar{\pi})$.

In this paper, we concentrate on series-parallel graphs, which are defined as follows (see for example [7] for more information).

**Definition 1.** A two-terminal series-parallel graph, or SP-graph, $G$ with terminals $s$ and $t$ is recursively defined to be either:

**Base case:** A graph with two vertices $s$ and $t$, and an edge $(s, t)$.

**Series composition:** The series composition of two SP-graphs $G_1$ with terminals $s_1, t_1$ and $G_2$ with terminals $s_2, t_2$ formed by identifying $s = s_1$, $t = t_2$ and $t_1 = s_2$, and denoted by $\langle G_1, G_2 \rangle$.

**Parallel composition:** The parallel composition of two SP-graphs $G_1$ with terminals $s_1, t_1$ and $G_2$ with terminals $s_2, t_2$ formed by identifying $s = s_1 = s_2$ and $t = t_1 = t_2$, and denoted by $\{G_1, G_2\}$.

The vertices $s$ and $t$ are called source and target of the graph.

When the graph is defined this way, the dependencies are from the source vertices to the target vertices. Series-parallel graphs can be recognized and decomposed into a tree of series and parallel combinations in linear time [27].

While solving the peak memory minimization problem for SP-graphs, we will need a solution for a sub-family of SP-graphs, which are called parallel-chains and are defined below. A sample parallel-chain graph is shown in Fig. 2.
Definition 2. A chain is a two-terminal series-parallel graph obtained without using any parallel composition. A parallel-chain graph is a two-terminal series-parallel graph obtained by the unique parallel composition of a number of chains.

3. Solving the peak memory problem on trees and parallel-chain graphs

We first recall Liu’s algorithm [18] for solving the peak memory minimization problem on rooted trees. We then propose its adaptation for parallel-chain graphs; this new algorithm is used later (in Section 4) as a building block for solving the peak memory problem on series-parallel graphs. The algorithm proposed by Liu applies to in-trees, that is trees whose dependencies are directed towards the root (contrarily to out-trees, where dependencies are directed towards leaves). Note that if $T$ is an in-tree and $\pi$ is the schedule of $T$ computed by Liu’s algorithm, then $\bar{\pi}$ is also a peak memory minimizing schedule of the out-tree $\bar{T}$.

3.1. Liu’s algorithm for trees

Liu [18] proposes an algorithm to find an optimal tree traversal for peak memory minimization. Liu’s original work concerns a different model where there is no edge weights (there are only vertex weights). We present here its immediate adaptation to our model.

Liu’s algorithm is shown in Algorithm 1. To compute an optimal traversal for a tree rooted at vertex $k$, it recursively computes an optimal traversal for the subtrees rooted at the children of $k$, then merges theses optimal traversals, and finally appends $k$ to the end. Merging the traversals of the children is the sophisticated part of the algorithm. There is no reason to schedule the subtrees one after the other; an optimal schedule may switch from one subtree to another. Liu makes the observation that in an optimal traversal the switching points between the subtrees’ processing have to be local minima in the memory.
Algorithm 1 Liu-Tree-Schedule($T$)

 Require: $T = (V, E, w_n, w_e)$: tree with vertex- and edge-weights.

 Ensure: $\pi$: Schedule with the minimum peak memory $\mu(\pi)$

 $\triangleright$ Base case
 if $V = \{u\}$ then
 return $\langle u \rangle$

 $\triangleright$ General case
 Let $r$ be the root of $T$ and $T_1, T_2, \ldots, T_k$ its subtrees
 for $i = 1$ to $k$ do
 $\quad \pi_i \leftarrow$ Liu-Tree-Schedule($T_i$)
 $\quad$ Compute the hill-valleys segments $s_1^i, \ldots, s_k^i$ of $T_i$ in schedule $\pi_i$ as in Definition 3
 $\quad$ Sort all segments of all subtrees in non-increasing ($\text{hill} - \text{valley}$) value
 $\quad$ Based on this segment ordering, order the vertices in each segment consecutively, followed by the root $r$, to build $\pi$. Within each segment $s_i^j$, vertices are ordered according to $\pi_i$.

 profile: while processing one subtree $T_i$, there is no reason to switch to $T_j$ if one can reduce the memory needed for $T_i$ by processing one more task in $T_i$. This leads to slicing the traversal into atomic parts, called segments. The end-points of segments (which are some particular local minima in the memory profile) are called valleys, while the peak memory vertices of each segment are called hills. The segments and their hill/valley values are formally defined as follows.

 Definition 3. Let $G$ be an in-trees and $\pi$ be a traversal of $G$. The first segments of $\pi$ consists in nodes $u \leq_\pi v_1$ and the $i$th segments of $\pi$ (for $i \geq 2$) contains nodes $u$ such that $v_{i-1} <_\pi u \leq_\pi v_i$ with:

 $\bullet$ $M_i^h$ is the peak memory of the whole traversal;
 $\bullet$ $M_i^v$ is the minimum amount of memory occurring after the step when $M_i^h$ is (last) attained, for $i \geq 1$;
 $\bullet$ $M_i^v$ is (last) attained on $v_i$, for $i \geq 1$;
 $\bullet$ $M_i^h$ (for $i \geq 2$) is the peak memory after $v_i$.

 The sequence of hill-valley ends when the last vertex is reached. The segments consist of the vertices comprised between two valleys. For example, for the tree depicted in Figure 1a, consider the traversal $(A, B, C, D, E)$ of the subtree rooted in $E$. The memory occupation during and after the processing of the tasks and the segments that are deduced from this memory profile are illustrated in Figure 1c. Similarly, the segments of the traversal $(F, G)$ of the subtree rooted in $G$ are detailed on Figure 1d.

 To merge the traversals of the subtrees, the first step is to compute all hill-valley segments. Then the lists of segments are merged using the following criterion: if several segments are available (one for each subtree in the beginning), it is always beneficial to start with the segment with the maximum ($\text{hill} - \text{valley}$)
difference. Intuitively, the residual memory will only increase when processing segments, so it seems better to start with (i) segments with larger peak memory (hill) to avoid large memory consumption later, and (ii) segments with smaller residual memory (valley) to ensure an increase of memory as small as possible. The tradeoff between both criteria is obtained using the difference \((\text{hill} - \text{valley})\).

In the example of Figure 1, when merging the traversals from the subtrees rooted at \(E\) and \(G\) at the vertex \(H\), we start by comparing the first segments of each subtree: segment \((F)\) is selected because it has a larger \((\text{hill} - \text{valley})\) value of \(9 - 1 = 8\). This segment is ordered, and then removed from the segments list, and we proceed by comparing segments \((A,B)\) and \((G)\): \((A,B)\) has larger \((\text{hill} - \text{valley})\) value of \(8 - 1 = 7\), so it is selected. By iterating this process, we end up with the following ordering: \((F), (A,B), (C,D,E), (G)\). The last step is to add the root \(H\) of the subtree to the traversal.

Liu proves that Algorithm 1 is correct and its worst-case runtime complexity is \(O(n^2)\). We note that even if this algorithm is designed for in-trees, we can compute an optimal schedule of an out-tree by reversing all edges to obtain an in-tree, applying this algorithm, and then reversing the obtained schedule.

3.2. Algorithm for parallel-chain graphs

The main idea (summarized in Fig. 2) is to remove one edge from each chain, so as to disconnect the graph into one out-tree (the part \(S\) in the figure) and one in-tree (the part \(T\) in the figure). Then, we can reuse Liu’s algorithm to compute an optimal traversal for these two trees. The following lemma states that if the removed edges are of minimal weight in each chain, it is possible to first schedule all the vertices that are before this minimal cut, and then all the vertices after the cut, without increasing the peak memory.

**Lemma 1.** Let \(G\) be a parallel-chain graph. For each chain \(C_i\) of this graph, let \(e_i^{\text{min}} = (u_i^{\text{min}}, v_i^{\text{min}})\) be an edge of \(C_i\) with the minimum weight. Let \(S\) be the set of ancestors of the \(u_i^{\text{min}}\)'s, including them. Let \(T\) be the set of successors of the \(v_i^{\text{min}}\)'s, including them. Let \(\pi\) be a schedule of \(G\) and \(\gamma\) be the schedule obtained from \(\pi\) by scheduling all vertices of \(S\) before vertices of \(T\), formally \(\gamma = \langle \pi[S], \pi[T]\rangle\). Then, \(\mu(\gamma) \leq \mu(\pi)\).
This intuitive result can be proved by using Theorem 2, Corollary 1 and Theorem 1 given below. We do not formalize the proof, since the objective of this section is to give an intuition on the algorithm for general SP-graphs.

Thanks to this result, we know that there exists an optimal schedule which ordered first vertices from $S$, and then vertices from $T$. Assume for a moment that the weight of all $e_i^\text{min}$ edges is zero ($w_e(e_i^\text{min}) = 0$). Then, it is as if the graph was disconnected, and we have two separate trees to schedule. $T$ is an in-tree, and Liu’s algorithm can compute an optimal schedule $\pi$ for it. $S$ is an out-tree, so that $\bar{S}$ is an in-tree: if $\gamma$ is the optimal schedule computed by Liu’s algorithm for $\bar{S}$, $\bar{\gamma}$ is optimal for $S$. Then, $\langle \bar{\gamma}, \pi \rangle$ is an optimal schedule of the whole graph. This approach can be generalized to parallel-chain graphs with non-zero weights on the minimal edges, as stated in Algorithm 2. For such graph, the weight of the minimal edges is subtracted from all edges of a chain, and is added to the weight of all vertex of the chain (except the terminals). By setting $C = \sum_i w_e(e_i^\text{min})$, it is easy to verify that for any schedule $\pi$, the memory footprint during the execution of a node or after its execution in the modified graph is the same memory as in the original graph minus $C$. Thus, any optimal schedule for the modified graph is an optimal schedule for the original graph. We will prove that this algorithm computes an optimal schedule of all parallel-chain graphs (Theorem 8).

Algorithm 2 PARALLEL-CHAINS-SCHEDULE($T$)

Require: $PC = (V, E, w_n, w_e)$: parallel-chain graph with vertex- and edge-weights.

Ensure: $\pi$: Schedule with minimal peak memory $\mu(\pi)$

Let $C_1, \ldots, C_q$ be the chains of $PC$

for $i = 1$ to $q$ do

Let $e_i^\text{min} = (u_i^\text{min}, v_i^\text{min})$ be the edge of minimum weight in $C_i$

Remove the edge $e_i^\text{min}$ from the graph

Update the weight of each other edge $e$ of $C_i$: $w_e(e) \leftarrow w_e(e) - w_e(e_i^\text{min})$

Update the weight of each vertex $u$ in $C_i$ (except $s$ and $t$): $w_n(u) \leftarrow w_n(u) + w_e(e_i^\text{min})$

Consider the two trees $T^{\text{out}}$, $T^{\text{in}}$ obtained after the removal of $e_i^\text{min}, \ldots,$

Let $T^{\text{out}}$ be the in-tree obtained by reversing all edges in $T^{\text{out}}$

$\pi_1 \leftarrow \text{LIU-TREE-SCHEDULE}(T^{\text{out}})$

$\pi_2 \leftarrow \text{LIU-TREE-SCHEDULE}(T^{\text{in}})$

return $\langle \pi_1, \pi_2 \rangle$

4. Solving the peak memory problem for series-parallel graphs

This section contains the proposed polynomial time algorithm to compute a peak memory minimizing schedule of series-parallel graphs. Let us first give a verbal overview of the final algorithm. As is common, the algorithm relies on the recursive structure of the series-parallel graphs. To solve the peak memory
problem for a series-parallel graph $G$ which is a composition of $G_1$ and $G_2$, we first recursively solve the peak memory problem on $G_1$ and $G_2$. If $G$ is a series composition of $G_1$ and $G_2$, it is straightforward to obtain a schedule for $G$ by concatenating those for $G_1$ and $G_2$. If $G$ is a parallel composition of $G_1$ and $G_2$, we first create a chain (according to the optimal schedules found) for $G_1$ and $G_2$. By identifying the terminal vertices in $G_1$ and $G_2$, we obtain a parallel-chain graph on which the peak memory problem is solved using the algorithm proposed in Section 3.2. This results in a peak memory minimizing schedule for the initial graph $G$. The algorithm is simple and intuitive as it follows the recursive definition of series-parallel graphs. However, the proof of optimality of the algorithm is complex and involved. This is not surprising as it was also the case for Liu’s algorithm on trees [18], which extended an already involved algorithm [29].

The formal algorithm (Section 4.4) is an adaptation of Liu’s algorithm for vertex weighted trees. In order to facilitate this adaptation, we define a new graph model (presented in Section 4.1) in which we have only vertex weights. This model is simpler, yet expressive enough to capture the peak memory objective. We then define a new relation on schedules and a new objective function (Sections 4.2 and 4.3) in this model that are needed to obtain the proof of its optimality (which is presented in Section 4.5). Some of the detailed proofs are delegated to the Appendix.

4.1. A simpler model with only vertex weights

We introduce here a new graph model, called the cumulative weight model, which has only vertex weights (no edge weights). We prove that this model can emulate the peak-memory minimization problem. Formally, let $G = (V, E, \omega)$, where $\omega : V \to \mathbb{Z}$ is a weight function on the vertices. For a given set $U \subseteq V$ of vertices, $\omega(U)$ denotes the sum of weights of vertices in $U$, i.e., $\omega(U) = \sum_{v \in U} \omega(v)$. The vertex-weight function $\omega$ should satisfy $\omega(G) = 0$. Let $\pi$ be a schedule and for each vertex $v \in V$, consider the cumulative sum of the weights of all vertices scheduled before $v$:

$$\Sigma(v, \pi) = \omega(\{u \in V, u \leq \pi v\}) . \tag{1}$$

We define the cutwidth $\rho(\pi)$ of a schedule $\pi$ as the maximum of all these sums:

$$\rho(\pi) = \max_{p \in V} \omega(\{q \in V, q \leq \pi p\}) = \max_{p \in V} \Sigma(p, \pi) . \tag{2}$$

Figure 3 presents a simple SP graph in the cumulative weight model as well as three schedules $\pi$ with cutwidth 3 (which is minimal), and $\gamma$ and $\lambda$ with cutwidth 6.

Note that the cutwidth as defined in the cumulative weight model is a straightforward adaptation of the CUTWIDTH problem (or minimum cut linear arrangement) as presented in the introduction: from a graph with only edge weights $w_e$, for each edge $(i, j)$ we simply set $\omega(i) = w_e(i, j)$ and $\omega(j) = -w_e(i, j)$ to obtain the same problem with the cumulative weight model.
Thus, the algorithm presented below for SP-graphs in the cumulative weight model also solves the classical **Cut Width** problem on SP-graphs with edge weights. We now exhibit a similar reduction from the peak memory problem presented in Section 2.

### 4.1.1. Minimizing the cutwidth allows to minimize the peak memory

Below (Theorem 1), we show that by minimizing the cutwidth in the cumulative weight model, one can minimize the peak memory in the original model. For this purpose we need some definitions. Given an instance \( G = (V,E,w_n,w_e) \) of the peak memory problem, we construct an instance of the cumulative weight problem, with a (directed) bipartite graph \( G_B = (V_B,E_B,\omega) \) as follows. For each vertex \( p \in V \), we introduce a pair of vertices \( p_{\text{start}}, p_{\text{stop}} \in V_B \) such that \( (p_{\text{start}}, p_{\text{stop}}) \in E_B \). The vertex \( p_{\text{start}} \) represents the beginning of the computation corresponding to the task \( p \), while \( p_{\text{stop}} \) represents the end of this computation. For each edge \( (p,q) \in E \), we add an edge \( (p_{\text{stop}}, q_{\text{start}}) \in E_B \). For each vertex \( p \), we set

\[
\omega(p_{\text{start}}) = w_n(p) + \sum_{(p,r) \in E} w_e(p, r),
\]

(3)

to represent the allocation of temporary and output data in the memory at the beginning of the task \( p \), and

\[
\omega(p_{\text{stop}}) = -w_n(p) - \sum_{(q,p) \in E} w_e(q, p),
\]

(4)

to represent the deallocation of temporary and input data from the memory at the end of the task \( p \). Note that with these definitions \( \omega(G_B) = 0 \). Let \( \pi_B \) be a schedule of \( G_B \). It is easy to see that a schedule can be constructed for \( G \) using the order of “stop” vertices in \( \pi_B \). Given \( \pi_B \), let \( \pi \) be a schedule of \( G \) such that \( p \leq_{\pi} q \) whenever \( p_{\text{stop}} \leq_{\pi_B} q_{\text{stop}} \). Observe that \( \sum(v_{\text{stop}}, \pi_B) = \sum_{x \leq v < y} w_e(x,y) \), that is the cumulative weight of \( v_{\text{stop}} \) corresponds to the weight of the edges (in \( G \)) which are cut by an imaginary line just after \( v \) under
the schedule \( \pi \). We now show how minimizing the cutwidth in \( G_B \) minimizes
the peak memory in \( G \).

**Theorem 1.** Let \( \pi_B \) be a schedule of \( G_B \) whose cutwidth \( \rho(\pi_B) \) is minimum for \( G_B \) and \( \pi \) be the corresponding schedule of \( G \). Then, \( \mu(\pi) \) is the minimum peak memory for \( G \).

**Proof.** — We provide the outline of the proof by using lemmas proved in Appendix A. By Lemma A.4, we can assume without loss of generality that \( p_{\text{start}} \) and \( p_{\text{stop}} \) are consecutive for all \( p \) in \( \pi_B \). This implies that \( \mu(\pi) = \rho(\pi_B) \) by Lemma A.3. Suppose for the sake of contradiction that \( \mu(\pi) \) is not minimum. In other words, there is a schedule \( \gamma \) of \( G \) where \( \mu(\gamma) < \mu(\pi) \). Then, we can construct \( \gamma_B \) for \( G_B \) from \( \gamma \) by replacing each vertex \( p \) with \( p_{\text{start}} \) and \( p_{\text{stop}} \). By Lemma A.3 again, \( \mu(\gamma) = \rho(\gamma_B) \) and hence \( \rho(\gamma_B) < \rho(\pi_B) \), a contradiction. \( \square \)

### 4.1.2 Reverse graph in the cumulative weight model

We now show a few useful results in the proposed cumulative weight model that uses the reverse graph. Remember that in our final algorithm, we will disconnect a parallel composition into both an in-tree and an out-tree, and that we will apply Liu’s algorithm on the reverse of the in-tree. Thus, it is important that to determine the cutwidth of the reverse graph, as done in the following two lemmas.

We first recall and extend the notion of reverse graph from Section 2 to the vertex-weighted model. Given a graph \( G = (V, E, \omega) \), its reverse graph \( \bar{G} = (V, \bar{E}, \bar{\omega}) \) has the same set of vertices as \( G \), however all edges are reversed \( \bar{E} = \{(q, p) : (p, q) \in E\} \) and all vertex weights take the opposite sign of their value in \( G \): \( \bar{\omega}(p) = -\omega(p) \) for any \( p \in V \). The reverse of a schedule \( \pi \) is defined as in Section 2: \( q \leq_{\pi} p \) whenever \( p \leq_{\pi} q \), for any pair of vertices \( p, q \).

The first result links the cumulative sums up to some vertex \( p \) in both \( \pi \) and \( \bar{\pi} \).

**Lemma 2.** For any vertex \( p \in G \), we have

\[
\Sigma(p, \pi) - \Sigma(p, \bar{\pi}) = \omega(p),
\]

where \( \Sigma(p, \pi) \) and \( \Sigma(p, \bar{\pi}) \) are defined over \( G \) and \( \bar{G} \), respectively.

**Proof.** — Notice that \( \{ q \leq_{\pi} p \} = \{ q \geq_{\pi} p \} \) due to the definition above. Recall that \( \omega(G) = 0 \), and thus \( \bar{\omega}(\bar{G}) = -\omega(G) = 0 \). Then,

\[
\Sigma(p, \bar{\pi}) = \bar{\omega}(\{ q \leq_{\pi} p \}) = \omega(\{ q \geq_{\pi} p \}) \\
= \bar{\omega}(\bar{G}) - \bar{\omega}(\{ q <_{\pi} p \}) \\
= -\bar{\omega}(\{ q <_{\pi} p \}) \\
= \omega(\{ q <_{\pi} p \}) = \Sigma(p, \pi) - \omega(p).
\]

\( \square \)
The second result shows that a schedule \( \pi \) has the same cutwidth as its reverse \( \bar{\pi} \).

**Lemma 3.** For any schedule \( \pi \) of \( G \), \( \rho(\pi) = \rho(\bar{\pi}) \).

**Proof.** Let \( \bar{p}^* \) be a vertex such that \( \rho(\bar{\pi}) = \Sigma(\bar{p}^*, \bar{\pi}) \) and \( q \) be its predecessor under \( \pi \). Then,
\[
\rho(\pi) \geq \Sigma(q, \pi) = \Sigma(\bar{p}^*, \pi) - \omega(\bar{p}^*) \quad \text{by Equation (5)}
\]
\[
= \Sigma(\bar{p}^*, \pi) - \omega(\bar{p}^*) = \rho(\bar{\pi}).
\]

By noting that the roles of \( \pi \) and \( \bar{\pi} \) can be changed in the above lines, we obtain \( \rho(\bar{\pi}) \geq \rho(\pi) \) and hence the equality \( \rho(\pi) = \rho(\bar{\pi}) \). \qed

### 4.2. A new relation on schedules

We present here a relation on schedules, denoted by \( \preceq \). In order to prove the optimality of our algorithm, we first prove that it produces a schedule which is minimal for \( \preceq \), and that this implies cutwidth optimality. The \( \preceq \) relation is stronger than cutwidth comparison and includes all the assumptions needed for the induction. This reasoning is largely implies by Liu’s proof for trees [18], and the new relation itself is the translation of the partial orders on subtree schedules that he introduced.

#### 4.2.1. Definition of the relation on schedules

Given a directed graph \( G \), two vertices \( p \) and \( q \) of \( G \), and two schedules \( \pi \) and \( \gamma \) of \( G \), we say that the schedule \( \pi \) at \( p \) dominates the schedule \( \gamma \) at \( q \) (and we write \( p \rightarrow_{\pi} \gamma q \)) if and only if

C1. \( \Sigma(p, \pi) \leq \Sigma(q, \gamma) \), and

C2. \( \min\{\Sigma(s, \pi) : s \geq \pi p\} \leq \min\{\Sigma(r, \gamma) : r \geq \gamma q\} \).

Note that the second condition (C2) is equivalent to stating that for any \( r \geq \gamma q \), there exists \( s \geq \pi p \) such that \( \Sigma(s, \pi) \leq \Sigma(r, \gamma) \).

Now, we define the relation \( \preceq \) on the set of schedules for \( G \) as follows.

**Definition 4 (Relation \( \preceq \)).** Let \( \pi \) and \( \gamma \) be two schedules of \( G \). We say that \( \pi \preceq \gamma \) for \( G \), if for each \( p \in G \), there is a vertex \( q \in G \) such that \( p \rightarrow_{\pi} \gamma q \).

In the sample graph presented in Fig. 3, we have \( \pi \preceq \gamma \) and \( \pi \preceq \lambda \) since for each vertex \( p \), \( p \rightarrow_{\pi} \gamma E \) and \( p \rightarrow_{\pi} \lambda E \). We also have \( \gamma \preceq \lambda \) and \( \lambda \preceq \gamma \) since
\[
\text{for } p \in \{A, B, C, E, F\}, \quad p \rightarrow_{\pi} \gamma B \text{ and } p \rightarrow_{\pi} \gamma E,
\]
\[
\text{for } p \in \{D, G, H\}, \quad p \rightarrow_{\lambda} \gamma G \text{ and } p \rightarrow_{\lambda} \gamma G.
\]

This example illustrates that the \( \preceq \) relation is not anti-symmetric, therefore it is not a partial order (in Liu’s case [18], the relation is partial order). We prove that \( \preceq \) is reflexive and transitive, and thus is a preorder.
Lemma 4. The relation $\preceq$ is a preorder (reflexive and transitive).

**Proof.** We need to show that the relation $\preceq$ is both reflexive and transitive. Let $\alpha$, $\beta$, and $\theta$ be schedules of $G$.

(i) **Reflexivity.** Since $p \rightarrow_{\alpha} p$ for each $p \in V$, $\alpha \preceq \alpha$, and thus, $\preceq$ is reflexive.

(ii) **Transitivity.** Assume that $\alpha \preceq \beta$ and $\beta \preceq \theta$. Take any $p \in G$. Let $v$ and $q$ be such that $p \rightarrow_{\alpha} \beta v$ and $v \rightarrow_{\beta} q$. We claim that $p \rightarrow_{\theta} q$, as well.

There are two conditions we should examine.

1) (C1). This follows as $\Sigma(p, \alpha) \leq \Sigma(v, \beta)$ and $\Sigma(v, \beta) \leq \Sigma(q, \theta)$, due to the first conditions of $p \rightarrow_{\alpha} \beta v$ and $v \rightarrow_{\beta} q$.

2) (C2). Take any vertex $r \geq_{\theta} q$. Then, there exists $s \geq_{\alpha} p$ and $w \geq_{\beta} v$ such that $\Sigma(s, \alpha) \leq \Sigma(w, \beta) \leq \Sigma(r, \theta)$, as a consequence of the second conditions of $p \rightarrow_{\alpha} \beta v$ and $v \rightarrow_{\beta} q$.

$\square$

4.2.2. **Minimality for the $\preceq$ relation implies cutwidth optimality**

In the example of Fig. 3, we noticed that $\pi \preceq \gamma$ and $\pi \preceq \lambda$ while $\pi$ has a smaller cutwidth than both $\gamma$ and $\lambda$. This is actually a major property of the $\preceq$ relation: it implies a comparison on the cutwidth, not only for the schedules being compared but also for their reverse schedule, as expressed by the following lemma and its corollary.

Lemma 5. If $\pi \preceq \gamma$ then $\rho(\pi) \leq \rho(\gamma)$ and $\rho(\bar{\pi}) \leq \rho(\bar{\gamma})$.

**Proof.** Assume that $\pi \preceq \gamma$. Then for any $p \in V$, there exists $q \in V$ such that $p \rightarrow_{\pi} q$, and thus, $\Sigma(p, \pi) \leq \Sigma(q, \gamma)$. Then, by definition, $\rho(\pi) \leq \rho(\gamma)$. Moreover, thanks to Lemma 3, we have $\rho(\bar{\gamma}) = \rho(\gamma) \geq \rho(\pi) = \rho(\bar{\pi})$. $\square$

**Corollary 1.** If $\pi$ is minimal for $\preceq$ on $G$, then $\pi$ and $\bar{\pi}$ have the minimum cutwidths (on $G$ and $\bar{G}$ respectively).

4.3. **Min-cut optimality**

We are now ready to present the central notion needed to provide an optimal algorithm for series-parallel graphs, namely the min-cut optimality. We show that a min-cut optimal schedule is also cutwidth optimal.
4.3.1. Definition of min-cut optimality

Min-cut optimality is based on the classical notion of cut in a graph: a cut \((S, T)\) of \(G\) is defined as a bisection of its vertices into two nonempty sets \(S\) and \(T\). We say that a cut is topological if there exists no edge \((p, q)\) \(\in E\) such that \(p \in T\) and \(q \in S\) (or equivalently, for any edge \((p, q)\) \(\in E\), we have either \(p \in S\) or \(q \in T\)). The width of a topological cut \((S, T)\) is defined as \(c(S, T) = \omega(S)\).

Consider a topological cut \((S, T)\) and a schedule \(\pi\). If in \(\pi\) all vertices of \(S\) appear before all vertices of \(T\), that is, for \(p \in S\) and \(q \in T\), we have \(p \leq \pi q\), then we say that \(\pi\) is in compliance with \((S, T)\). In this case, we have \(c(S, T) = \Sigma(p^*, \pi)\), where \(p^* = \max^\pi S\).

We say that a topological cut \((S, T)\) is minimum, or a min-\(\omega\)-cut, if its width is minimum, that is,

\[ c(S, T) = \min\{c(S', T') \text{ where } (S', T') \text{ is a topological cut}\}. \]

We define by \(G[S]\) the subgraph of \(G\) which contains only the vertices in \(S\) and the edges between these vertices. Similarly, for any schedule \(\pi\) of \(G\), \(\pi[S]\) is the schedule induced by \(\pi\) on \(G[S]\).

**Definition 5 (Min-cut optimality).** Let \((S, T)\) be a minimum topological cut. A schedule \(\pi\) is cut-optimal with \((S, T)\), if \(\pi\) is in compliance with \((S, T)\), \(\pi[S]\) is minimal for \(\preceq\) on \(G[S]\), and \(\pi[T]\) is minimal for \(\preceq\) on \(G[T]\). Furthermore, \(\pi\) is called min-cut optimal if \(\pi\) is cut-optimal with some min-\(\omega\)-cut of \(G\).

We now state a simple lemma which will be useful in the following.

**Lemma 6.** Let \(\pi\) be a schedule of \(G\). Let \((S, T)\) be any minimum topological cut of \(G\). Then,

\[ c(S, T) \leq \Sigma(p, \pi), \]

for any \(p < \pi \max^\pi G\).

**Proof.** — Take any \(p < \pi \max^\pi G\). Then suppose for the sake of contradiction that \(\Sigma(p, \pi) < c(S, T)\). Consider the topological cut \((S^p, T^p)\), where \(S^p = \{v \leq \pi p\}\). Then, by (6), we have \(c(S^p, T^p) = \omega(S^p) = \Sigma(p, \pi) < c(S, T)\), which contradicts that \(c(S, T)\) is minimum. \(\square\)

4.3.2. Properties of min-cut optimality

We present two important properties of min-\(\omega\)-cuts. The first property, shown in the next theorem, is that transforming a schedule so that it is in compliance with a min-\(\omega\)-cut will not make it larger in the sense of the \(\preceq\) relation (and thus, thanks to Lemma 5, will not increase its cutwidth). It generalizes Lemma 1, which was limited to parallel-chain graphs and expressed in the original graph model.
Theorem 2. Let $G$ be an acyclic graph with a single source vertex and a single sink vertex, and $\gamma$ be a schedule of $G$. Let $(S,T)$ be a min-$\omega$-cut of $G$, and $\pi = \langle \gamma[S], \gamma[T] \rangle$. Then, $\pi \preceq \gamma$ and $\overline{\pi} \preceq \overline{\gamma}$.

Proof — Since $(S,T)$ is a topological cut of $G$, $\pi$ is a schedule of $G$. Note that $\gamma$ may not be in compliance with $(S,T)$.

The proof relies on the two following properties: for each $p \in G$, $p \rightarrow \pi \gamma p$ (which proves that $\pi \preceq \gamma$ according to the definition of this relation) and $p \rightarrow \overline{\pi} \overline{\gamma} p$ (which proves $\overline{\pi} \preceq \overline{\gamma}$). We only provide the proof of the first property, as the second one can be proved using the very same arguments.

Let $s^+$ be the last scheduled vertex of $S$ in $\gamma$. Similarly, let $t^-$ be the first scheduled vertex of $T$ in $\gamma$. Formally, $s^+ = \max \gamma S$, $t^- = \min \gamma T$.

Note that $s^+$ is also the last scheduled vertex of $S$ in $\pi$ (and $t^-$ the first scheduled vertex of $T$ in $\pi$) and $\Sigma(s^+, \pi) = c(S,T)$.

To prove that $p \rightarrow \pi \gamma p$ for $p \in G$, we investigate $\Sigma(p, \pi)$ and $\Sigma(p, \gamma)$. First, for any $p \in V$, we consider $s_p$ (respectively $t_p$), the last scheduled vertex of $S$ (resp. of $T$) that does not come after $p$ in $\gamma$:

$$s_p = \max \gamma \{ s \in S, s \leq \gamma p \}, \quad t_p = \max \gamma \{ t \in T, t \leq \gamma p \}.$$  

Note that $s_p$ is always defined since $G$ has a single source vertex. However, $t_p$ may not be defined, as the set $\{ t \in T, t \leq \gamma p \}$ may be empty, which occurs when $p \in S$ and $p$ comes before $t^-$ in $\gamma$; in this case $p = s_p$. If $t_p$ is defined, we have:

$$\Sigma(p, \gamma) = \Sigma(s_p, \gamma[S]) + \Sigma(t_p, \gamma[T]) = \Sigma(s_p, \pi[S]) + \Sigma(t_p, \pi[T]) = \Sigma(s_p, \pi) + \Sigma(t_p, \pi) - \Sigma(s^+, \pi) = \Sigma(s_p, \pi) + \Sigma(t_p, \pi) - c(S,T).$$  

As a result,

$$\Sigma(p, \gamma) = \left\{ \begin{array}{ll} \Sigma(p, \pi) & \text{if } t_p \text{ is not defined,} \\ \Sigma(t_p, \pi) + \Sigma(s_p, \pi) - c(S,T) & \text{otherwise.} \end{array} \right. \quad (8)$$

We are now ready to show $p \rightarrow \pi \gamma p$, for any $p \in V$. We verify the two conditions defining this statement given in Section 4.2.1 for any $p \in V$, as follows.

1. The first condition to verify is C1: $\Sigma(p, \pi) \leq \Sigma(p, \gamma)$. When $t_p$ is not defined, this condition directly derives from Equation (8). Consider now that $t_p$ is defined. We consider two cases depending on which side of the cut $p$ lies:
(a) \( (p \in S) \). Then, \( s_p = p \). This implies
\[
\Sigma(p, \gamma) = \Sigma(p, \pi) + \Sigma(t_p, \pi) - c(S, T).
\]
Note that \( t_p <_\gamma p <_\gamma \max^\gamma G = \max^\pi G \), since \( p \in S \). Since \( \Sigma(t_p, \pi) \geq c(S, T) \) by Lemma 6 applied on \( \pi \), the condition C1 is met.

(b) \( (p \in T) \). Then, \( t_p = p \). This implies
\[
\Sigma(p, \gamma) = \Sigma(p, \pi) + \Sigma(s_p, \pi) - c(S, T).
\]
Note that \( s_p <_\gamma \max^\gamma G = \max^\pi G \), since \( s_p \in S \). Since \( \Sigma(s_p, \pi) \geq c(S, T) \) by Lemma 6, the condition C1 is met.

2. The second condition to verify (C2) is
\[
\min\{\Sigma(s, \pi) : s \geq_\pi p\} \leq \min\{\Sigma(r, \gamma) : r \geq_\gamma p\}
\]
(or equivalently, for any \( r \geq_\gamma p \), there exists \( s \geq_\pi p \) such that \( \Sigma(s, \pi) \leq \Sigma(r, \gamma) \)). First, note that the last vertex is the same in both schedules: \( r_{\text{end}} = \max^\pi G = \max^\gamma G \) and thus \( \Sigma(r_{\text{end}}, \pi) = \Sigma(r_{\text{end}}, \gamma) \). Now, consider any \( r \geq_\gamma p \) such that \( r <_\gamma \max^\gamma G \). We consider the two following cases:

a) \( p \) is in \( S \). Then, \( \Sigma(s^+, \pi) = c(S, T) \leq \Sigma(r, \gamma) \) and \( s^+ \geq_\pi p \).

b) \( p \) is in \( T \). Let \( t_r = \max^\gamma \{t \in T, t \leq_\gamma r\} \). Note that \( t_r \) is well defined, since \( r \geq_\gamma p \). We also have \( t_r \geq_\gamma p \). Then, by Equation (7),
\[
\Sigma(r, \gamma) = \Sigma(s_r, \pi) + \Sigma(t_r, \pi) - c(S, T).
\]
Since \( \Sigma(s_r, \pi) \geq c(S, T) \) by Lemma 6, we have \( \Sigma(t_r, \pi) \leq \Sigma(r, \gamma) \).
Notice that \( t_r \geq p \) since \( t_r \geq_\gamma p \) and, both \( p \in T \) and \( t_r \in T \).

\( \Box \)

The second property of min-\( \omega \)-cuts explains the relevance of min-cut optimality. It states that, for a schedule \( \pi \), being min-cut optimal implies optimality for the \( \leq \) relation both for \( \pi \) and its reverse \( \bar{\pi} \).

**Theorem 3.** Let \( G \) be a directed acyclic graph with a single source vertex and a single sink vertex, and \( \pi \) be a min-cut optimal schedule of \( G \). Then, \( \pi \) is minimal for \( \leq \) on \( G \) and \( \bar{\pi} \) is minimal for \( \leq \) on \( G \).

**Proof** — Consider a directed acyclic graph \( G \) with single source and sink vertices, and a min-cut optimal schedule \( \pi \). Since \( \pi \) is min-cut optimal, \( \pi \) is cut-optimal with some min-\( \omega \)-cut \((S, T)\). Take any schedule \( \lambda \) of \( G \), and consider the schedule \( \gamma = (\lambda[S], \lambda[T]) \), which is in compliance with \((S, T)\). We have \( \gamma \leq \lambda \) and \( \bar{\gamma} \leq \lambda \) by Theorem 2. Here, we only show \( \pi \leq \gamma \) for \( G \) (which
induces $\pi \preceq \lambda$, as with similar arguments one can also show $\bar{\pi} \preceq \bar{\gamma}$ (which induces $\bar{\pi} \preceq \bar{\lambda}$).

By the definition of a min-cut optimal schedule, $\bar{\pi}[S]$ (respectively $\bar{\pi}[T]$) is minimal for $\preceq$ on $S$ (resp. on $T$), thus $\bar{\pi}[S] \preceq \bar{\gamma}[S]$ and $\bar{\pi}[T] \preceq \bar{\gamma}[T]$. We show that for any vertex $p \in V$, there is a vertex $q \in V$ such that $p \xrightarrow{\pi} \gamma q$. We consider a vertex $p \in V$ and distinguish two cases depending where $p$ lies:

1. $(p \in S)$. Let $q$ be such that $\Sigma(q, \gamma[S]) = \rho(\gamma[S])$. We show $p \xrightarrow{\pi} \gamma q$ by examining the two conditions.
   
   (a) (C1: $\Sigma(p, \pi) \leq \Sigma(q, \pi)$). Since $\bar{\pi}[S] \preceq \bar{\gamma}[S]$, by Corollary 1 we have $\rho(\pi[S]) \leq \rho(\gamma[S])$. Hence,
   
   $$\Sigma(p, \pi) \leq \rho(\pi[S]) \leq \rho(\gamma[S]) = \Sigma(q, \gamma).$$  

   (b) (C2: $\min\{\Sigma(s, \pi) : s \geq p\} \leq \min\{\Sigma(r, \gamma) : r \geq q\}$). Let $t$ be the sink vertex. Note that $\Sigma(t, \pi) \leq \Sigma(t, \gamma)$ and $t \geq_p p$. Take any $r \geq \gamma q$ and $r \prec T$. For $t^+ = \max^\pi\{s \in S\}$, we have $\Sigma(s^+, \pi) = c(S, T) \leq \Sigma(r, \gamma)$. Notice that $s^+ \geq_p p$, as $p \in S$.

2. $(p \in T)$. Let $q$ be such that $p \xrightarrow{\pi[T]} \gamma[T]$; such a $q$ exists, because $\pi[T] \preceq \gamma[T]$. We show $p \xrightarrow{\pi} \gamma, q$ by examining the two conditions:
   
   (a) (C1: $\Sigma(p, \pi) \leq \Sigma(q, \gamma)$). It holds that
   
   $$\Sigma(p, \pi) = \Sigma(p, \pi[T]) + \Sigma(s^+, \pi[S]) \quad (9)$$
   $$\leq \Sigma(q, \gamma[T]) + \Sigma(s^+, \pi[S]) \quad (10)$$
   $$= \Sigma(q, \gamma[T]) + \Sigma(s^+, \gamma[S]) = \Sigma(q, \gamma). \quad (11)$$

   Equations (9) and (11) come from the fact that $\pi$ and $\gamma$ are in compliance with $(S, T)$. Equation (10) is derived from (9) and $p \xrightarrow{\pi[T]} \gamma[T]$.

   (b) (C2: $\min\{\Sigma(s, \pi) : s \geq p\} \leq \min\{\Sigma(r, \gamma) : r \geq q\}$). Take any $r \geq \gamma q$. Then, there exists $s \geq_p p$ such that $\Sigma(s, \pi[T]) \leq \Sigma(r, \gamma[T])$. Then,
   
   $$\Sigma(s, \pi) = \Sigma(s, \pi[T]) + \Sigma(s^+, \pi[S])$$
   $$\leq \Sigma(r, \gamma[T]) + \Sigma(s^+, \pi[S])$$
   $$= \Sigma(r, \gamma[T]) + \Sigma(s^+, \gamma[S]) = \Sigma(r, \gamma).$$

   $\square$

Note that the previous two theorems only apply to directed graphs with a single source and a single sink, and thus in particular to series-parallel graphs. However, it is easy to transform any directed graph so that it obeys these conditions: simply add two zero-weight artificial vertices, one for the source and one for the sink, connect all sources of the original graph to the new source, and connect the new sink to all original sinks.
4.4. Algorithm for general series-parallel graphs

We present here our main contribution, which is a recursive algorithm, called SP-Schedule, that computes a min-cut optimal schedule for a series-parallel graph $G$ in the cumulative weight model. As presented before, this means that the computed schedule is cut-optimal with some min-$\omega$-cut $(S, T)$ and implies that it also minimizes the cutwidth. The algorithm also outputs this $(S, T)$ cut.

This algorithm relies on an algorithm to compute a min-cut optimal schedule of a parallel-chain graph, PC-Schedule which is presented below. This algorithm for parallel-chain graphs is similar to Algorithm 2, but applies to our new cumulative weight model. Likewise, this latter algorithm relies on an algorithm for trees, Tree-Schedule, which is the translation of Liu’s algorithm for the cumulative weight model.

Algorithm 3 SP-Schedule($G$)

Require: $G = (V, E, \omega)$: series-parallel graph.
Ensure: $\pi$: schedule and $(S, T)$: min-$\omega$-cut

Base case
\begin{itemize}
  \item if $|E| = 1$ then
    $(S, T) \leftarrow (\{v\}, \{w\})$
    \textbf{return} $[\langle v, w \rangle, (S, T)]$
\end{itemize}

Series or parallel comb. of $G_1 = (V_1, E_1, \omega)$ and $G_2 = (V_2, E_2, \omega)$
\begin{itemize}
  \item $[\pi_1, (S_1, T_1)] \leftarrow$ SP-Schedule($G_1$)
  \item $[\pi_2, (S_2, T_2)] \leftarrow$ SP-Schedule($G_2$)
\end{itemize}

Series Composition
\begin{itemize}
  \item if $G = (G_1, G_2)$ then
    $(S, T) \leftarrow \arg\min \{(S_1 \cup T_2, T_1 \cup T_2)\}$
    \textbf{return} $[(\pi_1, \pi_2), (S, T)]$
\end{itemize}

Parallel Composition
\begin{itemize}
  \item if $G = \{G_1, G_2\}$ then
    $\tilde{G}_1 \leftarrow \text{Linearize}(G_1, \pi_1)$
    $\tilde{G}_2 \leftarrow \text{Linearize}(G_2, \pi_2)$
    $(S, T) \leftarrow (S_1 \cup S_2, T_1 \cup T_2)$
    $\pi \leftarrow \text{PC-Schedule}(\tilde{G}_1 \cup \tilde{G}_2, (S, T))$
    \textbf{return} $[\pi, (S, T)]$
\end{itemize}

The base case of the algorithm considers a series-parallel graph with a single edge, and outputs the unique schedule along with the unique topological cut.

In the general case, $G$ is a series or parallel composition of two smaller series-parallel graphs $G_1$ and $G_2$. We first recursively compute schedules $\pi_1$ and $\pi_2$ that are cut-optimal with topological cuts $(S_1, T_1)$ and $(S_2, T_2)$ for $G_1$ and $G_2$.

If $G$ is a series composition, the final schedule is obtained through a simple concatenation of $\pi_1$ and $\pi_2$. This schedule of $G$ is cut-optimal with both
topological cuts induced by \((S_1, T_1)\) and \((S_2, T_2)\) on \(G\). Thus, we select the one with lower cutwidth as it is a min-\(\omega\)-cut of \(G\). Therefore, \(\pi\) is a min-cut-optimal schedule of \(G\).

In case of parallel composition, we transform each subgraphs \(G_1\) and \(G_2\) into a chain using \textsc{Linearize}, based on schedules \(\pi_1\) and \(\pi_2\), respectively: \(\tilde{G}_1\) (resp. \(\tilde{G}_2\)) is a chain with the same vertices as \(G_1\) (resp. \(G_2\)) such that its unique topological order is \(\pi_1\) (resp. \(\pi_2\)). The graph obtained by replacing \(G_1\) and \(G_2\) by \(\tilde{G}_1\) and \(\tilde{G}_2\) is a parallel-chain graph with two chains. We consider the topological-cut \((S, T)\) obtained by unifying the min-\(\omega\)-cuts of \(G_1\) and \(G_2\): as we will prove later, it is a min-\(\omega\)-cut of the parallel-chain graph, but also of the original graph. We then call the routine \textsc{PC-Schedule} which finds a schedule \(\pi\) that is cut-optimal with this particular topological cut \((S, T)\).

\textbf{Algorithm 4} \textsc{PC-Schedule}(\(G, (S, T)\))

\textbf{Require:} \(G = (V, E, \omega)\): parallel-chain directed graph.
\textbf{Require:} \((S, T)\): Min-\(\omega\)-cut of \(G\).
\textbf{Ensure:} \(\pi\): Schedule

\)

\)

\)

Algorithm 4 presents \textsc{PC-Schedule}, which computes a schedule \(\pi\) that is cut-optimal with the given min-\(\omega\)-cut \((S, T)\) for a given parallel-chain graph \(G\). The algorithm simply divides the parallel-chain graph into two trees according to \((S, T)\). These trees have a special property: a subtree rooted at every vertex but the root itself has a non-negative total weight. This property follows from the fact that \((S, T)\) is a min-\(\omega\)-cut of \(G\). The algorithm then schedules the two trees independently using \textsc{Tree-Schedule} routine, which is a translation of Liu’s optimal algorithm for trees for the cumulative weight model, and can be found as Algorithm D.1 in Appendix D.

4.5. Correctness of the algorithm

We prove here that \textsc{SP-Schedule} computes a schedule which minimizes the cutwidth (and therefore, thanks to Theorem 1, it also minimizes peak memory). This result is expressed in Theorem 4.

\textbf{Theorem 4 (Main Theorem).} For any series-parallel graph, \textsc{SP-Schedule} computes a schedule \(\pi\) such that the cutwidth of \(\pi\) is optimal.

Theorem 4 is easily proved below once the following theorem is proved.

\textbf{Theorem 5.} For any series-parallel graph, \textsc{SP-Schedule} computes a schedule \(\pi\) and a min-\(\omega\)-cut \((S, T)\) such that \(\pi\) is min-cut optimal with \((S, T)\).

The proof of Theorem 5 is decomposed into several steps, following the different cases in the algorithm. These steps are formalized through the following three theorems.
The first step deals with the series composition. The following theorem states that concatenating two min-cut optimal schedules for the subgraphs leads to a min-cut optimal schedule of their series composition. This case seems straightforward, at least when considering cutwidth minimization: concatenating two schedules with minimal cutwidth on both subgraphs clearly gives a schedule with minimal cutwidth on the whole graph. However, this theorem is stronger and deserves more care as we need to prove min-cut optimality, that is minimality with respect to the \( \preceq \) relation.

**Theorem 6.** Let \( G_1 \) and \( G_2 \) be two series-parallel directed graphs. Let \( \pi_1 \) and \( \pi_2 \) each be a min-cut-optimal schedule of \( G_1 \) and \( G_2 \), respectively. Then, \( \pi = \langle \pi_1, \pi_2 \rangle \) is a min-cut-optimal schedule of their series composition \( G = \langle G_1, G_2 \rangle \).

**proof —** The statement follows as a corollary of Lemma B.1 in Appendix B. \( \square \)

The second step deals with the parallel composition. If we have a min-\( \omega \)-cut of a series-parallel directed graph and an optimal schedule of each part of this directed graph, then there is an optimal schedule of the whole graph which induces these two schedules. This theorem is used to compare the schedule returned by SP-SCHEDULE with an optimal one and show that it is indeed optimal itself.

**Theorem 7.** Let \( G_1 \) and \( G_2 \) be two series-parallel directed graphs, and \( G = \{ G_1, G_2 \} \) be their parallel composition. Let \( (S,T) \) be a min-\( \omega \)-cut of \( G \), and \( \pi_1 \) and \( \pi_2 \) be schedules that are cut-optimal with the topological cuts induced by \( (S,T) \) on \( G_1 \) and \( G_2 \), respectively. For each schedule \( \gamma \) in compliance with \( (S,T) \) of \( G \), there is a schedule \( \pi \) in compliance with \( (S,T) \) of \( G \) such that

(i) \( \pi \) induces \( \pi_1 \) and \( \pi_2 \),

(ii) \( \bar{\pi}[S] \preceq \bar{\gamma}[S] \) and \( \pi[T] \preceq \gamma[T] \).

**proof —** See Appendix C. \( \square \)

The final step is to prove that the PC-SCHEDULE algorithm used to process parallel-chain graphs produces a min-cut optimal schedule compatible with the provided cut.

**Theorem 8.** For any parallel-chain graph \( G \) and any min-\( \omega \)-cut \( (S,T) \) of \( G \), PC-SCHEDULE computes a schedule \( \pi \) that is cut-optimal with \( (S,T) \).

**proof —** See Appendix D. \( \square \)

We are now ready to prove the main theorem by proving Theorem 5.

**proof —** (Proof of Theorem 5) The proof is by induction on the number of edges of \( G \). In the base case, \( G \) has a single edge, that connects the source to the sinks. There is a unique schedule of \( G \), which is also cut-optimal with the unique topological cut.
We now assume that the theorem holds for any series-parallel graph with fewer than \( k \) edges, where \( k > 1 \), and consider a series-parallel graph \( G \) with exactly \( k \) edges. \( G \) is made by the (series or parallel) composition of two series-parallel graphs \( G_1 \) and \( G_2 \). Both subgraphs have fewer than \( k \) edges, thus by induction hypothesis, the recursive calls to SP-SCHEDULE produce two min-cut-optimal schedules \( \pi_1 \) and \( \pi_2 \) together with their respective min-\( \omega \)-cuts \( (S_1,T_1) \) and \( (S_2,T_2) \). We now distinguish between the two possible compositions.

**Series composition.** Theorem 6 shows that the schedule \( \pi = \langle \pi_1, \pi_2 \rangle \) computed by SP-SCHEDULE is a min-cut-optimal schedule of \( G \). Besides a min-\( \omega \)-cut of \( G \) can simply be found by selecting one of the min-\( \omega \)-cut of \( G_1 \) and \( G_2 \) with minimal cutwidth.

**Parallel composition.** Now, we consider that \( G = \{G_1,G_2\} \). The algorithm first compute the cut \((S,T)\) such that \( S = S_1 \cup S_2 \) and \( T = T_1 \cup T_2 \). We first prove that \((S,T)\) is a min-\( \omega \)-cut of \( G \). For the sake of contradiction assume the contrary. It means that there exists a topological cut \((S^*, T^*)\) such that \( c(S^*, T^*) < c(S,T) \). Let \((S_1^*, T_1^*)\) and \((S_2^*, T_2^*)\) be the topological cuts induced by \((S^*, T^*)\) on \( G_1 \) and \( G_2 \), respectively. Then,

\[
c(S_1^*, T_1^*) + c(S_2^*, T_2^*) = c(S^*, T^*) < c(S,T) = c(S_1, T_1) + c(S_2, T_2)
\]

This implies \( c(S_1^*, T_1^*) < c(S_1, T_1) \) or \( c(S_2^*, T_2^*) < c(S_2, T_2) \), which is a contradiction as \((S_1, T_1)\) and \((S_2, T_2)\) both are min-\( \omega \)-cuts.

In the case of a parallel composition, the algorithm computes the chain graph \( \bar{G}_1 \) (respectively \( \bar{G}_2 \)) by sequencing the vertices of \( G_1 \) (resp. \( G_2 \)) in the order of \( \pi_1 \) (resp. \( \pi_2 \)) and calls PC-SCHEDULE on the parallel-chain graph \( \bar{G} \) made by the parallel composition of \( \bar{G}_1 \) and \( \bar{G}_2 \) and the cut \((S,T)\). Thanks to Theorem 8, we know that PC-SCHEDULE outputs a schedule \( \pi \) cut-optimal with \((S,T)\). Thus, for any schedule \( \gamma \) of \( \bar{G} \) in compliance with \((S,T)\), we have

\[
\bar{\pi}[S] \preceq \bar{\gamma}[S], \text{ and } \pi[T] \preceq \gamma[T]. \tag{12}
\]

We now show that \( \pi \) is cut-optimal with \((S,T)\) for \( G \) as well, that is, the previous inequalities also holds for any schedule \( \gamma \) of \( G \) in compliance with \((S,T)\). We consider such a schedule \( \gamma \). Theorem 7 proves that there exists a schedule \( \pi^* \) that (i) induces \( \pi_1 \) and \( \pi_2 \), (ii) \( \pi^* \) is in compliance with \((S,T)\), and (iii)

\[
\bar{\pi}^*[S] \preceq \bar{\gamma}[S], \text{ and } \pi^*[T] \preceq \gamma[T]. \tag{13}
\]

As \( \pi^* \) induces \( \pi_1 \) and \( \pi_2 \), \( \pi^* \) is a valid schedule of \( \bar{G} \), we may thus apply Equation (12) to \( \gamma = \pi^* \). Combining it with Equation (13), we get

\[
\bar{\pi}[S] \preceq \bar{\pi}^*[S] \preceq \bar{\gamma}[S], \text{ and } \pi[T] \preceq \pi^*[T] \preceq \gamma[T].
\]

As \( \preceq \) is transitive, we have \( \bar{\pi}[S] \preceq \bar{\gamma}[S] \) and \( \pi[T] \preceq \gamma[T] \). \( \square \)
**Proof** — Proof of the Main Theorem 4 SP-Schedule computes a schedule \( \pi \) and a min-\( \omega \)-cut such that \( \pi \) is min-cut optimal with the found cut (see Theorem 5). Theorem 3 implies that \( \pi \) is also minimal for the \( \preceq \) relation, which in turn means that \( \pi \) minimizes the cutwidth \( \rho(\pi) \) due to Corollary 1.

**Algorithm complexity**

The PC-Schedule algorithm calls twice Liu’s algorithm for trees, whose worst-case complexity for an input of size \( n \) is \( O(n^2) \). Except for the recursive calls, this is the most costly step of the SP-Schedule. Since there are at most \( O(n) \) recursive calls, the overall worst-case complexity of SP-Schedule is \( O(n^3) \).

**5. Conclusion**

In this paper, we have proposed an algorithm to schedule a series-parallel task graph with the minimum peak memory. To prove the correctness of the algorithm, we have introduced a new and simpler model, based on a vertex-weighted graph. We have shown how to simulate task graphs with weights on vertices and edges using the new model. The proof of the proposed algorithm is complex, and consists in an extension of Liu’s work on trees [18].

The use of the proposed algorithm is limited to task graphs structured as series-parallel computations, which constitutes an important class of scientific computing applications. However, this algorithm may be applied to general graphs, if we first transform them into series-parallel graphs, for example using the SP-ization process [12], which is also suggested in the literature [2]. This will lead to suboptimal schedules, because some fictitious edges are added to a graph when it is turned into a series-parallel graph. Future research directions include looking for optimal schedules for other regular graph structures that appear in scientific computing (such as 2D or 3D meshes) structures, which could be approached using existing work on unweighted 2D grids by Diaz et al. [4, 6].

Appendix

The appendix is composed of four parts. Appendix A contains lemmas used in the proof of Theorem 1 in which we proved that minimizing the cutwidth in the cumulative weight model minimizes the peak memory in the original model. The sections Appendix B, C, and D contain lemmas used in showing the correctness of SP-SCHEDULE algorithm. These three sections give the proof of Theorems 6, 7, and 8, respectively. The last section Appendix D also contains the adaptation of Liu’s algorithm to the cumulative weight model.

A. Problem transformation

Lemmas A.1–A.4 are used in the proof of Theorem 1 and assume the same notation. In particular, the peak memory minimization problem is given by a graph \( G = (V, E, w_n, w_e) \), and the corresponding cutwidth instance has the bipartite graph \( G_B = (V_B, E_B, \omega) \).

Lemma A.1. Let \( \pi_B \) be a schedule of \( G_B \). There exists a vertex \( p \in G \) such that the cutwidth of \( \pi_B \) is reached on \( p_{\text{start}} \), i.e., \( \rho(\pi_B) = \Sigma(p_{\text{start}}, \pi_B) \).

Proof — For the sake of contradiction, assume that \( \rho(\pi_B) > \Sigma(p_{\text{start}}, \pi_B) \) for every \( p \in G \). Consider a vertex \( q \) of \( G \) such that the cutwidth of \( \pi_B \) is reached on \( q_{\text{stop}} \), i.e., \( \rho(\pi) = \Sigma(q_{\text{stop}}, \pi) \).

By construction (4), \( \omega(v_{\text{stop}}) \leq 0 \), for any vertex \( v \). We consider \( p_{\text{start}} \), the last “start” vertex scheduled before \( q_{\text{stop}} \) in \( \pi_B \): \( p_{\text{start}} = \max \{ v_{\text{start}} \leq \pi B \} \). Note that there exists such a \( p_{\text{start}} \) since \( q_{\text{start}} \) is scheduled before \( q_{\text{stop}} \). Then,

\[
\Sigma(q_{\text{stop}}, \pi_B) = \Sigma(p_{\text{start}}, \pi_B) + \sum_{p_{\text{start}} < \pi_B v_{\text{stop}} \leq \pi_B q_{\text{stop}}} \omega(v_{\text{stop}}) \leq \Sigma(p_{\text{start}}, \pi_B).
\]

Then, we have

\[
\rho(\pi_B) = \Sigma(q_{\text{stop}}, \pi_B) \leq \Sigma(p_{\text{start}}, \pi_B),
\]

which contradicts that \( \rho(\pi_B) > \Sigma(p_{\text{start}}, \pi_B) \). \( \square \)

Lemma A.2. Let \( \pi \) be a schedule of \( G \). Then, for any \( p \in G \),

\[
\mu(p, \pi) = \omega(p_{\text{start}}) + \sum_{v \leq p} (\omega(v_{\text{start}}) + \omega(v_{\text{stop}})).
\]

Proof — For this proof, we extend the definition of the edge weights in such a way that \( w_e(q, r) = 0 \) if there is no edge \( (q, r) \) in \( E \). With this extension, we may write

\[
\omega(v_{\text{start}}) = w_n(v) + \sum_{v \leq r} w_e(v, r),
\]

\[
\omega(v_{\text{stop}}) = -w_n(v) - \sum_{q \leq v} w_e(q, v).
\]
Now, consider any vertex \( p \in G \). We have

\[
\mu(p, \pi) = w_n(p) + \sum_{q \leq p \leq r} w_e(q, r)
\]

\[
= w_n(p) + \sum_{p \leq r} w_e(p, r) + \sum_{q \leq p \leq r} w_e(q, r)
\]

\[
= \omega(p_{\text{start}}) + \sum_{q \leq p \leq r} w_e(q, r) + \sum_{q \leq r < p} w_e(q, r) - \sum_{q \leq r < p} w_e(q, r)
\]

\[
= \omega(p_{\text{start}}) + \sum_{q < p \leq r} \left( \sum_{p \leq r} w_e(q, r) + \sum_{q \leq r < p} w_e(q, r) \right) - \sum_{q \leq r < p} w_e(q, r)
\]

\[
= \omega(p_{\text{start}}) + \sum_{q < p \leq r} \sum_{p \leq r} w_e(q, r) - \sum_{r < p} \sum_{q \leq r \leq p} w_e(q, r)
\]

\[
= \omega(p_{\text{start}}) + \sum_{v < p} (\omega(v_{\text{start}}) - w_n(v)) - \sum_{v < p} (-\omega(v_{\text{stop}}) - w_n(v))
\]

\[
= \omega(p_{\text{start}}) + \sum_{v < p} (\omega(v_{\text{start}}) - w_n(v) + \omega(v_{\text{stop}}) + w_n(v))
\]

\[
= \omega(p_{\text{start}}) + \sum_{v < p} (\omega(v_{\text{start}}) + \omega(v_{\text{stop}})).
\]

\[ \square \]

**Lemma A.3.** Let \( \pi_B \) be a schedule of \( G_B \) such that \( p_{\text{start}} \) and \( p_{\text{stop}} \) are consecutive in \( \pi_B \), for each \( p \in G \). Consider the schedule \( \pi \) of \( G \) such that \( p \leq \pi q \) whenever \( p_{\text{stop}} \leq \pi_B q_{\text{stop}} \). Then, \( \mu(\pi) = \rho(\pi_B) \).

**Proof.** As \( p_{\text{start}} \) and \( p_{\text{stop}} \) are consecutive in \( \pi_B \), for each \( p \in G \), we have

\[
\Sigma(p_{\text{start}}, \pi_B) = \omega(p_{\text{start}}) + \sum_{v < p} (\omega(v_{\text{start}}) + \omega(v_{\text{stop}}))
\]

and, due to Lemma A.2, \( \Sigma(p_{\text{start}}, \pi_B) = \mu(p, \pi) \), for any \( p \in G \). We consider the vertex \( p \) which reaches the cutwidth of \( \pi_B \), as defined by Lemma A.1: \( \rho(\pi_B) = \Sigma(p_{\text{start}}^*, \pi_B) \). Then,

\[
\rho(\pi_B) = \Sigma(p_{\text{start}}, \pi_B) = \mu(p, \pi) \leq \mu(\pi).
\]

(A.1)

Let \( q \in G \) be such that \( \mu(q, \pi) = \mu(q, \pi) \). Then,

\[
\mu(\pi) = \mu(q, \pi) = \Sigma(q_{\text{start}}, \pi_B) \leq \rho(\pi_B).
\]

(A.2)

By combining Equations A.1 and A.2, we have \( \mu(\pi) = \rho(\pi_B) \).

\[ \square \]

**Lemma A.4.** Let \( \pi_B \) be a schedule of \( G_B \). There exists a schedule \( \pi_B' \) of \( G_B \) such that (i) \( p_{\text{start}} \) and \( p_{\text{stop}} \) are consecutive in \( \pi_B' \), for each \( p \in G \), and (ii) \( \rho(\pi_B') \leq \rho(\pi_B) \).
We construct a schedule 

We show that

proof — Let \( p \in G \) be such that \( p_{\text{start}} \) and \( p_{\text{stop}} \) are not consecutive in \( \pi_B \). We construct a schedule \( \pi_B'' \) from \( \pi_B \), where \( p_{\text{start}} \) is placed right before \( p_{\text{stop}} \). We show that \( \pi_B'' \) has a cutwidth that is smaller than or equal to that of \( \pi_B \).

Let \( q \in G \) be such that \( \rho(\pi_B'') = \Sigma(q_{\text{start}}, \pi_B'') \), which exists due to Lemma A.1. We investigate the following two cases of \( q \):

- \( q_{\text{start}} \) is scheduled before \( p_{\text{start}} \) in \( \pi_B \). Then, moving \( p_{\text{start}} \) forward does not influence the cutwidth.

- \( q_{\text{start}} \) is scheduled after \( p_{\text{start}} \) in \( \pi_B \).

We first show that \( \Sigma(q_{\text{start}}, \pi_B'') \leq \Sigma(q_{\text{start}}, \pi_B) \) as follows. If \( q_{\text{start}} > p_{\text{start}} \), \( \Sigma(q_{\text{start}}, \pi_B'') = \Sigma(q_{\text{start}}, \pi_B) \). Otherwise, since \( \omega(p_{\text{stop}}) \leq 0 \), we have \( \Sigma(q_{\text{start}}, \pi_B'') = \Sigma(q_{\text{start}}, \pi_B) + \omega(p_{\text{stop}}) \leq \Sigma(q_{\text{start}}, \pi_B) \). Thus, we have \( \rho(\pi_B') = \Sigma(q_{\text{start}}, \pi_B') \leq \Sigma(q_{\text{start}}, \pi_B) \leq \rho(\pi_B) \).

We repeat this process until \( p_{\text{start}}, p_{\text{stop}} \) vertices are scheduled consecutively, which does not degrade the cutwidth. \( \square \)

B. Series composition (used for Theorem 6)

**Lemma B.1.** Let \( G_1 = (V_1, E_1) \) and \( G_2 = (V_2, E_2) \) be two series-parallel directed graphs. Let \( (S_1, T_1) \) and \( (S_2, T_2) \) be \( \min-\omega \)-cuts, and \( \pi_1 \) and \( \pi_2 \) be schedules cut-optimal with \( (S_1, T_1) \) and \( (S_2, T_2) \) for \( G_1 \) and \( G_2 \), respectively. Let \( \pi = (\pi_1, \pi_2) \) be the schedule of the series composition \( G = (G_1, G_2) \) inducing \( \pi_1 \) and \( \pi_2 \). Then,

(i) \( \pi \) is cut-optimal with both \( (S_1, T_1 \cup V_2) \) and \( (V_1 \cup S_2, T_2) \),

(ii) \( (S, T) \) is a \( \min-\omega \)-cut of \( G \), where

\[
(S, T) = \arg\min \{ (S_1, T_1 \cup V_2), (V_1 \cup S_2, T_2) \}.
\]

**Proof.** We first concentrate on item (i) of the lemma. We only show that \( \pi \) is cut-optimal with \( (S_1, T_1 \cup G_2) \), as the other can be proven similarly. Let \( (S, T) = (S_1, T_1 \cup G_2) \). We need to show \( \bar{\pi}[S] \) and \( \pi[T] \) both are minimal for \( \preceq \). First consider \( \bar{\pi}[S] \). Since \( \pi_1 \) is cut-optimal with \( (S_1, T_1) \) for \( G_1 \), \( \bar{\pi}_1[S] \) is minimal for \( \preceq \) on \( G_1 \). Then, \( \bar{\pi}[S] \) is minimal for \( \preceq \) on \( G \).

Now consider \( \tau = \pi[T] \). For any schedule \( \kappa \) of \( G[T] \), we need to show \( \tau \preceq \kappa \). Take any schedule \( \kappa \) of \( G[T] \). We show that there is a vertex \( q \in T \) for each vertex \( p \in T \) such that \( p \rightarrow_\kappa q \).

Take any \( p \in T \). We consider two scenarios of \( p \in T_1 \) and \( p \in G_2 \), separately.

a) \( p \in T_1 \). Let \( \tau_1 = \tau[T_1] = \pi_1[T_1] \) and \( \kappa_1 = \kappa[T_1] \). Notice that \( \pi_1 \) is min-cut-optimal for \( G_1 \). Then, \( \pi_1[T_1] \), and equivalently \( \tau_1 \), is minimal for \( \preceq \) by definition. Then, \( \tau_1 \preceq \kappa_1 \). Then, there is a vertex \( q^* \in T_1 \) such that \( p \rightarrow_\kappa q^* \). Note that \( q^* \in T_1 \subseteq T \), and we show \( p \rightarrow_\kappa q^* \), as follows.
1) (C1: \( \Sigma(p, \tau) \leq \Sigma(q^*, \kappa) \)). \( \Sigma(p, \tau) = \Sigma(p, \tau_1) \leq \Sigma(q^*, \kappa_1) = \Sigma(q^*, \kappa) \).

2) (C2: \( \min\{\Sigma(s, \tau): s \geq \tau, p\} \leq \min\{\Sigma(r, \kappa): r \geq \kappa, q^*\} \)). We examine a vertex \( r \geq \kappa q^* \), in relation to the vertex \( t^o = \max^\kappa T = \max^\tau T \), which is the single sink vertex of \( G \).

Case 1. \( (r \in T_1) \). Since \( p, \tau_1 \rightarrow \kappa_1 q^* \), there is a vertex \( s \in T_1 \) and \( s \geq \tau_1 p \) such that \( \Sigma(s, \tau_1) \leq \Sigma(r, \kappa_1) \). Then, \( s \geq \tau p \) and

\[
\Sigma(s, \tau) = \Sigma(s, \tau_1) \leq \Sigma(r, \kappa_1) = \Sigma(r, \kappa).
\]

Case 2. \( (r \in G_2 \text{, } r < \kappa t^o) \). Consider \( s \in G_2 \) such that \( \Sigma(s, \pi_2) = c(S_2, T_2) \). Then, \( \Sigma(s, \pi_2) \leq \Sigma(r, \kappa_2) \), where \( \kappa_2 = \kappa[G_2] \), due to Lemma 6. Then, \( s \geq \tau p \) and

\[
\Sigma(s, \tau) = \Sigma(s, \pi_2) + \omega(T_1) \\
\leq \Sigma(r, \kappa_2) + \omega(T_1) = \Sigma(r, \kappa).
\]

Case 3. \( (r = t^o) \). Consider \( s = t^o \). Then, \( s \geq \tau p \), and

\[
\Sigma(s, \tau) = \Sigma(t^o, \tau) = \Sigma(t^o, \kappa) = \Sigma(r, \kappa).
\]

b) \( (p \in G_2) \). Let \( \tau_2 = \tau[G_2] = \pi_2 \) and \( \kappa_2 = \kappa[G_2] \). Notice that \( \pi_2 \) is min-cut-optimal for \( G_2 \). Then, \( \pi_2 \), and equivalently \( \tau_2 \), is minimal for \( \leq \) on \( G_2 \), due to Theorem 3. Then, \( \tau_2 \leq \kappa_2 \). Then, there is a vertex \( q^* \in G_2 \) such that \( p, \tau_2 \rightarrow \kappa_2 q^* \). Notice that \( \Sigma(v, \tau) = \Sigma(v, \tau_2) + \omega(T_1) \) and \( \Sigma(v, \kappa) = \Sigma(v, \kappa) + \omega(T_1) \), for any vertex \( v \in G_2 \). Since both \( p \in G_2 \) and \( q^* \in G_2 \), and \( p, \tau_2 \rightarrow \kappa_2 q^* \), it holds \( p, \tau \rightarrow \kappa q^* \), and \( q^* \in G_2 \subseteq T \).

We now concentrate on item (ii) of the lemma. We recall that \( (S_1, T_1) \) and \( (S_2, T_2) \) are both min-\( \omega \)-cuts. Now, for the sake of contradiction, suppose that none of \( (S_1, T_1 \cup G_2) \) and \( (G_1 \cup S_2, T_2) \) is a min-\( \omega \)-cut of \( G \). Take any min-\( \omega \)-cut \( (S^*, T^*) \) of \( G \). Consider the vertex, say \( v \), that is shared by \( G_1 \) and \( G_2 \). We analyze the cases of \( v \in S^* \) and \( v \in T^* \), as follows.

a) \( (v \in S^*) \). Let \( (S_2^*, T_2^*) \) be the topological cut induced by \( (S^*, T^*) \) on \( G_2 \). Then,

\[
c(S_2^*, T_2^*) = c(G_1 \cup S_2^*, T_2^*) - \omega(G_1) \\
= c(S^*, T^*) - \omega(G_1) \\
< c(G_1 \cup S_2, T_2) - \omega(G_1) = c(S_2, T_2).
\]

This contradicts with the fact that \( (S_2, T_2) \) is a min-\( \omega \)-cut of \( G_2 \).
b) \((v \in T^+)\). Let \((S_1^*, T_1^*)\) be the topological cut induced by \((S^*, T^*)\) on \(G_1\). Then,

\[
\begin{align*}
  c(S_1^*, T_1^*) &= c(S_1^*, T_1^* \cup G_2) \\
  &= c(S^*, T^*) \\
  &< c(S_1, T_1 \cup G_2) = c(S_1, T_1).
\end{align*}
\]

This contradicts with the fact that \((S_1, T_1)\) is a min-\(\omega\)-cut of \(G_1\).

\[\blacksquare\]

C. Compatible orders are sufficient (Theorem 7)

In this section, we prove Theorem 7 which allows to transform subgraphs into chains using \textsc{Linearize} before their parallel composition in Algorithm 3. We first define the segmentation of a graph into blocks, which is a coarsening of the graph following a topological order.

**Definition C.1 (Segmentation into blocks).** Let \(G\) be an directed acyclic graph, and \(\kappa\) be a schedule of \(G\). We say \(Q_\kappa = \{Q_1, Q_2, \ldots\}\) is a segmentation into blocks on \(G\) for \(\kappa\), if \(Q_\kappa\) is a partition of the vertices of \(G\), and for any two vertices \(p \in Q_j\) and \(q \in Q_k\), \(p \leq \kappa q\) implies \(j \leq k\). Each \(Q_j \in Q_\kappa\) is called a block of \(Q_\kappa\). We define the highest value \(H(Q_j)\) of a block \(Q_j \in Q_\kappa\) as

\[
H(Q_j) = \max_{q \in Q_j} \Sigma(q, \kappa).
\]

Similar to that of Liu [18], we define the hill-valley segmentation of a schedule of a directed acyclic graph, as follows.

**Definition C.2 (Hill-valley segmentation).** Let \(G\) be a directed acyclic graph, and \(\tau\) be a schedule of \(G\). The hill-valley segmentation \(P_\tau = \{P_1, P_2, \ldots\}\) is a particular block segmentation into blocks on \(G\) for \(\tau\), which is defined as follows. Let \(v_0 = \min^\tau G\) and \(h_1 = \max^\tau \{h \in G : \Sigma(h, \tau) = \rho(\tau)\}\).

Define \(v_i\) and \(h_i\), recursively, as

\[
v_i = \max^\tau \{\arg \min_{v \geq h_i} \Sigma(v, \tau)\},
\]

and

\[
h_i = \max^\tau \{\arg \max_{h > v_i} \Sigma(h, \tau)\}.
\]

Finally, define \(P_1 = \{v : v_0 \leq \tau v \leq v_1\}\), and \(P_i = \{v : v_{i-1} < v \leq v_i\}\), for \(i > 1\). We say that each \(P_i \in P_\tau\) is a segment of \(P_\tau\). The hill-value \(H_i\) and the valley-value \(V_i\) of a segment \(P_i \in P_\tau\) are defined as

\[
H_i = \Sigma(h_i, \tau), \quad \text{and} \quad V_i = \Sigma(v_i, \tau).
\]

Note that \(\Sigma(p, \tau) \leq H_i\), for any \(p \in P_i\).
The following property, similar to that given by Liu [18, Lemma 5.1], of the hill-valley segmentation is clear from the definition.

**Lemma C.1.** Let $G$ be a directed acyclic graph, $\tau$ be a schedule of $G$, and $P_\tau = \{P_1, P_2, \ldots, P_r\}$ be the hill-valley segmentation of $G$ for $\tau$. Then,

$$H_1 > H_2 > \cdots > H_r \geq V_r > \cdots > V_2 > V_1.$$  

Hereafter, we assume that $P_\tau$ implies a hill-valley segmentation of $G$ for a schedule $\tau$, implicitly. Similarly, $Q_\kappa$ implies any arbitrary segmentation, unless explicitly stated, of $G$ into blocks for a schedule $\kappa$.

**Definition C.3 (Segment indicates block).** Let $G$ be a directed acyclic graph, $\tau$ and $\kappa$ be schedules of $G$. Let $P_i \in P_\tau$ be a segment and $Q_j \in Q_\kappa$ be a block. We write $P_i \rightarrow Q_j$, and read $P_i$ indicates $Q_j$, if there is a vertex $q^*_j \in Q_j$ such that $h_i \rightarrow \tau, \kappa q^*_j$.

We now demonstrate some properties of the hill-valley segmentation. For Propositions C.1–C.4, we assume $G$ is any arbitrary directed acyclic, and $\tau$ and $\kappa$ are schedules of $G$.

**Proposition C.1.** Let $P_i \in P_\tau$ be a segment and $Q_j \in Q_\kappa$ be a block. If $P_i \rightarrow Q_j$, then

(i) $H_i \leq H(Q_j)$,

(ii) $V_i \leq \min\{\Sigma(r,\kappa) : r \geq \kappa q^*_j\}$, where $q^*_j = \max\kappa Q_j$.

**Proof.** Assume $P_i \rightarrow Q_j$. Then, there is a $q^*_j \in Q_j$ such that $h_i \rightarrow \tau, \kappa q^*_j$, following the definition of dominance given in Section 4.2.1. We prove the two results separately as follows.

(i) By the first condition (C1) of $h_i \rightarrow \tau, \kappa q^*_j$, we conclude

$$H_i = \Sigma(h_i, \tau) \leq \Sigma(q^*_j, \kappa) \leq H(Q_j).$$

(ii) By the second condition (C2) of $h_i \rightarrow \tau, \kappa q^*_j$, we have

$$V_i = \min\{\Sigma(s, \tau) : s \geq h_i\}$$

$$\leq \min\{\Sigma(r, \kappa) : r \geq h_i\} \leq \min\{\Sigma(r, \kappa) : r \geq \kappa q^*_j\} \leq \min\{\Sigma(r, \kappa) : r \geq \kappa q^*_j\}.$$  

□

**Proposition C.2.** Let $P_i \in P_\tau$ be a segment and $Q_j \in Q_\kappa$ be a block. Let $Q_k \in Q_\kappa$ be another block with $k < j$. If $P_i \rightarrow Q_k$ and $P_i \not\rightarrow Q_j$, then $H(Q_j) < H_i$.  

28
Suppose, for the sake of contradiction, that $P_i \rightarrow Q_k$ and $P_i \not\rightarrow Q_j$ but $H(Q_j) \geq H_i$. Since $P_i \rightarrow Q_k$, there is $q^*_k \in Q_k$ such that $h_i \rightarrow q^*_k$. Then,

$$\min\{\Sigma(s,\tau): s \geq \tau, h_i\} \leq \min\{\Sigma(r,\kappa): r \geq \kappa, q^*_k\}.$$  

Consider $q^*_j \in Q_j$ such that $\Sigma(q^*_j,\kappa) = H(Q_j)$. Then, $q^*_j \leq \kappa q^*_k$, and thus,

$$\min\{\Sigma(s,\tau): s \geq \tau, h_i\} \leq \min\{\Sigma(r,\kappa): r \geq \kappa, q^*_j\}.$$  

(C.1)

Since $H_i \leq H(Q_j)$, as we have supposed for the sake of contradiction, we have

$$\Sigma(h_i,\tau) = H_i \leq H(Q_j) = \Sigma(q^*_j,\kappa).$$  

(C.2)

Then, Equations (C.1) and (C.2) together imply $h_i \rightarrow q^*_j$, which arises a contradiction with $P_i \not\rightarrow Q_j$.  

Proposition C.3. Let $\tau \preceq \kappa$. For any segment $P_i \in P_{\tau}$, there is a block $Q_j \in Q_{\kappa}$ such that $P_i \rightarrow Q_j$.

Proof — Take any $P_i \in P_{\tau}$. Since $\tau \preceq \kappa$, we have $h_i \rightarrow q^*_j$, for some $q^*_j \in G$. For $q^*_j \in Q_j$, this implies $P_i \rightarrow Q_j$, by Definition C.3.

Definition C.4 (Monotonic segments-to-blocks function). A function $g: P_{\tau} \rightarrow Q_{\kappa}$ is called monotonic if

(i) $P_i \rightarrow g(P_i)$, for any $P_i \in P_{\tau}$, and

(ii) $Q_j = g(P_i)$ and $Q_k = g(P_{i+1})$ implies $j \leq k$.

Proposition C.4, together with Proposition C.3, proves that there is a monotonic segments-to-blocks function $g_{\tau \rightarrow \kappa}$ whenever $\tau \preceq \kappa$.

Proposition C.4. Let $\tau \preceq \kappa$. For any consecutive segments $P_i, P_{i+1} \in P_{\tau}$ and any block $Q_j \in Q_{\kappa}$ with $P_i \rightarrow Q_j$, there is a block $Q_k \in Q_{\kappa}$ such that $P_{i+1} \rightarrow Q_k$ and $j \leq k$.

Proof — We prove by contradiction. Suppose the contrary that, $P_{i+1} \not\rightarrow Q_k$ for any $k \geq j$. Take any $Q_k \in Q_{\kappa}$ such that $P_{i+1} \rightarrow Q_k$, which exists due to Preposition C.3. Then we have, $P_i \rightarrow Q_j$, $P_{i+1} \not\rightarrow Q_j$, $P_{i+1} \rightarrow Q_k$, and $k < j$.

(1) $H_{i+1} < H_i$, due to Lemma C.1,

(2) $H_i \leq H(Q_j)$, due to Proposition C.1,

(3) $H(Q_j) < H_{i+1}$, due to Proposition C.2.

Then, we obtain $H_{i+1} < H_{i+1}$, which arises a contradiction.  

Hereafter, we focus on a particular kind of directed acyclic graph, so called half-series-parallel. We use half-series-parallel directed graphs and Lemma C.4 as building blocks of the proof of Theorem 7.
Definition C.5 (Half-series-parallel directed graph). A directed acyclic graph \( H \) is called half-series-parallel, if there is a series-parallel directed graph \( G \) and a min-\( \omega \)-cut \((S, T)\) of \( G \) such that \( H = G[T] \).

Lemma C.2. Let \( H \) be a half-series-parallel directed graph, and \( t^o \) be the single sink vertex of \( H \). Let \( \tau \) be a schedule of \( H \). Then, \( \Sigma(p, \tau) \geq 0 \), for any \( p \in H \setminus \{t^o\} \).

Proof — Consider a series-parallel directed graph \( G \), a min-\( \omega \)-cut \((S, T)\) of \( G \) such that \( G[T] = H \). Take any \( p \in H \setminus \{t^o\} \). For the sake of contradiction, suppose \( \Sigma(p, \tau) < 0 \). Consider the set \( P = \{v \in T : v \leq \tau p \} \). Then, \((S \cup P, T/P)\) is topological and \( \omega(P) = \Sigma(p, \tau) < 0 \). Therefore, \( c(S \cup P, T/P) = \omega(S) + \omega(P) < \omega(S) = c(S, T) \), which contradicts with the minimality of \((S, T)\).

Lemma C.3. Let \( H_1 \) and \( H_2 \) be two half-series-parallel directed graphs, and \( H \) be the half-series-parallel directed graph obtained from \( H_1 \) and \( H_2 \) by unifying their unique sink vertex. Let \( \lambda \) be a schedule of \( H \) and \( p^* \in H \). Consider \( p_i^* = \max_{\lambda} \{p \in H_i : p \leq_{\lambda} p^*\} \), for \( i = 1, 2 \). If \( p_1^* \) and \( p_2^* \) both are defined, then

\[
\Sigma(p^*, \lambda) = \Sigma(p_1^*, \lambda[H_1]) + \Sigma(p_2^*, \lambda[H_2]).
\]

Proof — Assume \( p_1^* \) and \( p_2^* \) are defined. Then,

\[
\Sigma(p^*, \lambda) = \omega(\{p \in H : p \leq_{\lambda} p^*\}) = \omega(\{p \in H_1 : p \leq_{\lambda} p^*\}) + \omega(\{p \in H_2 : p \leq_{\lambda} p^*\}) = \omega(\{p \in H_1 : p \leq_{\lambda[H_1]} p_1^*\}) + \omega(\{p \in H_2 : p \leq_{\lambda[H_2]} p_2^*\}) = \Sigma(p_1^*, \lambda[H_1]) + \Sigma(p_2^*, \lambda[H_2]).
\]

Lemma C.4. Let \( H_1 \) and \( H_2 \) be two half-series-parallel directed graphs, and \( H \) be the half-series-parallel directed graph obtained from \( H_1 \) and \( H_2 \) by unifying their unique sink vertex. Let \( \tau \) be a schedule of \( H_1 \) minimal for \( \leq \). For any schedule \( \lambda \) of \( H \), there is a schedule \( \eta \) of \( H \) such that (i) \( \eta \) induces \( \tau \), and (ii) \( \eta \leq \lambda \).

Before proving Lemma C.4, we state and prove Propositions C.5–C.6, which are used in the proof of Lemma C.4. For Propositions C.5-C.6, we use the definitions in Lemma C.4. That is, \( H_1 \) and \( H_2 \) are half-series-parallel directed graphs, and \( H \) is the half-series-parallel directed graph obtained from \( H_1 \) and \( H_2 \) by unifying their sink vertex. Accordingly, \( \lambda \) is a schedule of \( H \) and induces \( \kappa \) on \( H_1 \) (\( \kappa = \lambda[H_1] \)), and \( Q_{\kappa} \) is the segmentation of \( H_1 \) into blocks induced by \( \kappa \). This particular segmentation is built such that for any \( p, q \in H_1 \) with \( p \leq_{\kappa} q \), where \( p \in Q_j \) and \( q \in Q_k \), it holds that \( j = k \) if and only if there is no \( r \in H_2 \) with \( p \leq_{\lambda} r \leq_{\lambda} q \). We assume \( \tau \) is a schedule of \( H_1 \) such that \( \tau \leq \kappa \), and
\( g_{\tau \rightarrow \kappa} : \mathcal{P}_\tau \rightarrow \mathcal{Q}_\kappa \) is a monotonic segments-to-block function (see Definition C.4 and the discussion after it). We introduce a schedule \( \eta \) which is built upon \( g_{\tau \rightarrow \kappa} \) over \( \lambda \), as follows. We replace in \( \lambda \) each block \( Q_j \in \mathcal{Q} \) with the segments of 

\[
\tau^{-1}(Q_j) = \{ P_i \in \mathcal{P}_\tau : g_{\tau \rightarrow \kappa}(P_i) = Q_j \}.
\]

By virtue of the monotonic character of \( g_{\tau \rightarrow \kappa} \), we end up with a schedule \( \eta \) that induces \( \tau \) by the above-mentioned replacement. Note that \( \eta \) is equivalent to \( \lambda \) on \( H_2 \), i.e., \( \eta[H_2] = \lambda[H_2] \). Figure C.2 illustrates the construction of \( \eta \) and the notations used in the following propositions. Then, there only remains to show that \( \eta \preceq \lambda \) in order to prove Lemma C.4. To do so, we need Propositions C.5–C.7, concerned with the schedule \( \eta \) of \( H \) that is built upon \( g_{\tau \rightarrow \kappa} \) over schedule \( \lambda \) of \( H \).

**Proposition C.5.** Let \( P_i \in \mathcal{P}_\tau \) be a segment and \( Q_j \in \mathcal{Q}_\kappa \) be a block such that \( g_{\tau \rightarrow \kappa}(P_i) = Q_j \). Recall from above that \( \tau \) is minimal for \( \preceq \) on \( H_1 \) and \( \lambda \) is any schedule of \( H_1 \). Let \( \kappa \) be the schedule induced by \( \lambda \) on \( H_1 \), and \( \eta \) be the schedule of \( H \) built upon \( g_{\tau \rightarrow \kappa} \) over \( \lambda \). For any \( p \in P_i \) and any \( q \in Q_j \), if \( \Sigma(p, \tau) \leq \Sigma(q, \kappa) \), then \( \Sigma(p, \eta) \leq \Sigma(q, \lambda) \).

**Proof.** Assume \( \Sigma(p, \tau) \leq \Sigma(q, \kappa) \). Let \( p^\lambda = \max^\lambda \{ w \in H_2, w \leq \lambda p \} \). Then, we have two cases to consider.

1. \( p^\lambda \) is not defined. Then, \( \Sigma(p, \eta) = \Sigma(p, \tau) \leq \Sigma(q, \kappa) = \Sigma(q, \lambda) \).
2. \( p^\lambda \) is defined. Then, by the use of Lemma C.3, we have

\[
\Sigma(p, \eta) = \Sigma(p, \tau) + \Sigma(p^\lambda, \eta[H_2]) \\
\leq \Sigma(q, \kappa) + \Sigma(p^\lambda, \lambda[H_2]) = \Sigma(q, \lambda).
\]

Note that by construction of \( \eta \), \( p^\lambda = \max^\lambda \{ w \in H_2, w \leq \lambda q \} \) which justifies the last equality.
Proposition C.6. Recall that $\eta$ and $\lambda$ are schedules of $H$ where $\eta$ is built upon $g_{\tau \rightarrow \kappa}$ over $\lambda$ using the same $\tau$ and $\kappa$ as before. Let $p \in H_1$ and $p^\lambda = \max^\lambda \{ w \in H_2, w \leq \lambda p \}$. If $p^\lambda$ is defined, then $\Sigma(p^\lambda, \eta) \leq \Sigma(p, \lambda)$.

**Proof.** Assume $p^\lambda$ is defined. Let $p^\tau = \max^\tau \{ w \in H_1, w \leq \eta p^\lambda \}$. We consider the following two cases, separately.

1. ($p^\tau$ is not defined). Since $H_1$ is half-series-parallel, $\Sigma(p, \kappa) \geq 0$, as suggested by Lemma C.2. Then, by the use of Lemma C.3, we have

$$
\Sigma(p^\lambda, \eta) = \Sigma(p^\lambda, \eta[H_2]) 
\leq \Sigma(p^\lambda, \lambda[H_2]) + \Sigma(p, \kappa) = \Sigma(p, \lambda).
$$

2. ($p^\tau$ is defined). Let $P_i \in P_\tau$ such that $p^\tau \in P_i$, and notice that $p^\tau = u_i$. Similarly, let $Q_j \in Q_\kappa$ such that $p \in Q_j$. Let $Q_k = g_{\tau \rightarrow \kappa}(P_i)$, and $q_k^\kappa = \max^\kappa Q_k$. By definition of $p^\lambda$ and $p^\tau$, we have $k < j$, and thus, $p \geq \kappa q_k^\kappa$. Note that $P_i \rightarrow Q_k$. Then, due to Proposition C.1, we have

$$
\Sigma(p^\tau, \tau) = V_i \leq \min \{ \Sigma(r, \kappa) : r \geq \kappa q_k^\kappa \} \leq \Sigma(p, \kappa).
$$

Then, by Lemma C.3, we have

$$
\Sigma(p^\lambda, \eta) = \Sigma(p^\tau, \tau) + \Sigma(p^\lambda, \eta[H_2]) 
\leq \Sigma(p, \kappa) + \Sigma(p^\lambda, \lambda[H_2]) = \Sigma(p, \lambda).
$$

□

![Figure C.2: Illustration of a schedule $\eta$ built upon $g_{\tau \rightarrow \kappa}$ over $\lambda$, and notations used in Proposition C.7.](image)
Proposition C.7. Recall that $\eta$ and $\lambda$ are schedules of $H$ where $\eta$ is built upon $g_{\tau \rightarrow \kappa}$ over $\lambda$ using the same $\tau$ and $\kappa$ as before. For any $p \in H_2$, we have $\Sigma(p, \eta) \leq \Sigma(p, \lambda)$.

**Proof.** Let $p^\kappa = \max^\lambda \{ w \in H_1, w \leq^\lambda p \}$ and $p^\tau = \max^\eta \{ w \in H_1, w \leq^\eta p \}$. Note that when $p^\kappa$ is not defined, then $p^\tau$ is not defined either. Then, we have the following three cases to consider.

1. (Either $p^\kappa$ or $p^\tau$ is not defined). Then,
   
   $\Sigma(p, \eta) = \Sigma(p, \eta[H_2]) = \Sigma(p, \lambda[H_2]) = \Sigma(p, \lambda)$.

2. ($p^\kappa$ is defined, but $p^\tau$ is not). Since $H_1$ is half-series-parallel, $\Sigma(p^\kappa, \kappa) \geq 0$, as Lemma C.2 suggests. Thus, by the use of Lemma C.3, we have
   
   $\Sigma(p, \eta) = \Sigma(p, \lambda[H_2]) \leq \Sigma(p, \lambda[H_2]) + \Sigma(p^\kappa, \kappa) = \Sigma(p, \kappa)$.

3. (Both $p^\kappa$ and $p^\tau$ are defined). Let $P_i \in P_\tau$ such that $p^\tau = v_i$. Similarly, let $Q_j \in Q_\kappa$ such that $p^\kappa = Q_j$. Let $Q_k = g_{\tau \rightarrow \kappa}(P_i)$, and $q_k^\kappa = \max^\kappa Q_k$. By definition of $p^\kappa$ and $p^\tau$, we have $j \geq k$, and thus, $p^\kappa \geq^\kappa q_k^\kappa$. Note that $P_i \rightarrow Q_k$. Then, due to Proposition C.1, we have
   
   $\Sigma(p^\tau, \tau) = V_i \leq \min \{ \Sigma(r, \kappa) : r \geq^\kappa q_k^\kappa \} \leq \Sigma(p^\kappa, \kappa)$.

Then, by Lemma C.3, we have

$$
\Sigma(p, \eta) = \Sigma(p^\tau, \tau) + \Sigma(p, \eta[H_2]) \leq \Sigma(p^\kappa, \kappa) + \Sigma(p, \lambda[H_2]) = \Sigma(p, \lambda).
$$

□

Now, we are ready to prove Lemma C.4.

**Proof.** (Proof of Lemma C.4) Recall that $\tau$ is a schedule of $H_1$ which is minimal for $\preceq$, and $\lambda$ is an arbitrary schedule of $H$ that induces $\kappa$ on $H_1$. Since $\tau$ is minimal for $\preceq$, $\tau \preceq \kappa$. Then, let $g_{\tau \rightarrow \kappa}$ be a monotonic segments-to-blocks function, which exists due to Propositions C.3 and C.4. Let $\eta$ be a schedule of $H$ built upon $g_{\tau \rightarrow \kappa}$ over $\lambda$.

With the above construction (i) is proved, as $\eta$ induces $\tau$ in $H_1$.

We now establish (ii) $\eta \preceq \lambda$. For this, we show that for each $p \in H$, there is $q^* \in H$ such that $p_{\eta} \rightarrow^\lambda q^*$. For any $p$, either $p \in H_1$ or $p \in H_2$. We explore these two cases separately.

a) ($p \in H_1$). Let $p \in P_i$ and $Q_j = g_{\tau \rightarrow \kappa}(P_i)$. Since $P_i \rightarrow Q_j$, there is a vertex $q_j^* \in Q_j$ such that $p_{\tau} \rightarrow^\kappa q_j^*$. Now, we show that it also holds $p_{\eta} \rightarrow^\lambda q_j^*$.
1) (C1: $\Sigma(p, \eta) \leq \Sigma(q_j^*, \lambda)$). Since $p \rightarrow_\kappa q_j^*$, we have $\Sigma(p, \tau) \leq \Sigma(q_j^*, \kappa)$. Then, Proposition C.7 suggests that C1 is met.

2) (C2: $\min\{\Sigma(s, \eta) : s \geq_\eta p\} \leq \min\{\Sigma(r, \lambda) : r \geq_\lambda q_j^*\}$). We show that for each $r \geq_\lambda q_j^*$, there is a vertex $s \geq_\eta p$ such that $\Sigma(s, \eta) \leq \Sigma(r, \lambda)$. We examine three cases: $r \in Q_j$, or $r \in H_1 \setminus Q_j$, or $r \in H_2$.

Case 1. $(r \in Q_j)$. Since $p \rightarrow_\kappa q_j^*$, there is a vertex $s \geq_\tau p$ such that $\Sigma(s, \tau) \leq \Sigma(r, \kappa)$. We consider two scenarios of $s \in P_i$ and $s \not\in P_i$.

i) $(s \in P_i)$. Then, Proposition C.5 suggests

$$\Sigma(s, \eta) \leq \Sigma(r, \lambda),$$

and notice that $s \geq_\eta p$, as $s \geq_\tau p$.

ii) $(s \not\in P_i)$. Then, $s \geq_\tau v_i \geq_\tau p$. Since $\Sigma(v_i, \tau) \leq \Sigma(s, \tau)$, by the definition of $v_i$, we have $\Sigma(v_i, \tau) \leq \Sigma(r, \kappa)$. Then, Proposition C.5 suggests

$$\Sigma(v_i, \eta) \leq \Sigma(r, \lambda),$$

and notice that $v_i \geq_\eta p$, as $v_i \geq_\tau p$.

Case 2. $(r \in H_1 \setminus Q_j)$. Let $r \in Q_k$ and $r^\lambda = \max^\lambda\{w \in H_2, w \leq_\lambda r\}$. Since $r \geq_\lambda q_j^*$ and $r \not\in Q_j$, it holds $k > j$, and thus, $r^\lambda$ is defined and $r^\lambda \geq_\lambda q_j^*$. Then, Proposition C.6 suggests

$$\Sigma(r^\lambda, \eta) \leq \Sigma(r, \lambda),$$

and notice that $r^\lambda \geq_\eta p$, as $r^\lambda \geq_\lambda q_j^*$.

Case 3. $(r \in H_2)$. Then, Proposition C.7 suggests

$$\Sigma(r, \eta) \leq \Sigma(r, \lambda),$$

and notice that $r \geq_\eta p$, as $r \geq_\lambda q_j^*$.

b) $(p \in H_2)$. We show $p \rightarrow_\eta \kappa p$. The first condition (C1) directly holds due to Proposition C.7. Considering the second condition (C2), we show, for any $r \geq_\lambda p$, there is $s \geq_\eta p$, such that $\Sigma(s, \eta) \leq \Sigma(r, \lambda)$. We explore the two cases of $r \in H_1$ and $r \in H_2$, separately.

Case 1. $(r \in H_1)$. Let $r^\lambda = \max^\lambda\{w \in H_2, w \leq_\lambda r\}$. Since $r \geq_\lambda p$ and $p \in H_2$, $r^\lambda$ is defined and $r^\lambda \geq_\lambda p$. Due to Proposition C.6, we have

$$\Sigma(r^\lambda, \eta) \leq \Sigma(r, \lambda),$$

and notice that $r^\lambda \geq_\eta p$, as $r^\lambda \geq_\lambda p$.

Case 2. $(r \in H_2)$. Proposition C.7 suggests

$$\Sigma(r, \eta) \leq \Sigma(r, \lambda),$$

and notice that $r \geq_\eta p$, as $r \geq_\lambda q_j^*$.
We first recall Theorem 7, and show the proof as a consequence of Lemma C.4.

**Theorem C.1 (Restatement of Theorem 7).** Let $G_1$ and $G_2$ be two series-parallel directed graphs, and $G = \{G_1, G_2\}$ be their parallel composition. Let $(S, T)$ be a min-$\omega$-cut of $G$, and $\pi_1$ and $\pi_2$ be schedules that are cut-optimal with the topological cuts induced by $(S, T)$ on $G_1$ and $G_2$, respectively. For each schedule $\gamma$ in compliance with $(S, T)$ of $G$, there is a schedule $\pi$ in compliance with $(S, T)$ of $G$ such that

1. $\pi$ induces $\pi_1$ and $\pi_2$,
2. $\bar{\pi}[S] \leq \bar{\gamma}[S]$ and $\pi[T] \leq \gamma[T]$.

**Proof** — (Proof of Theorem 7) Take any schedule $\gamma$ in compliance with $(S, T)$ of $G$. Let $(S_1, T_1)$ be topological cut induced by $(S, T)$ on $G_1$. Consider $\lambda' = \gamma[T]$ and $\tau_1' = \pi_1[T_1]$. Then, $\tau_1'$ is minimal for $\preceq$, since $\pi_1$ is cut-optimal with $(S_1, T_1)$. Then, we have a schedule $\eta'$ of $G[T]$ inducing $\tau_1'$ such that $\eta' \leq \lambda'$, as suggested by Lemma C.4. Now, consider $\lambda^* = \bar{\gamma}[S]$ and $\tau_1^* = \bar{\pi}_1[S_1]$. Then, $\tau_1^*$ is minimal for $\preceq$, since $\pi_1$ is cut-optimal with $(S_1, T_1)$. Then, we have a schedule $\bar{\eta}^*$ of $G[S]$ inducing $\tau_1^*$ such that $\bar{\eta}^* \leq \lambda^*$, as suggested by Lemma C.4. We consider $\bar{\pi} = (\bar{\eta}^*, \eta^*)$. We notice that (i) $\bar{\pi}$ induces $\pi_1$ and $\gamma[G_2]$ on $G_1$ and $G_2$, respectively. It also holds that (ii) $\bar{\pi}[S] \leq \bar{\gamma}[S]$ and $\bar{\pi}[T] \leq \gamma[T]$.

Now, apply the procedure given above on $\bar{\pi}$ (instead of $\gamma$) for $\pi_2$ (instead of $\pi_1$). Then, we obtain $\pi = (\bar{\eta}^*, \eta'^*)$ that (i) induces $\bar{\pi}[G_1]$ and $\pi_2$ on $G_1$ and $G_2$, respectively. It also holds that (ii) $\bar{\pi}[S] \leq \bar{\gamma}[S]$ and $\pi[T] \leq \gamma[T]$.

As a result, (i) $\pi$ induces $\pi_1$ and $\pi_2$. Secondly, since $\preceq$ is transitive, it holds that (ii) $\pi[S] \leq \bar{\gamma}[S]$ and $\pi[T] \leq \gamma[T]$. \hfill $\Box$

**D. PC-Schedule is min-cut-optimal (Theorem 8)**

PC-Schedule, presented in Algorithm 4, relies on Tree-Schedule to compute schedules for trees that are minimal for $\preceq$. This latter algorithm, which we describe below, in turn relies on Liu’s algorithm for trees. However, Liu’s algorithm uses another model, namely the generalized pebble game: each node is provided with a number of pebbles which should be use to pebble it. As usual in pebble games, the objective is to pebble the tree up to the root using a minimal number of pebbles. In order to prove that his algorithm is optimal, Liu’s relies on the notion of $P\text{cost}$ sequences. In the following, we prove that a schedule minimal for $P\text{cost}$ sequences is also minimal for our relation $\preceq$. The proof of Theorem D.1 thus largely relies on notations and concepts borrowed from [18]. We first introduce a restriction on the trees on which Tree-Schedule may be applied.
Definition D.1 (Liu-compatible tree). Let $T$ be a directed in-tree and $r$ be its root vertex. We say $T$ is Liu-compatible if $\omega(T[v]) \geq 0$ for each vertex $v \in T - \{r\}$, where $T[v]$ is the subtree rooted at $v$.

Algorithm D.1 $\text{T-Schedule}(G, (S,T))$

Require: $G = (V,E,\omega)$: Liu-compatible vertex-weighted tree with root $r$
Ensure: $\pi$: A minimal schedule for $\preceq$

for $v \in V$ do
  if $v = r$ then
    $\tau(v) \leftarrow \omega(T - \{r\})$
  else
    $\tau(v) \leftarrow \omega(T - \{r\}[v])$
  Call Algorithm 4.1 in [18] (“Pebble-Ordering”) on $T$, with “Combine” procedure from Algorithm 6.1 (ibid.) to compute schedule $\pi$
return $\pi$

Theorem D.1. For any Liu-compatible tree $T$, Algorithm D.1 computes a schedule which is minimal for $\preceq$.

Proof — For this proof, we use the notations given in [18], and we assume that the reader is familiar with its results. In this article, Liu considers for any vertex $v$ of a tree a non-negative value $\tau(v)$ which represents the number of pebbles required to satisfy this node. We consider here the following pebbling function as defined in Algorithm D.1, namely:

$$\tau(v) = \begin{cases} 
\omega(T[v]) & v \in T - \{r\} \\
\omega(T - \{r\}) & v = r.
\end{cases} \quad (D.1)$$

Notice that $\tau(v) \geq 0$ for each $v \in T$, as $T$ is Liu-compatible. Let $\text{PARENT}(v)$ represent the parent vertex of $v$, for a vertex $v \in T - \{r\}$. As in [18], we consider for any schedule $\pi$ of $T$ the value $\text{peb}_\pi(v)$ which represents the “total number of pebbles used during the pebbling of the vertex $v$” while following schedule $\pi$.

We first prove that with the previous pebbling function, $\text{peb}_\pi(v) = \Sigma(v, \pi)$, for each $v \in T - \{r\}$. Take any $v \in T - \{r\}$. Let $F_v = \{r \in T : r \leq_\pi v <_\pi \text{PARENT}(v)\}$, that is, the set populated by the root vertices of the pruned forest. Then,

$$\text{peb}_\pi(v) = \sum_{r \in F_v} \tau(r) = \sum_{r \in F_v} \omega(T[r]) = \omega(\{u \leq_\pi v\}) = \Sigma(v, \pi).$$

We then consider the $P_{\text{cost}}(\pi)$, the cost sequence of a schedule $\pi$, as defined in [18]. We prove that if $P_{\text{cost}}(\pi) \preceq P_{\text{cost}}(\gamma)$ then $\pi \preceq \gamma$, for two schedules $\pi$ and $\gamma$ of $T$.

Assume $P_{\text{cost}}(\pi) \preceq P_{\text{cost}}(\gamma)$. Now, for each vertex $p \in T$, we need to exhibit a vertex $q^* \in T$ such that $p \pi \rightarrow q^*$. Since $r = \max_{\pi} T = \max_{\gamma} T$, we have
Consider a vertex $p \in T - \{r\}$. Let $p$ reside in the $i$th hill-valley segment with respect to $\pi$. By definition of $<$ in [18, Section 5.2], there exists $j$ such that $H_i \leq H_j$, and $\tilde{V}_i \leq V_j$, where $(H_i, \tilde{V}_i)$ and $(H_j, V_j)$ are the hill-valley values for $i$th and $j$th segments with respect to schedules $\pi$ and $\gamma$, respectively. Consider a vertex $q^* \in T - \{r\}$ so that $q^*$ resides in the $j$th hill-valley segment with respect to $\gamma$, and $peb_\gamma(q^*) = H_j$, where such $q^*$ exists due to Equation D.1. Now, we show $p \triangleright_\gamma q^*$ as follows.

1) (C1: $\Sigma(p, \pi) \leq \Sigma(q^*, \gamma)$). Recall that $peb_\pi(p) = \Sigma(p, \pi)$ and $peb_\gamma(q^*) = \Sigma(q^*, \gamma)$. Then, we have:

$$\Sigma(p, \pi) = peb_\pi(p) \leq \tilde{H}_i \leq H_j = peb_\gamma(q^*) = \Sigma(q^*, \gamma).$$

2) (C2: $\min\{\Sigma(s, \pi) : s \geq_\pi p\} \leq \min\{\Sigma(r, \gamma) : r \geq_\gamma q^*\}$). Recall that $peb_\pi(v) = \Sigma(v, \pi)$ and $peb_\gamma(v) = \Sigma(v, \gamma)$, for each $v \in T - \{r\}$. By definition of $\tilde{V}_i$ and $V_j$:

$$\min\{\Sigma(s, \pi) : s \geq_\pi p\} = \tilde{V}_i \leq V_j = \min\{\Sigma(r, \gamma) : r \geq_\gamma q^*\}.$$

Thanks to [18, Theorem 6.4], we known that Algorithm 4.1 in [18] with Combine procedure 6.1 (ibid.) computes a schedule $\pi$ of $T$ so that $Pcost(\pi) \prec Pcost(\gamma)$, for any schedule $\gamma$ of $T$. As a corollary, $\pi$ is minimal for $\preceq$ on $T$. □

**Theorem D.2 (Restatement of Theorem 8).** For any parallel-chain graph $G$ and any min-$\omega$-cut $(S, T)$ of $G$, PC-SCHEDULE computes a schedule $\pi$ that is cut-optimal with $(S, T)$.

**Proof —** (Proof of Theorem 8) Let $G$ be a parallel-chain directed graph and $(S, T)$ be a min-$\omega$-cut of $G$. We first check that both $G[S]$ and $G[T]$ are Liu-compatible trees.

We only show that $G[T]$ is Liu-compatible, as the other can be proven similarly. For the sake of contradiction, suppose that $G[T]$ is not Liu-compatible. Then, there is a vertex, say $v$, such that $\omega(T[v]) < 0$. Consider the topological cut $(S', T')$, where $S' = S \cup T[v]$ and $T' = G - S'$. Then, $c(S', T') = \omega(S') = \omega(T[v]) < \omega(S) = c(S, T)$. This contradicts the fact that $(S, T)$ is a min-$\omega$-cut of $G$.

The first steps of PC-SCHEDULE as described in Algorithm 4 is to compute schedules $\tilde{\sigma}$ and $\tau$ for $G[S]$ and $G[T]$ using Tree-Schedule. Thanks to Theorem D.1, we know that these schedules are minimal for $\preceq$.

Then, by definition, $\pi = \langle \sigma, \tau \rangle$ is cut-optimal with $(S, T)$, as $\pi$ is in compliance with $(S, T)$, $\tilde{\sigma}$ is minimal for $\preceq$ on $G[S]$, and $\tau$ is minimal for $\preceq$ on $G[T]$. □
