Preface

This volume contains the papers presented at the 20th International Conference on Descriptional Complexity of Formal Systems (DCFS 2018), which was held at Saint Mary's University in Halifax, Nova Scotia, Canada, during July 25–27, 2018. It was jointly organized by the Working Group 1.02 on Descriptional Complexity of the International Federation for Information Processing (IFIP) and by the Department of Mathematics and Computing Science at Saint Mary's University.

The DCFS conference series is an international venue for the dissemination of new results related to all aspects of descriptional complexity including, but not limited to:

- Automata, grammars, languages, and other formal systems; various modes of operations and complexity measures
- Succinctness of description of objects, state-explosion-like phenomena
- Circuit complexity of Boolean functions and related measures
- Size complexity of formal systems
- Structural complexity of formal systems
- Trade-offs between computational models and mode of operation
- Applications of formal systems for instance in software and hardware testing, in dialogue systems, in systems modelling or in modelling natural languages – and their complexity constraints
- Co-operating formal systems
- Size or structural complexity of formal systems for modelling natural languages
- Complexity aspects related to the combinatorics of words
- Descriptional complexity in resource-bounded or structure-bounded environments
- Structural complexity as related to descriptional complexity
- Frontiers between decidability and undecidability
- Universality and reversibility
- Nature-motivated (bio-inspired) architectures and unconventional models of computing
- Blum static (Kolmogorov/Chaitin) complexity, algorithmic information

DCFS became an IFIP working conference in 2016, continuing the former Workshop on Descriptional Complexity of Formal Systems, which was a merger in 2002 of two other workshops: FDSR (Formal Descriptions and Software Reliability) and DCAGRS (Descriptional Complexity of Automata, Grammars and Related Structures). DCAGRS was previously held in Magdeburg (1999), London (2000), and Vienna (2001). FDSR was previously held in Paderborn (1998), Boca Raton (1999), and San Jose (2000). Since 2002, DCFS has been successively held in London, Ontario, Canada (2002), Budapest, Hungary (2003), London, Ontario, Canada (2004), Como, Italy (2005), Las Cruces, New Mexico, USA (2006), Nový Smokovec, High Tatras, Slovakia (2007), Charlottetown, Prince Edward Island, Canada (2008), Magdeburg, Germany (2009), Saskatoon, Canada (2010), Giessen, Germany (2011), Braga, Portugal (2012), London, Ontario, Canada (2013), Turku, Finland (2014), Waterloo, Ontario, Canada (2015), Bucharest, Romania (2016), and Milan, Italy (2017).

The submission and refereeing process was supported by the EasyChair conference system. In total, 24 papers were submitted by authors in 14 different countries. Each paper was reviewed by at least three Program Committee members. The Program Committee selected 19 papers for presentation at the conference and publication in this volume. There were three invited talks by:

- Jacques Sakarovitch, CNRS/Paris Diderot University and Telecom ParisTech, France
- Peter Selinger, Dalhousie University, Halifax, Canada
- Ludwig Staiger, Martin-Luther-Universität, Halle, Germany

We are very thankful to all invited speakers, contributing authors, Program Committee members, and external referees for their valuable contributions towards the realization of DCFS 2018.

We also thank Alfred Hofmann and Anna Kramer of Springer for their guidance during the process of publishing this volume.

Finally, we are indebted to the Organizing Committee members Ms. Rose Daurie, Dr. Paul Muir, Dr. Juraj Šebej, and the graduate students of the Department of Mathematics and Computing Science at Saint Mary's University, Halifax.

We look forward to the next DCFS in Košice, Slovakia.

The Complexity of Carry Propagation for Successor Functions (Extended Abstract)

Valérie Berthé¹, Christiane Frougny¹, Michel Rigo², and Jacques Sakarovitch³

 ¹ IRIF - UMR 8243 - CNRS/Paris Diderot University, France

³ IRIF - UMR 8243 - CNRS/Paris Diderot University and Telecom ParisTech, France

Carry propagation is the nightmare of school pupils and the headache of computer engineers: not only can the addition of two digits give rise to a carry, but this carry itself, when added to the next digits to the left¹ may give rise to another carry, and so on, and so forth, and this may happen for an arbitrarily long time. Since the beginnings of computer science, the evaluation of the carry propagation length has been the subject of many works and it is known that the average carry propagation length (or complexity) for addition of two uniformly distributed *n*-digits binary numbers is $\log_2(n) + O(1)$ (see [5, 7, 10]).

We consider here the problem of carry propagation from a more theoretical perspective and in an apparently elementary case. We investigate the amortized carry propagation of the *successor function* in various numeration systems. The central case of integer base numeration system allows us to describe quickly what we mean. Let us take an integer p greater than 1 as a base. In the representations of the succession of the integers which is exactly what the successor function does — the least digit changes at every step, the penultimate digit changes every p steps, the ante-penultimate digit changes every p^2 steps, and so on and so forth ... As a result, the average carry propagation of the successor function, computed over the first N integers, should tend to the quantity

$$1 + \frac{1}{p} + \frac{1}{p^2} + \frac{1}{p^3} + \dots = \frac{p}{p-1},$$

when N tends to infinity. It can be shown that it is indeed the case. Motivated by various works on non-standard numeration systems, we investigate the questions of evaluating and computing the amortized carry propagation in those systems. We thus consider several such numeration systems different from the classical integer base numeration systems: the greedy numeration systems and the beta-numeration systems, see [6], which are a particular case of the former, the rational base numeration systems [1] which are not greedy numeration systems, and the abstract numeration systems [8] which are a generalization of the classical *positional numeration systems*.

¹ We write numbers under MSDF (Most Significant Digit First) convention.

The approach of *abstract numeration systems* of [8], namely the study of a numeration system via the properties of the set of expansions of the natural integers is well-fit to this problem. Such systems consist of a totally ordered alphabet A of the non-negative integers \mathbb{N} and a language L of A^* , ordered by the *radix order* deduced from the ordering on A. The representation of an integer n is then the (n + 1)-th word of L in the radix order. This definition is consistent with every classical standard and non-standard numeration system.

Given a system defined by a language *L* ordered by radix order, we denote by $CP_L(i)$ the carry propagation in the computation from the representation of *i* in *L* to that of *i* + 1. The *(amortized) carry propagation* of *L*, which we denote by CP_L , is the limit, *if it exists*, of the mean of the carry propagation at the first *N* words of *L*:

$$\mathsf{CP}_{L} = \lim_{N \to \infty} \frac{1}{N} \sum_{i=0}^{N-1} \mathsf{cp}_{L}(i) \,. \tag{1}$$

A further hypothesis is to consider *prefix-closed* and *right-extensible* languages, called 'PCE' languages in the sequel: every left-factor of a word of L is a word of L and every word of L is a left-factor of a longer word of L. Hence, L is the branch language of an infinite labelled tree T_L and, once again, every classical standard and non-standard numeration system meets that hypothesis.

We first prove two easy properties of the carry propagation of PCE languages. First, CP_L does not depend upon the labelling of \mathcal{T}_L , but only on its 'shape' which is completely defined by the infinite sequence of the degrees of the nodes visited in a breadth-first traversal \mathcal{T}_L , and which is called *signature* of \mathcal{T}_L (or of L) in [9]. For instance, the signature of the representation language in base p is the constant sequence p^{ω} . Second, we call *local growth rate* of a language L, and we denote by γ_L , the limit, *if it exists*, of the ratio $\mathbf{u}_L(\ell + 1)/\mathbf{u}_L(\ell)$, where $\mathbf{u}_L(\ell)$ is the number of words of L of length ℓ . If CP_L exists, then γ_L exists and it holds:

$$\mathsf{CP}_L = \frac{\gamma_L}{\gamma_L - 1} \,. \tag{2}$$

Examples show that γ_L may exist without CP_L exist. By virtue of this equality, the *computation* of CP_L is usually not an issue, the problem lies in proving its *existence*. We develop three different methods of existence proof, whose domains of application are pairwise incomparable: *combinatorial, algebraic,* and *ergodic,* and which are built upon very different mathematical backgrounds.

A combinatorial method shows that languages with *eventually periodic signature* have a carry propagation. These languages are essentially the rational base numeration systems (including the integer base numeration systems), possibly with non-canonical alphabets of digits [9].

We next consider the *rational abstract numeration systems*, that is, those systems which are defined by languages accepted by *finite automata*. Examples of such systems are the Fibonacci numeration system, more generally, beta-numeration systems where beta is a *Parry number* [6], and other systems different from beta-numeration. By means of a property of rational power series with positive coefficients which is reminiscent of

Perron-Frobenius Theorem, we prove that the carry propagation of a rational PCE language L exists if L has a local growth rate and all its quotients also have a local growth rate.

The definition of carry propagation (Eq. 1) inevitably reminds of Ergodic Theorem. We then consider the *greedy numeration systems*. The language of greedy expansions in such a system is embedded into a compact set, and the successor function is extended as an action, called *odometer*, on that compactification. This gives a dynamical system, but Ergodic Theorem does not directly apply as the odometer is not continuous in general. Recently tools in ergodic theory [2] allow us to prove the existence of the carry propagation for greedy systems with exponential growth, and thus for beta-numeration in general.

This work was indeed motivated by a paper where the *amortized (algorithmic) complexity* of the successor function for some beta-numeration systems was studied [3]. Whatever the chosen computation model, the (amortized) complexity is greater than the (amortized) carry propagation, hence can be seen as the sum of two quantities: the carry propagation itself and an *overload*. The study of carry propagation lead to quite unexpected and winding developments that form a subject on its own, leaving the evaluation of the overload to future works. A complete version of this present work [4] will appear soon.
