HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
On finite-time stability of homogeneous systems with multiplicative bounded function∗

Y. Braidiz1, A. Polyakov 2, D. Efimov2 and W. Perruquetti 1

Abstract—In this paper, we study the finite-time stability of a class of nonlinear systems \( \dot{x} = f(x) = H(x)b(x) \), where \( H \) is homogeneous and \( b \) is bounded. We define the homogeneous extension of the non-homogeneous function \( f \) and use this extension to prove that, under some conditions on \( b \), if the system \( \dot{x} = f(x) \) is globally asymptotically stable, then it is finite-time stable. An example of global asymptotic stable system with some additional conditions is presented in the last section to illustrate the obtained results.

I. INTRODUCTION

Stability is one of the main research directions in the mathematical study of dynamical systems and there is a large number of papers and books that have been published on the subject (see [1]–[4] and references therein). In general, there are different rates of convergence.

Over the years, researchers mainly focused their attention on asymptotic and exponential stability: trajectories converge to an equilibrium state in “infinite time” [4], [5]. However, in a lot of engineering domains, the time is a critical constraint which must be taken into account. Hence, in many applications, it is desirable to get the so called finite-time convergence of the solutions to an operating point. This possibility has been mentioned by Erugin 1951 and Zubov 1957, and studied by Roxin 1966, Korobov 1979 [6], [7].

The novelty of this paper consists in a result about FTS of a class of non-homogeneous systems of the form \( \dot{x} = H(x)b(x) \), with \( H \) is homogeneous and \( b \) satisfies boundedness conditions. We extend the result that was proved for a GAS homogeneous system with negative degree of homogeneity. In particular, we prove that, with some sufficient conditions on the function \( b \), we may guarantee the global FTS (GFTS) of the GAS system \( \dot{x} = H(x)b(x) \).

To do so, we use a homogeneous extension which is given by a homogeneous differential inclusion. The main peculiarity of a homogeneous extension is that it can be defined in the cases when homogeneous approximations do not exist. Then, using the results that were proven for GAS homogeneous differential inclusion with a negative degree of homogeneity (see for more details [20]), we will prove the FTS of the original dynamical system.

The paper is organized as follows. After introducing some notations and definitions about finite-time stability and homogeneity in Section II, we define the homogeneous extension of a non-homogeneous continuous function \( f : \mathbb{R}^n \to \mathbb{R}^n \), that we use, by giving a sufficient conditions on \( f \), to prove the global FTS of a GAS system of the form \( \dot{x} = f(x) \) (in Section III and Section IV). In the last section we present one example which shows how to apply the obtained results. The aim of this paper is to investigate the GFTS of non-homogeneous differential equation using a constructed homogeneous differential inclusion and Lyapunov functions.

II. PRELIMINARIES

A. Notations

- \( \mathbb{R}^+ = \{ x \in \mathbb{R} : x \geq 0 \} \), where \( \mathbb{R} \) is the set of real numbers.

B. Notations

- \( \mathbb{R}^+ = \{ x \in \mathbb{R} : x \geq 0 \} \), where \( \mathbb{R} \) is the set of real numbers.

\[ | \cdot | \text{ denotes the absolute value in } \mathbb{R}, \, \| \cdot \| \text{ denotes the Euclidean norm in } \mathbb{R}^n. \]
\[ S = \{ x \in \mathbb{R}^n : \| x \| = 1 \} \text{ denotes the unit sphere in } \mathbb{R}^n. \]
\[ B(x_0, r) = \{ x \in \mathbb{R}^n : \| x - x_0 \| < r \} \text{ denotes the open ball of radius } r > 0 \text{ centered at a point } x_0. \]
\[ M_{m,n} \text{ is the set of all } m \times n \text{-matrices over the real numbers, and it forms a vector space. When } m = n \text{ we write } M_n \text{ instead of } M_{n,n}. \]
\[ \| \cdot \|_{M_{m,n}} \text{ denotes the matrix norm induced by } \| \cdot \|, \text{ i.e.,} \]
\[ \| A \|_{M_{m,n}} = \sup_{x \in S} \| Ax \| \]

A continuous function \( \alpha : \mathbb{R}_+ \to \mathbb{R}_+ \) belongs to the class \( \mathcal{K} \) if \( \alpha(0) = 0 \) and the function is strictly increasing. The function \( \alpha : \mathbb{R}_+ \to \mathbb{R}_+ \) belongs to the class \( \mathcal{K}_\infty \) if \( \alpha \in \mathcal{K} \) and it is increasing to infinity.

The notation \( \{ DV(x), f(x) \} \) stands for the directional derivative of a continuously differentiable function \( V \) with respect to the vector field \( f \) evaluated at point \( x \).

\[ \mathcal{C}^p(\mathbb{R}^n, \mathbb{R}) \text{ denotes the space of functions } f : \mathbb{R}^n \to \mathbb{R} \text{ which have } p \text{ continuous derivatives and } \mathcal{C}^\infty(\mathbb{R}^n, \mathbb{R}) \text{ denotes the space of functions } f : \mathbb{R}^n \to \mathbb{R} \text{ which are smooth.} \]

In addition, if \( V = \mathbb{R}^n \), then the origin is a globally FTS (GFTS).

The following proposition shows how to investigate the FTS by using Lyapunov theory.

**Proposition 2.1:** [13] Assume that the \( (1) \) has a unique solution in forward time outside the origin. The origin of this system is FTS with a continuous settling-time function at the origin if and only if there exists a real number \( c > 0, \alpha \in ]0,1[ \) and a class \( \mathcal{C}_\infty \) Lyapunov function \( V : \mathcal{V} \to \mathbb{R}^+ \)
\[ \langle DV(x), f(x) \rangle \leq -c[\mathcal{V}(x)]^\alpha \]
for all \( x \in \mathcal{V} \).

2) Homogeneity: In control theory, homogeneity simplifies qualitative analysis of nonlinear dynamic systems. So that, it allows a local properties (e.g., local stability) to be extended globally using a property of the solutions (homogeneity is a special kind of Lie symmetry). In order to define this notion, let us introduce the notion of dilation group.

**Definition 2.2:** A map \( d : \mathbb{R} \to M_n(\mathbb{R}) \) is called a dilation in \( \mathbb{R}^n \) if it satisfies

- **Group property:** \( d(0) = I_n, \quad d(t+s) = d(t)d(s), \quad t, s \in \mathbb{R} \)
- **Continuity property:** \( d \) is continuous, i.e., \( \forall t > 0, \forall s, s' > 0, \exists \gamma > 0 : |s - t| < \gamma \implies \|d(s) - d(t)\|_{M_n} \leq \varepsilon \)
- **Limit property:** \( \lim_{s \to +\infty} \|d(s)x\| = 0 \) and \( \lim_{s \to +\infty} \|d(s)x\| = +\infty \) uniformly on the unite sphere.

**Definition 2.3:** The dilation \( d \) is monotonous if \( \|d(s)\|_{M_n} \leq 1, \forall s \leq 0 \) and it is strictly monotonous in \( \mathbb{R}^n \) if \( \exists \beta > 0 \) such that \( \|d(s)\|_{M_n} \leq e^{\beta s}, \forall s \leq 0 \).

**Property 2.1:** [22], [23] The matrix \( G_d \in M_n \) defined as \( G_d = \lim_{s \to +\infty} \frac{s^iG_d}{s^i} \) is known as the generator of the group \( d(s) \) and satisfies the following properties:
\[ \frac{d}{ds}d(s) = G_dd(s) = d(s)G_d \text{ and } d(s) = e^{G_ds} = \sum_{i=0}^{+\infty} \frac{s^iG_d}{i!}. \]

Let \( S_d(r) = \{ x \in \mathbb{R}^n : \|d(-1r)(x)\| = 1 \} \), \( r > 0 \) is called the homogeneous sphere of radius \( r \). If \( r = 1 \) we write \( S_d \) instead of \( S_d(1) \). Now we will defined the canonical homogeneous norm.

**Definition 2.4:** A continuous function \( p : \mathbb{R}^n \to \mathbb{R}_+ \) is said to be \( d \)-homogeneous norm if \( p(x) \to 0 \) as \( x \to 0 \) and \( p(d(s)x) = e^{p(x)} > 0 \) for \( x \in \mathbb{R}^n \setminus \{ 0 \} \) and \( s \in \mathbb{R} \).

For monotone dilations the homogeneous norm \( \| \cdot \|_d \) is called the canonical homogeneous norm
\[ \|x\|_d = e^{px}, \text{ where } s_x \in \mathbb{R} : \|d(-s_x)x\| = 1. \]

**Definition 2.5:** A vector field \( f : \mathbb{R}^n \to \mathbb{R}^n \) (resp., a function \( h : \mathbb{R}^n \to \mathbb{R} \)) is said to be \( d \)-homogeneous of degree \( \nu \in \mathbb{R} \) (iff for all \( s \in \mathbb{R} \) and all \( x \in \mathbb{R}^n \) we have \( e^{-\nu s}d(-s)f(d(s)x) = f(x) \), (resp., \( e^{-\nu s}h(d(s)) = h(x) \)).

Homogeneity property was introduced also for Banach spaces [19], [23], and it is given by a group of dilations.
in Banach or Hilbert space. The following lemma provides a useful comparison between homogeneous functions.

**Lemma 2.1**: Suppose that $V_1$ and $V_2$ are continuous real-valued functions on $\mathbb{R}^n$, $d$--homogeneous of degrees $l_1 > 0$ and $l_2 > 0$, respectively, and $V_1$ is positive definite. Then, for every $x \in \mathbb{R}^n$ we have
\[
\alpha_1 [V_1(x)]^{\frac{l_2}{l_1}} \leq V_2(x) \leq \alpha_2 [V_1(x)]^{\frac{l_2}{l_1}},
\]
with $\alpha_1 = \min_{\{z : V_1(z) = 1\}} V_2(z)$ and $\alpha_2 = \max_{\{z : V_1(z) = 1\}} V_2(z)$.

The Lemma 2.1 has been proven in [9] for weighted homogeneous functions and we can use the same trick to prove it for $d$--homogeneous functions $V_1$ and $V_2$. Hence, because $V_1 > 0$ then for every $x \in \mathbb{R}^n \setminus \{0\}$, $\exists z \in \{y : V_1(y) = 1\}$ such that $z = d(-\ln(V_1(x)))x$.

In the next section we will use the Lyapunov theory to show some robust stability results. The existence of a homogeneous Lyapunov function for a GAS homogeneous system was provided by Zubov in 1957, Rosier [18] and Polyakov [24], [22] by using weighted and generalized homogeneity.

### III. Homogeneous Extension

In this section, we define a homogeneous extension which allows some homogeneity methods to be applied for non-homogeneous systems (see [23]). This extension is given by a differential inclusion.

Differential inclusions appear as a model of dynamical systems which do not satisfy the classical assumptions of regularity. Regularization of the system (1) proposed by Filippov [25] consists in replacing (1) with a suitable differential inclusion
\[
\dot{x} \in F(x), \ x \in \mathbb{R}^n, \ F : \mathbb{R}^n \to 2^\mathbb{R}^n.
\]
The notions of solution obtained in this way depend on the construction of the set valued map $F$. If the set valued map $F(x)$ is upper semicontinuous, compact and convex valued, and locally bounded, then (5) has solutions.

**Definition 3.1**: Homogeneous extension of a function $f : \mathbb{R}^n \to \mathbb{R}^n$ is a set valued $d$-homogeneous map $F : \mathbb{R}^n \to \mathbb{R}^n$, such that $f(x) \in F(x)$ for any $x \in \mathbb{R}^n$ and $F(x)$ is bounded for every fixed $x \in \mathbb{R}^n$.

This extension appears, for example, as a result of Filippov regularization of a homogeneous discontinuous vector field (see [26]). In this paper the set-valued map $F$ is defined by
\[
F(x) = \bigcup_{s \in \mathbb{R}} \{e^{-\nu s}d(-s)f(d(s)x)\}, \ x \in \mathbb{R}^n,
\]
where $d$ is a generalized dilation and $\nu \in \mathbb{R}$. $F$ is the homogeneous extension (see [23]) of the continuous function $f$. Indeed, this set valued map $F$ is $d$-homogeneous in the following sense
\[
e^{\nu d(s)}F(x) = F(d(s)x), \ s \in \mathbb{R}, \ x \in \mathbb{R}^n.
\]
Another goal for which we define this extension is that there exist some functions which do not have a homogeneous approximation. Therefore, to study its stability and to evaluate its rate of convergence the homogeneous extension can be used. The investigation of this issue is presented in the rest of this section.

An example of such a system is the following:
\[
\dot{x}(t) = -\left(2 + \cos \left(\frac{1}{x(t)}\right)\right)x(t), \ t \geq 0.
\]
The right-hand side of (8) does not have a homogeneous approximation, but it has a homogeneous extension, which will allow us to study the behaviour of its solution: $\dot{x}(t) \in F(x(t)) = -x(t) \setminus [1, 3]$, $t \geq 0$.

**Remark 3.1**: We mention that we do not need to prove the existence of a solution to the extended inclusion $\dot{x} \in F(x)$, where $F$ is given by (6), since $f(x) \in F(x)$ and solution of $\dot{x} = f(x)$ always exists if $f$ is continuous: the solution of the system (1) belongs to the set of the solutions of the differential inclusion $\dot{x} \in F(x)$. The idea of this paper is to study the FTS of the differential inclusion (5), with $F$ defined by (6), by using the Lyapunov theory.

If (5), where $F$ defined by (6), is GAS, then (1) is also GAS. It is interesting to know when the inverse result holds. Thus, we choose the function $f$ such that the system (1) has a solution. The function $f$ of the system (1) satisfies the following assumptions
\begin{align*}
\mathcal{H}_1 : \ f : \mathbb{R}^n \to \mathbb{R}^n \quad &f(x) = H(x)b(x) \in \mathbb{R}^n. \\
\mathcal{H}_2 : \ H : \mathbb{R}^n \to M_{n,m} \quad &\text{is continuous and } d\text{-homogeneous of degree } \nu \text{ for every } b \in \mathbb{R}^m \text{ the function } x \mapsto H(x)b \text{ is } d\text{-homogeneous of degree } \nu, \text{ see below) and } H(x) = 0 \iff x = 0. \\
\mathcal{H}_3 : \ b : \mathbb{R}^n \to \mathbb{R}^m \quad &\text{is bounded (}\exists M > 0, \ |b(x)| \leq M, \forall x \in \mathbb{R}^n\text{) and } b : \mathbb{R}^n \setminus \{0\} \to \mathbb{R}^m \text{ is continuous.} \\
\mathcal{H}_4 : \ The \ system \ (1) \ is \ GAS.
\end{align*}

In particular, the hypothesis $\mathcal{H}_4$ implies that $b(x)$ does not belong to the kernel of $H(x)$, $\forall x \in \mathbb{R}^n \setminus \{0\}$. By the definition of the function $f(x) = H(x)b(x) \in \mathbb{R}^n$, since $b$ is bounded, then the set $F(x)$ is also bounded for any fixed $x$. This ensures that the supremum of $F$ on $S$ is finite. In the following theorem we give a sufficient condition which guarantee GAS of the differential inclusion $\dot{x} \in F(x)$.

**Theorem 3.1**: Let
\begin{itemize}
  \item the system (1) satisfies the assumptions $\mathcal{H}_1, \mathcal{H}_2, \mathcal{H}_3$ and $\mathcal{H}_4$,
  \item the dilation $d$ is strictly monotone,
  \item there exist a Lyapunov function $V$ of the system (1) and $0 < \beta < 1$, such that
    \[
    \max_{|s| = 1} ||b(y) - b(x)|| \leq \frac{\beta}{\max_{|s| = 1} ||D\nu(V, f)|x||} ||D\nu(V, f)|x||,
    \]
  \end{itemize}

Then the differential inclusion (5), with $F$ defined by (6), is GAS and there exists a $d$-homogeneous positive definite Lyapunov function $W$ such that
\[
\langle DW(x), h \rangle < 0, \forall h \in F(x), \text{ and } x \in \mathbb{R}^n \setminus \{0\}.
\]
All proofs are excluded due to space limitations. The following Remark treats the case when a nonlinear dynamical systems cannot satisfy the condition (9).
Remark 3.2: If the function $b$ satisfies the condition
- $\max_{\|x\| = 1} \|b(x)\| \leq \max_{\|x\| = 1} \|b(y) - b(x)\|, \forall y \in \mathbb{R}^n \setminus \{0\}$.
Then the system (1) with the assumptions $\mathcal{H}_1, \mathcal{H}_2, \mathcal{H}_3$ and $\mathcal{H}_4$, will not satisfy the condition (9).

Next, we consider the simple case when the function $b$ is a scalar function.

Corollary 3.1: If the vector field $f$ of the system (1) is defined by $f(x) = H(x)b(x)$, such that the function $b : \mathbb{R}^n \rightarrow \mathbb{R}$, is continuous, bounded and $H : \mathbb{R}^n \rightarrow \mathbb{R}^n$ is continuous, $d$-homogeneous with degree of homogeneity $\nu$. We assume that the system (1) is GAS, and $b(x) = 0 \implies x = 0$. Then the differential inclusion (5), with $F$ defined by (6), is GAS.

IV. Finite time stability results

The following theorem shows the FTS of the system (1) when the degree of homogeneity of $H$ is negative and (9) is satisfied.

Theorem 4.1: If
- the system (1) satisfies the assumptions $\mathcal{H}_1, \mathcal{H}_2, \mathcal{H}_3$ and $\mathcal{H}_4$,
- the dilation $d$ is strictly monotone,
- the degree of homogeneity of $H$ is negative ($\nu < 0$) and (9) holds.

Then the system (1) is GFTS. If the two first assumptions hold and the degree of homogeneity of $H$ is positive ($\nu > 0$), then the system (1) is fixed-time convergent to a ball.

Remark 4.1: If the vector field $f$ of the system (1) ensure the boundedness of the homogeneous extension $F(x)$ for every fixed $x \in \mathbb{R}^n$, the dilation $d$ is strictly monotone, the degree of homogeneity of $F$ is negative and there exist a Lyapunov function $V$ of the system (1) and $0 < \beta < 1$, such that

$$\max_{\|x\| = 1} \|e^{-\nu \tau} d(-\tau) f(d(\tau)x) - f(x)\| \leq -\beta \max_{\|x\| = 1} \langle DV(x), f(x)\rangle$$

for every fixed $\tau \in \mathbb{R}$. Then the system (1) is GFTS.

- If the degree of homogeneity of $F$ is positive, then we may guarantee the fixed-time convergence of the system (1) to a ball.
- If $\max_{\|x\| = 1} \|f(x)\| \leq \max_{\|x\| = 1} \|e^{-\nu \tau} d(-\tau) f(d(\tau)x) - f(x)\|, \forall \tau \in \mathbb{R}$. Then the condition (11) will not hold.

Corollary 4.1: If the vector field $f$ of the system (1) is defined by $f(x) = H(x)b(x)$, such that the function $b : \mathbb{R}^n \rightarrow \mathbb{R}$, is continuous, bounded and $H : \mathbb{R}^n \rightarrow \mathbb{R}^n$ is continuous, $d$-homogeneous with degree of homogeneity $\nu < 0$. We assume that the system (1) is GAS, and $b(x) = 0 \implies x = 0$. Then the system (1) is GFTS.

Example 4.1: Let us consider the following example:

$$f : x \in \mathbb{R} \mapsto -(1 + 0.5 \cos(\frac{1}{x}))x^{\frac{3}{2}} \in \mathbb{R}. \quad (12)$$

Let $F(x) = \bigcup_{s \in \mathbb{R}} \{e^{-s}d(-s)f(d(s)x)\}$ be the homogeneous extension of the function $f$, with $d(s) = e^{3s}$. Then $F(x) = -x^{\frac{3}{2}} \left[\frac{1}{2}, \frac{3}{2}\right]$. For a fixed $x$, $F(x)$ is bounded. The system $\dot{x}(t) = f(x(t))$ is GAS, then there exists a Lyapunov function $V$ for the system (1). From the definition of $f$, one has

$$e^\tau d(-\tau) f(d(\tau)x) = -\left(1 + 0.5 \cos \left(\frac{1}{d(\tau)x}\right)\right)x^{\frac{3}{2}}. \quad (13)$$

The fact that $\left(\frac{1 + 0.5 \cos \left(\frac{1}{d(\tau)x}\right)}{(1 + 0.5 \cos (\frac{1}{x}))}\right) > 0$, $\forall x \in \mathbb{R}^n$ and $\forall \tau \in \mathbb{R}$, gives

$$\frac{\partial V(x)}{\partial x} f(x) \frac{\partial \dot{V}(x)}{\partial x} = \frac{\partial V(x)}{\partial x} f(x) \left(1 + 0.5 \cos \left(\frac{1}{d(\tau)x}\right)\right) x^{\frac{3}{2}}\left(\frac{1 + 0.5 \cos (\frac{1}{x})}{1 + 0.5 \cos (\frac{1}{x})}\right) < 0.$$ 

Which proves the GAS of the origin under the set valued $F(x)$. This inequality and the fact that the degree of homogeneity $\nu = -1$ imply that the system $\dot{x} = f(x)$ is globally FTS.

V. Academic Example

Let us illustrate this results by the following example, for $\alpha, \beta > 0$

$$\begin{align*}
\dot{x} &= y - x^\frac{3}{2}\text{sign}(x), \\
\dot{y} &= -\alpha x^\frac{3}{4} - \beta \left(2 - \cos \left(\frac{1}{\sqrt{x^2 + y^2}}\right)\right)|y|^\frac{3}{2}\text{sign}(y) \quad (15)
\end{align*}$$

Again, we can write the system (15), as the following

$$\dot{z} = H(z)b(z), \quad z = \begin{pmatrix} x \\ y \end{pmatrix},$$

with

$$H(x, y) = \begin{pmatrix} y - x^\frac{3}{2}\text{sign}(x) & 0 \\
-\alpha x^\frac{3}{4} & -\beta |y|^\frac{3}{2}\text{sign}(y) \end{pmatrix}$$

and

$$b(x, y) = \begin{pmatrix} 2 - \cos \left(\frac{1}{\sqrt{x^2 + y^2}}\right) \end{pmatrix}.$$ 

The function $H$ is continuous and $d$-homogeneous of degree of homogeneity $\nu = -1$, provided that the dilation $d$ is defined as follows $d(s) = \begin{pmatrix} e^{3s} & 0 \\
0 & e^{2s} \end{pmatrix}$, which corespond to a weighted homogeneity. The function $b$ is continuous and bounded. We use the Lyapunov function

$$V(x, y) = \alpha \frac{3}{4} x^\frac{3}{2} + \frac{1}{2} y^2,$$

(17)
one gets $\dot{V} = -\alpha |x| - \beta \left( 2 - \cos \left( \frac{1}{\sqrt{x^2 + y^2}} \right) \right) |y|^2$. Then, we deduce that the origin of system (15) is GAS. The homogeneous extension of the function $f$ is given by

$$F(z) = \bigcup_{s \in \mathbb{R}} \{ H(z)b(d(s)z) \}.$$  \hfill (18)

Again by using the homogeneous Lyapunov function $V$, one has

$$\langle DV(z), H(z)b(d(s)z) \rangle = -\alpha |x| - \beta \left( 2 - \cos \left( \frac{1}{\sqrt{d^2 + x^2 + y^2}} \right) \right) |y|^2 < 0;$$  \hfill (19)

$\forall z \in S_d$ and $\forall s \in \mathbb{R}$. This proves that the differential inclusion given by the homogenous extension (18) is GAS, and the degree of homogeneity $\nu = -1 < 0$, then the theorem (3.1) implies that the origin of system (15) is FTS. The Figure 1 shows the solution of the system (16) with initial condition (3, 2) which reach the origin in finite time (less than $t = 6$).

VI. CONCLUSION

Finite-time stability of a non-homogeneous GAS system (homogeneous system with multiplicative bounded function) is investigated using the homogeneous extension and Lyapunov approach. Specifically, we presented some sufficient conditions on the vector fields to guarantee the finite-time stability of dynamical systems which are not homogeneous. By using the results that were proved for a homogeneous systems [9] we showed the FTS of our system. Example from Section V demonstrates that we can use the homogeneous extension to study the FTS of dynamical systems, which do not admit a homogeneous approximation. The homogeneous extension is also useful for stabilizing in finite-time a non-homogeneous evolution equations. This can be considered as a possible direction for the future research.
