# Deciding Feasibility of a Booking in the European Gas Market on a Cycle is in P 

Martine Labbé, Fränk Plein, Martin Schmidt, and Johannes Thürauf

#### Abstract

We show that the feasibility of a booking in the European entryexit gas market can be decided in polynomial time on single-cycle networks. The feasibility of a booking can be characterized by solving polynomially many nonlinear potential-based flow models for computing so-called potentialdifference maximizing load flow scenarios. We thus analyze the structure of these models and exploit both the cyclic graph structure as well as specific properties of potential-based flows. This enables us to solve the decision variant of the nonlinear potential-difference maximization by reducing it to a system of polynomials of constant dimension that is independent of the cycle's size. This system of fixed dimension can be handled with tools from real algebraic geometry to derive a polynomial-time algorithm. The characterization in terms of potential-difference maximizing load flow scenarios then leads to a polynomialtime algorithm for deciding the feasibility of a booking. Our theoretical results extend the existing knowledge about the complexity of deciding the feasibility of bookings from trees to single-cycle networks.

## 1. Introduction

During the last decades, the European gas market has undergone ongoing liberalization [29-31], resulting in the so-called entry-exit market system [22]. The main goal of this market re-organization is the decoupling of trading and actual gas transport. To achieve this goal within the European entry-exit market, gas traders interact with transport system operators (TSOs) via bookings and nominations. A booking is a capacity-right contract in which a trader reserves a maximum injection or withdrawal capacity at an entry or exit node of the TSO's network. On a day-ahead basis, these traders are then allowed to nominate an actual load flow up to the booked capacity. To this end, the traders specify the actual amount of gas to be injected to or withdrawn from the network such that the total injection and withdrawal quantities are balanced. On the other hand, the TSO is responsible for the transport of the nominated amounts of gas. By having signed the booking contract, the TSO guarantees that the nominated amounts can actually be transported through the network. More precisely, the TSO needs to be able to transport every set of nominations that complies with the signed booking contracts. Thus, an infinite number of possible nominations must be anticipated and checked for feasibility when the TSO accepts bookings. As a consequence, the entry-exit market decouples trading and transport. However, it also introduces many new challenges, e.g., the checking of feasibility of bookings or the computation of bookable capacities on the network [10, 26].

A large branch of research considers the feasibility of nominations, as well as the physics and the optimal control of gas networks w.r.t. single nominations.

[^0]Early works such as [28] or [8] study the physical properties of pipe networks. In particular, it is shown that in pressure-based networks the flows corresponding to a given load scenario are unique (given that the pressure at an arbitrary node is fixed). This result holds more generally for a potential-based flow model; see, e.g., [33]. Such a potential-based flow model is also used in [17] as an abstract model that approximates, among others like water or lossless direct current (DC) power flow, the physics of stationary flows in gas networks. The impact of potential-based physics models on the pricing in the corresponding market models is discussed in [36]. More generally, the study of gas transport and the feasibility of nominations has been researched from many different optimization perspectives. For instance, in [9] and [4], the authors study the cost-optimal transport of gas in the Belgian network before and after the market liberalization. An extension of the simplex algorithm is proposed to solve the problem for the case in which gas physics are approximated by piecewise-linear functions, enabling mixed-integer linear programming (MILP) techniques to be used. MILP approaches can also be found, e.g., in [12, 13, 27]. On the other hand, purely continuous and highly accurate nonlinear optimization (NLP) models are discussed in [41-43]. The combination of both worlds leads to challenging mixed-integer nonlinear models that are tackled, e.g., in [14, 15, 23]. Furthermore, approaches based on complementarity-constrained modeling are used in $[6,20,35,38-40]$. For the literature on optimization with partial differential equations and optimal control of gas networks, we refer to the recent survey [19] and the references therein. For an in-depth overview of optimization problems in gas networks, we also refer to the recent survey [32] as well as the book [24] and the references therein.

In contrast to the very rich literature on nominations, there is much less literature on checking the feasibility of a booking. First mathematical analyses of bookings are presented in the PhD theses [21, 44]. Moreover, the early technical report [11] discusses the reservation-allocation problem, which is highly related to the feasibility of bookings in the European entry-exit gas market. Deciding the feasibility of a booking can also be seen as an adjustable robust feasibility problem [7], where the set of booking-compliant nominations is the uncertainty set. Exploiting this perspective, the authors of [3] propose set containment techniques to decide robust feasibility and infeasibility with an application to the Greek gas transport network. With an application to the same network, the problem of robust discrete arc sizing is discussed in [34]. In [2], the uncertainty of physical parameters is considered. On the other hand, structural properties of the sets of feasible nominations and bookings such as nonconvexity and star-shapedness are discussed in [37]. For networks consisting of pipes only, a characterization of feasible bookings is given in [25] by conditions on nominations with maximum potential difference in the network. Using a linear potential-based flow model, these nominations can be computed efficiently using linear programming. In the nonlinear case, the authors give a polynomial-time dynamic programming approach for deciding the feasibility of a booking, if the underlying network is a tree. For the general case, i.e., nonlinear potential-based physics and arbitrary network topologies, the complexity of deciding the feasibility of a booking is not clear. Exponential upper bounds are given in [21] and the problem is shown to be in coNP in [11, 25]. However, neither hardness results nor polynomial-time algorithms can be found in the literature for cases where the network is not a tree.

In the light of this literature, our contribution is as follows. We further push back the frontier of hardness by showing that deciding the feasibility of a booking on single-cycle networks is in P. We analyze the structure of potential-difference maximizing nominations by exploiting the cyclic structure of the network as well
as techniques specific to potential-based flow models. Interestingly, this allows to reduce the task of checking the feasibility of a booking to checking the solvability of a system of polynomial equalities and inequalities in fixed dimension, where the latter does not depend on the size of the cycle. These systems of fixed dimension can then be tackled with tools from real algebraic geometry to derive a polynomial-time algorithm for deciding the feasibility of a booking.

The remainder of this paper is structured as follows. In Section 2, the problem of checking the feasibility of a booking is formally defined. Section 3 collects notations and known results that are used in this work. In Section 4, we introduce a notion of so-called flow-meeting points in cycle networks and study properties of potentialdifference maximizing nominations in Section 5. These results are then combined in Section 6 to derive a polynomial-time algorithm for deciding the feasibility of a booking on a cycle. Finally, we draw a conclusion and pose some open questions for future research in Section 7.

## 2. Problem Description

We model a gas network as a directed graph $G=(V, A)$ with node set $V$ and arc set $A$. The set of nodes is partitioned into the set $V_{+}$of entry nodes, at which gas is supplied, the set $V_{-}$of exit nodes, where gas is withdrawn, and the set $V_{0}$ of the remaining inner nodes. The node types are encoded in a vector $\sigma=\left(\sigma_{u}\right)_{u \in V}$, given by

$$
\sigma_{u}= \begin{cases}1, & \text { if } u \in V_{+} \\ -1, & \text { if } u \in V_{-} \\ 0, & \text { if } u \in V_{0}\end{cases}
$$

In real-world gas networks, the arc set is typically partitioned into different types of arcs that correspond to different elements of the network; e.g., pipes, compressors, control valves, etc. However, we restrict our analysis to passive networks that consist of pipes only. Furthermore, we assume that the graph $G$ is weakly connected. We follow the notation and definitions of [37], which we briefly introduce in the following.

Definition 2.1. A load flow is a vector $\ell=\left(\ell_{u}\right)_{u \in V} \in \mathbb{R}_{\geq 0}^{V}$, with $\ell_{u}=0$ for all $u \in V_{0}$. The set of load flow vectors is denoted by $L$.

A load flow thus corresponds to an actual situation at a single point in time by specifying the amount of gas $\ell_{u}$ that is supplied at $u \in V_{+}$or withdrawn at $u \in V_{-}$. Since, we only consider stationary flows, we need to impose that the supplied amount of gas equals the withdrawn amount, which leads to the definition of a nomination.

Definition 2.2. A nomination is a balanced load flow $\ell$, i.e., $\sigma^{\top} \ell=0$. The set of nominations is given by

$$
N:=\left\{\ell \in L: \sigma^{\top} \ell=0\right\} .
$$

Definition 2.3. A booking is a vector $b=\left(b_{u}\right)_{u \in V} \in \mathbb{R}_{\geq 0}^{V}$, with $b_{u}=0$ for all $u \in V_{0}$.

Nominations and bookings are connected by the following definition.
Definition 2.4. A nomination $\ell$ is called booking-compliant w.r.t. the booking $b$ if $\ell \leq b$ holds, where " $\leq$ " is meant component-wise. The set of booking-compliant (or $b$-compliant) nominations is given by

$$
N(b):=\{\ell \in N: \ell \leq b\} .
$$

Next, we introduce the notion of feasibility for nominations and bookings. We model stationary gas flows using an abstract physics model based on the Weymouth pressure drop equation and potential flows; see, e.g., [17] or [25]. It consists of arc flow variables $q=\left(q_{a}\right)_{a \in A} \in \mathbb{R}^{A}$ and potentials on the nodes $\pi=\left(\pi_{u}\right)_{u \in V} \in \mathbb{R}_{\geq 0}^{V}$. We note that in this context the potentials are closely linked to the gas pressures at the nodes, e.g., $\pi_{u}=p_{u}^{2}$ for the case of horizontal pipes. An in-depth explanation for non-horizontal pipes is given in [17].

Definition 2.5. A nomination $\ell \in N$ is feasible if a point $(q, \pi)$ exists that satisfies

$$
\begin{align*}
\sum_{a \in \delta^{\text {out }}(u)} q_{a}-\sum_{a \in \delta^{\text {in }}(u)} q_{a} & =\sigma_{u} \ell_{u}, & & u \in V,  \tag{1a}\\
\pi_{u}-\pi_{v} & =\Lambda_{a} q_{a}\left|q_{a}\right|, & & a=(u, v) \in A,  \tag{1b}\\
\pi_{u} & \in\left[\pi_{u}^{-}, \pi_{u}^{+}\right], & & u \in V, \tag{1c}
\end{align*}
$$

where $\Lambda_{a}>0$ is an arc-specific constant for any $a \in A$ and $0<\pi_{u}^{-} \leq \pi_{u}^{+}$are potential bounds for any $u \in V$.

Constraints (1a) ensure that flow is conserved at every node w.r.t. the nomination $\ell$. For any $a=(u, v) \in A$, Constraint (1b) links the flow $q_{a}$ to the difference $\pi_{u}-\pi_{v}$ of potentials at the endpoints of $a$. We note that flow can be negative, if it flows in the opposite direction of the orientation of the arc. Finally, due to technical restrictions of the network, the potentials need to satisfy bounds (1c).

In a network that only consists of pipes, the flows $q=q(\ell)$ corresponding to a given nomination $\ell \in N$ are unique since they are the optimal solution of a strictly convex minimization problem [28]. The potentials $\pi=\pi(\ell)$ are the corresponding dual variables and are unique as soon as a reference potential is fixed; see, e.g., [33]. The potentials are therefore unique up to shifts, which in particular implies that potential differences between nodes are unique for a given nomination $\ell$. Thus, in this case, the feasibility of a given nomination can be checked in polynomial time as described in [16]. In contrast, verifying the feasibility of a booking is less researched and much more difficult.

Definition 2.6. We say that a booking $b$ is feasible if all booking-compliant nominations $\ell \in N(b)$ are feasible.

To assess the feasibility of a booking, by definition, possibly an infinite number of nominations need to be checked. We make the following non-restrictive assumption on the potential bounds.

Assumption 2.7. The potential bound intervals have a non-empty intersection, i.e.,

$$
\bigcap_{u \in V}\left[\pi_{u}^{-}, \pi_{u}^{+}\right] \neq \emptyset
$$

This assumption ensures that zero flow is allowed in the network, which corresponds to the zero nomination. The latter is always booking-compliant and thus, it is a necessary condition for a booking to be feasible that the zero nomination is feasible. It is shown in [25], that a feasible booking $b$ can be characterized by constraints on the maximum potential differences between all pairs of nodes. Therefore, the authors introduce, for every fixed pair of nodes $\left(w_{1}, w_{2}\right) \in V^{2}$, the following problem

$$
\begin{align*}
\varphi_{w_{1} w_{2}}(b):=\max _{\ell, q} & \pi_{w_{1}}-\pi_{w_{2}}  \tag{2a}\\
\text { s.t. } & (1 \mathrm{a}),(1 \mathrm{~b}), \\
& 0 \leq \ell_{u} \leq b_{u}, \quad u \in V \tag{2b}
\end{align*}
$$

where $\varphi_{w_{1} w_{2}}$ is the corresponding optimal value function (depending on the booking $b$ ). Then, the booking $b$ is feasible if and only if

$$
\begin{equation*}
\varphi_{w_{1} w_{2}}(b) \leq \pi_{w_{1}}^{+}-\pi_{w_{2}}^{-} \tag{3}
\end{equation*}
$$

holds for every fixed pair of nodes $\left(w_{1}, w_{2}\right) \in V^{2}$. Hence, to verify the feasibility of a booking using this approach, it is necessary to solve the nonlinear and nonconvex global optimization problems (2). For tree-shaped networks, the authors give a polynomial-time dynamic programming algorithm solving (2). As a consequence, verifying the feasibility of a booking on trees can be done in polynomial time, which can also be obtained by adapting the results of [37]. In this paper, we extend this result to cycles and show that (3) can still be decided in polynomial time.

## 3. Notations and Basic Observations

Entry and exit nodes $v \in V_{+} \cup V_{-}$are called active if $\ell_{v}>0$ holds. We denote by $V_{+}^{>}:=\left\{v \in V_{+}: \ell_{v}>0\right\}$ and $V_{-}^{>}:=\left\{v \in V_{-}: \ell_{v}>0\right\}$ the set of active entries and exits, respectively. Furthermore, let the set of non-zero nominations be denoted by $N^{0}:=N \backslash\{0\}$.

Using directed graphs to represent gas networks is a modeling choice that allows to interpret the direction of flows. However, the physical flow in a potential-based network is not influenced by the direction of the arcs. Thus, for $u, v \in V$, we introduce the so-called flow-path $P:=P(u, v)=(V(P(u, v)), A(P(u, v)))$ in which $V(P(u, v)) \subseteq V$ contains the nodes of the path from $u$ to $v$ in the undirected version of the graph $G$ and $A(P(u, v)) \subseteq A$ contains the corresponding arcs of this path. For another pair of nodes $u^{\prime}, v^{\prime} \in V$, we say that $P\left(u^{\prime}, v^{\prime}\right)$ is a flow-subpath of $P(u, v)$ if $P\left(u^{\prime}, v^{\prime}\right) \subseteq P(u, v)$ holds and if $P\left(u^{\prime}, v^{\prime}\right)$ is itself a flow-path. In particular, this allows us to define an order on the nodes of a flow-path. For $P=P(u, v)$ and $u^{\prime}, v^{\prime} \in P$, we define $u^{\prime} \preceq_{P} v^{\prime}$ if and only if a flow-subpath $P\left(u, u^{\prime}\right) \subseteq P\left(u, v^{\prime}\right) .{ }^{1}$ If $u^{\prime} \neq v^{\prime}$ holds, we write $u^{\prime} \prec_{P} v^{\prime}$.

We now introduce the characteristic function of an $\operatorname{arc} a=(u, v) \in A$. For any flow-path $P$, it is given by

$$
\chi_{a}(P):= \begin{cases}1, & \text { if } u \prec_{P} v \\ -1, & \text { if } v \prec_{P} u, \\ 0, & \text { if } a \notin P .\end{cases}
$$

Next, we adapt a classical result from linear flow models to construct a flow decomposition in a gas network.

Lemma 3.1. Given $\ell \in N^{0}$, let $\mathcal{P}_{\ell}:=\left\{P(u, v): u \in V_{+}^{>}, v \in V_{-}^{>}\right\}$be the set of flow-paths in $G$ with an active entry as start node and an active exit as end node. Then, a decomposition of the given arc flows $q=q(\ell)$ into path flows exists, such that

$$
\begin{equation*}
q_{a}=\sum_{P \in \mathcal{P}_{\ell}} \chi_{a}(P) q(P), \quad a \in A \tag{4}
\end{equation*}
$$

where $q(P)$ is the nonnegative flow along the flow-path $P \in \mathcal{P}_{\ell}$.

[^1]Furthermore, we require that if $q_{a}>0$ for $a \in A$ and $\chi_{a}(P)=-1$ for $P \in \mathcal{P}_{\ell}$, then $q(P)=0$ holds. Similarly, if $q_{a}<0$ for $a \in A$ and $\chi_{a}(P)=1$ for $P \in \mathcal{P}_{\ell}$, then $q(P)=0$ holds.

Proof. If $q_{a}<0$ holds, then we replace arc $a=(u, v)$ by $(v, u)$ and set $q_{(v, u)}=$ $-q_{(u, v)}$. The resulting flow still corresponds to nomination $\ell$. We now apply Theorem 3.5 of Chapter 3.5 of the book by Ahuja et al. [1]. Given Constraints (1b), the flows $q$ cannot contain any cycle flows. As a consequence, we obtain a flow decomposition that satisfies all the properties.

Observe that, by construction, the flows $q$ and the path flows need to traverse arcs in the same direction. A direct consequence of the flow decomposition is that the nomination can be expressed as a function of the path flows.

Corollary 3.2. For any $u \in V_{+}^{>}$, the condition

$$
\begin{equation*}
\sum_{v \in V_{-}^{\geq}} q(P(u, v))=\ell_{u} \tag{5}
\end{equation*}
$$

and for any $v \in V_{-}^{>}$, the condition

$$
\begin{equation*}
\sum_{u \in V_{+}^{>}} q(P(u, v))=\ell_{v} \tag{6}
\end{equation*}
$$

is satisfied.
Next, we define the potential-difference function along a given flow-path.
Definition 3.3. Let $\ell \in N$ and a flow-path $P$ be given. Then, the potentialdifference function along $P$ is given by

$$
\begin{equation*}
\Pi_{P}: \mathbb{R}^{A} \rightarrow \mathbb{R}, \quad \Pi_{P}(q):=\sum_{a \in P} \chi_{a}(P) \Lambda_{a} q_{a}\left|q_{a}\right| \tag{7}
\end{equation*}
$$

where $q=q(\ell)$.
As a consequence of Constraint (1b), for any node pair $u, v \in V$ and for any flow-path $P:=P(u, v)$, the equation $\pi_{u}(\ell)-\pi_{v}(\ell)=\Pi_{P}(q(\ell))$ holds. We note that if the path $P$ is directed from $u$ to $v$, the potential-difference function simplifies to

$$
\Pi_{P}(q)=\sum_{a \in P} \Lambda_{a} q_{a}\left|q_{a}\right|
$$

Since, we will mostly use directed paths in what follows, we state some properties that hold in this case.

Lemma 3.4. For $u, v \in V$, let $P:=P(u, v)$ be a directed path. Then, the following holds:
(a) $\Pi_{P}$ is continuous.
(b) $\Pi_{P}$ is strictly increasing w.r.t. every component. That means, for $q$ fixed except for one value $q_{a}, a \in P, \Pi_{P}$ is increasing in $q_{a}$.
(c) $\Pi_{P}$ is unbounded w.r.t. every component, i.e., for $a \in P$,

$$
\lim _{q_{a} \rightarrow-\infty} \Pi_{P}=-\infty \quad \text { and } \quad \lim _{q_{a} \rightarrow \infty} \Pi_{P}=\infty
$$

(d) $\Pi_{P}$ is additive w.r.t. the flow-path, i.e., for all $v^{\prime} \in P$,

$$
\Pi_{P}=\Pi_{P\left(u, v^{\prime}\right)}+\Pi_{P\left(v^{\prime}, v\right)}
$$

where $P=P\left(u, v^{\prime}\right) \cup P\left(v^{\prime}, v\right)$.

Figure 1. Example of a cyclic gas network. Dashed arcs to or from a node indicate entries or exits, respectively.
(e) $\Pi_{P} \geq 0$ holds if and only if $\pi_{u} \geq \pi_{v}$ holds.

## 4. Problem Reduction via Flow-Meeting Points

In the remainder of this paper, we restrict ourselves to a network that is a single cycle. A stylized example of a cyclic gas network is shown in Figure 1. A first observation is that in a potential-based flow model, there cannot be any cycling flow. Thus, flow in a cycle has to "meet" in at least one node. In this section, we show that the set of all feasible flows in Problem (2) can be restricted to flows along two different paths and that these flows always admit the same direction along these paths.

In a cycle, for every pair of nodes $u, v \in V$, exactly two flow-paths exist. We denote by $P^{\mathrm{l}}(u, v)=\left(V^{\mathrm{l}}(u, v), A^{1}(u, v)\right)$ the left path obtained when $v$ is reached in counterclockwise direction from $u$. Similarly, $P^{\mathrm{r}}(u, v)=\left(V^{\mathrm{r}}(u, v), A^{\mathrm{r}}(u, v)\right)$ is the right path obtained by using the clockwise direction. Moreover, $A=A^{\mathrm{l}}(u, v) \cup A^{\mathrm{r}}(u, v)$ holds. If it is clear from the context, we use previously introduced notations indexed by "l" (left) or "r" (right), when they have to be understood w.r.t. $P^{\mathrm{l}}$ or $P^{\mathrm{r}}$, respectively.

It is not hard to observe that, given Constraints (1a) and (1b), the highest potential in $G$ is attained at an entry node.

Lemma 4.1. Let $\ell \in N^{0}$ and $o \in V_{+}$be an entry with highest potential. Then, $\pi_{o}(\ell) \geq \pi_{v}(\ell)$ holds for all $v \in V$.

Given that no cycle flow is possible in a gas network, flows need to change directions along a single cycle. We now specify a node as flow-meeting point if arc flows from different directions "meet" at this node.

Definition 4.2. Let $\ell \in N^{0}$ and $o \in V_{+}$be an entry node with highest potential, i.e., $\pi_{o}(\ell) \geq \pi_{v}(\ell)$ for all $v \in V$. Then, $w \in V \backslash\{o\}$ is a flow-meeting point if there exist $u \in V^{\mathrm{l}}(o, w)$ adjacent to $w$ that satisfies $\pi_{u}(\ell)>\pi_{w}(\ell)$ as well as $v \in V^{\mathrm{r}}(o, w)$ such that $\pi_{v}(\ell)>\pi_{w}(\ell)$ and $\pi_{v^{\prime}}(\ell)=\pi_{w}(\ell)$ holds for all $v^{\prime} \in V^{\mathrm{r}}(v, w) \backslash\{v\}$.

This definition is illustrated in Figure 2. Note that we choose the node $o \in V_{+}$ with highest potential to ensure that there is no flow through node $o$. If multiple entry nodes with highest potential exist, flow-meeting points are still well-defined. In fact, as a direct consequence of Lemma 4.1, the definition of a flow-meeting point

Figure 2. Flow directions and resulting flow-meeting points. Bold arcs indicate entry-exit activity and flow directions, whereas gray arcs indicate inactive nodes or zero arc-flow. In this example, exits $w$ and $w^{\prime}$ are flow-meeting points.
is independent of the choice of node $o$. By definition, the flow-meeting point $w$ has non-zero flow entering on one arc and possibly zero flow on the other arc. Thus, $w$ is necessarily an exit.

From Constraints (1a) and (1b), it directly follows that for every non-zero nomination at least one flow-meeting point exists. We note that there can be multiple flow-meeting points with different potentials. However, since every flowmeeting point is an exit, it is not hard to observe that the following result holds.

Lemma 4.3. Let $\ell \in N^{0}$ and $w$ be a flow-meeting point with lowest potential. Then, $\pi_{w}(\ell) \leq \pi_{v}(\ell)$ holds for all $v \in V$.

In the remainder of this section, we show that for fixed $\left(w_{1}, w_{2}\right) \in V^{2}$ there are optimal solutions of (2) with at most one flow-meeting point. More precisely, we prove that an optimal solution exists that admits a special entry node $o \in V_{+}$, a special exit node $w \in V_{-}$, and has nonnegative flow from $o$ to $w$.

Before we prove several auxiliary results, let us first make a notational comment. For $(o, w) \in V_{+} \times V_{-}$, we are interested in the partition of the cycle into two flowpaths $P^{\mathrm{l}}(o, w)$ and $P^{\mathrm{r}}(o, w)$. When discussing the order of nodes along $P^{\mathrm{l}}(o, w)$, we therefore simply write $u \preceq_{1} v$ instead of $u \preceq_{P^{1}(o, w)} v$. We use an analogous simplification for $P^{\mathrm{r}}(o, w)$.

A first observation is that nominations can be modified such that the flow from an entry node with highest potential to an exit node with lowest potential is nonnegative, while preserving particular potential differences.

Lemma 4.4. Given $\ell \in N^{0}$ with flows $q=q(\ell)$, let $o \in V_{+}$be an entry with highest potential and $w$ a flow-meeting point with lowest potential. Furthermore, assume that $P^{\mathrm{l}}(o, w)$ and $P^{\mathrm{r}}(o, w)$ are directed paths. Then, for a given $x \in V^{\mathrm{l}}(o, w)$, a nomination $\ell^{\prime} \in N$ exists such that the following properties hold (with $q^{\prime}=q\left(\ell^{\prime}\right)$ ),
(a) $\ell^{\prime} \leq \ell$,
(b) $0 \leq q_{a}^{\prime}$ for all $a \in A^{1}(o, w)$,
(c) $q_{a}^{\prime}=q_{a}$ for all $a \in A^{\mathrm{r}}(o, w)$,
(d) $\Pi_{P^{1}(o, x)}\left(q^{\prime}\right)=\Pi_{P^{1}(o, x)}(q) \geq 0$,
(e) $\Pi_{P^{1}(o, w)}\left(q^{\prime}\right)=\Pi_{P^{1}(o, w)}(q)$.

Proof. We modify nomination $\ell$ and $q(\ell)$ such that the required properties are satisfied. To this end, we consider a flow decomposition as in Lemma 3.1.

Since $o \in V_{+}$has highest potential and $P^{\mathrm{l}}(o, w)$ and $P^{\mathrm{r}}(o, w)$ are directed paths, it follows $q_{a} \geq 0$ for all $a \in \delta^{\text {out }}(o)$. In analogy, $q_{a} \geq 0$ for all $a \in \delta^{\text {in }}(w)$. From Lemma 3.1, we then deduce that $q(P(u, v))=0$ if one of the following four conditions holds:

- $u \in V_{+}^{1}(o, w) \backslash\{o\}$ and $v \in V_{-}^{\mathrm{r}}(o, w) \backslash\{w\}$,
- $u \in V_{+}^{\mathrm{r}}(o, w) \backslash\{o\}$ and $v \in V_{-}^{1}(o, w) \backslash\{w\}$,
- $u \in V_{+}^{1}(o, w) \backslash\{o\}, v \in V_{-}^{1}(o, w) \backslash\{w\}$, and $P^{\mathrm{r}}(o, w) \subseteq P(u, v)$, or
- $u \in V_{+}^{\mathrm{r}}(o, w) \backslash\{o\}, v \in V_{-}^{\mathrm{r}}(o, w) \backslash\{w\}$, and $P^{\mathrm{l}}(o, w) \subseteq P(u, v)$.

In other words, since there is no flow through $o$ or $w$, there cannot be a flow-path with non-zero flow through them, neither. Consequently, for an arc $a \in P^{\mathrm{l}}(o, w)$, we can simplify Equation (4) to

$$
\begin{equation*}
q_{a}=\sum_{P^{\mathrm{l}} \in \mathcal{P}_{\ell}} \chi_{a}\left(P^{\mathrm{l}}\right) q\left(P^{\mathrm{l}}\right) \tag{8}
\end{equation*}
$$

We now modify the flows $q$ such that Property 4.4 (b) is satisfied. To this end, for every arc $a \in P^{\mathrm{l}}(o, w)$ and for every $P^{\mathrm{l}} \in \mathcal{P}_{\ell}$, we set the flow $q\left(P^{\mathrm{l}}\right)=0$ if $\chi_{a}\left(P^{\mathrm{l}}\right)=-1$ holds. We denote the modified flows and the corresponding nomination by $q^{\prime}$ and $\ell^{\prime}$. Then, for $a \in A^{1}(o, w)$, the modified flows are given by

$$
\begin{equation*}
q_{a}^{\prime}=\sum_{P^{\mathrm{l}} \in \mathcal{P}_{\ell}: \chi_{a}\left(P^{\mathrm{l}}\right)=1} q\left(P^{\mathrm{l}}\right) \tag{9}
\end{equation*}
$$

and satisfy 4.4 (b). Furthermore, by Corollary 3.2, the corresponding modified nomination $\ell^{\prime}$ satisfies 4.4 (a). Additionally, 4.4 (c) is satisfied because we have not modified any flows $q_{a}$ for $a \in A^{\mathrm{r}}(o, w)$. Due to Lemma 3.4 (b), the modifications possibly increase the potential difference between $o$ and $x$, as well as, between $o$ and $w$. This is the case if and only if the corresponding flow-path contains an arc with negative flow in $q$, which is now set to zero in the modified flows $q^{\prime}$. Next, we need to iteratively adapt nomination $\ell^{\prime}$ and flows $q^{\prime}$ to ensure the remaining properties $4.4(\mathrm{~d})$ and 4.4 (e).

Step 1: If an arc $a \in A^{1}(o, x)$ with $q_{a}<0$ exists, then, the potential difference between $o$ and $x$ is increased, i.e., $\Pi_{P^{1}(o, x)}\left(q^{\prime}\right)>\Pi_{P^{1}(o, x)}(q)$ holds. Let $u \in V^{1}(o, x)$, possibly with $u=x$, such that $q_{a^{\prime}} \geq 0$ holds for all $a^{\prime} \in A^{1}(u, x)$ and $\left|V^{1}(u, x)\right|$ is maximal. Given the flow decomposition, we then know that we have not modified arc flows on $P^{\mathrm{l}}(u, x)$. Consequently, $\Pi_{P^{1}(u, x)}\left(q^{\prime}\right)=\Pi_{P^{1}(u, x)}(q)$ holds. Thus, $\Pi_{P^{1}(o, u)}\left(q^{\prime}\right)>\Pi_{P^{1}(o, u)}(q)$ must hold. In particular, we have $a \in A^{1}(o, u)$. From Lemma 3.1 and the construction of $u$ it follows that for $v_{1} \in V_{+}^{1}(o, u) \backslash\{u\}$ and $v_{2} \in V_{-}^{1}(u, w)$, we have $q\left(P^{\mathrm{l}}\left(v_{1}, v_{2}\right)\right)=0$. Consequently, the potential difference $\Pi_{P^{1}(o, u)}\left(q^{\prime}\right)$ is only determined by positive flows $q\left(P^{\mathrm{l}}\left(v_{1}, v_{2}\right)\right)$ with $o \preceq_{1} v_{1} \preceq_{1} v_{2} \preceq_{1} u$. We further note that $\Pi_{P^{1}(o, u)}(0)=0$ and, by Lemma $3.4(\mathrm{e}), \Pi_{P^{1}(o, u)}(q) \geq 0$ holds because $\pi_{o} \geq \pi_{u}$. Consequently, due to Lemma 3.4 (a) and 3.4 (b), we can decrease flows $q\left(P^{\mathrm{l}}\left(v_{1}, v_{2}\right)\right)$ with $o \preceq_{1} v_{1} \preceq_{1} v_{2} \preceq_{1} u$ such that $\Pi_{P^{1}(o, u)}\left(q^{\prime}\right)=\Pi_{P^{1}(o, u)}(q)$ holds. These flow modifications only decrease the nomination at entries and exits in $V^{1}(o, u)$. Thus, Lemma 3.4 (d) implies the Properties 4.4 (a)-4.4 (d). We note that we have not changed an arc flow of $A^{1}(x, w)$ in the modifications of Step 1.

Now it is left to show that we can modify the flows $q^{\prime}$ and the corresponding nomination $\ell^{\prime}$ such that, additionally, Property 4.4 (e) is satisfied. To this end, we assume that an arc $a \in A^{1}(x, w)$ with $q_{a}<0$ exists. Otherwise the claim follows directly from Lemma 3.4.

Step 2: If an arc $a \in A^{1}(x, w)$ with $q_{a}<0$ exists, then, $\Pi_{P^{1}(x, w)}\left(q^{\prime}\right)>\Pi_{P^{1}(x, w)}(q)$ holds. Let $u \in V^{1}(x, w)$ be a node such that $q_{a^{\prime}} \geq 0$ holds for all $a^{\prime} \in A^{1}(x, u)$ and $\left|V^{1}(x, u)\right|$ is maximal. Given the flow decomposition, we then know that we have not modified arc flows on $A^{1}(x, u)$. Thus, $\Pi_{P^{1}(x, u)}\left(q^{\prime}\right)=\Pi_{P^{1}(x, u)}(q)$ and $\Pi_{P^{1}(u, w)}\left(q^{\prime}\right)>\Pi_{P^{1}(u, w)}(q)$ hold. Furthermore, $\Pi_{P^{1}(u, w)}(0)=0$ and $\Pi_{P^{1}(u, w)}(q) \geq 0$ are valid. The latter is satisfied due to $\pi_{w} \leq \pi_{u}$ and Lemma 3.4 (e). Similarly to Step 1, the potential difference $\Pi_{P^{1}(u, w)}\left(q^{\prime}\right)$ is only determined by positive flows $q\left(P^{\mathrm{l}}\left(v_{1}, v_{2}\right)\right)$ with $u \preceq_{1} v_{1} \preceq_{1} v_{2} \preceq_{1} w$. Due to Lemma 3.4, we can again decrease flows $q\left(P^{\mathrm{l}}\left(v_{1}, v_{2}\right)\right)$ for $u \preceq_{1} v_{1} \preceq_{1} v_{2} \preceq_{1} w$ such that $\Pi_{P^{1}(u, w)}\left(q^{\prime}\right)=\Pi_{P^{1}(u, w)}(q)$ holds and Property 4.4 (e) is satisfied. Furthermore, this modification does not affect any of Properties 4.4 (b)-4.4 (d). Since we only decrease the nomination at entries and exits, Property 4.4 (a) is also satisfied.

In total, we can modify nomination $\ell$ and $q(\ell)$ by repeatedly applying Step 1 and 2 such that $\ell^{\prime}$ and the corresponding $q\left(\ell^{\prime}\right)$ satisfy Properties 4.4 (a)-4.4 (e).

The same result can be established for the symmetric situation.
Corollary 4.5. Given $\ell \in N^{0}$ with flows $q=q(\ell)$, let $o \in V_{+}$be an entry with highest potential and $w$ a flow-meeting point with lowest potential. Furthermore, assume that $P^{\mathrm{l}}(o, w)$ and $P^{\mathrm{r}}(o, w)$ are directed paths. Then, for a given $x \in V^{\mathrm{r}}(o, w)$, a nomination $\ell^{\prime} \in N$ exists such that the following properties hold (with $q^{\prime}=q\left(\ell^{\prime}\right)$ ),
(a) $\ell^{\prime} \leq \ell$,
(b) $0 \leq q_{a}^{\prime}$ for all $a \in A^{\mathrm{r}}(o, w)$,
(c) $q_{a}^{\prime}=q_{a}$ for all $a \in A^{1}(o, w)$,
(d) $\Pi_{P^{\mathrm{r}}(o, x)}\left(q^{\prime}\right)=\Pi_{P^{\mathrm{r}}(o, x)}(q) \geq 0$,
(e) $\Pi_{P^{\mathrm{r}}(o, w)}\left(q^{\prime}\right)=\Pi_{P^{\mathrm{r}}(o, w)}(q)$.

Lemma 4.6. Given $\ell \in N^{0}$ with flows $q=q(\ell)$, let $o \in V_{+}$be an entry with highest potential and $w$ a flow-meeting point with lowest potential. Furthermore, assume that $P^{1}(o, w)$ and $P^{\mathrm{r}}(o, w)$ are directed paths. Then, for given $o \preceq_{1} x \preceq_{1}$ $y \preceq_{1} w$ with $\Pi_{P^{1}(x, y)}(q) \geq 0$, a nomination $\ell^{\prime} \in N$ with $q^{\prime}=q\left(\ell^{\prime}\right)$ exists such that Properties 4.4 (a) and 4.4 (b) are satisfied and $\Pi_{P^{1}(x, y)}\left(q^{\prime}\right)=\Pi_{P^{1}(x, y)}(q) \geq 0$ holds.

Proof. In analogy to the proof of Lemma 4.4, we consider a flow decomposition of Lemma 3.1. Furthermore, for every arc $a \in A^{1}(o, w)$, we set the flow $q\left(P^{\mathrm{l}}\left(v_{1}, v_{2}\right)\right)=0$ if $\chi_{a}\left(P^{\mathrm{l}}\left(v_{1}, v_{2}\right)\right)=-1$ holds. Consequently, the modified flows $q^{\prime}$, given as in (9), and the corresponding nomination $\ell^{\prime}$ satisfy 4.4 (a) and 4.4 (b). By this modification, we increase the potential difference only if an $\operatorname{arc}$ in $P^{l}(o, w)$ with negative flow in $q$ exists.

If an arc $a \in A^{1}(o, x)$ with $q_{a}<0$ exists, we apply Step 1 of the proof of Lemma 4.4, where we do not change the flow on any $\operatorname{arc}$ of $P^{l}(x, w)$. On the other hand, if an $\operatorname{arc} a \in A^{1}(y, w)$ with $q_{a}<0$ exists, we apply Step 2 , where we do not change the flow on any arc of $P^{\mathrm{l}}(o, y)$. If an arc $a \in A^{1}(x, y)$ with $q_{a}<0$ exists, then, $\Pi_{P^{1}(x, y)}\left(q^{\prime}\right)>\Pi_{P^{1}(x, y)}(q) \geq 0$ holds. Due to Lemma 3.4 (a), 3.4 (b), and $\Pi_{P^{1}(x, y)}(0)=0$, we can decrease flows $q\left(P^{1}\left(v_{1}, v_{2}\right)\right)$ such that $\Pi_{P^{1}(x, y)}\left(q^{\prime}\right)=$ $\Pi_{P^{1}(x, y)}(q)$ and Properties $4.4(\mathrm{a})$ and $4.4(\mathrm{~b})$ are still satisfied. This modification possibly decreases the potential differences $\Pi_{P^{1}(o, x)}\left(q^{\prime}\right)$ and $\Pi_{P^{1}(y, w)}\left(q^{\prime}\right)$. As a consequence of Lemma 3.4, we deduce that $\Pi_{P^{1}(o, w)}\left(q^{\prime}\right) \leq \Pi_{P^{\mathrm{r}}(o, w)}\left(q^{\prime}\right)$.

If $\Pi_{P^{1}(o, w)}\left(q^{\prime}\right)<\Pi_{P^{\mathrm{r}}(o, w)}\left(q^{\prime}\right)$ is satisfied, $q^{\prime}$ is not feasible. However, this can be easily fixed. Since the arc flow of any $a \in A^{\mathrm{r}}(o, w)$ stays unchanged, $\Pi_{P^{\mathrm{r}}(o, w)}\left(q^{\prime}\right)=\Pi_{P^{\mathrm{r}}(o, w)}(q) \geq 0$ holds as a consequence of Lemma 3.4 (e). Since Property $4.4(\mathrm{~b})$ is satisfied for the modified flows $q^{\prime}$, we deduce that $\Pi_{P^{1}(o, w)}\left(q^{\prime}\right) \geq 0$. It follows that $0=\Pi_{P^{\mathrm{r}}(o, w)}(0) \leq \Pi_{P^{\mathrm{L}}(o, w)}\left(q^{\prime}\right)<\Pi_{P^{\mathrm{r}}(o, w)}\left(q^{\prime}\right)$. By Lemma 3.4, we
can decrease $q\left(P^{\mathrm{r}}\left(v_{1}, v_{2}\right)\right)$ such that $\Pi_{P^{1}(o, w)}\left(q^{\prime}\right)=\Pi_{P^{\mathrm{r}}(o, w)}\left(q^{\prime}\right)$ holds. Furthermore, $\Pi_{P^{1}(x, y)}\left(q^{\prime}\right)=\Pi_{P^{1}(x, y)}(q)$ and Properties 4.4 (a) and $4.4(\mathrm{~b})$ still hold.

Analogously, we derive the symmetric result.
Corollary 4.7. Given $\ell \in N^{0}$ with flows $q=q(\ell)$, let $o \in V_{+}$be an entry with highest potential and $w$ a flow-meeting point with lowest potential. Furthermore, assume that $P^{\mathrm{l}}(o, w)$ and $P^{\mathrm{r}}(o, w)$ are directed paths. Then, for given $o \preceq_{\mathrm{r}} x \preceq_{\mathrm{r}}$ $y \preceq_{\mathrm{r}} w$ with $\Pi_{P^{\mathrm{r}}(x, y)}(q) \geq 0$, a nomination $\ell^{\prime} \in N$ with $q^{\prime}=q\left(\ell^{\prime}\right)$ exists such that Properties 4.5 (a) and 4.5 (b) are satisfied and $\Pi_{P^{1}(x, y)}\left(q^{\prime}\right)=\Pi_{P^{1}(x, y)}(q) \geq 0$ holds.

As a final auxiliary result, we give a sufficient condition for the existence of a unique flow-meeting point.

Lemma 4.8. Given $\ell \in N^{0}$ with flows $q=q(\ell)$, let $o \in V_{+}$be an entry with highest potential and let $w \in V \backslash\{o\}$ be an arbitrary node. Furthermore, assume that $P^{\mathrm{l}}(o, w)$ and $P^{\mathrm{r}}(o, w)$ are directed paths. If $q_{a} \geq 0$ for all $a \in A=A^{1}(o, w) \cup A^{\mathrm{r}}(o, w)$, then there is a unique flow-meeting point $x$. Furthermore, $x \in V^{\mathrm{l}}(o, w)$ holds.

Proof. Since $q \geq 0$, it holds $\pi_{w} \leq \pi_{v}$ for all $v \in V$. Let $x \in V^{1}(o, w)$ be such that $q_{a}=0$ holds for all $a \in A^{1}(x, w)$ and $\left|V^{1}(x, w)\right|$ is maximal. By construction of $x$, it is the only flow-meeting point and it may hold $x=w$.

Recall that it is sufficient to solve Problem (2) for each fixed node pair $\left(w_{1}, w_{2}\right) \in V^{2}$ and then check Inequality (3) to decide the feasibility of a booking. We now combine the previous results to show that an optimal solution of Problem (2) with at most one flow-meeting point exists.

Theorem 4.9. Let $b$ be a booking and $\left(w_{1}, w_{2}\right) \in V^{2}$ a fixed pair of nodes. Then, there is an optimal solution of Problem (2) that admits at most one flow-meeting point $w$.

Proof. Let $(\ell, q, \pi)$ be an optimal solution of (2). Choose an entry $o \in V_{+}$with highest potential and a flow-meeting point $w$ with lowest potential. Due to Lemma 4.3, $\pi_{w} \leq \pi_{v}$ holds for all $v \in V$. Without loss of generality, we assume that $P^{\mathrm{l}}(o, w)$ and $P^{\mathrm{r}}(o, w)$ are directed.

The zero nomination corresponds to a feasible point that satisfies the claim and $\pi_{w_{1}}-\pi_{w_{2}}=0$. Thus, we can assume that

$$
\begin{equation*}
\pi_{w_{1}}-\pi_{w_{2}}>0 \tag{10}
\end{equation*}
$$

holds. If there is only one flow-meeting point, we are done. Hence, we now additionally assume that $\ell$ admits at least two different flow-meeting points.

Case 1: $w_{1} \in V^{\mathrm{l}}(o, w)$ and $w_{2} \in V^{\mathrm{r}}(o, w)$ holds. Thus, we can equivalently reformulate (10) as

$$
0<\pi_{w_{1}}-\pi_{w_{2}}=-\Pi_{P^{1}\left(o, w_{1}\right)}(q)+\Pi_{P^{\mathrm{r}}\left(o, w_{2}\right)}(q)
$$

We now apply Lemma 4.4 with $x=w_{1}$ and Corollary 4.5 with $x=w_{2}$. We denote the obtained nomination by $\ell^{\prime}$ and the corresponding flows by $q^{\prime}=q\left(\ell^{\prime}\right)$. Consequently, (10) is satisfied by $q\left(\ell^{\prime}\right) \geq 0$. The claim then follows by Lemma 4.8.

Case 2: $w_{1} \in V^{\mathrm{r}}(o, w)$ and $w_{2} \in V^{1}(o, w)$ holds. The claim follows in analogy to Case 1.

Case 3: $w_{1}, w_{2} \in V^{1}(o, w)$ and $w_{1} \preceq_{1} w_{2}$. In this case, (10) reads

$$
0<\pi_{w_{1}}-\pi_{w_{2}}=\Pi_{P^{\mathrm{l}}\left(w_{1}, w_{2}\right)}(q) .
$$

We first apply Corollary 4.5 with $x=w$. Thus, (10) is still satisfied and $q_{a}^{\prime} \geq 0$ holds for every $a \in P^{\mathrm{r}}(o, w)$. We now apply Lemma 4.6 with $x=w_{1}$ and $y=w_{2}$. Consequently, $q^{\prime} \geq 0$ holds and (10) is still satisfied. The claim then again follows from Lemma 4.8.

Case 4: $w_{1}, w_{2} \in V^{\mathrm{r}}(o, w)$ and $w_{1} \preceq_{\mathrm{r}} w_{2}$. The claim follows in analogy to Case 3 .
Case 5: $w_{1}, w_{2} \in V^{1}(o, w)$ and $w_{2} \preceq_{1} w_{1}$. Inequality (10) then reads

$$
0<\pi_{w_{1}}-\pi_{w_{2}}=-\Pi_{P^{1}\left(w_{2}, w_{1}\right)}(q)
$$

We first apply Corollary 4.5 with $x=w$. Thus, (10) is still satisfied and $q_{a}^{\prime} \geq 0$ for every $a \in P^{\mathrm{r}}(o, w)$. Now take $u \in V^{\mathrm{l}}(o, w)$ such that $q_{a}^{\prime} \geq 0$ for all $a \in A^{1}(u, w)$ and $\left|A^{1}(u, w)\right|$ is maximal. If $u \in V^{1}\left(o, w_{2}\right)$, then $q_{a}^{\prime} \geq 0$ for all $a \in A^{1}\left(w_{2}, w_{1}\right)$. Thus, $\Pi_{P^{1}\left(w_{2}, w_{1}\right)}(q) \geq 0$ also holds, which contradicts (10). Hence, we conclude that $u \in V^{1}\left(w_{2}, w\right) \backslash\left\{w_{2}\right\}$. By Lemma 3.1 and the construction of $u$, we deduce that for $a \in A^{1}(u, w)$ the flow is given by

$$
q_{a}^{\prime}=\sum_{P^{\mathrm{l}} \in \overline{\mathcal{P}}_{\ell}} q\left(P^{\mathrm{l}}\right), \quad \overline{\mathcal{P}}_{\ell}:=\left\{P^{\mathrm{l}} \in \mathcal{P}_{\ell}: P^{\mathrm{l}} \subseteq P^{\mathrm{l}}(u, w), \chi_{a}\left(P^{\mathrm{l}}\right)=1\right\}
$$

We now set the flow $q\left(P^{\mathrm{l}}\right)=0$ for $P^{\mathrm{l}} \subseteq P^{\mathrm{l}}(u, w)$ and $\chi_{a}\left(P^{\mathrm{l}}\right)=1$. By this modification, we have possibly decreased $\Pi_{P^{1}\left(w_{2}, w_{1}\right)}$ and thus also $\Pi_{P^{1}(o, w)}$. In particular, (10) is still satisfied. Lemma 3.4 (d) implies

$$
\Pi_{P^{1}(o, w)}\left(q^{\prime}\right)=\Pi_{P^{1}(o, u)}\left(q^{\prime}\right)+\Pi_{P^{\mathrm{l}}(u, w)}\left(q^{\prime}\right)
$$

After modification, we have $\Pi_{P^{1}(u, w)}\left(q^{\prime}\right)=\Pi_{P^{1}(u, w)}(0)=0$ and $\Pi_{P^{1}(o, u)}\left(q^{\prime}\right)=$ $\Pi_{P^{1}(o, u)}(q)$. By Lemma 3.4 (e) and $\pi_{o} \geq \pi_{u}, \Pi_{P^{1}(o, u)}(q)$ is nonnegative. We deduce that $\Pi_{P^{1}(o, u)}\left(q^{\prime}\right) \geq 0$. Given Lemma 3.4 (a) and $3.4(\mathrm{~b})$, we can now decrease flows $q\left(P^{\mathrm{r}}\right)$ such that $\Pi_{P^{\mathrm{l}}(o, w)}\left(q^{\prime}\right)=\Pi_{P^{\mathrm{r}}(o, w)}\left(q^{\prime}\right)$ holds. After this modification, $(10)$ is still satisfied. Thus, $w$ is now connected to a flow-meeting point in $V^{1}(o, u)$ because $q_{a}^{\prime}=0$ holds for all $a \in P^{\mathrm{l}}(u, w)$. Consequently, for nomination $\ell^{\prime}$ a flowmeeting point in $V^{1}(o, u)$ with lowest potential exists. We now repeat this procedure until either the claim holds or a new flow-meeting point with lowest potential is an element of $V^{1}\left(o, w_{1}\right)$. Then, we apply the respective case of Cases $1-4$.

Case 6: $w_{1}, w_{2} \in V^{\mathrm{r}}(o, w)$ and $w_{2} \preceq_{\mathrm{r}} w_{1}$. The claim follows in analogy to Case 5.

As a direct consequence of this result, we deduce the following corollary.
Corollary 4.10. Let $b$ be a booking and $\left(w_{1}, w_{2}\right) \in V^{2}$ a fixed pair of nodes. Then, there exist nodes $(o, w) \in V_{+} \times V_{-}$and an optimal solution ( $\ell, q, \pi$ ) of Problem (2) with $q \geq 0$, if we assume that $P^{\mathrm{l}}(o, w)$ and $P^{\mathrm{r}}(o, w)$ are directed paths.

The previous result implies that when determining potential-difference maximizing nominations solving Problem (2) for fixed $\left(w_{1}, w_{2}\right) \in V^{2}$, we can additionally restrict the search space by iteratively considering $(o, w) \in V_{+} \times V_{-}$and imposing that there is flow from $o$ to $w$. This is further formalized and exploited in the next section.

## 5. Structure of Potential-Difference Maximizing Nominations

In this section, we fix $\left(w_{1}, w_{2}\right) \in V^{2}$ and show that there exist optimal solutions of (2) with additional structure that allows to reduce the dimension of the problem. For convenience, we denote by $\varphi:=\varphi_{w_{1} w_{2}}$ the optimal value function of the corresponding problem.

Based on the results of Section 4, in particular, Corollary 4.10, we next show that (3) can be decided by considering the following variant of Problem (2) for every

$$
\begin{align*}
&(o, w) \in V_{+} \times V_{-}: \\
&  \tag{11a}\\
& \bar{\varphi}_{o w}(b):=\max _{\ell, q} \pi_{w_{1}}-\pi_{w_{2}} \\
& \text { s.t. }(1 \mathrm{a}),(2 \mathrm{~b}),  \tag{11b}\\
& \pi_{u}-\pi_{v}=\Lambda_{a} q_{a}\left|q_{a}\right|, \quad a \in A^{\prime},  \tag{11c}\\
& q_{a} \geq 0, \quad a \in A^{\prime},  \tag{11d}\\
& \pi_{u} \in[0, M], \quad u \in V,
\end{align*}
$$

where $P^{\mathrm{l}}(o, w)$ and $P^{\mathrm{r}}(o, w)$ are directed paths, $A^{\prime}=A^{\mathrm{l}}(o, w) \cup A^{\mathrm{r}}(o, w)$, and $M>0$ is a large but finite constant. Note that in addition to the constraints of (2), we now also impose nonnegative flow from $o$ to $w$, thus effectively reducing the feasible domain of the problem.

Theorem 5.1. There exists a finite constant $M>0$ such that

$$
\varphi(b)=\max _{(o, w) \in V_{+} \times V_{-}} \bar{\varphi}_{o w}(b)
$$

holds. Furthermore, the optimal values are finite.
Proof. The variables $\ell$ and $q(\ell)$ are bounded in (2). Then, the variables $\pi$ can be bounded by a finite constant $M$ without changing the objective value due to Theorem 7.1 of Chapter 7 in [24]. Consequently, the feasible region can be reduced to a bounded and thus compact set. By Assumption 2.7, the vector of all zeros is feasible. It follows, that both (2) and (11) are feasible and bounded.

Let $(\ell, q, \pi)$ be the optimal solution corresponding to $\max _{(o, w) \in V_{+} \times V_{-}} \bar{\varphi}_{o w}(b)$. First, observe that the arc orientation does not play any role in Problem (2). If an arc has a different orientation, we just switch the sign of the corresponding flow variable. Thus, we assume w.l.o.g. that $P^{\mathrm{l}}(o, w)$ and $P^{\mathrm{r}}(o, w)$ are directed paths in the given instance of (2). Consequently, $(\ell, q, \pi)$ is feasible for (2). Thus,

$$
\varphi(b) \geq \max _{(o, w) \in V_{+} \times V_{-}} \bar{\varphi}_{o w}(b) .
$$

The other inequality follows directly from Corollary 4.10.
As a consequence, the feasibility of a booking can be characterized using Problem (11) as follows.

Corollary 5.2. A booking $b$ is feasible if and only if for every pair $\left(w_{1}, w_{2}\right) \in V^{2}$ and for every $(o, w) \in V_{+} \times V_{-}$,

$$
\begin{equation*}
\bar{\varphi}_{o w}(b) \leq \pi_{w_{1}}^{+}-\pi_{w_{2}}^{-} \tag{12}
\end{equation*}
$$

We now further analyze the structure of optimal solutions of (11) for fixed $(o, w) \in V_{+} \times V_{-}$and given $\left(w_{1}, w_{2}\right) \in V^{2}$ w.r.t. their respective position in the cycle. Without loss of generality, we assume that $P^{\mathrm{l}}(o, w)$ and $P^{\mathrm{r}}(o, w)$ are directed paths.
5.1. Nodes on Different Sides of $G$. Assume that $w_{1} \in P^{\mathrm{l}}(o, w)$ and $w_{2} \in$ $P^{\mathrm{r}}(o, w)$ holds. We show that an optimal solution $(\ell, q, \pi)$ of (11) exists that additionally satisfies the following properties:
(a) Two entries $s_{1}^{l}, s_{2}^{l} \in V_{+}^{1}(o, w)$ with $s_{1}^{l} \preceq_{1} s_{2}^{l}$ exist such that

$$
\begin{array}{ll}
\ell_{v}=0, & v \in\left(V_{+}^{1}\left(o, s_{1}^{l}\right) \cup V_{+}^{1}\left(s_{2}^{l}, w\right)\right) \backslash\left\{o, s_{1}^{l}, s_{2}^{l}\right\}, \\
\ell_{v}=b_{v}, & v \in V_{+}^{1}\left(s_{1}^{l}, s_{2}^{l}\right) \backslash\left\{s_{1}^{l}, s_{2}^{l}\right\} .
\end{array}
$$

Figure 3. Configuration of $s$ and $t$ nodes if $w_{1} \in P^{\mathrm{l}}(o, w)$ and $w_{2} \in P^{\mathrm{r}}(o, w)$. Boxes qualitatively illustrate the amount of the booking that is nominated.
(b) An exit $t_{1}^{l} \in V_{-}^{1}(o, w)$ exists such that

$$
\begin{array}{cc}
\ell_{v}=0, & v \in V_{-}^{1}\left(o, t_{1}^{l}\right) \backslash\left\{t_{1}^{l}\right\} \\
\ell_{v}=b_{v}, & v \in V_{-}^{1}\left(t_{1}^{l}, w\right) \backslash\left\{t_{1}^{l}\right\} .
\end{array}
$$

(c) An entry $s_{1}^{r} \in V_{+}^{\mathrm{r}}(o, w)$ exists such that

$$
\begin{array}{cc}
\ell_{v}=b_{v}, & v \in V_{+}^{\mathrm{r}}\left(o, s_{1}^{r}\right) \backslash\left\{s_{1}^{r}\right\} \\
\ell_{v}=0, & v \in V_{+}^{\mathrm{r}}\left(s_{1}^{r}, w\right) \backslash\left\{s_{1}^{r}\right\} .
\end{array}
$$

(d) Two exits $t_{1}^{r}, t_{2}^{r} \in V_{-}^{\mathrm{r}}(o, w)$ with $t_{1}^{r} \preceq_{\mathrm{r}} t_{2}^{r}$ exist such that

$$
\begin{array}{ll}
\ell_{v}=0, & v \in\left(V_{-}^{\mathrm{r}}\left(o, t_{1}^{r}\right) \cup V_{-}^{\mathrm{r}}\left(t_{2}^{r}, w\right)\right) \backslash\left\{t_{1}^{r}, t_{2}^{r}, w\right\}, \\
\ell_{v}=b_{v}, & v \in V_{-}^{\mathrm{r}}\left(t_{1}^{r}, t_{2}^{r}\right) \backslash\left\{t_{1}^{r}, t_{2}^{r}\right\}
\end{array}
$$

A possible configuration of nodes $o, w_{1}, s_{1}^{l}, s_{2}^{l}, t_{1}^{l}, w, w_{2}, s_{1}^{r}, t_{1}^{r}, t_{2}^{r}$ is given in Figure 3. To show the existence of such a solution, we introduce a bilevel problem, where the lower level is given by (11) and the upper level chooses, among all lower-level
optimal solutions，one with the additional structure．It is given by

$$
\begin{align*}
& \min \quad f_{1}\left(\ell, x^{\preceq_{1}}, x^{乙_{1}}\right)+f_{2}\left(\ell, y^{\preceq_{1}}\right)+f_{3}\left(\ell, x^{\succeq_{\mathrm{r}}}\right)+f_{4}\left(\ell, y^{\preceq_{\mathrm{r}}}, y^{\succeq_{\mathrm{r}}}\right)  \tag{13a}\\
& \text { s.t. (11), } \\
& \tilde{M} x_{v}^{\preceq_{1}} \geq \sum_{u \in V_{+}^{1}(o, v) \backslash\{o\}} \ell_{u}, \quad v \in V_{+}^{1}(o, w) \backslash\{o\},  \tag{13b}\\
& \tilde{M} x_{v}^{\succeq} \geq \sum_{u \in V_{+}^{1}(v, w)} \ell_{u}, \quad v \in V_{+}^{1}(o, w) \backslash\{o\},  \tag{13c}\\
& \tilde{M} y_{v}^{\preceq_{1}} \geq \sum_{u \in V_{-}^{1}(o, v)} \ell_{u}, \quad v \in V_{-}^{1}(o, w),  \tag{13d}\\
& \tilde{M} x_{v}^{\succeq \mathrm{r}} \geq \sum_{u \in V_{+}^{\mathrm{r}}(v, w)} \ell_{u}, \quad v \in V_{+}^{\mathrm{r}}(o, w),  \tag{13e}\\
& \tilde{M} y_{v}^{\preceq_{\mathrm{r}}} \geq \sum_{u \in V_{-}^{\mathrm{r}}(o, v)} \ell_{u}, \quad v \in V_{-}^{\mathrm{r}}(o, w) \backslash\{w\},  \tag{13f}\\
& \tilde{M} y_{v}^{\succeq \mathrm{r}} \geq \sum_{u \in V_{-}^{\mathrm{r}}(v, w) \backslash\{w\}} \ell_{u}, \quad v \in V_{-}^{\mathrm{r}}(o, w) \backslash\{w\},  \tag{13~g}\\
& x_{\bar{v}}^{\preceq_{1}}, x_{\bar{v}}^{\succeq}, x_{\bar{v}}^{\succeq \mathrm{r}}, y_{v}^{\preceq_{v}}, y_{v}^{\preceq_{\mathrm{r}}}, y_{\bar{v}}^{\succeq \mathrm{r}} \in\{0,1\}, \quad v \in V, \tag{13h}
\end{align*}
$$

where $\tilde{M}=\sum_{u \in V} b_{u}$ and $f_{1}, \ldots, f_{4}$ are continuous functions that we specify later． By Constraints（13b）and（13c），the variables $x_{\bar{v}}^{\complement_{1}}$ and $x_{\bar{v}}^{\succeq_{1}}$ model the existence of an active entry before and after $v$ on $P^{1}$ ．Similarly，Constraints（13d）ensure that $y_{v}^{\preceq_{1}}$ determines the existence of an active exit before $v$ on $P^{1}$ ．An analogous interpretation can be given for Constraints（13e）－（13g）and the variables $x^{乙_{\mathrm{r}}}, y^{\unlhd_{\mathrm{r}}}, y^{\succeq_{\mathrm{r}}}$ ．For simplicity，we write $\bar{\varphi}:=\bar{\varphi}_{\text {ow }}$ ．Then，the optimal value function reformulation of（13）is given by

$$
\begin{array}{cl}
\min & f_{1}\left(\ell, x^{\preceq_{1}}, x^{\succeq_{1}}\right)+f_{2}\left(\ell, y^{\preceq_{1}}\right)+f_{3}\left(\ell, x^{\succeq_{\mathrm{r}}}\right)+f_{4}\left(\ell, y^{\preceq_{\mathrm{r}}}, y^{\succeq_{\mathrm{r}}}\right) \\
\text { s.t. } & (1 \mathrm{a}),(2 \mathrm{~b}),(11 \mathrm{~b})-(11 \mathrm{~d}), \\
& (13 \mathrm{~b})-(13 \mathrm{~h}), \\
& \pi_{w_{1}}-\pi_{w_{2}} \geq \bar{\varphi}(b) . \tag{14d}
\end{array}
$$

Here，Constraint（14b）determines the feasible domain of Problem（11）and Con－ straint（14d）guarantees feasible points with a potential difference of at least $\bar{\varphi}(b)$ ． Thus，we only consider optimal solutions of（11）．We denote by

$$
z:=\left(\ell, q, \pi, x^{\preceq_{1}}, x^{\succeq_{1}}, x^{\succeq_{\mathrm{r}}}, y^{\preceq_{1}}, y^{\preceq_{\mathrm{r}}}, y^{\succeq_{\mathrm{r}}}\right)
$$

a feasible point of（14）．In particular，we have the following result．
Lemma 5．3．Let $z$ be feasible for（14），then $(\ell, q, \pi)$ is an optimal solution of（11）． Conversely，every optimal solution of（11）can be extended to a feasible point of（14）．

Proof．The first statement follows from the previous discussion．For the converse，let an optimal solution $(\ell, q, \pi)$ of（11）be given．We construct a solution $z$ as follows：

$$
x_{v}^{\preceq_{v}^{1}}=1, \quad \text { if and only if an active } u \in V_{+}^{1}(o, v) \backslash\{o\} \text { exists, }
$$

$x_{v}^{\succeq}=1$ ，if and only if an active $u \in V_{+}^{1}(v, w) \backslash\{o\}$ exists，
$y_{v}^{\swarrow_{1}}=1, \quad$ if and only if an active $u \in V_{-}^{1}(o, v)$ exists，
$x_{v}^{\succeq \mathrm{r}}=1, \quad$ if and only if an active $u \in V_{+}^{\mathrm{r}}(v, w)$ exists，
$y_{v}^{\preceq_{\mathrm{r}}}=1$ ，if and only if an active $u \in V_{-}^{\mathrm{r}}(o, v) \backslash\{w\}$ exists，

$$
y_{v}^{\succeq \mathrm{r}}=1, \quad \text { if and only if an active } u \in V_{-}^{\mathrm{r}}(v, w) \backslash\{w\} \text { exists. }
$$

We now specify the parts of the objective function of (14) and prove connections between these functions and the stated Properties (a)-(d). We discuss and prove the results for $f_{1}$ and $f_{2}$ in detail, whereas we only state the results for $f_{3}$ and $f_{4}$, since they are very similar. The missing proofs can be found in Appendix A.

Lemma 5.4. Let $z$ be feasible for (14) and

$$
\begin{equation*}
f_{1}\left(\ell, x^{\preceq_{1}}, x^{\succeq_{1}}\right):=\sum_{\substack{i, j \in V_{+}^{1}(o, w) \backslash\{o\}: \\ i \preceq_{1 j}}} x_{i}^{\preceq_{1}} x_{j}^{\succeq_{1}} \sum_{v \in V_{+}^{1}(i, j) \backslash\{i, j\}}\left(b_{v}-\ell_{v}\right) \tag{15}
\end{equation*}
$$

Then, $f_{1}\left(\ell, x^{\preceq_{1}}, x^{\succeq_{1}}\right)=0$ holds if and only if $\ell$ satisfies Property (a).
Proof. Let $z$ be feasible for (14). For $i, j \in V_{+}^{1}(o, w) \backslash\{o\}$ where $i \preceq_{1} j$,

$$
x_{i}^{\preceq_{1}} x_{j}^{\succeq_{1}} \sum_{v \in V_{+}^{1}(i, j) \backslash\{i, j\}}\left(b_{v}-\ell_{v}\right) \geq 0
$$

holds. Assume now that Property (a) does not hold. Consequently, there are $u_{1}, u_{2}, u_{3} \in V_{+}^{1}(o, w) \backslash\{o\}$ with $u_{1} \prec_{1} u_{2} \prec_{1} u_{3}$ such that $\ell_{u_{1}}>0, \ell_{u_{2}}<b_{u_{2}}$, and $\ell_{u_{3}}>0$ hold. Thus, $x_{u_{1}}^{\complement_{1}}=1=x_{u_{3}}^{\succeq_{1}}$ and $\sum_{v \in V_{+}^{1}\left(u_{1}, u_{3}\right) \backslash\left\{u_{1}, u_{3}\right\}}\left(b_{v}-\ell_{v}\right)>0$, therefore

$$
x_{\bar{u}_{1}}^{\preceq_{1}} x_{\bar{u}_{3}}^{\succ_{1}} \sum_{v \in V_{+}^{1}\left(u_{1}, u_{3}\right) \backslash\left\{u_{1}, u_{3}\right\}}\left(b_{v}-\ell_{v}\right)>0
$$

holds. Consequently, $f_{1}\left(\ell, x^{\preceq_{1}}, x^{\succeq_{1}}\right)>0$.
If $\ell$ satisfies Property (a), then we set $x_{\bar{u}}^{\swarrow_{1}}=0$ for all $u \in P^{1}\left(o, s_{1}^{l}\right) \backslash\left\{s_{1}^{l}\right\}$. Otherwise, we set $x_{\bar{u}}^{\complement_{1}}=1$. Additionally, we set $x_{\bar{u}}^{\complement_{1}}=1$ for all $u \in P^{1}\left(o, s_{2}^{l}\right)$ and otherwise we set $x_{\bar{u}}^{\succ}=0$. Consequently, for $i \in V_{+}^{1}\left(o, s_{1}^{l}\right) \backslash\left\{s_{1}^{l}\right\}$ or $j \in$ $V_{+}^{1}\left(s_{2}^{l}, w\right) \backslash\left\{s_{2}^{l}\right\}$, we have $x_{i}^{\preceq ㇒} x_{j}^{\succeq 1}=0$ and for $i, j \in V_{+}^{1}\left(s_{1}^{l}, s_{2}^{l}\right)$,

$$
\sum_{v \in V_{+}^{1}(i, j) \backslash\{i, j\}}\left(b_{v}-\ell_{v}\right)=0
$$

holds due to Property (a). Consequently, $f_{1}\left(\ell, x^{\preceq_{1}}, x^{\succeq_{1}}\right)=0$ holds.
Lemma 5.5. Let $z$ be feasible for (14) and

$$
\begin{equation*}
f_{2}\left(\ell, y^{\preceq_{1}}\right):=\sum_{i \in V_{-}^{1}(o, w)} y_{i}^{\preceq_{1}} \sum_{v \in V_{-}^{1}(i, w) \backslash\{i\}}\left(b_{v}-\ell_{v}\right) . \tag{16}
\end{equation*}
$$

Then, $f_{2}\left(\ell, y^{\preceq_{1}}\right)=0$ holds if and only if $\ell$ satisfies Property (b).
Proof. Let $z$ be feasible for (14). For $i \in V_{-}^{1}(o, w)$,

$$
y_{i}^{\preceq_{1}} \sum_{v \in V_{-}^{1}(i, w) \backslash\{i\}}\left(b_{v}-\ell_{v}\right) \geq 0
$$

holds. Assume now that Property (b) does not hold. Consequently, there are $u_{1}, u_{2} \in V_{-}^{1}(o, w)$ with $u_{1} \prec_{1} u_{2}$ such that $\ell_{u_{1}}>0$ and $\ell_{u_{2}}<b_{u_{2}}$ hold. Thus, $y_{\bar{u}_{1}}^{\preceq_{1}}=1$ and

$$
\sum_{v \in V_{-}^{1}\left(u_{1}, w\right) \backslash\left\{u_{1}\right\}}\left(b_{v}-\ell_{v}\right)>0
$$

holds, which implies $f_{2}\left(\ell, y^{\preceq_{1}}\right)>0$.

If $\ell$ satisfies Property (b), then we set $y_{u}^{\swarrow_{1}^{1}}=0$ for all $u \in V_{-}^{1}\left(o, t_{1}^{l}\right) \backslash\left\{t_{1}^{l}\right\}$. Otherwise, we set $y_{u}^{\preceq_{1}^{l}}=1$. Furthermore, for $i \in V_{-}^{1}\left(t_{1}^{l}, w\right)$,

$$
\sum_{v \in V_{-}^{1}(i, w) \backslash\{i\}}\left(b_{v}-\ell_{v}\right)=0
$$

holds due to Property (b). Consequently, $f_{2}\left(\ell, y^{\preceq_{1}}\right)=0$ holds.
Lemma 5.6. Let $z$ be feasible for (14) and

$$
\begin{equation*}
f_{3}\left(\ell, x^{\succeq \mathrm{r}}\right):=\sum_{i \in V_{+}^{\mathrm{r}}(o, w)} x_{i}^{\succeq_{\mathrm{r}}} \sum_{v \in V_{+}^{\mathrm{r}}(o, i) \backslash\{i\}}\left(b_{v}-\ell_{v}\right) . \tag{17}
\end{equation*}
$$

Then, $f_{3}\left(\ell, x^{\succeq \mathrm{r}}\right)=0$ holds if and only if $\ell$ satisfies Property (c).
Lemma 5.7. Let $z$ be feasible for (14) and

$$
\begin{equation*}
f_{4}\left(\ell, y^{\preceq_{\mathrm{r}}}, y^{\succeq_{\mathrm{r}}}\right)=\sum_{\substack{i, j \in V_{-}^{\mathrm{r}}(o, w) \backslash\{w\}: \\ i \preceq_{\mathrm{r}} j}} y_{i}^{\preceq_{\mathrm{r}}} y_{j}^{\succeq_{\mathrm{r}}} \sum_{v \in V_{-}^{\mathrm{r}}(i, j) \backslash\{i, j\}}\left(b_{v}-\ell_{v}\right) . \tag{18}
\end{equation*}
$$

Then, $f_{4}\left(\ell, y^{\preceq_{\mathrm{r}}}, y^{\succeq_{\mathrm{r}}}\right)=0$ holds if and only if $\ell$ satisfies Property (d).
In the following, we consider $f_{1}, \ldots, f_{4}$ as specified in Lemmas 5.4-5.7. As a next step, we show that changes on the boundary nodes of Properties (a)-(d) do not affect the values of $f_{1}, \ldots, f_{4}$, since their corresponding binary products are zero.

Lemma 5.8. Let $z$ be an optimal solution of (14) and let $u_{1}, u_{3} \in V_{+}^{1}(o, w)$ with $u_{1} \preceq_{1} u_{3}$ be nodes such that $\ell_{u_{1}}>0, \ell_{u_{3}}>0, \ell_{u}=0$ for all $u \in\left(V_{+}^{1}\left(o, u_{1}\right) \cup\right.$ $\left.V_{+}^{1}\left(u_{3}, w\right)\right) \backslash\left\{o, u_{1}, u_{3}\right\}$. Suppose further that $z^{\prime}$ is feasible for (14) with

$$
\ell_{u_{1}}^{\prime}>0, \quad \ell_{u_{3}}^{\prime}>0, \quad \ell_{u}^{\prime}=\ell_{u}, \quad u \in V_{+}^{1}(o, w) \backslash\left\{o, u_{1}, u_{3}\right\}
$$

Then, $f_{1}\left(\ell^{\prime}, x^{\preceq_{1}}, x^{\succeq 1}\right)=f_{1}\left(\ell, x^{\preceq_{1}}, x^{乙_{1}}\right)$ holds.
Proof. Optimality of $z$ and the choice of $u_{1}$ and $u_{3}$ imply $x_{\bar{u}}^{\preceq_{1}}=0$ for all $u \in$ $V_{+}^{1}\left(o, u_{1}\right) \backslash\left\{o, u_{1}\right\}$ and $x_{u}^{\succeq}=0$ for all $u \in V_{+}^{1}\left(u_{3}, w\right) \backslash\left\{u_{3}\right\}$. Hence, for $i, j \in$ $V_{+}^{1}(o, w) \backslash\{o\}$ with $i \preceq_{1} j$ we have

$$
x_{i}^{\preceq_{1}} x_{j}^{\succeq_{1}} \sum_{v \in V_{+}^{1}(i, j) \backslash\{i, j\}}\left(b_{v}-\ell_{v}\right)=0,
$$

whenever $u_{1}$ or $u_{3}$ is in $V_{+}^{1}(i, j) \backslash\{i, j\}$, because then $x_{i}^{\preceq_{1}} x_{j}^{\succeq_{1}}=0$. Consequently, a change of $\ell_{u_{1}}$ or $\ell_{u_{3}}$ does not change $f_{1}\left(\ell, x^{\preceq_{1}}, x^{\succeq}\right)$.

Lemma 5.9. Let $z$ be an optimal solution of (14) and let $v_{1} \in V_{-}^{1}(o, w)$ be a node such that $\ell_{v_{1}}>0$ and $\ell_{v}=0$ for all $v \in V_{-}^{1}\left(o, v_{1}\right) \backslash\left\{v_{1}\right\}$. Suppose further that $z^{\prime}$ is feasible for (14) with

$$
\ell_{v_{1}}^{\prime}>0, \quad \ell_{v}^{\prime}=\ell_{v}, \quad u \in V_{-}^{1}(o, w) \backslash\left\{v_{1}, w\right\}
$$

Then, $f_{2}\left(\ell^{\prime}, y^{\preceq_{1}}\right)=f_{2}\left(\ell, y^{\preceq_{1}}\right)$ holds.
Proof. Optimality of $z$ and the choice of $v_{1}$ imply $y_{\stackrel{\swarrow}{v}}^{1}=0$ for all $v \in V_{-}^{1}\left(o, v_{1}\right) \backslash\left\{v_{1}\right\}$. Hence,

$$
y_{i}^{\preceq_{1}} \sum_{v \in V_{-}^{1}(i, w) \backslash\{i\}}\left(b_{v}-\ell_{v}\right)=0
$$

holds whenever $v_{1} \in V_{-}^{1}(i, w) \backslash\{i\}$. Thus, a change of $\ell_{v_{1}}$ does not change $f_{2}\left(\ell, y^{\preceq_{1}}\right)$.

Lemma 5.10. Let $z$ be an optimal solution of (14) and let $u_{1} \in V_{+}^{\mathrm{r}}(o, w)$ be a node such that $\ell_{u_{1}}>0$ and $\ell_{u}=0$ for all $u \in V_{+}^{\mathrm{r}}\left(u_{1}, w\right) \backslash\left\{u_{1}\right\}$. Suppose further that $z^{\prime}$ is feasible for (14) with

$$
\ell_{u_{1}}^{\prime}>0, \quad \ell_{u}^{\prime}=\ell_{u}, \quad u \in V_{+}^{\mathrm{r}}(o, w) \backslash\left\{o, u_{1}\right\}
$$

Then, $f_{3}\left(\ell, x^{\succeq_{\mathrm{r}}}\right)=f_{3}\left(\tilde{\ell}, x^{\succeq_{\mathrm{r}}}\right)$ holds.
Lemma 5.11. Let $z$ be an optimal solution of (14) and let $v_{1}, v_{3} \in V_{-}^{\mathrm{r}}(o, w)$ with $v_{1} \preceq_{\mathrm{r}} v_{3}$ be nodes such that $\ell_{v_{1}}>0, \ell_{v_{3}}>0, \ell_{u}=0$ for all $u \in\left(V_{-}^{\mathrm{r}}\left(o, v_{1}\right) \cup\right.$ $\left.V_{-}^{\mathrm{r}}\left(v_{3}, w\right)\right) \backslash\left\{v_{1}, v_{3}, w\right\}$. Suppose further that $z^{\prime}$ is feasible for (14) with

$$
\ell_{v_{1}}^{\prime}>0, \quad \ell_{v_{3}}^{\prime}>0, \quad \ell_{u}^{\prime}=\ell_{u}, \quad u \in V_{-}^{\mathrm{r}}(o, w) \backslash\left\{v_{1}, v_{3}, w\right\}
$$

Then, $f_{4}\left(\ell^{\prime}, y^{\preceq_{\mathrm{r}}}, y^{\succeq_{\mathrm{r}}}\right)=f_{4}\left(\ell, y^{\preceq_{\mathrm{r}}}, y^{\succeq_{\mathrm{r}}}\right)$ holds.
We show that there is an optimal solution of (11) that satisfies Properties (a)-(d). More precisely, we prove that the optimal value of (14) is zero by individually treating $f_{1}, \ldots, f_{4}$. The final result then easily follows from Lemmas 5.4-5.7.

Lemma 5.12. If $z$ is an optimal solution of (14), then $f_{1}\left(\ell, x^{\preceq_{1}}, x^{\succeq}\right)=0$ holds.
Proof. Let $z$ be an optimal solution of (14). By contradiction, we assume that $f_{1}\left(\ell, x^{\preceq_{1}}, x^{\succeq 1}\right)>0$ holds. Lemma 5.4 implies that $\ell$ does not satisfy Property (a). Consequently, there are entries $u_{1}, u_{2}, u_{3} \in V_{+}^{1}(o, w) \backslash\{o\}$ with $u_{1} \prec_{1} u_{2} \prec_{1} u_{3}$ such that $\ell_{u_{1}}>0, \ell_{u_{2}}<b_{u_{2}}$, and $\ell_{u_{3}}>0$. If $q_{a}>0$ for $a \in \delta^{\text {out }}(o) \cap P^{\mathrm{l}}(o, w)$, we replace $u_{1}=o$. Otherwise, we choose $u_{1} \neq o$ such that $\ell_{u}=0$ holds for all $u \in V_{+}^{1}\left(o, u_{1}\right) \backslash\left\{o, u_{1}\right\}$ and we choose $u_{3}$ such that $\ell_{u}=0$ holds for all $u \in V_{+}^{1}\left(u_{3}, w\right) \backslash\left\{u_{3}\right\}$. We now consider a flow decomposition as in Lemma 3.1. Due to $q \geq 0$, an exit $v_{3} \in V_{-}^{1}\left(u_{3}, w\right)$ with $q\left(P^{\mathrm{l}}\left(u_{3}, v_{3}\right)\right)>0$ exists. Moreover, by the choice of $u_{1}$, there is an exit $v_{1} \in V_{-}^{1}\left(u_{1}, w\right)$ with $\ell_{v}=0$ for all $v \in V_{-}^{1}\left(o, v_{1}\right) \backslash\left\{v_{1}\right\}$ and $q\left(P^{\mathrm{l}}\left(u_{1}, v_{1}\right)\right)>0$. We need to distinguish two cases.

Case 1: $v_{1} \prec_{1} u_{2}$ holds. We now decrease $q\left(P^{\mathrm{l}}\left(u_{3}, v_{3}\right)\right)$ by $\varepsilon>0$ and increase $q\left(P^{\mathrm{l}}\left(u_{2}, v_{3}\right)\right)$ by the same amount $\varepsilon$. This increases the potential difference $\Pi_{P^{1}(o, w)}(q)$ due to $u_{2} \prec_{1} u_{3}$. Thus, we decrease $q\left(P^{\mathrm{l}}\left(u_{1}, v_{1}\right)\right)$ by $\tilde{\varepsilon}>0$. Due to Lemma 3.4, we can choose $\varepsilon$ and $\tilde{\varepsilon}$ such that $\Pi_{P^{1}(o, w)}(q)$ stays the same as before the modification and $\ell_{u_{1}}>0, \ell_{u_{2}} \leq b_{u_{2}}, \ell_{u_{3}}>0, \ell_{v_{1}}>0$ holds. In particular, the binary variables of $z$ stay the same after modification. Due to this and Lemmas 5.95.11 , the values of $f_{2}, f_{3}$, and $f_{4}$ stay the same. Moreover, the modified solution satisfies Constraints (14b). Furthermore, by this modification we decrease $q_{a}$ for $a \in P^{\mathrm{l}}\left(u_{1}, v_{1}\right)$, increase $q_{a}$ for $a \in P^{\mathrm{l}}\left(u_{2}, u_{3}\right)$, and the remaining flows stay the same. Hence, since $u_{1} \prec_{1} v_{1} \prec_{1} u_{2} \prec_{1} u_{3}$ and by Lemma 3.4 (d), we possibly increase the potential difference between $w_{1}$ and $w_{2}$ and Constraint (14d) is still satisfied. Consequently, $z$ is still feasible for (14). Due to this modification, we decrease $\ell_{u_{1}}>0$ and $\ell_{u_{3}}>0$ and increase $\ell_{u_{2}}$. By Lemma 5.8, considering only the decrease of $\ell_{u_{1}}$ and $\ell_{u_{3}}$ does not change the objective value. In contrast, the increase of $\ell_{u_{2}}$ decreases $f_{1}$ because

$$
x_{u_{1}}^{\preceq_{1}} x_{u_{3}}^{\succeq_{1}} \sum_{v \in V_{+}^{1}\left(u_{1}, u_{3}\right) \backslash\left\{u_{1}, u_{3}\right\}}\left(b_{v}-\ell_{v}\right)
$$

decreases. Thus, the modification decreases the objective value, which contradicts the optimality of the original solution.

Case 2: $u_{2} \prec_{1} v_{1}$ holds. We now decrease $q\left(P^{\mathrm{l}}\left(u_{1}, v_{1}\right)\right)$ by $\varepsilon>0$ and increase $q\left(P^{\mathrm{l}}\left(u_{2}, v_{1}\right)\right)$ by the same amount $\varepsilon$. This decreases the potential difference $\Pi_{P^{\mathrm{l}}(o, w)}(q)$ due to $u_{1} \prec_{1} u_{2}$. Thus, we now decrease $q\left(P^{\mathrm{l}}\left(u_{3}, v_{3}\right)\right)$ by $\tilde{\varepsilon}>0$ and
increase $q\left(P^{\mathrm{l}}\left(u_{2}, v_{3}\right)\right)$ by the same amount $\tilde{\varepsilon}$, which increases the potential difference $\Pi_{P^{1}(o, w)}(q)$ due to $u_{2} \prec_{1} u_{3}$. Due to Lemma 3.4, we can choose $\varepsilon$ and $\tilde{\varepsilon}$ such that $\Pi_{P^{1}(o, w)}(q)$ stays the same and $\ell_{u_{1}}>0, \ell_{u_{2}} \leq b_{u_{2}}, \ell_{u_{3}}>0$ holds. In analogy to Case 1 , the function values of $f_{2}, f_{3}$, and $f_{4}$ stay the same and the modified solution satisfies Constraints (14b). Further, the modification only decreases $q_{a}$ for $a \in P^{\mathrm{l}}\left(u_{1}, u_{2}\right)$ and increases flow $q_{a}$ for $a \in P^{\mathrm{l}}\left(u_{2}, u_{3}\right)$. The remaining flows stay the same. Hence, since $u_{1} \prec_{1} u_{2} \prec_{1} u_{3}$ and by Lemma 3.4 (d), we possibly increase the potential difference between $w_{1}$ and $w_{2}$ and Constraint (14d) is still satisfied. Consequently, $z$ is feasible for (14) after modification. In analogy to Case 1 , the modification decreases $f_{1}$, which contradicts the optimality of the original solution.

Lemma 5.13. If $z$ is an optimal solution of (14), then $f_{2}\left(\ell, y^{\preceq_{1}}\right)=0$ holds.
Proof. Let $z$ be an optimal solution of (14). By contradiction, we assume that $f_{2}\left(\ell, y^{\preceq}\right)>0$ holds. Lemma 5.5 implies that $\ell$ does not satisfy Property (b). Consequently, there are exits $v_{1}, v_{2} \in V_{-}^{1}(o, w)$ with $v_{1} \prec_{1} v_{2}, \ell_{v_{1}}>0$ and $\ell_{v_{2}}<b_{v_{2}}$. We now choose $v_{1}$ such that $\ell_{u}=0$ holds for all $u \in V_{-}^{1}\left(o, v_{1}\right) \backslash\left\{v_{1}\right\}$ and $v_{2}$ such that $\ell_{u}=b_{u}$ holds for all $u \in V_{-}^{1}\left(v_{1}, v_{2}\right) \backslash\left\{v_{1}, v_{2}\right\}$. Next, let an entry $u_{1} \in V_{+}^{1}(o, w)$ be given so that $\ell_{u_{1}}>0, \ell_{u}=0$ for all $u \in V_{+}^{1}\left(o, u_{1}\right) \backslash\left\{o, u_{1}\right\}$, and in a flow decomposition as by Lemma 3.1, $q\left(P^{\mathrm{l}}\left(u_{1}, v_{1}\right)\right)>0$ holds. Due to Lemma 3.4 and $v_{1} \prec_{1} v_{2}$, we can decrease $q\left(P^{\mathrm{l}}\left(u_{1}, v_{1}\right)\right)$ and increase $q\left(P^{\mathrm{l}}\left(u_{1}, v_{2}\right)\right)$ such that $\Pi_{P^{1}(o, w)}(q)$ remains the same and $0<\ell_{u_{1}} \leq b_{u_{1}}, \ell_{v_{1}}>0,0<\ell_{v_{2}} \leq b_{v_{2}}$ hold. Thus, the binary variables of $z$ stay the same. Furthermore, by Lemmas 5.8, 5.10, and 5.11 the values of $f_{1}, f_{3}$, and $f_{4}$ stay the same. The modified solution satisfies Constraints (14b) and we only decrease $q_{a}$ for $a \in P^{\mathrm{l}}\left(u_{1}, v_{1}\right)$ and increase $q_{a}$ for $a \in P^{\mathrm{l}}\left(v_{1}, v_{2}\right)$. The remaining flows are unchanged. Then, since $u_{1} \prec_{1} v_{1} \prec_{1} v_{2}$ and by Lemma $3.4(\mathrm{~d})$, Constraint (14d) is still satisfied. Consequently, $z$ is still feasible for (14). Due to this modification, we decrease $\ell_{v_{1}}>0$ and increase $\ell_{v_{2}}$. By Lemma 5.9, considering only the decrease of $\ell_{v_{1}}$ does not change the objective value. In contrast, the increase of $\ell_{v_{2}}$ decreases $f_{2}$ because

$$
y_{\bar{v}_{1}}^{\preceq_{1}} \sum_{v \in V_{-}^{1}\left(v_{1}, w\right) \backslash\left\{v_{1}\right\}}\left(b_{v}-\ell_{v}\right)
$$

decreases. Thus, the modification decreases the objective value, which contradicts the optimality of the original solution.

Lemma 5.14. If $z$ is an optimal solution of (14), then $f_{3}\left(\ell, x^{\succeq \mathrm{r}}\right)=0$ holds.
Lemma 5.15. If $z$ is an optimal solution of (14), then $f_{4}\left(\ell, y^{\preceq_{\mathrm{r}}}, y^{\succeq^{\mathrm{r}}}\right)=0$ holds.
Theorem 5.16. Let $(o, w) \in V_{+} \times V_{-}$be fixed, $w_{1} \in P^{\mathrm{l}}(o, w)$, and $w_{2} \in P^{\mathrm{r}}(o, w)$. Then, an optimal solution $(\ell, q, \pi)$ of (11) exists that satisfies Properties (a)-(d).

Proof. The zero nomination is feasible for Problem (11). Furthermore, the feasible region of the latter problem is compact and thus, an optimal solution is attained. Consequently, Problem (14) has an optimal solution, which is attained. Due to Lemmas 5.12-5.15 and Lemmas 5.4-5.7, an optimal solution of Problem (14) exists that satisfies Properties (a)-(d). Additionally, the solution is also optimal for Problem (11).
5.2. Nodes on the Same Side of $G$. Assume $w_{1}, w_{2} \in P^{1}(o, w)$ or $w_{1}, w_{2} \in$ $P^{\mathrm{r}}(o, w)$ holds. We can w.l.o.g. assume that $w_{1}, w_{2} \in P^{\mathrm{r}}(o, w)$ holds. If $w_{2} \prec_{\mathrm{r}} w_{1}$ holds, then from $q \geq 0$ in Problem (11) it follows that $\Pi_{P^{\mathrm{r}}\left(w_{1}, w_{2}\right)}(q) \leq 0$ is valid.

Figure 4. Configuration of $s$ and $t$ nodes with $o \preceq_{\mathrm{r}} w_{1} \prec_{\mathrm{r}} w_{2} \preceq_{\mathrm{r}} w$. Boxes qualitatively illustrate the amount of the booking that is nominated.

Thus, the zero nomination is an optimal solution for Problem (11). Consequently, we now assume that $w_{1} \prec_{\mathrm{r}} w_{2}$ holds.

We again want to show that an optimal solution $(\ell, q, \pi)$ of Problem (11) exists such that Properties (a), (b), (d), and (a) w.r.t. $P^{\mathrm{r}}(o, w)$, i.e., two entries $s_{1}^{r}, s_{2}^{r} \in$ $V_{+}^{\mathrm{r}}(o, w)$ with $s_{1}^{r} \preceq_{\mathrm{r}} s_{2}^{r}$ exists such that

$$
\begin{array}{ll}
\ell_{v}=0, & v \in\left(V_{+}^{\mathrm{r}}\left(o, s_{1}^{r}\right) \cup V_{+}^{\mathrm{r}}\left(s_{2}^{r}, w\right)\right) \backslash\left\{o, s_{1}^{r}, s_{2}^{r}\right\}, \\
\ell_{v}=b_{v}, & v \in V_{+}^{\mathrm{r}}\left(s_{1}^{r}, s_{2}^{r}\right) \backslash\left\{s_{1}^{r}, s_{2}^{r}\right\}
\end{array}
$$

is satisfied. Figure 4 illustrates a possible node configuration. To this end, we introduce an optimization problem similar to (13), which is given by

$$
\begin{array}{cl}
\min & f_{1}\left(\ell, x^{\preceq_{1}}, x^{\succeq_{1}}\right)+f_{2}\left(\ell, y^{\preceq_{1}}\right)+f_{3}\left(\ell, x^{\preceq_{\mathrm{r}}}, x^{\succeq_{\mathrm{r}}}\right)+f_{4}\left(\ell, y^{\preceq_{\mathrm{r}}}, y^{\succeq_{\mathrm{r}}}\right) \\
\text { s.t. } & (1 \mathrm{a}),(2 \mathrm{~b}),(11 \mathrm{~b})-(11 \mathrm{~d}),(13 \mathrm{~b})-(13 \mathrm{~h}),(14 \mathrm{~d}), \\
& \tilde{M} x_{\bar{v}}^{\preceq_{\mathrm{r}}} \geq \sum_{u \in V_{+}^{r_{\mathrm{r}}}(o, v) \backslash\{o\}} \ell_{u}, \quad v \in V_{+}^{\mathrm{r}}(o, v) \backslash\{o\}, \\
& x_{\hat{v}}^{\preceq_{\mathrm{r}} \in\{0,1\}, \quad v \in V .} \text {. } \tag{19c}
\end{array}
$$

Note that an analogous variant of Lemma 5.3 is also valid for Problem (19).
We specify the parts of the objective function of (19) as follows: the functions $f_{1}$, $f_{2}$, and $f_{4}$ are defined as in Lemmas 5.4, 5.5, and 5.7. The function $f_{3}$ is defined in analogy to Lemma 5.4 w.r.t. $P^{\mathrm{r}}$. We note that $f_{i}$ for $i=1, \ldots, 4$ also inherit the corresponding properties of Lemmas 5.4-5.11. We now prove that the optimal objective value of (19) is zero.

Lemma 5.17. If $z$ is an optimal solution of (19), then $f_{1}\left(\ell, x^{\preceq_{1}}, x^{\succeq_{1}}\right)=0$ holds.
Proof. The claim follows in analogy to Lemma 5.12. In doing so, we note that the modifications in the proof of Lemma 5.12 only affect nodes of $P^{\mathrm{l}}(o, w)$. Consequently,
we do not change the potential difference between $w_{1}$ and $w_{2}$ due to $w_{1}, w_{2} \in$ $P^{\mathrm{r}}(o, w)$.

Lemma 5.18. If $z$ is an optimal solution of (19), then $f_{2}\left(\ell, y^{\preceq_{1}}\right)=0$ holds.
Proof. The claim follows in analogy to Lemma 5.13.
To show analogous results for $f_{3}$ and $f_{4}$, we make use of an auxiliary lemma.
Lemma 5.19. An optimal solution $z$ of (19) exists such that $\ell_{v}=0$ for all $v \in$ $V_{-}^{\mathrm{r}}\left(o, w_{1}\right)$ and $\ell_{u}=0$ for all $u \in V_{+}^{\mathrm{r}}\left(w_{2}, w\right)$ is satisfied.

Proof. We choose an optimal solution $z$ of (19) such that

$$
\sum_{v \in V_{-}^{\mathrm{r}}\left(o, w_{1}\right)} \ell_{v}+\sum_{u \in V_{+}^{\mathrm{r}}\left(w_{2}, w\right)} \ell_{u}
$$

is minimal. Note that every addend is nonnegative. By contradiction, we assume that

$$
\sum_{v \in V_{-}^{\mathrm{r}}\left(o, w_{1}\right)} \ell_{v}+\sum_{u \in V_{+}^{\mathrm{r}}\left(w_{2}, w\right)} \ell_{u}>0
$$

holds.
Case 1: There exists $v \in V_{-}^{\mathrm{r}}\left(o, w_{1}\right)$ with $\ell_{v}>0$. We now choose $v$ such that $\ell_{v^{\prime}}=0$ for all $v^{\prime} \in V_{-}^{\mathrm{r}}(o, v) \backslash\{v\}$ is satisfied. Consequently, an entry $u \in V_{+}^{\mathrm{r}}(o, v)$ exists such that $\ell_{u^{\prime}}=0$ holds for all $u^{\prime} \in V_{+}^{\mathrm{r}}(o, u) \backslash\{o\}$ and in a flow decomposition, such as in Lemma 3.1, $q\left(P^{\mathrm{r}}(u, v)\right)>0$ is satisfied. We can now decrease the latter by $\varepsilon>0$ such that $\ell_{u}>0$ and $\ell_{v}>0$ holds. This decreases the potential drop $\Pi_{P^{\mathrm{r}}(o, w)}(q)$. Due to Lemmas 5.17 and 5.18 , we can assume that $q\left(P^{\mathrm{l}}\left(s_{1}^{l}, t_{1}^{l}\right)\right)>0$ holds. By using Lemma 3.4, we can now decrease the latter by $\tilde{\varepsilon}$ and choose $\varepsilon$ such that $\Pi_{P^{1}(o, w)}(q)=\Pi_{P^{\mathrm{r}}(o, w)}(q)$ holds and $\ell_{u}, \ell_{v}, \ell_{s_{1}^{l}}, \ell_{t_{1}^{l}}$ are positive. Moreover, Lemmas 5.8-5.11 imply that the solution obtained after the modifications is still feasible and optimal for (19). In doing so, we note that the modifications do not change any flow of $P^{\mathrm{r}}\left(w_{1}, w_{2}\right)$ and thus, the potential difference between $w_{1}$ and $w_{2}$ stays the same. This is a contradiction to the choice of $z$ because

$$
\sum_{v \in V_{-}^{\mathrm{r}}\left(o, w_{1}\right)} \ell_{v}+\sum_{u \in V_{+}^{\mathrm{r}}\left(w_{2}, w\right)} \ell_{u}
$$

is decreased in the modified solution.
Case 2: There is $u \in V_{+}^{\mathrm{r}}\left(w_{2}, w\right)$ with $\ell_{u}>0$. We now choose $u$ such that $\ell_{u^{\prime}}=0$ for all $u^{\prime} \in V_{+}^{\mathrm{r}}(u, w)$. Due to $q \geq 0$, an exit $v \in V_{-}^{\mathrm{r}}(u, w)$ exists such that $\ell_{v^{\prime}}=0$ holds for all $v^{\prime} \in V_{-}^{\mathrm{r}}(v, w) \backslash\{v, w\}$ and $q\left(P^{\mathrm{r}}(u, v)\right)>0$. In analogy to Case 1, the claim follows by decreasing the flow $q\left(P^{\mathrm{r}}(u, v)\right)$ by $\varepsilon>0$ and $q\left(P^{\mathrm{l}}\left(s_{1}^{l}, t_{1}^{l}\right)\right)$ by $\tilde{\varepsilon}>0$.

Lemma 5.20. If $z$ is an optimal solution of (19), then $f_{3}\left(\ell, x^{\preceq_{\mathrm{r}}}, x^{\succeq_{\mathrm{r}}}\right)=0$ holds.
Proof. Let $z$ be an optimal solution of (19) that satisfies Lemma 5.19. By contradiction, we assume that $f_{3}\left(\ell, x^{\preceq_{\mathrm{r}}}, x^{乙_{\mathrm{r}}}\right)>0$ holds. Lemma 5.4 implies that $\ell$ does not satisfy Property (a) w.r.t. $P^{\mathrm{r}}$. Consequently, there are entries $u_{1}, u_{2}, u_{3} \in V_{+}^{\mathrm{r}}(o, w) \backslash\{o\}$ with $u_{1} \prec_{\mathrm{r}} u_{2} \prec_{\mathrm{r}} u_{3}$ such that $\ell_{u_{1}}>0, \ell_{u_{2}}<b_{u_{2}}$, and $\ell_{u_{3}}>0$ hold. If $q_{a}>0$ for $a \in \delta^{\text {out }}(o) \cap P^{\mathrm{r}}(o, w)$, we replace $u_{1}=o$. Otherwise, we choose $u_{1} \neq o$ such that $\ell_{u}=0$ holds for all $u \in V_{+}^{\mathrm{r}}\left(o, u_{1}\right) \backslash\left\{o, u_{1}\right\}$ and we choose $u_{3}$ such that $\ell_{u}=0$ holds for all $u \in V_{+}^{\mathrm{r}}\left(u_{3}, w\right) \backslash\left\{u_{3}\right\}$. We now consider a flow decomposition as in Lemma 3.1. Due to $q \geq 0$, an exit $v_{3} \in V_{-}^{\mathrm{r}}\left(u_{3}, w\right)$ with $q\left(P^{\mathrm{r}}\left(u_{3}, v_{3}\right)\right)>0$ exists. By the choice
of $u_{1}$, there is an exit $v_{1} \in V_{-}^{\mathrm{r}}\left(u_{1}, w\right)$ with $\ell_{v}=0$ for all $v \in V_{-}^{\mathrm{r}}\left(o, v_{1}\right) \backslash\left\{v_{1}\right\}$ and $q\left(P^{\mathrm{r}}\left(u_{1}, v_{1}\right)\right)>0$. Consequently, $v_{1} \preceq_{\mathrm{r}} v_{3}$ holds. We now distinguish two cases.

Case 1: $u_{2} \preceq_{\mathrm{r}} w_{1}$. Due to Lemma 5.19, $w_{1} \preceq_{\mathrm{r}} v_{1}$ holds. Consequently, we can decrease $q\left(P^{\mathrm{r}}\left(u_{1}, v_{1}\right)\right)>0$ by $\varepsilon>0$ and we increase $q\left(P^{\mathrm{r}}\left(u_{2}, v_{1}\right)\right)$ by the same amount such that $\ell_{u_{1}}>0$ and $\ell_{u_{2}} \leq b_{u_{2}}$ holds. Since $u_{1} \prec_{\mathrm{r}} u_{2}$ holds, this modification decreases the potential difference $\Pi_{P^{\mathrm{r}}(o, w)}(q)$ but the flows on arcs of $P^{\mathrm{r}}\left(w_{1}, w_{2}\right)$ stay the same due to $u_{2} \preceq_{\mathrm{r}} w_{1}$. Consequently, $\Pi_{P^{\mathrm{r}}\left(w_{1}, w_{2}\right)}(q)$ is unchanged. From the proof of Lemma 5.12, it follows that this modification decreases $f_{3}$. In analogy to Case 1 of Lemma 5.19, we can now decrease $\Pi_{P^{1}(o, w)}(q)$ by modifying $\ell_{s_{1}^{l}}$ and $\ell_{t_{1}^{l}}$ such that $\Pi_{P^{\mathrm{r}}(o, w)}(q)=\Pi_{P^{\mathrm{l}}(o, w)}(q)$ holds without changing the values of $f_{i}$ for $i=1, \ldots, 4$. This is a contradiction to the optimality of $z$ because we have decreased $f_{3}$ in the first part of the modification.

Case 2: $w_{1} \prec_{\mathrm{r}} u_{2}$. Due to $u_{2} \prec_{\mathrm{r}} u_{3}$ and Lemma 3.4, we can decrease $q\left(P^{\mathrm{r}}\left(u_{3}, v_{3}\right)\right)$ by $\varepsilon>0$ and increase $q\left(P^{\mathrm{r}}\left(u_{2}, v_{3}\right)\right)$ by $0<\tilde{\varepsilon} \leq \varepsilon$ such that $\Pi_{P^{\mathrm{r}}(o, w)}(q)=\Pi_{P^{1}(o, w)}(q)$, $\ell_{u_{3}}>0, \ell_{v_{3}}>0$, and $\ell_{u_{2}} \leq b_{u_{2}}$ holds. Consequently, the binary variables of $z$ stay the same. By using Lemmas $5.8,5.9$, and 5.11 , the values $f_{1}, f_{2}$, and $f_{4}$ stay the same as well. The modified solution satisfies Constraints (14b). Further, the modification only increases $q_{a}$ for $a \in P^{\mathrm{r}}\left(u_{2}, u_{3}\right)$ and decreases the flow $q_{a}$ for $a \in P^{\mathrm{r}}\left(u_{3}, v_{3}\right)$. The remaining flows stay unchanged. Due to $w_{1} \prec_{\mathrm{r}} u_{2} \prec_{\mathrm{r}} u_{3} \prec_{\mathrm{r}} w_{2}$ and Lemma 3.4 (d), we possibly increase the potential difference between $w_{1}$ and $w_{2}$ and thus, Constraint (14d) is still satisfied. Case 1 of Lemma 5.12 implies that the previous modification decreases $f_{3}$, which is a contradiction to the optimality of $z$.

Lemma 5.21. If $z$ is an optimal solution of (19), then $f_{4}\left(\ell, y^{\preceq_{\mathrm{r}}}, y^{\succeq_{\mathrm{r}}}\right)=0$ holds.
Proof. Let $z$ be an optimal solution of (19) that satisfies Lemma 5.19. By contradiction, we assume that $f_{4}\left(\ell, y^{\preceq_{\mathrm{r}}}, x^{\succeq \mathrm{r}}\right)>0$ holds. Lemma 5.7 implies that $\ell$ does not satisfy Property (d). Consequently, there are exits $v_{1}, v_{2}, v_{3} \in V_{-}^{\mathrm{r}}(o, w) \backslash\{w\}$ with $v_{1} \prec_{\mathrm{r}} v_{2} \prec_{\mathrm{r}} v_{3}, \ell_{v_{1}}>0, \ell_{v_{2}}<b_{v_{2}}$, and $\ell_{v_{3}}>0$. Furthermore, we choose $v_{1}$ such that $\ell_{v}=0$ holds for all $v \in V_{-}^{\mathrm{r}}\left(o, v_{1}\right) \backslash\left\{v_{1}\right\}$. If $q_{a}>0$ for $a \in \delta^{\text {in }}(w) \cap P^{\mathrm{r}}(o, w)$, we replace $v_{3}=w$. Otherwise, we choose $v_{3} \neq w$ such that $\ell_{v}=0$ holds for all $v \in V_{-}^{1}\left(v_{3}, w\right) \backslash\left\{v_{3}, w\right\}$. We now consider a flow decomposition as in Lemma 3.1. Due to $q \geq 0$, there is an entry $u_{3} \in V_{+}^{\mathrm{r}}\left(o, v_{3}\right)$ with $\ell_{u}=0$ for all $u \in V_{+}^{\mathrm{r}}\left(u_{3}, w\right) \backslash\left\{u_{3}\right\}$ and $q\left(P^{\mathrm{r}}\left(u_{3}, v_{3}\right)\right)>0$. Furthermore, an entry $u_{1} \in V_{+}^{\mathrm{r}}(o, w)$ with $\ell_{u}=0$ for all $u \in V_{+}^{\mathrm{r}}\left(o, u_{1}\right) \backslash\left\{o, u_{1}\right\}$ exists that satisfies $q\left(P^{\mathrm{r}}\left(u_{1}, v_{1}\right)\right)>0$. Due to Lemma 5.19, $w_{1} \prec_{\mathrm{r}} v_{1} \prec_{\mathrm{r}} v_{2} \prec_{\mathrm{r}} v_{3}$ holds. We now distinguish two cases.

Case 1: $v_{2} \preceq_{\mathrm{r}} w_{2}$. Consequently, $v_{1} \prec_{\mathrm{r}} v_{2} \preceq_{\mathrm{r}} w_{2}$ holds. We can now decrease $q\left(P^{\mathrm{r}}\left(u_{1}, v_{1}\right)\right)$ by $\varepsilon>0$ and increase $q\left(P^{\mathrm{r}}\left(u_{1}, v_{2}\right)\right)$ by $0<\tilde{\varepsilon} \leq \varepsilon$ such that $\Pi_{P^{\mathrm{r}}(o, w)}$ stays the same and $\ell_{u_{1}}>0, \ell_{v_{1}}>0$, and $\ell_{v_{2}} \leq b_{v_{2}}$ holds. In particular, the binary variables of $z$ stay the same after the modification. Due to this and Lemmas 5.8 and 5.10 , the values of $f_{1}, f_{2}$, and $f_{3}$ stay unchanged. The modified solution satisfies Constraints (14b). Further, this modification only decreases $q_{a}$ for $a \in P^{\mathrm{r}}\left(u_{1}, v_{1}\right)$ and increases flows $q_{a}$ for $a \in P^{\mathrm{r}}\left(v_{1}, v_{2}\right)$. The remaining flows stay the same. Hence, since $w_{1} \prec_{\mathrm{r}} v_{1} \prec_{\mathrm{r}} v_{2} \preceq_{\mathrm{r}} w_{2}$ and by Lemma 3.4 (d), we possibly increase the potential difference between $w_{1}$ and $w_{2}$ and Constraint (14d) is still satisfied. Consequently, $z$ is still a feasible for (19). In analogy to Case 1 of Lemma 5.15, it follows that the modification decreases $f_{4}$, which is a contradiction to the optimality of $z$.

Case 2: $w_{2} \prec_{\mathrm{r}} v_{2}$. Consequently, $u_{3} \prec_{\mathrm{r}} w_{2} \prec_{\mathrm{r}} v_{2} \prec_{\mathrm{r}} v_{3}$ holds. We can now apply Case 2 of Lemma 5.15. In doing so, we keep in mind that $w_{1} \prec_{\mathrm{r}} v_{1}$ and $w_{2} \prec_{\mathrm{r}} v_{2} \prec_{\mathrm{r}} v_{3}$ hold which ensures that $z$ still satisfies (14d) after the applied modifications.

Finally, we obtain analogous result to Theorem 5.16 for the present case.

Theorem 5.22. Let $(o, w) \in V_{+} \times V_{-}$be fixed and $w_{1}, w_{2} \in P^{\mathrm{r}}(o, w)$. Then, an optimal solution $(\ell, q, \pi)$ of (11) exists that satisfies Properties (a), (b), (d) and (a) w.r.t. $P^{\mathrm{r}}$.

Proof. The zero nomination is feasible for Problem (11) and it is optimal if $w_{2} \preceq_{\mathrm{r}} w_{1}$ holds. Furthermore, the feasible region of the latter problem is compact and thus, an optimal solution is attained. Consequently, Problem (19) has an optimal solution, which is attained. Due to Lemmas 5.17-5.21 and Lemmas 5.4-5.7, for $w_{1} \prec_{r} w_{2}$ an optimal solution of Problem (19) exists that satisfies Properties (a), (b), (d) and, (a) w.r.t. $P^{\mathrm{r}}$. Additionally, the solution is also optimal for Problem (11).

## 6. A Polynomial-Time Algorithm

Exploiting the special structure of nominations that maximize the potential difference between a pair of nodes, we now show that the feasibility of a booking can be checked in polynomial time on a cycle. First, we obtain an estimate on the number of arithmetic operations necessary to detect the existence of an infeasible nomination, or otherwise certify its non-existence. In a second step, we then translate this result to a Turing model of computation, resulting in a polynomialtime algorithm for deciding the feasibility of a booking. For doing so, we make the following non-restrictive assumption on the rationality of the problem data.

Assumption 6.1. We consider a booking $b \in \mathbb{Q}^{V}$ and assume that $\Lambda_{a} \in \mathbb{Q}$ for all $a \in A$ and $\pi_{u}^{-}, \pi_{u}^{+} \in \mathbb{Q}$ for all $u \in V$. Additionally, we assume that all bit sizes are bounded from above by $\tau-1$.

In particular, observe that if all numerical parameters have a bit size of at most $\tau-1$, a signed parameter has bit size at most $\tau$.

As a consequence of Corollary 5.2, a booking $b$ is feasible if and only if, for every $\left(w_{1}, w_{2}\right) \in V^{2}$ and $(o, w) \in V_{+} \times V_{-}$,

$$
\begin{equation*}
\pi_{w_{1}}-\pi_{w_{2}}>\pi_{w_{1}}^{+}-\pi_{w_{2}}^{-}, \quad(1 \mathrm{a}),(2 \mathrm{~b}),(11 \mathrm{~b})-(11 \mathrm{~d}) \tag{20}
\end{equation*}
$$

admits no solution. We now make several observations. First, recall that $A^{\prime}$ is obtained from $A$ by orienting all arcs from $o$ to $w$. Then, given (11c), the right-hand sides of (11b) simplify to $\Lambda_{a} q_{a}^{2}$ for all $a \in A^{\prime}$. Second, we eliminate the potentials $\pi$ by aggregating the resulting constraints along $P^{\mathrm{l}}(o, w)$ and $P^{\mathrm{r}}(o, w)$. We treat only the situation corresponding to Section 5.2 in which $o \preceq_{\mathrm{r}} w_{1} \prec_{\mathrm{r}} w_{2} \preceq_{\mathrm{r}} w$ is valid, since it has the highest number of $s$ and $t$ nodes and thus represents the worst case in terms of complexity. The situation corresponding to Section 5.1 with $w_{1}$ and $w_{2}$ on different paths w.r.t. $o$ and $w$ can however be treated in a similar way. We obtain

$$
\begin{aligned}
\sum_{a \in P^{\mathrm{r}}\left(w_{1}, w_{2}\right)} \Lambda_{a} q_{a}^{2} & >\pi_{w_{1}}^{+}-\pi_{w_{2}}^{-} \\
\sum_{a \in P^{\mathrm{1}}(o, w)} \Lambda_{a} q_{a}^{2}-\sum_{a \in P^{\mathrm{r}}(o, w)} \Lambda_{a} q_{a}^{2} & =0
\end{aligned}
$$

It is well-known that if the nomination is balanced, the rank of the flow conservation constraints (1a) is $|V|-1$, resulting in a single degree of freedom in the case of a cycle. Thus, we introduce $\ell_{w}=\ell_{w}^{\mathrm{l}}+\ell_{w}^{\mathrm{r}}$ to take into account the supply to the flow-meeting point $w$ along $P^{\mathrm{l}}$ and $P^{\mathrm{r}}$ separately. Then, for $a=(u, v) \in A^{\prime}$, (1a) leads to

$$
q_{a}= \begin{cases}-\sum_{v^{\prime} \in P^{1}(v, w) \backslash\{w\}} \sigma_{v^{\prime}} \ell_{v^{\prime}}+\ell_{w}^{1}, & \text { if } a \in P^{\mathrm{l}}(o, w), \\ -\sum_{v^{\prime} \in P^{r}(v, w) \backslash\{w\}} \sigma_{v^{\prime}} \ell_{v^{\prime}}+\ell_{w}^{\mathrm{r}}, & \text { if } a \in P^{\mathrm{r}}(o, w) .\end{cases}
$$

As a consequence of the previous discussion, we need to check that the system

$$
\begin{align*}
& \sum_{a=(u, v) \in P^{\mathrm{r}}\left(w_{1}, w_{2}\right)} \Lambda_{a}\left(-\sum_{v^{\prime} \in P^{\mathrm{r}}(v, w) \backslash\{w\}} \sigma_{v^{\prime}} \ell_{v^{\prime}}+\ell_{w}^{\mathrm{r}}\right)^{2}>\pi_{w_{1}}^{+}-\pi_{w_{2}}^{-}  \tag{21a}\\
& \sum_{a=(u, v) \in P^{\mathrm{l}}(o, w)} \Lambda_{a}\left(-\sum_{v^{\prime} \in P^{\mathrm{l}}(v, w) \backslash\{w\}} \sigma_{v^{\prime}} \ell_{v^{\prime}}+\ell_{w}^{1}\right)^{2} \\
&-\sum_{a=(u, v) \in P^{\mathrm{r}}(o, w)} \Lambda_{a}\left(-\sum_{v^{\prime} \in P^{\mathrm{r}}(v, w) \backslash\{w\}} \sigma_{v^{\prime}} \ell_{v^{\prime}}+\ell_{w}^{\mathrm{r}}\right)^{2}=0,  \tag{21b}\\
&-\sum_{v^{\prime} \in P^{\mathrm{l}}(v, w) \backslash\{w\}} \sigma_{v^{\prime}} \ell_{v^{\prime}}+\ell_{w}^{1} \geq 0, \quad(u, v) \in P^{\mathrm{l}},  \tag{21c}\\
&-\sum_{v^{\prime} \in P^{\mathrm{r}}(v, w) \backslash\{w\}} \sigma_{v^{\prime}} \ell_{v^{\prime}}+\ell_{w}^{\mathrm{r}} \geq 0, \quad(u, v) \in P^{\mathrm{r}},  \tag{21d}\\
& \ell_{w}^{1}+\ell_{w}^{\mathrm{r}}=\ell_{w}, \quad \ell \in N(b), \tag{21e}
\end{align*}
$$

of polynomials admits no solution.
We now reduce the dimension of (21) to obtain a system with a constant number of constraints and variables independent of the problem size. Hence, we make use of the structure analyzed in Section 5.2 for potential-difference maximizing nominations.

In what follows, we consider a configuration of Properties (a), (b), (d) and (a) w.r.t. $P^{\mathrm{r}}$, determined by $s_{1}^{l}, s_{2}^{l} \in V_{+}^{\mathrm{l}}(o, w), t_{1}^{l} \in V_{-}^{1}(o, w), s_{1}^{r}, s_{2}^{r} \in V_{+}^{\mathrm{r}}(o, w)$ as well as $t_{1}^{r}, t_{2}^{r} \in V_{-}^{\mathrm{r}}(o, w)$, and the corresponding partially fixed $\ell \in N(b)$.

Lemma 6.2. There exists a system equivalent to (21e) that has at most 9 variables and 16 constraints, independent of the size of the cycle.

Proof. First, observe that we can substitute the nomination entries for $o$ and $w$ using

$$
\ell_{w}=\ell_{w}^{1}+\ell_{w}^{\mathrm{r}}, \quad \ell_{o}=-\sum_{u \in V \backslash\{o\}} \sigma_{u} \ell_{u}
$$

Fixing nomination entries either to their booking bound or to zero, as by Properties (a)-(d), it is easy to observe that $\ell_{s_{1}^{l}}, \ell_{s_{2}^{l}}, \ell_{t_{1}^{l}}, \ell_{s_{1}^{r}}, \ell_{s_{2}^{r}}, \ell_{t_{1}^{r}}, \ell_{2}^{r}, \ell_{w}^{1}, \ell_{w}^{\mathrm{r}}$, are the only remaining 9 variables. Note that in some situations these variables may coincide. In particular, there are at most 14 constraints corresponding to the booking bounds, namely $0 \leq \ell_{u} \leq b_{u}$ for all $u \in\left\{s_{1}^{l}, s_{2}^{l}, t_{1}^{l}, s_{1}^{r}, s_{2}^{r}, t_{1}^{r}, t_{2}^{r}\right\}$.

The number of additional constraints due to $o$ and $w$ depend on the configuration under consideration. If $o \notin\left\{s_{1}^{l}, s_{1}^{r}\right\}$, then the additional constraint $\ell_{o}=b_{o}$ is necessary. If $w \notin\left\{t_{1}^{l}, t_{2}^{r}\right\}$, then $\ell_{w}=b_{w}$ is required.

A combinatorial analysis of (21c) and (21d) also leads to the following constant number of constraints.

Lemma 6.3. There exists a system equivalent to (21c) and (21d) with at most 24 constraints, independent of the size of the cycle. This system can be determined in $O(|A|)$.

Proof. Let us first consider (21d). There are four $s$ and $t$ nodes on $P^{\mathrm{r}}(o, w)$, namely $s_{1}^{r}, s_{2}^{r}, t_{1}^{r}, t_{2}^{r}$. Thus, assuming that constants have been moved to the right-hand
sides in (21d), there can be at most $2^{4}$ left-hand sides with different constant righthand sides. For every left-hand side, it is sufficient to impose a single constraint admitting the maximum constant on the right-hand side. This is easily achieved by iterating over all arcs of $P^{\mathrm{r}}(o, w)$. Similarly, (21c) can be reduced to a system with $2^{3}$ constraints.

The following result now is a direct consequence of the two previous results.
Theorem 6.4. System (21) can be reduced in $O(|A|)$ to a system with at most 9 variables and 42 constraints.

Next, we apply a general decision algorithm for the existence of solutions for systems of polynomial equations and inequalities, given by Algorithm 14.16 in [5], to estimate the number of arithmetic operations necessary to decide the existence of a solution for (21).

Theorem 6.5. Suppose Assumption 6.1 holds. Then, the existence of a solution of (21) can be decided in $O\left((\log |V|+\tau)\left|V_{+}\right|^{4}\left|V_{-}\right|^{3}\right)$.

Proof. Algorithm 14.16 in [5] has a complexity in the arithmetic computation model of $s^{k} d^{O(k)}$, where $s$ is the number of constraints, $k$ is the number of variables, and $d$ is the highest degree of the polynomials. For a given configuration of Properties (a), (b), (d), and (a) w.r.t. $P^{\mathrm{r}}$, the number of variables and constraints in (21) can be reduced to a constant by Theorem 6.4 and $d=2$. Consequently, the existence of a solution for this reduced system can be checked in $O(1)$ arithmetic operations.

Under Assumption 6.1, the bit sizes of the rational coefficients of (21) are bounded by $O(\log |V|+\tau)$. This can easily be deduced by analyzing the constant term in, e.g., (21a). Given the constant number of variables and constraints in the reduced version of (21), the bit size of integers coefficients after scaling is still bounded by $O(\log |V|+\tau)$. In this case, the bit sizes of coefficients appearing in intermediate computations and the output of Algorithm 14.16 in [5] are also bounded by $O(\log |V|+\tau)$. From a discussion in Chapter 1 of [18], the existence of a solution to the reduced version of System (21) can then be checked in $O(\log |V|+\tau) O(1)=$ $O(\log |V|+\tau)$ time on a Turing machine.

By Lemmas 5.17-5.21, a solution of (21) exists if and only if there is a configuration of Properties (a), (b), (d), and (a) w.r.t. $P^{\mathrm{r}}$, such that a solution of the reduced version of (21) exists. Consequently, the result follows by iterating over all combinations of $s_{1}^{l}, s_{2}^{l}, t_{1}^{l}, s_{1}^{r}, s_{2}^{r}, t_{1}^{r}, t_{2}^{r}$.

Furthermore, iterating this procedure over all $(o, w) \in V_{+} \times V_{-}$, we obtain the final result for validating a booking on a cycle, which ensures that checking the feasibility of a booking on a cycle can be done in polynomial time.

Corollary 6.6. Under Assumption 6.1, the feasibility of booking $b \in \mathbb{Q}_{\geq 0}^{V}$ can be checked in $O\left((\log |V|+\tau)\left|V_{+}\right|^{5}\left|V_{-}\right|^{4}\right)$ on a cycle.

## 7. Conclusion

In this work, we prove that deciding the feasibility of a booking in the European entry-exit gas market model is in $P$ for the special case of cycle networks. To the best of our knowledge, this is the first in-depth complexity analysis in this context that considers a nonlinear flow model and a network topology that is not a tree. Our approach requires the combination of both the cyclic structure of the network and properties of the underlying nonlinear potential-based flow model with a general decision algorithm from real algebraic geometry. We show that the size of
a polynomial equality and inequality system for deciding the feasibility of a booking is constant and, in particular, does not depend on the size of the cycle. Thus, a general algorithm for solving this system can serve as a constant-time oracle used in an enumeration of polynomial complexity.

Although our theoretical result moves the frontier of knowledge about the hardness of deciding the feasibility of bookings in the European entry-exit gas market, it still remains an open question to exactly determine the frontier between easy and hard cases if a nonlinear and potential-based flow model is considered. Although we believe that the problem is hard on general networks, no hardness results are known so far. Since both trees and cyclic networks are now well understood, a reasonable next case to be considered may be cactus graphs.

## Acknowledgments

Martine Labbé has been partially supported by the Fonds de la Recherche Scientifique - FNRS under Grant no PDR T0098.18. Fränk Plein thanks the Fonds de la Recherche Scientifique - FNRS for his Aspirant fellowship supporting the research for this publication. He also thanks the Deutsche Forschungsgemeinschaft for their support within the project Z01 in CRC TRR 154. This research has been performed as part of the Energie Campus Nürnberg and is supported by funding of the Bavarian State Government. The third and fourth author also thank the DFG for their support within projects A05, B07, and B08 in CRC TRR 154. Finally, we want to thank Lars Schewe for many fruitful discussions on the topic of this paper.

## Appendix A. Omitted Proofs

Proof of Lemma 5.6. Let $z$ be feasible for (14). For $i \in V_{+}^{\mathrm{r}}(o, w)$,

$$
x_{i}^{\succeq_{\mathrm{r}}} \sum_{v \in V_{+}^{1}(o, i) \backslash\{i\}}\left(b_{v}-\ell_{v}\right) \geq 0
$$

holds. Assume now that Property (c) does not hold. Consequently, there are $u_{1}, u_{2} \in V_{+}^{\mathrm{r}}(o, w)$ with $u_{1} \prec_{\mathrm{r}} u_{2}$ such that $\ell_{u_{1}}<b_{u_{1}}$ and $\ell_{u_{2}}>0$ hold. Consequently, $x_{u_{2}}^{\succeq_{\mathrm{r}}}=1$ and

$$
\sum_{v \in V_{+}^{1}\left(o, u_{2}\right) \backslash\left\{u_{2}\right\}}\left(b_{v}-\ell_{v}\right)>0
$$

holds. Thus, $f_{3}\left(\ell, x^{乙_{r}}\right)>0$.
If $\ell$ satisfies Property (c), then we set $x_{\bar{u}}^{\succeq \mathrm{r}}=0$ for all $u \in V_{+}^{\mathrm{r}}\left(s_{1}^{r}, w\right) \backslash\left\{s_{1}^{r}\right\}$, otherwise we set $x_{\bar{u}}^{\succeq \mathrm{r}}=1$. Furthermore, for $i \in V_{+}^{\mathrm{r}}\left(o, s_{1}^{r}\right)$,

$$
\sum_{v \in V_{+}^{\mathrm{r}}(o, i) \backslash\{i\}}\left(b_{v}-\ell_{v}\right)=0
$$

holds due to Property (c). Consequently, $f_{3}\left(\ell, x^{\succeq r}\right)=0$.

Proof of Lemma 5.7. Let $z$ be feasible for (14). For $i, j \in V_{-}^{\mathrm{r}}(o, w)$ where $i \preceq_{\mathrm{r}} j$

$$
y_{i}^{\preceq_{\mathrm{r}}} y_{j}^{\succ_{\mathrm{r}}} \sum_{v \in V_{-}^{\mathrm{r}}(i, j) \backslash\{i, j\}}\left(b_{v}-\ell_{v}\right) \geq 0
$$

holds. Assume now that Property (d) does not hold. Consequently, there are $u_{1}, u_{2}, u_{3} \in V_{-}^{\mathrm{r}}(o, w) \backslash\{w\}$ with $u_{1} \prec_{\mathrm{r}} u_{2} \prec_{\mathrm{r}} u_{3}$ such that $\ell_{u_{1}}>0, \ell_{u_{2}}<b_{u_{2}}$, and $\ell_{u_{3}}>0$ hold. Thus, $y_{\bar{u}_{1}}^{\preceq_{\mathrm{r}}}=y_{u_{3}}^{\succeq \mathrm{r}}=1$ and

$$
\sum_{\left.v \in V_{-}^{\mathrm{x}}\left(u_{1}, u_{3}\right)\right) \backslash\left\{u_{1}, u_{3}\right\}}\left(b_{v}-\ell_{v}\right)>0
$$

holds. Thus, $f_{4}\left(\ell, y^{\preceq_{\mathrm{r}}}, y^{\succeq_{\mathrm{r}}}\right)>0$.
If $\ell$ satisfies Property (d), then we set $y \underset{v}{\bigotimes_{\mathrm{r}}^{\mathrm{r}}}=0$ for all $v \in V_{-}^{\mathrm{r}}\left(o, t_{1}^{r}\right) \backslash\left\{t_{1}^{r}\right\}$, otherwise we set $y_{\bar{v}}^{\preceq \mathrm{r}}=1$. Additionally, we set $y_{\bar{v}}^{\succeq \mathrm{r}}=1$ for all $v \in V_{-}^{\mathrm{r}}\left(o, t_{2}^{r}\right)$ and otherwise we set $y_{\bar{v}}^{\succeq}=0$. Consequently, for $i \in V_{-}^{\mathrm{r}}\left(o, t_{1}^{r}\right) \backslash\left\{t_{1}^{r}\right\}$ or $j \in V_{-}^{\mathrm{r}}\left(t_{2}^{r}, w\right) \backslash\left\{t_{2}^{r}\right\}$, the equality $y_{i}^{\preceq \underline{1}} y_{j}^{\succeq \mathrm{r}}=0$ holds and for $i, j \in V_{-}^{\mathrm{r}}\left(t_{1}^{r}, t_{2}^{r}\right)$,

$$
\sum_{v \in V_{-}^{\mathbf{r}}(i, j) \backslash\{i, j\}}\left(b_{v}-\ell_{v}\right)=0
$$

holds due to Property (d). Consequently, $f_{4}\left(\ell, y^{\preceq_{\mathrm{r}}}, y^{\succeq_{\mathrm{r}}}\right)=0$.
Proof of Lemma 5.10. Optimality of $z$ and the choice of $u_{1}$ imply $x_{\bar{u}}^{\succeq \mathrm{r}}=0$ for all $u \in V_{+}^{\mathrm{r}}\left(u_{1}, w\right) \backslash\left\{u_{1}\right\}$. Hence,

$$
x_{i}^{\succeq_{\mathrm{r}}} \sum_{v \in V_{+}^{\mathrm{r}}(o, i) \backslash\{i\}}\left(b_{v}-\ell_{v}\right)=0,
$$

whenever $u_{1} \in V_{+}^{\mathrm{r}}(o, i) \backslash\{i\}$. Thus, a change of $\ell_{u_{1}}$ does not change $f_{3}\left(\ell, x^{\succeq_{\mathrm{r}}}\right)$.
Proof of Lemma 5.11. Optimality of $z$ and the choice of $v_{1}$ and $v_{3}$ imply $y_{\bar{u}}^{\complement_{\mathrm{r}}}=0$ for all $u \in V_{-}^{\mathrm{r}}\left(o, v_{1}\right) \backslash\left\{o, v_{1}\right\}$ and $y_{\bar{u}}^{\succeq_{\mathrm{r}}}=0$ for all $u \in V_{-}^{\mathrm{r}}\left(v_{3}, w\right) \backslash\left\{v_{3}, w\right\}$. Hence,

$$
y_{i}^{\complement_{\mathrm{r}}^{\mathrm{r}}} y_{j}^{\succeq_{\mathrm{r}}} \sum_{v \in V_{-}^{\mathrm{r}}(i, j) \backslash\{i, j\}}\left(b_{v}-\ell_{v}\right)=0,
$$

whenever $v_{1}$ or $v_{3}$ are in $V_{-}^{\mathrm{r}}(i, j) \backslash\{i, j\}$. Consequently, a change of $\ell_{v_{1}}$ or $\ell_{v_{3}}$ does not change $f_{4}\left(\ell, y^{\preceq_{\mathrm{r}}}, y^{\succeq \mathrm{r}}\right)$.
Proof of Lemma 5.14. Let $z$ be an optimal solution of (14). By contradiction, we assume that $f_{3}\left(\ell, x^{\succeq_{\mathrm{r}}}\right)>0$ holds. Lemma 5.6 implies that $\ell$ does not satisfy Property (c). Consequently, there are entries $u_{1}, u_{2} \in V_{+}^{\mathrm{r}}(o, w)$ with $u_{1} \prec_{\mathrm{r}} u_{2}$, $\ell_{u_{1}}<b_{u_{1}}$, and $\ell_{u_{2}}>0$. We now choose $u_{1}$ such that $\ell_{u}=b_{u}$ holds for all $u \in V_{+}^{\mathrm{r}}\left(o, u_{1}\right) \backslash\left\{u_{1}\right\}$ and $u_{2}$ such that $\ell_{u}=0$ holds for all $u \in V_{+}^{\mathrm{r}}\left(u_{2}, w\right) \backslash\left\{u_{2}\right\}$. Due to the latter, there is an exit $v_{2} \in V_{-}^{\mathrm{r}}\left(u_{2}, w\right)$ with $\ell_{v_{2}}>0$ and $\ell_{v}=0$ for all $v \in V_{-}^{\mathrm{r}}\left(v_{2}, w\right) \backslash\left\{v_{2}, w\right\}$. Furthermore, we can assume w.l.o.g. that in a flow decomposition, see Lemma 3.1, $q\left(P^{\mathrm{r}}\left(u_{2}, v_{2}\right)\right)>0$ holds. Due to Lemma 3.4 and $u_{1} \prec_{\mathrm{r}} u_{2}$, we can decrease $q\left(P^{\mathrm{r}}\left(u_{2}, v_{2}\right)\right)$ and increase $q\left(P^{\mathrm{r}}\left(u_{1}, v_{2}\right)\right)$ such that $\Pi_{P^{\mathrm{r}}(o, w)}(q)$ stays the same as before the modification and $0<\ell_{u_{1}} \leq b_{u_{1}}, \ell_{u_{2}}>$ $0, \ell_{v_{2}}>0$ hold. Thus, the binary variables of $z$ stay the same. Furthermore, by Lemmas $5.8,5.9$, and 5.11 the values of $f_{1}, f_{2}$, and $f_{4}$ stay the same. The modified solution satisfies Constraints (14b). The modification only decreases $q_{a}$ for $a \in P^{\mathrm{r}}\left(u_{2}, v_{2}\right)$, increases $q_{a}$ for $a \in P^{\mathrm{r}}\left(u_{1}, u_{2}\right)$, and the remaining flows stay the same. Hence, since $u_{1} \prec_{\mathrm{r}} u_{2} \prec_{\mathrm{r}} v_{2}$ and by Lemma 3.4 (d), Constraint (14d) is still satisfied. Consequently, $z$ is still feasible for (14). Due to this modification, we increase $\ell_{u_{1}}>0$ and decrease $\ell_{u_{2}}$. By Lemma 5.10, considering only the decrease
of $\ell_{u_{2}}$ does not change the objective value. In contrast, the increase of $\ell_{u_{1}}$ decreases $f_{3}$ because

$$
x_{u_{2}}^{\succeq_{\mathrm{r}}^{\mathrm{r}}} \sum_{v \in V_{+}^{\mathrm{r}}\left(o, u_{2}\right) \backslash\left\{u_{2}\right\}}\left(b_{v}-\ell_{v}\right)
$$

decreases. Thus, the modification decreases the objective value, which is a contradiction to the optimality of the original solution.
Proof of Lemma 5.15. Let $z$ be an optimal solution of (14). By contradiction, we assume that $f_{4}\left(\ell, y^{\preceq_{\mathrm{r}}}, y^{\succeq_{\mathrm{r}}}\right)>0$ holds. Lemma 5.7 implies that $\ell$ does not satisfy Property (d). Consequently, there are exits $v_{1}, v_{2}, v_{3} \in V_{-}^{\mathrm{r}}(o, w) \backslash\{w\}$ with $v_{1} \prec_{\mathrm{r}} v_{2} \prec_{\mathrm{r}} v_{3}, \ell_{v_{1}}>0, \ell_{v_{2}}<b_{v_{2}}$, and $\ell_{v_{3}}>0$. Furthermore, we choose $v_{1}$ such that $\ell_{v}=0$ holds for all $v \in V_{-}^{\mathrm{r}}\left(o, v_{1}\right) \backslash\left\{v_{1}\right\}$. If $q_{a}>0$ for $a \in \delta^{\operatorname{in}}(w) \cap P^{\mathrm{r}}(o, w)$, we replace $v_{3}=w$. Otherwise, we choose $v_{3} \neq w$ such that $\ell_{v}=0$ holds for all $v \in V_{-}^{1}\left(v_{3}, w\right) \backslash\left\{v_{3}, w\right\}$. We now consider a flow decomposition such as in Lemma 3.1. Due to $q \geq 0$, there is an entry $u_{3} \in V_{+}^{\mathrm{r}}\left(o, v_{3}\right)$ with $\ell_{u}=0$ for all $u \in V_{+}^{\mathrm{r}}\left(u_{3}, w\right) \backslash\left\{u_{3}\right\}$ and $q\left(P^{\mathrm{r}}\left(u_{3}, v_{3}\right)\right)>0$. Furthermore, an entry $u_{1} \in V_{+}^{\mathrm{r}}(o, w)$ with $\ell_{u}=0$ for all $u \in V_{+}^{\mathrm{r}}\left(o, u_{1}\right) \backslash\left\{o, u_{1}\right\}$ exists which satisfies $q\left(P^{\mathrm{r}}\left(u_{1}, v_{1}\right)\right)>0$. We now distinguish two cases.

Case 1: $v_{2} \prec_{\mathrm{r}} u_{3}$ holds. We now decrease $q\left(P^{\mathrm{r}}\left(u_{1}, v_{1}\right)\right)$ by $\varepsilon>0$ and increase $q\left(P^{\mathrm{l}}\left(u_{1}, v_{2}\right)\right)$ by the same amount $\varepsilon$. This increases the potential difference $\Pi_{P(o, w)}(q)$. Thus, we decrease $q\left(P^{\mathrm{l}}\left(u_{3}, v_{3}\right)\right)$ by $\tilde{\varepsilon}>0$. Due to Lemma 3.4, we can choose $\varepsilon$ and $\tilde{\varepsilon}$ such that $\Pi_{P(o, w)}(q)$ stays the same and $\ell_{v_{1}}>0,0<\ell_{v_{2}} \leq b_{v_{2}}, \ell_{u_{3}}>$ $0, \ell_{v_{3}}>0$ hold. Thus, the binary variables of $z$ stay the same. Furthermore, by Lemmas 5.8-5.10, the values of $f_{1}, f_{2}$, and $f_{3}$ stay the same. The modified solution satisfies Constraints (14b). Further, the modification only decreases $q_{a}$ for $a \in P^{\mathrm{r}}\left(u_{3}, v_{3}\right)$, increases $q_{a}$ for $a \in P^{\mathrm{r}}\left(v_{1}, v_{2}\right)$, and the remaining flows stay the same. Hence, since $v_{1} \prec_{\mathrm{r}} v_{2} \prec_{\mathrm{r}} u_{3} \prec_{\mathrm{r}} v_{3}$ and by Lemma 3.4 (d), Constraint (14d) is still satisfied. Consequently, $z$ is still feasible for (14). Due to this modification, we decrease $\ell_{v_{1}}>0$ and $\ell_{v_{3}}>0$ and increase $\ell_{v_{2}}$. By Lemma 5.11, considering only the decrease of $\ell_{v_{1}}$ and $\ell_{v_{3}}$ does not change the objective value. In contrast, the increase of $\ell_{v_{2}}$ decreases $f_{4}$ because

$$
y_{\bar{v}_{1}}^{\preceq_{\mathrm{r}}^{\mathrm{r}}} y_{v_{3}}^{\succeq \mathrm{r}} \sum_{v \in V_{-}^{\mathrm{r}}\left(v_{1}, v_{3}\right) \backslash\left\{v_{1}, v_{3}\right\}}\left(b_{v}-\ell_{v}\right)
$$

decreases. Thus, the modification decreases the objective value, which contradicts the optimality of the original solution.

Case 2: $u_{3} \prec_{\mathrm{r}} v_{2}$ holds. We now decrease $q\left(P^{\mathrm{r}}\left(u_{3}, v_{3}\right)\right)$ by $\varepsilon>0$ and increase $q\left(P^{\mathrm{r}}\left(u_{3}, v_{2}\right)\right)$ by the same amount $\varepsilon$. This decreases the potential difference $\Pi_{P^{\mathrm{r}}(o, w)}(q)$. Thus, we decrease $q\left(P^{\mathrm{r}}\left(u_{1}, v_{1}\right)\right)$ by $\tilde{\varepsilon}>0$ and increase $q\left(P^{\mathrm{r}}\left(u_{1}, v_{2}\right)\right)$ by the same amount $\tilde{\varepsilon}$ which increases the potential difference $\Pi_{P^{\mathrm{r}}(o, w)}(q)$. Due to Lemma 3.4, we can choose $\varepsilon$ and $\tilde{\varepsilon}$ such that $\Pi_{P^{\mathrm{r}}(o, w)}(q)$ stays the same and $\ell_{v_{1}}>0,0<\ell_{v_{2}} \leq b_{v_{2}}, \ell_{v_{3}}>0$ hold. In particular, the binary variables of $z$ stay the same. Furthermore, by Lemmas 5.8-5.10, the values of $f_{1}, f_{2}$, and $f_{3}$ stay the same. The modified solution satisfies Constraints (14b). Further, the modification only decreases $q_{a}$ for $a \in P^{\mathrm{r}}\left(v_{2}, v_{3}\right)$, increases $q_{a}$ for $a \in P^{\mathrm{r}}\left(v_{1}, v_{2}\right)$, and the remaining flows stay the same. Hence, since $v_{1} \prec_{\mathrm{r}} v_{2} \prec_{\mathrm{r}} v_{3}$ and by Lemma 3.4 (d), Constraint (14d) is still satisfied.

Consequently, $z$ is still feasible for (14). In analogy to Case 1, the modification decreases $f_{4}$, which contradicts the optimality of the original solution.
