Abstract. Petri Nets are a well-known model of concurrency and provide an ideal setting for the study of fundamental aspects in concurrent systems. Despite their simplicity, they still lack a satisfactory causally reversible semantics. We develop such semantics for Place/Transitions Petri Nets (P/T nets) based on two observations. Firstly, a net that explicitly expresses causality and conflict among events, e.g., an occurrence net, can be straightforwardly reversed by adding reversal for each of its transitions. Secondly, the standard unfolding construction associates a P/T net with an occurrence net that preserves all of its computation. Consequently, the reversible semantics of a P/T net can be obtained as the reversible semantics of its unfolding. We show that such reversible behaviour can be expressed as a finite net whose tokens are coloured by causal histories. Colours in our encoding resemble the causal memories that are typical in reversible process calculi.

1 Introduction

Reversible computing is attracting interest for its applications in many fields including hardware design and quantum computing [30], the modelling of biochemical reactions [25,12,26], parallel discrete event simulation [27] and program reversing for debugging [8,16,11].

A model for reversible computation features two computation flows: the standard forward direction and the reverse one, which allows to reach back any past state of the computation. Reversibility is well understood in a sequential setting in which executions are totally ordered sets of events (see [17]): a sequential computation can be reversed by successively undoing the last not yet undone event. Reversibility becomes more challenging in a concurrent setting because there is no natural way for totally ordering events. Often concurrency models account for the causal dependencies among events, which are reflected as a partial order. Reversing an execution consisting of a partially ordered set of events reduces to successively undoing one of the maximal events not yet undone. This is at the basis of the *causally-consistent reversibility* [6,23,15], which relates reversibility with causality. Intuitively, this notion stipulates that any event can be undone provided that all its consequences, if any, are undone beforehand. Reversibility in distributed systems such as in checkpoint/rollback protocols [29] and in transactions [7,13] can be modelled by causal-consistent reversibility. The interplay between reversibility and concurrency has been widely studied in process

Fig. 1. Backward conflict and naive reversing.

calculi [6,23,14,4,19], event structures [24,5,28,9] and lately Petri Nets [21,1]. Despite being a very basic model of concurrency, Petri nets still lack a satisfactory causally-consistent reversible semantics. For instance, no current models are able to handle cyclic nets.

A key point when reversing computation in Petri nets is to handle backward conflicts, i.e., the fact that a token can be generated in a place because of different causes. Consider the net in Figure 1(a) showing the initial state of a system that can either perform t_1 followed by t_3 , or t_2 followed by t_4 . The final state of a complete computation is depicted in Figure 1(b). The information in that state is not enough to deduce whether the token in d has been produced because of t_3 or t_4 . Even worse, if we “naively” reverse the net by just adding transitions in the reverse direction, as shown in Figure 1(c), the reverse transition will do more than undoing the computation. In fact, the token in d can be put back either in b or c regardless of the previous computation.

Analogous problems arise when a net is cyclic. Previous approaches [21,1] to reversing Petri nets tackle backward conflicts by relying on a new kind of tokens, called *bonds* that keep track of the execution history. Bonds are rich enough for allowing other approaches to reversibility, such as *out-of-order* reversibility [12], but they cannot cope with cyclic nets. We propose here a reversible model for P/T nets that can handle cyclic nets by relying on standard notions in Petri net theory. We first observe that a Petri Net can be mapped via the standard unfolding construction to an occurrence net, i.e., an acyclic net that does not have backward conflicts and makes causal dependencies explicit. Then, an occurrence net can be “simply” reversed by reversing each of its transitions. Such construction gives a model that features causally-consistent reversibility. This is shown by proving that each reachable marking in the reversible version of the occurrence net is a marking that can be reached by just forward computational steps. We observe that the unfolding construction could produce an infinite occurrence net. However, the unfolding can be seen as the definition of a coloured

net, where colours account for causal histories. Such interpretation associates a P/T net with an equivalent coloured P/T net, which can be reversed in the “simple” way. The correctness of the construction is shown by exhibiting a one-to-one correspondence of its executions with the ones of the reversible version of the unfolding. Interestingly, the colours used by the construction resemble the memories common in reversible calculi [14,6].

We remark that our proposal deals with reversing (undoing) computation in a Petri net and not with the classical problem of reversibility [3] which requires every computation to be able to reach back the initial state of the system (but not necessary by undoing the previous events). In this sense, the problem of making a net reversible equates to adding a minimal amount of transitions that make a net reversible [2]. Reversibility is a global property while reversing a computation is a local one, as discussed in [2].

2 Background

2.1 Petri Nets

Petri nets are built up from *places* (denoting, e.g., resources and message types), which are repositories for *tokens* (representing instances of resources), and *transitions*, which fetch and produce tokens. We consider the infinite sets \mathcal{P} of places and \mathcal{T} of transitions, and assume that they are disjoint, i.e., $\mathcal{P} \cap \mathcal{T} = \emptyset$. We let $\mathbf{a}, \mathbf{a}', \dots$ range over \mathcal{P} and $\mathbf{t}, \mathbf{t}', \dots$ over \mathcal{T} . We write x, y, \dots for elements in $\mathcal{P} \cup \mathcal{T}$.

A *multiset* over a set S is a function $m : S \rightarrow \mathbb{N}$ (where \mathbb{N} denotes the natural numbers including zero). We write \mathbb{N}^S for the set of multisets over S . For $m \in \mathbb{N}^S$, $\text{supp}(m) = \{x \in S \mid m(x) > 0\}$ is the *support* of m , and $|m| = \sum_{x \in S} m(x)$ stands for its *cardinality*. We write \emptyset for the empty multiset, i.e., $\text{supp}(\emptyset) = \emptyset$. The union of $m_1, m_2 \in \mathbb{N}^S$, written $(m_1 \oplus m_2)$, is defined such that $(m_1 \oplus m_2)(x) = m_1(x) + m_2(x)$ for all $x \in S$. Note that \oplus is associative and commutative, and has \emptyset as identity. Hence, \mathbb{N}^S is the free commutative monoid S^\oplus over S . We write x for a singleton multiset, i.e., $\text{supp}(x) = \{x\}$ and $m(x) = 1$. Moreover, we write $x_1 \dots x_n$ for $x_1 \oplus \dots \oplus x_n$. Let $f : S \rightarrow S'$, we write f also for its obvious extension to multisets, i.e., $f(x_0 \dots x_n) = f(x_0) \dots f(x_n)$. We avoid writing $\text{supp}(\cdot)$ when applying set operators to multisets, e.g., we write $x \in m$ or $m_1 \cap m_2$ instead of $x \in \text{supp}(m)$ or $\text{supp}(m_1) \cap \text{supp}(m_2)$.

Definition 1 (Petri Net). A net N is a 4-tuple $N = (S_N, T_N, \bullet_{-N}, \bullet_{-N})$ where $S_N \subseteq \mathcal{P}$ is the (nonempty) set of places, $T_N \subseteq \mathcal{T}$ is the set of transitions and the functions $\bullet_{-N}, \bullet_{-N} : T_N \rightarrow 2^{S_N}$ assign source and target to each transition such that $\bullet_{-N} \mathbf{t} \neq \emptyset$ and $\bullet_{-N} \mathbf{t} \neq \emptyset$ for all $\mathbf{t} \in T_N$. A marking of a net N is a multiset over S_N , i.e., $m \in \mathbb{N}^{S_N}$. A Petri net is a pair (N, m) where N is a net and m is a marking of N .

We denote $S_N \cup T_N$ by N , and omit the subscript N if no confusion arises. We abbreviate a transition $\mathbf{t} \in T$ with *preset* $\bullet \mathbf{t} = s_1$ and *postset* $\mathbf{t} \bullet = s_2$ as $s_1 \rfloor s_2$. Hereafter, we only consider nets whose transitions have non-empty presets. The

pre and postset of a place $a \in S$ are defined respectively as $\bullet a = \{t \mid a \in t^\bullet\}$ and $a^\bullet = \{t \mid a \in \bullet t\}$. We let ${}^\circ N = \{x \in N \mid \bullet x = \emptyset\}$ and $N^\circ = \{x \in N \mid x^\bullet = \emptyset\}$ denote the sets of *initial* and *final elements* of N respectively. Note that we only consider nets whose initial and final elements are places since transitions have non-empty pre and postsets, i.e., $\bullet t \neq \emptyset$ and $t^\bullet \neq \emptyset$ holds for all t .

Definition 2 (Net morphisms). *Let N, N' be nets. A pair $f = (f_S : S_N \rightarrow S_{N'}, f_T : T_N \rightarrow T_{N'})$ is a net morphism from N to N' (written $f : N \rightarrow N'$) if $f_S(\bullet t_N) = \bullet(f_T(t))_{N'}$ and $f_S(t_N^\bullet) = (f_T(t))_{N'}^\bullet$ for any t . Moreover, we say N and N' are isomorphic if f is bijective.*

The operational (interleaving) semantics of a Petri net is given by the least relation on Petri nets satisfying the following inference rule:

$$\frac{\text{(FIRING)} \quad t = m \upharpoonright m' \in T_N}{(N, m \oplus m'') \xrightarrow{t} (N, m' \oplus m'')}$$

which describes the evolution of the state of a net (represented by the marking $m \oplus m''$) by the firing of a transition $m \upharpoonright m'$ that consumes the tokens m in its preset and produces the tokens m' in its postset. We sometimes omit t in \xrightarrow{t} when the fired transition is uninteresting.

According to Definition 1, transitions consume and produce at most one token in each place. On the other hand, P/T nets below fetch and consume multiple tokens by defining the pre- and postsets of transitions as multisets.

Definition 3 (P/T net). *A Place / Transition Petri net (P/T net) is a 4-tuple $N = (S_N, T_N, \bullet_{-N}, \bullet_{-N})$ where $S_N \subseteq \mathcal{P}$ is the (nonempty) set of places, $T_N \subseteq \mathcal{T}$ is the set of transitions and the functions $\bullet_{-N}, \bullet_{-N} : T_N \rightarrow \mathbb{N}^{S_N}$ assign source and target to each transition. A marking of a net N is multiset over S_N , i.e., $m \in \mathbb{N}^{S_N}$. A marked P/T net is a pair (N, m) where N is a P/T net and m is a marking of N .*

The notions of pre- and postset, initial and final elements, morphisms and operational semantics are straightforwardly extended to P/T nets. Note that Petri nets can be regarded as a P/T net whose arcs have unary weights.

Next, we introduce some notation for sequences of transitions. Let ‘;’ denote concatenation of such sequences. For the sequence $s = t_1; t_2; \dots; t_n$, we write $(N, m_0) \xrightarrow{s} (N, m_n)$ if $(N, m_0) \xrightarrow{t_1} (N, m_1) \xrightarrow{t_2} \dots \xrightarrow{t_n} (N, m_n)$; we call s a firing sequence. We write $(N, m_0) \rightarrow^* (N, m_n)$ if there exists s such that $(N, m_0) \xrightarrow{s} (N, m_n)$, and ϵ_m for the empty sequence.

Definition 4. *Let (N, m) be a P/T net. The set of reachable markings $\text{reach}(N, m)$ is defined as $\{m' \mid (N, m) \rightarrow^* (N, m')\}$.*

We say a marked P/T net (N, m) is (1-)safe if every reachable marking is a set, i.e., $m' \in \text{reach}(N, m)$ implies $m' \in 2^{S_N}$.

Fig. 2. P/T nets

Example 5. Figure 2 shows different P/T nets, which will be used throughout the paper. As usual, places and transitions are represented by circles and boxes, respectively. The nets O_1 and N_4 are Petri nets, and N_1 , N_2 and N_3 are P/T nets which, when executing, may produce multiple tokens in some places.

2.2 Unfolding of P/T nets

Our approach to reversing Petri nets relies on their occurrence net semantics, which explicitly exhibit the causal ordering, concurrency, and conflicts among events. We start by introducing several useful notions and notations. First, we shall describe a flow of causal dependencies in a net with the relation \prec :

Definition 6. Let \prec be $\{(a, t) | a \in S_N \wedge t \in a^\bullet\} \cup \{(t, a) | a \in S_N \wedge t \in \bullet a\}$. We write \preceq for the reflexive and transitive closure of \prec .

Consider Figure 2. We have $a \prec t_1$ and $t_1 \prec c$ in O_1 as well as $t_1 \preceq t_2$ in N_1 .

Two transitions t_1 and t_2 are in an *immediate conflict*, written $t_1 \#_0 t_2$, when $t_1 \neq t_2$ and $\bullet t_1 \cap \bullet t_2 \neq \emptyset$. For example, t_1 and t_2 in N_4 in Figure 2 are in an immediate conflict since they share a token in the place c . Correspondingly, for t_2 and t_3 in N_1 . The *conflict* relation $\#$ is defined by letting $x \# y$ if $x \neq y$ and there are $t_1, t_2 \in T$ such that $t_1 \preceq x$, and $t_2 \preceq y$, and $t_1 \#_0 t_2$.

We are now ready to give the definition of an occurrence net following [20,10].

Definition 7 (Occurrence net). A net (N, m) is an occurrence net if

1. N is acyclic;
2. N is a (1-)safe net, i.e., any reachable marking is a set;
3. $m = {}^\circ N$, i.e., the initial marking is identified with the set of initial places;
4. there are no backward conflicts, i.e., $|\bullet a| \leq 1$ for all a in S_N ;
5. there are no self-conflicts, i.e., $\neg(t\#t)$ for all t in T_N .

We use O to range over occurrence nets.

Example 8. The net O_1 in Figure 2 is an occurrence net, while the remaining nets are not. N_1 is not an occurrence net since there is a token in place c and c is not an initial place of the net. N_2 has a backward conflict since two transitions produce tokens on the place d . N_3 is cyclic, and N_4 is cyclic and has a backward conflict on c .

The absence of backward conflicts in occurrence nets ensures that each place appears in the postset of at most one transition. Hence, pre- and postset relations can be interpreted as a causal dependency. So, \preceq represents causality.

We say $x, y \in N$ are *concurrent*, written $x \text{ co } y$, if $x \neq y$ and $x \not\preceq y$, $y \not\preceq x$, and $\neg x\#y$. A set $X \subseteq N$ is concurrent, written $CO(X)$, if $\forall x, y \in X : x \neq y \Rightarrow x \text{ co } y$, and $|\{t \in T_N \mid \exists x \in X, t \preceq x\}|$ is finite. For example, the set $\{t_1, t_2\}$ of firings in O_1 of Figure 2 is concurrent, so we can write $CO(\{t_1, t_2\})$.

Two transitions are *coinitial* if they start with the same marking, and *cofinal* if they end up in the same marking. We now have a simple version of the Square Lemma [6] for forward concurrent transitions. It will be helpful in proving our Lemma 16 in the next section.

Lemma 9. *Let t and t' be coinitial concurrent transitions. Then, there exist transitions t_1 and t'_1 such that $t; t'_1$ and $t'; t_1$ are cofinal.*

The lemma says that if transitions t and t' originate from one corner of a square, and if they represent independent (concurrent) events, then the square completes with two other independent transitions (t_1 and t'_1) meeting at the opposite corner of the square. The order in which concurrent transitions are executed in a firing sequence does not matter. Indeed, the order which should be preserved among firings in a sequence is the causal order. We then consider sequences equivalent up to the swapping of concurrent transitions. This corresponds to considering the set of Mazurkiewicz traces induced by co as the independence relation.

Formally, trace equivalence \equiv is the least congruence over firing sequences s such that $\forall t_1, t_2 : t_1 \text{ co } t_2 \implies t_1; t_2 \equiv t_2; t_1$. The equivalence classes of \equiv are the (Mazurkiewicz) traces. We use ω to range over such traces. We also will use ϵ for the empty trace, and $;$ for the concatenation operator.

For occurrence nets we have this standard property:

$$s_1 \equiv s_2 \text{ iff } (O, m_0) \xrightarrow{s_1} (O, m_n) \iff (O, m_0) \xrightarrow{s_2} (O, m_n) \quad (1)$$

Two traces are *coinitial* if they start with the same marking, and *cofinal* if they end up in the same marking. Hence, equation (1) tells us that two traces that are *coinitial* and *cofinal* are then trace equivalent.

$$\begin{array}{c}
 \text{(INI-MK)} \\
 \hline
 m(\mathbf{a}) = n \\
 \hline
 \{\mathbf{a}(\emptyset, i) \mid 1 \leq i \leq n\} \subseteq S \\
 \\
 \text{(PRE)} \\
 \hline
 H = \{\mathbf{a}_j(h_j, i_j) \mid j \in J\} \subseteq S \quad Co(H) \quad \mathbf{t} \in T_N \quad \bullet \mathbf{t}_N = \bigoplus_{j \in J} \mathbf{a}_j \\
 \hline
 \mathbf{t}(H) \in T, \quad \bullet(\mathbf{t}(H)) = H \\
 \\
 \text{(POST)} \\
 \hline
 x = \mathbf{t}(H) \in T \\
 \hline
 Q = \{\mathbf{a}(\{x\}, i) \mid 1 \leq i \leq \mathbf{t}_N^*(\mathbf{a})\} \subseteq S, \quad x^\bullet = Q
 \end{array}$$

Fig. 3. Unfolding rules.

Fig. 4. Unfoldings of P/T nets

The unfolding of a net N is the least occurrence net that can account for all the possible computations of N and makes explicit causal dependencies, conflicts and concurrency between firings [20].

Definition 10 (Unfolding). Let (N, m) be a P/T net. The unfolding of N is the occurrence net $\mathcal{U}[N, m] = (S, T, \delta_0, \delta_1)$ generated inductively by the inference rules in Figure 3 and the folding morphism $(f_S, f_T) : \mathcal{U}[N, m] \rightarrow N$ defined such that $f_S(\mathbf{a}, -, -) = \mathbf{a}$ and $f_T(\mathbf{t}, -) = \mathbf{t}$.

Places are named by triples $\mathbf{a}(H, i)$ where: \mathbf{a} is a place of N where tokens reside; H is the set of immediate causes (i.e., the history of tokens); and i is a positive integer used to disambiguate tokens with the same history. Transitions (or events) are encoded as $\mathbf{t}(H)$, where H is as above and \mathbf{t} is the fired transition.

Example 11. The unfoldings of the nets $(N_1, \mathbf{a} \oplus \mathbf{b} \oplus \mathbf{c} \oplus \mathbf{d})$, $(N_2, \mathbf{a} \oplus \mathbf{b} \oplus \mathbf{c})$ and (N_3, \mathbf{a}) in Figure 2 are shown in Figure 4. Note that since O_1 is an occurrence net its unfolding is isomorphic to O_1 , thus it is omitted. Consider the occurrence net $\mathcal{U}[N_1, \mathbf{a} \oplus \mathbf{b} \oplus \mathbf{c} \oplus \mathbf{d}]$. The leftmost transition \mathbf{t}_2 is different from the other

transition t_2 since they have different histories: the leftmost t_2 is caused by the tokens in b and c (which are available in the initial marking), whereas the other t_2 is caused only by the token in b and the token that is produced by the firing of t_1 . Correspondingly, for the two transitions labelled t_3 . Consider $\mathcal{U}[N_2, \mathbf{a} \oplus \mathbf{b} \oplus \mathbf{c}]$. After the transitions t_1 and t_2 have fired, there is a token in each of the places labelled d . The token in the leftmost d has the history t_1 and the token in the other d has the history t_2 . Once t_3 has fired, we can tell the copies of t_3 apart by inspecting their histories: the leftmost t_3 is caused by a token in d with the history t_1 (as well as the token in c), whereas the other t_3 is caused by d with the history t_2 and by c .

3 Reversing Occurrence Nets

Definition 12. Let O be an occurrence net. The reversible version of O is $\overleftarrow{O} = (S_{\overleftarrow{O}}, T_{\overleftarrow{O}}, \bullet_{\overleftarrow{O}}, \circ_{\overleftarrow{O}})$ defined such that

$$\begin{aligned} S_{\overleftarrow{O}} &= S_O & T_{\overleftarrow{O}} &= T_O \cup \{\overleftarrow{t} \mid t \in T_O\} \\ \bullet_{\overleftarrow{O}} &= \begin{cases} \bullet_{t_O} & \text{if } t \in T_O \\ \bullet_{\overleftarrow{t_O}} & \text{otherwise} \end{cases} & \circ_{\overleftarrow{O}} &= \begin{cases} \circ_{\overleftarrow{t_O}} & \text{if } t \in T_O \\ \circ_{t_O} & \text{otherwise} \end{cases} \end{aligned}$$

Given a transition t we write \overleftarrow{t} for a transition that reverses t . We shall call transitions like \overleftarrow{t}_1 and \overleftarrow{t}_2 in Figure 5 *reverse* (or backwards) transitions (or firings), and use t, t_1 and t_2 to denote transitions or reverse transitions.

For \overleftarrow{O} , we write $(\overleftarrow{O}, m) \xrightarrow{t} (\overleftarrow{O}, m')$ for a forward firing when $t \in T_O$, and $(\overleftarrow{O}, m) \xrightarrow{\overleftarrow{t}} (\overleftarrow{O}, m')$ for the reverse (or backward) firing when $\overleftarrow{t} \notin T_O$. We also let \xrightarrow{t} be $\xrightarrow{t} \cup \xrightarrow{\overleftarrow{t}}$. We will often refer to a firing $(\overleftarrow{O}, m) \xrightarrow{t} (\overleftarrow{O}, m')$ as t . Given a firing t we indicate with \overleftarrow{t} its inverse that is

$$\begin{aligned} (\overleftarrow{O}, m) &\xrightarrow{\overleftarrow{t}} (\overleftarrow{O}, m') & \text{if } (\overleftarrow{O}, m') \xrightarrow{t} (\overleftarrow{O}, m) \\ (\overleftarrow{O}, m) &\xrightarrow{t} (\overleftarrow{O}, m') & \text{if } (\overleftarrow{O}, m') \xrightarrow{\overleftarrow{t}} (\overleftarrow{O}, m) \end{aligned}$$

Hence, we have $\overleftarrow{\overleftarrow{t}} = t$. We shall work with sequences of transitions and reverse transitions, ranged over by s, s_1 and s_2 . We say that a sequence is a *forward* (resp. *backward*) *sequence* when all its firings are forward (resp. backward).

Next, we extend the notions of causality, conflict and concurrency to transitions and reverse transitions in reverse versions of occurrence nets. We extend \prec in Definition 6 to cover reverse transitions in an obvious way using Definition 12. As a result, we obtain $t \preceq \overleftarrow{t}$ and $\overleftarrow{t} \preceq t$. As for the conflict relation, we define an immediate conflict between different \overleftarrow{t}_1 and \overleftarrow{t}_2 as $\bullet_{\overleftarrow{t}_1} \cap \bullet_{\overleftarrow{t}_2} \neq \emptyset$. This is $t_1 \bullet \cap t_2 \bullet \neq \emptyset$, meaning t_1 and t_2 are in backward conflict, which is ruled out in occurrence nets. Hence, the immediate conflict relation is empty between reverse

transitions, and so is the conflict relation. The immediate conflict relation between t and $\overleftarrow{t'}$ is defined as $\bullet t \cap \bullet \overleftarrow{t'} \neq \emptyset$. This is equivalent to $\bullet t \cap \bullet \overleftarrow{t'} \neq \emptyset$, which means $t' \preceq t$. Consequently, the conflict relation on transitions in \overleftarrow{O} is given by the conflict relation on the forward transitions, and can be defined using the causality relation for pairs of a transition and reverse transition. This allows us to define concurrent transitions in \overleftarrow{O} . We say t *co* t' if (a) t *co* t' for $t, t' \in T_O$, (b) $t \not\prec t'$ and $t' \not\prec t$ if t, t' are reverse transitions, and (c) $t \not\prec t', t' \not\prec t$ and $\overleftarrow{t'} \not\prec t$ if t is a transition and t' is a reverse transition.

Next, we show that \overleftarrow{O} is a conservative extension of O .

Lemma 13. $(O, m) \xrightarrow{t} (O, m')$ iff $(\overleftarrow{O}, m) \xrightarrow{t} (\overleftarrow{O}, m')$.

In general, a reversible occurrence net is not an occurrence net. This is because adding reverse transitions may introduce backward conflict for these transitions. Consider N_1 in Figure 2. We notice that initially t_1 and t_2 are in conflict. Then, in \overleftarrow{N}_1 in Figure 5, the place c with a token has two reverse transitions in its preset, namely $\overleftarrow{t_2}$ and $\overleftarrow{t_3}$, hence there is a backward conflict.

4 Properties

We now study the properties of the reversible versions of occurrence nets.

An important property of a *fully* reversible system is the Loop Lemma stating that any reduction can be undone. Formally:

Lemma 14 (Loop Lemma). $(\overleftarrow{O}, m) \xrightarrow{t} (\overleftarrow{O}, m')$ iff $(\overleftarrow{O}, m') \xrightarrow{\overleftarrow{t}} (\overleftarrow{O}, m)$.

We can generalise the result of the Loop Lemma to sequences as follows:

Corollary 15. $(\overleftarrow{O}, m) \rightarrow^* (\overleftarrow{O}, m')$ iff $(\overleftarrow{O}, m') \rightarrow^* (\overleftarrow{O}, m)$.

Next, we have a lemma which is instrumental for the proof of causal-consistent reversibility in reversible calculi [6,14]. Note that t and t' can be either forward or reverse transitions.

Lemma 16 (Square Lemma). *Let t and t' be coinital concurrent transitions. Then, there exist transitions t_1 and t'_1 such that $t; t'_1$ and $t'; t_1$ are cofinal.*

In order to prove causal consistency we first define a notion of equivalence on sequences of transitions and reverse transitions in reversible occurrence nets. By following Lévy's approach [18], we define the notion of *reverse equivalence* on such sequences as the least equivalence relation \asymp which is closed under composition with $;$ such that the following hold (recall that t, t' are transitions or reverse transitions):

$$t; t' \asymp t'; t \quad \text{if } t \text{ co } t' \quad \mathbf{t}; \overleftarrow{\mathbf{t}} \asymp \epsilon \quad \overleftarrow{\mathbf{t}}; \mathbf{t} \asymp \epsilon$$

Reversible equivalence \asymp allows us to swap the order of t and t' in an execution sequence as long as t, t' are concurrent. Moreover, it allows cancellation of a

transition and its inverse. We have that $\equiv \subset \succ$. The equivalence classes of \succ are called *traces*; it is clear that they contain the Mazurkiewicz traces. Hence, we shall use ω, ω_1 and ω_2 to range over such traces.

The following lemma says that, up to reverse equivalence, one can always reach for the maximum freedom of choice, going backward, and only then going forwards.

Lemma 17 (Parabolic Lemma). *Let ω be a trace. There exist two forward traces ω_1 and ω_2 such that $\omega \succ \overleftarrow{\omega_1}; \omega_2$.*

Proof. By lexicographic induction on length of ω and on the distance between the beginning of ω and the earliest pair of opposing firings in ω . The analysis uses both the Loop Lemma (Lemma 14) and the Square Lemma (Lemma 16).

The following lemma says that, if two traces ω_1 and ω_2 are coinitial and cofinal (e.g. they start from the same marking and end in the same marking) and ω_2 is a forward only trace, then ω_1 has some forward firings and their reverse ones that cancel each other. And this implies that ω_1 is causally equivalent to a forward trace in which all those pairs of firings are cancelled out.

Lemma 18 (Shortening Lemma). *Let $\omega_1 \succ \omega_2$ with ω_2 forward. Then, $|\omega_2| \leq |\omega_1|$.*

Proof. The proof is by induction on length of ω_1 , using Lemma 16 and Lemma 17. In the proof, the forward trace ω_2 is the main guideline for shortening ω_1 into a forward trace. Indeed, the proof relies crucially on the fact that ω_1 and ω_2 share the same source and target and that ω_2 is a forward trace.

Theorem 19 (Causal Consistency). *Two traces ω_1 and ω_2 are reversible equivalent iff they are coinitial and cofinal, namely*

$$\omega_1 \succ \omega_2 \text{ iff } (\overleftarrow{\mathcal{O}}, m_0) \xrightarrow{\omega_1} (\overleftarrow{\mathcal{O}}, m_n) \iff (\overleftarrow{\mathcal{O}}, m_0) \xrightarrow{\omega_2} (\overleftarrow{\mathcal{O}}, m_n).$$

Proof. The “if” direction follows by definition of reverse equivalence and trace composition. The “only if” direction exploits the properties the Square, Parabolic and Shortening Lemmas.

With Theorem 19 we proved that the notion of causal consistency characterises a space for admissible rollbacks which are: (1) consistent (in the sense that they do not lead to previously unreachable configurations) and (2) flexible enough to allow rearranging of undo actions. This implies that starting from an initial marking, all the markings reached by mixed computations are markings that could be reached by performing only forward computations. Hence, we have:

Theorem 20. *Let \mathcal{O} be an occurrence net and m_0 an initial marking. Then,*

$$(\overleftarrow{\mathcal{O}}, m_0) \rightarrow^* (\overleftarrow{\mathcal{O}}, m') \iff (\overleftarrow{\mathcal{O}}, m_0) \rightarrow^* (\overleftarrow{\mathcal{O}}, m').$$

Fig. 5. Reversible P/T and Petri nets

5 Reversing P/T nets

This section takes advantage of the classical unfolding construction for P/T nets and the reversible semantics of occurrence nets to add causally-consistent reversibility to P/T nets.

Definition 21. Let (N, m) be a marked P/T net and $\mathcal{U}[N, m]$ its unfolding. The reversible version of (N, m) , written $(\overleftarrow{N}, \overleftarrow{m})$, is $\overleftarrow{\mathcal{U}[N, m]}$.

Example 22. The reversible version of the nets in Figure 2 are shown in Figure 5. We remark that they are the reversible versions of the nets in Figure 4, which are the unfoldings of the original nets.

The following result states that a reversible net is a conservative extension of its original version, i.e., reversibility does not change the set of reachable markings. The result is a direct consequence of Lemma 13 and the fact that unfoldings preserve reductions up-to the folding morphism \mathcal{U} .

Lemma 23. $(N, m) \rightarrow^* (N, m')$ iff $\overleftarrow{(N, m)} \rightarrow^* (\overleftarrow{O}, m'')$ and $m' = f_s(m'')$, where $(f_s, f_t) : \mathcal{U}[N, m] \rightarrow N$, defined such that $f_s(\mathbf{a}, -, -) = \mathbf{a}$ and $f_t(\mathbf{t}, -) = \mathbf{t}$, is the folding morphism.

We remark that the reversible version of a P/T is defined as the reversible version of an occurrence net (i.e., its unfolding). Consequently, all properties shown in the previous section apply to the reversible semantics of P/T nets. In particular, Lemma 23 combined with Theorem 20 ensures that all markings reachable by the reversible semantics are just the reachable markings of the original P/T net.

6 Finite Representation of Reversible P/T Nets

As shown in Figure 5(c), the reversible version of a finite net may be infinite. In this section we show how to represent reversible nets in a compact, finite way by using coloured Petri nets. We assume infinite sets \mathcal{X} of variables and \mathcal{C} of colours, defined such that $\mathcal{X} \subset \mathcal{C}$. For $c \in \mathcal{C}$, we write $\text{vars}(c)$ for the set of variables in c . With abuse of notation we write $\text{vars}(m)$ for the set of variables in a multiset $m \in \mathbb{N}^{\mathcal{P} \times \mathcal{C}}$. Let $\sigma : \mathcal{X} \rightarrow \mathcal{C}$ be a partial function and c a colour (also, $m \in \mathbb{N}^{\mathcal{P} \times \mathcal{C}}$), we write $c\sigma$ (resp., $m\sigma$) for the simultaneous substitution of each variable x in c (resp., m) by $\sigma(x)$.

Definition 24 (C-P/T net). A coloured place / transition net (C-P/T net) is a 4-tuple $N = (S_N, T_N, \bullet_{-N}, \bullet_{-N})$ where $S_N \subseteq \mathcal{P}$ is the (nonempty) set of places, $T_N \subseteq \mathcal{T}$ is the set of transitions and the functions $\bullet_{-N}, \bullet_{-N} : T_N \rightarrow \mathbb{N}^{S_N \times \mathcal{C}}$ assign source and target to each transition defined such that $\text{vars}(\bullet_{-N}) \subseteq \text{vars}(\bullet_{-N})$. A marking of a C-P/T net N is multiset over $S_N \times \mathcal{C}$ that does not contain variables, i.e., $m \in \mathbb{N}^{S_N \times \mathcal{C}}$ and $\text{vars}(m) = \emptyset$. A marked C-P/T net is a pair (N, m) where N is a P/T net and m is a marking of N .

C-P/T nets generalise P/T nets by extending markings to multisets of coloured tokens, and transitions to patterns that need to be instantiated with appropriate colours for firing, as formally stated by the firing rule below.

$$\begin{array}{c} \text{(COLOURED-FIRING)} \\ \frac{\mathbf{t} = m \mid m' \in T_N}{(N, m\sigma \oplus m'') \xrightarrow{\mathbf{t}} (N, m'\sigma \oplus m'')} \end{array}$$

The firing of a transition $t = m \mid m'$ requires to instantiate m and m' by substituting variables by colours, i.e., the firing of t consumes the instance $m\sigma$ of the preset m and produces the instance $m'\sigma$ of the postset of m' .

We now introduce an encoding that associates each P/T net N with an equivalent C-P/T net $\llbracket N \rrbracket$, whose tokens carry their execution history. We rely on the set of colours \mathcal{C} defined as the least set that contains \mathcal{X} and it is closed under the following rules.

$$\begin{array}{c} \text{(TOKEN)} \\ \frac{h \in 2^{\mathcal{C}} \quad n \in \mathbb{N}}{(h, n) \in \mathcal{C}} \end{array} \qquad \begin{array}{c} \text{(ELEM)} \\ \frac{x \in \mathcal{T} \cup \mathcal{P} \quad h \in 2^{\mathcal{C}}}{x(h) \in \mathcal{C}} \end{array}$$

Colours resemble the unfolding construction (Figure 3): the colours for tokens are (h, n) , where h denotes its (possible empty) set of causes and n is a natural number used for distinguishing tokens with identical causal history. Causal histories are build from coloured versions of transitions ($\mathbf{t}(h)$) and places ($\mathbf{a}(h)$).

Definition 25 (P/T as C-P/T). *Let $N = (S_N, T_N, \bullet_{-N}, \circ_{-N})$ be a P/T net. Then, $\llbracket N \rrbracket$ is the C-P/T defined such that $\llbracket N \rrbracket = (S_N, T_N, \bullet_{-\llbracket N \rrbracket}, \circ_{-\llbracket N \rrbracket})$ and*

- $\bullet_{\llbracket N \rrbracket} = \mathbf{a}_1(x_1) \oplus \dots \oplus \mathbf{a}_n(x_n)$ where $\bullet_{T_N} = \mathbf{a}_1 \dots \mathbf{a}_n$ and $\forall 1 \leq i \leq n. x_i \in \mathcal{X}$.
- $\circ_{\llbracket N \rrbracket} = \{\mathbf{a}(\{\mathbf{t}(h)\}), i \mid \mathbf{a} \in \text{supp}(\bullet_{T_N}) \wedge 1 \leq i \leq \mathbf{t}_N^{\bullet}(\mathbf{a}) \wedge h = \bullet_{\llbracket N \rrbracket}\}$.

A marked net (N, m) is encoded as $\llbracket (N, m) \rrbracket = (\llbracket N \rrbracket, \llbracket m \rrbracket)$ where $\llbracket m \rrbracket = \{\mathbf{a}(\emptyset, i) \mid \mathbf{a} \in \text{supp}(m) \wedge 1 \leq i \leq m(\mathbf{a})\}$.

The encoding does not alter the structure of a net; it only adds colours to its tokens. In fact, an encoded net has the same places and transitions as the original net, and pre- and postsets of each transition have the same support. Added colours do not interfere with firing because the preset of each transition uses different colour variables for different tokens. The colour $\{\mathbf{t}(h)\}$ assigned to each token produced by the firing of \mathbf{t} describes the causal history of the token, i.e., it indicates that the token has been produced by \mathbf{t} after consuming the tokens in the preset of \mathbf{t} , which is denoted by h . The natural number i is used for distinguishing multiple tokens produced by the same firing. Tokens in the initial marking are coloured as (\emptyset, i) , i.e., they have empty causal history.

Example 26. The encoding of the nets in Figure 2 are shown in Figure 6. We comment on the encoding of N_1 . The transition $\mathbf{t}_1 = \mathbf{a} \mid \mathbf{c}$ in N_1 is encoded as $\mathbf{a}(x) \mid \mathbf{c}(\mathbf{t}_1(a(x)), 1)$, i.e., the firing of \mathbf{t}_1 that consumes a token with colour h from place \mathbf{a} generates a token in \mathbf{c} with colour $(\mathbf{t}_1(a(h)), 1)$. The transition $\mathbf{t}_2 = \mathbf{b} \oplus \mathbf{c} \mid \mathbf{e}$ has two places in the preset and uses two variables x and y in its encoded form $\mathbf{b}(x) \oplus \mathbf{c}(y) \mid \mathbf{e}(\mathbf{t}_2(\mathbf{b}(x) \oplus \mathbf{c}(y)), 1)$. Note that the colour of the token produced in \mathbf{c} carries the information of the tokens consumed from both places \mathbf{b} and \mathbf{c} . The encoding for \mathbf{t}_3 is defined analogously.

We illustrate a sequence of firings of $\llbracket (N_1, \mathbf{a} \oplus \mathbf{b} \oplus \mathbf{c} \oplus \mathbf{d}) \rrbracket$.

$$\begin{aligned} & (\llbracket N_1 \rrbracket, \mathbf{a}(\emptyset, 1) \oplus \mathbf{b}(\emptyset, 1) \oplus \mathbf{c}(\emptyset, 1) \oplus \mathbf{d}(\emptyset, 1)) \\ & \xrightarrow{\mathbf{t}_1} (\llbracket N_1 \rrbracket, \mathbf{b}(\emptyset, 1) \oplus \mathbf{c}(\mathbf{t}_1(\mathbf{a}(\emptyset, 1)), 1) \oplus \mathbf{c}(\emptyset, 1) \oplus \mathbf{d}(\emptyset, 1)) \\ & \xrightarrow{\mathbf{t}_2} (\llbracket N_1 \rrbracket, \mathbf{e}(\mathbf{t}_2(\mathbf{b}(\emptyset, 1) \oplus \mathbf{c}(\mathbf{t}_1(\mathbf{a}(\emptyset, 1))), 1), 1) \oplus \mathbf{c}(\emptyset, 1) \oplus \mathbf{d}(\emptyset, 1)) \end{aligned}$$

The firing of \mathbf{t}_1 consumes the token $(\emptyset, 1)$ from \mathbf{a} and produces the token $(\mathbf{t}_1(\mathbf{a}(\emptyset, 1)), 1)$ in place \mathbf{c} . The causal history of the token $\mathbf{t}_1(\mathbf{a}(\emptyset, 1))$ indicates that the token has been produced by the firing of \mathbf{t}_1 that consumed the token $(\emptyset, 1)$ from \mathbf{a} . The second reduction takes place because of the firing of \mathbf{t}_2 . By inspecting the causal history of the token produced in the place \mathbf{e} we can conclude that \mathbf{t}_2 has consumed the token previously generated by \mathbf{t}_1 .

The following result shows that there is a tight correspondence between the semantics of the coloured version of a P/T net and its unfolding.

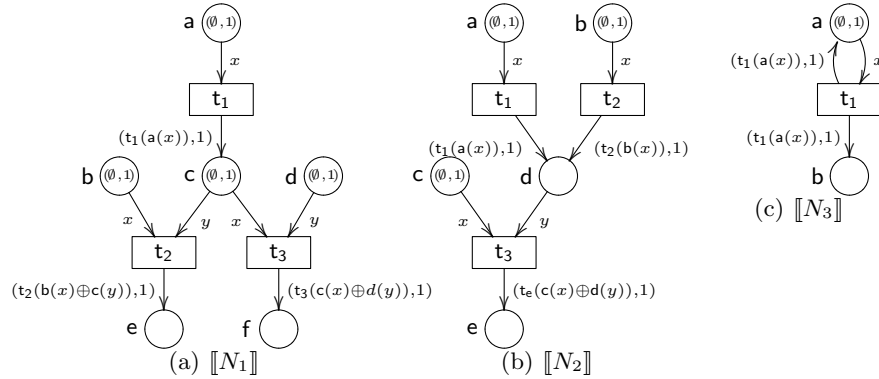

Fig. 6. P/T nets as C-P/T nets

Lemma 27. *Let (N, m) be a marked P/T net and $\mathcal{U}[N, m] = (O, m')$ its unfolding. Then, $\llbracket N, m \rrbracket \xrightarrow{s} (\llbracket N \rrbracket, m'')$ iff $(O, m') \xrightarrow{s} (O, m'')$.*

Proof. The *if* part follows by induction on the length of the reduction. The base case follows by taking $m'' = m'$ and noting that $\llbracket N, m \rrbracket = (\llbracket N \rrbracket, m')$. The inductive step $s = s'; t$ follows by applying inductive hypothesis on s' to conclude that $\llbracket N, m \rrbracket \xrightarrow{s'} (\llbracket N \rrbracket, m''')$ iff $(O, m) \xrightarrow{s'} (O, m''')$. *If* $(\llbracket N \rrbracket, m''') \xrightarrow{t} (\llbracket N \rrbracket, m'')$ implies $m''' = \bullet t_{\llbracket N \rrbracket} \oplus m''''$ and $m'' = t_{\llbracket N \rrbracket} \oplus m''''$. Since $(O, m) \xrightarrow{s'} (O, m''')$, $CO(\bullet t)$. Then, by the unfolding construction we conclude $(O, m''') \xrightarrow{t} (O, m'')$. The *only if* follows analogously.

The reversible version of $\llbracket N \rrbracket$ is defined as for occurrence nets, by adding transitions that are the swapped versions of the ones in N .

Definition 28 (Reversible P/T net). *Let N be a P/T net. The reversible version of N is $\overleftarrow{\llbracket N \rrbracket}$. The reversible version of a marked P/T net (N, m) is the marked C-P/T net $(\overleftarrow{\llbracket N \rrbracket}, \llbracket m \rrbracket)$.*

Example 29. The net $\overleftarrow{\llbracket N_2 \rrbracket}$, the reversible version of $\llbracket N_2 \rrbracket$ from Figure 6, is shown in Figure 7. We now illustrate the execution of $\overleftarrow{\llbracket N_2 \rrbracket}$.

$$\begin{aligned}
& (\overleftarrow{\llbracket N_2 \rrbracket}, a(\emptyset, 1) \oplus b(\emptyset, 1) \oplus c(\emptyset, 1) \oplus d(\emptyset, 1)) \\
& \xrightarrow{t_1} (\overleftarrow{\llbracket N_2 \rrbracket}, b(\emptyset, 1) \oplus b(t_1(a(\emptyset, 1)), 1) \oplus c(\emptyset, 1) \oplus d(\emptyset, 1)) \\
& \xrightarrow{t_2} (\overleftarrow{\llbracket N_2 \rrbracket}, b(t_1(a(\emptyset, 1)), 1) \oplus c(\emptyset, 1) \oplus e(b(\emptyset, 1)c(\emptyset, 1), 1), d(\emptyset, 1)) \\
& \xrightarrow{\tilde{t}_1} (\overleftarrow{\llbracket N_2 \rrbracket}, a(\emptyset, 1) \oplus e(b(\emptyset, 1)c(\emptyset, 1), 1) \oplus d(\emptyset, 1)) \\
& \xrightarrow{\tilde{t}_2} (\overleftarrow{\llbracket N_2 \rrbracket}, a(\emptyset, 1) \oplus b(\emptyset, 1) \oplus c(\emptyset, 1) \oplus d(\emptyset, 1))
\end{aligned}$$

Fig. 7. Reversible coloured net $\llbracket \overleftarrow{N}_2 \rrbracket$.

In the example above, the firing t_2 can choose to consume either the token $b(\emptyset, 1)$ or the token $b(t_1(a(\emptyset, 1)), 1)$. Since the first one is chosen, then after t_2 it is still possible to undo t_1 . If t_2 chose the second token, then in order to undo t_1 we would first undo t_2 , since firing $\overleftarrow{t_1}$ is not enabled by the token $a(\emptyset, 1)$.

The following result states that the reductions of the reversible C-P/T of a net are in one-to-one correspondence with the reductions of its reversible unfolding.

Theorem 30 (Correctness). *Let (N, m) be a marked P/T net and $\mathcal{U}[N, m] = (O, m')$ its unfolding. Then, $\llbracket \overleftarrow{N}, [m] \rrbracket \xrightarrow{s} (\llbracket N \rrbracket, m'')$ iff $(\overleftarrow{O}, m') \xrightarrow{s} (\overleftarrow{O}, m'')$.*

7 Conclusions

We have presented a causally reversible semantics for Place/Transitions Petri Nets (P/T nets) based on two observations. First, occurrence net can be straightforwardly reversed by adding for each transition its reverse. Second, the standard unfolding construction associates a P/T net with an occurrence net that preserves all of its computation. Consequently, the reversible semantics of a P/T net can be obtained as the reversible semantics of its unfolding. We have showed that reversibility in reversible occurrence net is causal-consistent, that is it preserves causality. The unfolding of an occurrence net can be infinite (e.g., if the original P/T net is not acyclic). Therefore we have shown that the reversible behaviour of reversible occurrence nets can be expressed as a finite net whose tokens are coloured by causal histories. Colours in our encoding resemble the causal memories that are typical in reversible process calculi [14,6].

Occurrence nets have a direct mapping into prime event structures. We shall investigate in the future the relation between reversible event structures [24,5,28,9] and our reversible occurrence nets. There is an alternative method for proving

causally-consistent reversibility in a reversible model of computation. It is based on showing other properties than those in Section 4, mainly the well-foundedness (lack of infinite reverse sequences) and Reverse Diamond properties [23,22]. It would be worthwhile to prove the alternative properties for our reversible nets, and compare the two approaches.
