ABSTRACT
In this paper, we propose a low-power, high-speed, multi-carrier reconfigurable transceiver based on Frequency Division Multiplexing to ensure data transfer in future Wireless NoCs. The proposed transceiver supports a medium access control method to sustain unicast, broadcast and multicast communication patterns, providing dynamic data exchange among wireless nodes. The proposed transceiver designed using a 28-nm FDSOI technology consumes only 2.37 mW and 4.82 mW in unicast/broadcast and multicast modes, respectively, with an area footprint of 0.0138 mm².

CCS CONCEPTS
• Networks → Network on chip; • Hardware → Radio frequency and wireless interconnect.

KEYWORDS
Wireless Network-on-Chip, WiNoC Channel, Communication Reliability, Digital Transceiver Architecture

1 INTRODUCTION
Massive parallelism in manycore architectures for emerging high-performance computing applications requires the use of an efficient interconnection system. However, current electrical interconnection technologies are not efficient enough to support an increasing number of cores while ensuring high performance and energy efficiency. For this reason, on-chip wireless interconnection technologies can provide a promising solution for a massive number of cores requiring a large Network-on-Chip (NoC), especially when considering broadcast/multicast system requirements. Nevertheless, the bandwidth needed to reach very high-speed data rate for each wireless link, highly increases the power consumption in all the Wireless NoC (WiNoC) transceivers. In order to keep a reasonable trade-off between power consumption and data rate, WiNoC designers have decreased the minimum required bandwidth to support a given data rate (e.g. 16 Gbps). However, this reduction produces significant communication errors that have to be compensated by increasing the transmission signal power and the receiver sensitivity.

Current Single-carrier Non-Coherent On-Off Keying (SNC-OOK) transceiver architectures are designed to reach a communication link of 20 mm with a data transfer rate of 16 Gbps. The SNC-OOK transmitter output power $P_t$ required to establish a wireless link into a noisy wireless channel is $-14$ dBm. However, as a large receiver bandwidth (BW) can reach prohibited levels of power consumption [3], designers have reduced the 3 dB receiver BW required to achieve 16 Gbps, from 16 GHz to 9.2 GHz [6]. This reduction intensifies the bit error rate (BER) at the receiver side and necessitate to increase $P_t = -0.5$ dBm to reach the same $BER = 10^{-15}$. This problem was modeled in MATLAB to verify the effects of the receiver BW reduction, using a second-order band-pass Butterworth filter configured with the parameters described above. As shown in Fig. 1, the system SNR is degraded by 14 dB at $10^{-7}$, which is traduced in a high $P_t$ to reach the same BER. In order to overcome this performance degradation, this work proposes a Multi-carrier NC-OOK (MNC-OOK) transceiver architecture, which allows to avoid BW reduction.

The SNC-OOK transmitter output power $P_t$ required to establish a wireless link into a noisy wireless channel is $-14$ dBm. However, as a large receiver bandwidth (BW) can reach prohibited levels of power consumption [3], designers have reduced the 3 dB receiver BW required to achieve 16 Gbps, from 16 GHz to 9.2 GHz [6]. This reduction intensifies the bit error rate (BER) at the receiver side and necessitate to increase $P_t = -0.5$ dBm to reach the same $BER = 10^{-15}$. This problem was modeled in MATLAB to verify the effects of the receiver BW reduction, using a second-order band-pass Butterworth filter configured with the parameters described above. As shown in Fig. 1, the system SNR is degraded by 14 dB at $10^{-7}$, which is traduced in a high $P_t$ to reach the same BER. In order to overcome this performance degradation, this work proposes a Multi-carrier NC-OOK (MNC-OOK) transceiver architecture, which allows to avoid BW reduction.

2 PROPOSED MULTI-CARRIER WIRELESS INTERFACE ARCHITECTURE
The MNC-OOK transceiver is based on Frequency Division Multiplexing (FDM) and Direct Sequence Spread Spectrum (DSSS) to overcome bandwidth reduction problems. The FDM technique is used as a mean to divide the total bandwidth into four different carrier frequencies with shorter bandwidth, e.g., 10 GHz/4 = 2.5 GHz. On the other hand, the DSSS technique enables parallel channel access, reusing existing frequencies.

Digital Transmitter Architecture. A transmitter assigned to a carrier frequency $f_i$ is composed of three blocks: a serializer $SER(32/1/2/8)$, a DSSS encoder, and an SER(8:1), as illustrated in Fig. 2. The DSSS encoder is designed using 8-bit and 4-bit registers initialized by the considered Hadamard codes ($C_i$). The output of this sub-block is a specific code ($C_i$) or its complement ($\overline{C_i}$). The $SER(32/1/2/8)$ 2-bit output is associated with a 4-bit code, and the 1-bit output is related with an 8-bit code. In case of a simple point-to-point communication, no code is necessary and the system therefore
configures the SER 8-bit output. Hadamard codes are only used for multicast (all/many-to-one, many-to-many, and multiple-unicast) communications. Otherwise, in unicast/broadcast mode, no code is required.

**Figure 2: Proposed MNC-OOK transceiver architecture.**

Digital Receiver Architecture. A receiver sub-block tuned for a certain carrier frequency $f_i$, receives an analog signal and converts it into eight 4-bit words using its respective ADC, as depicted in Fig. 2. Afterwards, this digitized signal is forwarded to the DSSS decoder and hard decision sub-blocks. The DSSS decoder follows the architecture from [5], but without considering the channel compensation techniques. Each DSSS decoder and hard decision sub-block outputs are forwarded into their respective deserializer DESER(1:32), DESER(2:32), DESER(8:32) and buffer blocks. The access control sub-block deactivates unused sub-blocks during the configuration phase of the communication patterns, to save energy.

3 RESULTS

In order to evaluate the BER, the end-to-end system is modeled in MATLAB using the channel model provided by [4]. This channel model consists of 4 antennas tuned at 200 GHz with a frequency range of 62 GHz, which is used by the FDM scheme. The non-overlapping frequency bands are distributed using different carrier frequencies: $f_1 = 195$ GHz, $f_2 = 200$ GHz, $f_3 = 205$ GHz, and $f_4 = 210$ GHz. Simulation results are reported in Fig. 3 for unicast/broadcast and multicast communications. The modeled communication system comprises four wireless nodes, which requires three codes ($i = 1, 2, 3$) by each code size group $j$. The first group $j = 1$ provides a Processing Gain $PG = 6$ dB using a 4-bit code size, and the second group $j = 2$ brings a $PG = 9$ dB for 8-bit code size. The PG has two applications [2]. The first one is to improve the signal resilience providing better BER with the same $P_L$, and the second one aims at reducing $P_L$ keeping the same BER. However, in order to make a fair comparison between both code sizes in terms of BER, the PG effects were suppressed during simulation. The different communication patterns based on the MNC-OOK scheme are compared with the theoretical BER for SNC-OOK. As shown in Figure 3, the average BER for each communication pattern is slightly different from the theoretical BER for SNC-OOK. Consequently, the $P_L$ does not require to be highly incremented, as previously explained. Moreover, in case of multicast mode, an 8-bit code size will provide better signal resilience considering the PG effects, as well as it can allocate more parallel channels [5].

**Figure 3: BER performance for multicast with (a) $PG = 6$ dB, (b) $PG = 9$ dB, and (c) unicast/broadcast.**

The digital transceiver architecture is modeled in C/C++, synthesized from C to RTL by Catapult HLS and to the gate level by Synopsys Design Compiler. A 28-nm FDSOI technology library is used during hardware synthesis as a target with a supply voltage of 1 Volt. Data interfaces with the router/switch have 32-bit width. Synthesis results of the digital transceiver are detailed in Table 1, which reports both static and dynamic power consumption of each component.

The area overhead of the MNC-OOK digital transceiver for a four-cluster architecture is around 0.0138 mm², which is 17 times smaller than the digital transceiver proposed in [1] for multicast communications. Unfortunately, the authors do not provide the power consumption, however, the large area overhead suggests a high power consumption compared to our proposition, which consumes only 2.37 mW in unicast/broadcast mode and 4.82 mW for the full multicast mode.
