Partitions in the S-Box of Streebog and Kuznyechik

Léo Perrin

Iria, France

leo.perrin@ria.fr

Abstract. Streebog and Kuznyechik are the latest symmetric cryptographic primitives standardized by the Russian GOST. They share the same S-Box, π , whose design process was not described by its authors. In previous works, Biryukov, Perrin and Udovenko presented two completely different decompositions of this S-Box. We revisit their results and identify a third decomposition of π . It is an instance of a fairly small family of permutations operating on 2m bits which we call TKlog and which is closely related to finite field logarithms. Its simplicity and the small number of components it uses lead us to claim that it has to be the structure intentionally used by the designers of Streebog and Kuznyechik.

The 2m-bit permutations of this type have a very strong algebraic structure: they map multiplicative cosets of the subfield $\text{GF}(2^{m/2})$ to additive cosets of $\text{GF}(2^{m/2})$. Furthermore, the function relating such multiplicative coset to the corresponding additive coset is always essentially the same. To the best of our knowledge, we are the first to expose this very strong algebraic structure.

We also investigate other properties of the TKlog and show in particular that it can always be decomposed in a fashion similar to the first decomposition of Biryukov et al., thus explaining the relation between the two previous decompositions. It also means that it is always possible to implement a TKlog efficiently in hardware and that it always exhibits a visual pattern in its LUT similar to the one present in π . While we could not find attacks based on these new results, we discuss the impact of our work on the security of Streebog and Kuznyechik. To this end, we provide a new simpler representation of the linear layer of Streebog as a matrix multiplication in the exact same field as the one used to define π . We deduce that this matrix interacts in a non-trivial way with the partitions generated by π .

1 Introduction

Many symmetric primitives rely on S-Boxes as their unique source of non-linearity, including the AES [AES01]. Such objects are small functions mapping \mathbb{F}_2^m to \mathbb{F}_2^m which are often specified via their look-up tables.

Their choice is crucial as both the security and the efficiency of the primitive depends heavily on their properties. For example, a low differential uniformity [N169] implies a higher resilience against differential attacks [BS91a, BS91b]. On the other hand, the existence of a simple decomposition greatly helps with an efficient bit-level or hardware implementation [LV14, CKL16]. Thus, algorithm designers are expected to provide detailed explanation about their choice of S-Box. Each cipher that was published at a cryptography or security conference has provided such explanations.

There are two prominent S-Boxes for which this information has not been provided. The first is the so-called “F-table” of Skipjack [U596], a lightweight block cipher designed

S-Boxes

Definition (S(ubstitution)-box)

An S-box $S : \mathbb{F}_2^n \rightarrow \mathbb{F}_2^n$ is a small **non-linear** function operating on a small block size (typically $n \in \{4, 8\}$) which **can** be specified via its lookup table.

Specifying the AES S-box

7.2 The ByteSub S-box

The design criteria for the S-box are inspired by differential and linear cryptanalysis on the one hand and attacks using algebraic manipulations, such as interpolation attacks, on the other:

1. Invertibility;
2. Minimisation of the largest non-trivial correlation between linear combinations of input bits and linear combination of output bits;
3. Minimisation of the largest non-trivial value in the EXOR table;
4. Complexity of its algebraic expression in $\text{GF}(2^8)$;
5. Simplicity of description.

In [Ny94] several methods are given to construct S-boxes that satisfy the first three criteria. For invertible S-boxes operating on bytes, the maximum input/output correlation can be made as low as 2^{-3} and the maximum value in the EXOR table can be as low as 4 (corresponding to a difference propagation probability of 2^{-3}).

We have decided to take from the candidate constructions in [Ny94] the S-box defined by the mapping $x \Rightarrow x^3$ in $\text{GF}(2^8)$.

By definition, the selected mapping has a very simple algebraic expression. This enables algebraic manipulations that can be used to mount attacks such as interpolation attacks [Jaf97]. Therefore, the mapping is modified by composing it with an additional invertible affine transformation. This affine transformation does not affect the properties with respect to the first three criteria, but if properly chosen, allows the S-box to satisfy the fourth criterion.

We have chosen an affine mapping that has a very simple description per se, but a complicated algebraic expression if combined with the 'inverse' mapping. It can be seen as modular polynomial multiplication followed by an addition:

$$b(x) = (x^7 + x^5 + x^2 + x) + a(x)(x^7 + x^6 + x^4 + x^3 + 1) \bmod x^8 + 1$$

The modulus has been chosen as the simplest modulus possible. The multiplication polynomial has been chosen from the set of polynomials coprime to the modulus as the one with the simplest description. The constant has been chosen in such a way that the S-box has no fixed points (S-box(a) = a) and no 'opposite fixed points' (S-box(a) = \bar{a}).

Note: other S-boxes can be found that satisfy the criteria above. In the case of suspicion of a trapdoor being built into the cipher, the current S-box might be replaced by another one. The cipher structure and number of rounds as defined even allow the use of an S-box that does not optimise the differential and linear cryptanalysis properties (criteria 2 and 3). Even an S-box that is "average" in this respect is likely to provide enough resistance against differential and linear cryptanalysis.

7.2 The ByteSub S-box

The design criteria for the S-box are inspired by differential and linear cryptanalysis on the one hand, and the following on the other:

1. Invertibility;
2. Minimisation of the largest non-trivial correlation between linear combinations of input bits and linear combination of output bits;
3. Minimisation of the largest non-trivial value in the EXOR table;
4. Complexity of its algebraic expression in $\text{GF}(2^8)$;
5. Simplicity of description.

In [Nyb94] it is shown that for invertible S-boxes operating on bytes, the maximum input/output correlation can be made as low as 2^{-3} and the maximum value in the EXOR table can be as low as 4 (corresponding to a difference propagation probability of 2^{-3}).

We have decided to take from the candidate constructions in [Nyb94] the S-box defined by the mapping $x \Rightarrow x^3$ in $\text{GF}(2^8)$.

By definition, the selected mapping has a very simple algebraic expression. This enables algebraic manipulations that can be used to mount attacks such as interpolation attacks [Jaf97]. Therefore, the mapping is modified by composing it with an additional invertible affine transformation. This affine transformation does not affect the properties with respect to the first three criteria, but if properly chosen, allows the S-box to satisfy the fourth criterion.

We have chosen an affine mapping that has a very simple description per se, but a complicated algebraic expression if combined with the 'inverse' mapping. It can be seen as modular polynomial multiplication followed by an addition:

$$b(x) = (x^7 + x^5 + x^2 + x) + a(x)(x^7 + x^6 + x^4 + x^3 + 1) \bmod x^8 + 1$$

The modulus has been chosen as the simplest modulus possible. The multiplication polynomial has been chosen from the set of polynomials coprime to the modulus as the one with the simplest description. The constant has been chosen in such a way that the S-box has no fixed points ($\text{S-box}(a) = a$) and no 'opposite fixed points' ($\text{S-box}(a) = \bar{a}$).

Note: other S-boxes can be found that satisfy the criteria above. In the case of suspicion of a trapdoor being built into the cipher, the current S-box might be replaced by another one. The cipher structure and number of rounds as defined even allow the use of an S-box that does not optimise the differential and linear cryptanalysis properties (criteria 2 and 3). Even an S-box that is "average" in this respect is likely to provide enough resistance against differential and linear cryptanalysis.

- 4 Conclusion

The Russian S-box

$\pi' = (252, 238, 221, 17, 207, 110, 49, 22, 251, 196, 250, 218, 35, 197, 4, 77, 233, 119, 240, 219, 147, 46, 153, 186, 23, 54, 241, 187, 20, 205, 95, 193, 249, 24, 101, 90, 226, 92, 239, 33, 129, 28, 60, 66, 139, 1, 142, 79, 5, 132, 2, 174, 227, 106, 143, 160, 6, 11, 237, 152, 127, 212, 211, 31, 235, 52, 44, 81, 234, 200, 72, 171, 242, 42, 104, 162, 253, 58, 206, 204, 181, 112, 14, 86, 8, 12, 118, 18, 191, 114, 19, 71, 156, 183, 93, 135, 21, 161, 150, 41, 16, 123, 154, 199, 243, 145, 120, 111, 157, 158, 178, 177, 50, 117, 25, 61, 255, 53, 138, 126, 109, 84, 198, 128, 195, 189, 13, 87, 223, 245, 36, 169, 62, 168, 67, 201, 215, 121, 214, 246, 124, 34, 185, 3, 224, 15, 236, 222, 122, 148, 176, 188, 220, 232, 40, 80, 78, 51, 10, 74, 167, 151, 96, 115, 30, 0, 98, 68, 26, 184, 56, 130, 100, 159, 38, 65, 173, 69, 70, 146, 39, 94, 85, 47, 140, 163, 165, 125, 105, 213, 149, 59, 7, 88, 179, 64, 134, 172, 29, 247, 48, 55, 107, 228, 136, 217, 231, 137, 225, 27, 131, 73, 76, 63, 248, 254, 141, 83, 170, 144, 202, 216, 133, 97, 32, 113, 103, 164, 45, 43, 9, 91, 203, 155, 37, 208, 190, 229, 108, 82, 89, 166, 116, 210, 230, 244, 180, 192, 209, 102, 175, 194, 57, 75, 99, 182).$

*Screen capture of the specification of **Kuznyechik** (2015).*

How Was it Generated?

According to the designers (April 2018)

questioned is the S-box π . This S-box was chosen from Streebog hash-function and it was synthesized in 2007. Note that through many years of cryptanalysis no weakness of this S-box was found. The S-box π was obtained by pseudo-random search and the following properties were taken into account.

[..]

No secret structure was enforced during construction of the S-box. At the same time, it is obvious that for any transformation a lot of representations are possible (see, for example, a lot of AES S-box representations).

What I proved (IACR ToSC 2019)

$$\Pi \begin{cases} \mathbb{F}_{2^8} & \rightarrow \mathbb{F}_{2^8} \\ 0 & \mapsto \kappa(0), \\ (\alpha^{2^m+1})^j & \mapsto \kappa(2^m - j), \text{ for } 1 \leq j \leq 2^m - 1, \\ \alpha^{i+(2^m+1)j} & \mapsto \kappa(2^m - i) \oplus (\alpha^{2^m+1})^{s(j)}, \text{ for } 0 < i, 0 \leq j < 2^m - 1. \end{cases}$$

Such a Structure is Beyond Unlikely

Lemma (more details available online¹)

*There are $256! \approx 2^{1684}$ different 8-bit permutations, meaning you need at least **1684 bits** to represent all of them in **any** language.*

Outline

- 1 Standards and S-boxes
- 2 On the S-box of RFC 6986 and 7801
- 3 The Core Issue: the S-Box Generation Process
- 4 Conclusion**

Conclusion

No secret structure was enforced during construction of the S-box. At the same time, it is obvious that for any transformation a lot of representations are possible (see, for example, a lot of AES S-box representations).

vs.

```
p(x){unsigned char*k="0~rFTDVbpPB  
vdtfRQ\xacp?\xe2>4\xa6\xe9{z\xe3q  
5\xa7\xe8",a=2,l=0,b=17;while(x&&  
(l++,a^x))a=2*a^a/128*29;return l  
%b?k[l%b]^k[b+l/b]^b:k[l/b]^188;}
```

- This claim and this fact **cannot** be reconciled.

Conclusion

No secret structure was enforced during construction of the S-box. At the same time, it is obvious that for any transformation a lot of representations are possible (see, for example, a lot of AES S-box representations).

vs.

```
p(x){unsigned char*k="0~rFTDVbpPB  
vdtfRQ\xacp?\xe2>4\xa6\xe9{z\xe3q  
5\xa7\xe8",a=2,l=0,b=17;while(x&&  
(l++,a^x))a=2*a^a/128*29;return l  
%b?k[l%b]^k[b+l/b]^b:k[l/b]^188;}
```

- This claim and this fact **cannot** be reconciled.
- In my opinion, the designers of these algorithms **have provided misleading information** for the external analysis of their design.

Conclusion

No secret structure was enforced during construction of the S-box. At the same time, it is obvious that for any transformation a lot of representations are possible (see, for example, a lot of AES S-box representations).

vs.

```
p(x){unsigned char*k="0~rFTDVbpPB  
vdtfRQ\xacp?\xe2>4\xa6\xe9{z\xe3q  
5\xa7\xe8",a=2,l=0,b=17;while(x&&  
(l++,a^x))a=2*a^a/128*29;return l  
%b?k[l%b]^k[b+l/b]^b:k[l/b]^188;}
```

- This claim and this fact **cannot** be reconciled.
- In my opinion, the designers of these algorithms **have provided misleading information** for the external analysis of their design.
- Security analysis is hard enough with proper information: **there is no good reason** to complicate it further with wrong data!

Conclusion

No secret structure was enforced during construction of the S-box. At the same time, it is obvious that for any transformation a lot of representations are possible (see, for example, a lot of AES S-box representations).

vs.

```
p(x){unsigned char*k="Q~rFTDVbpPB  
vdtfRQ\xacp?\xe2>4\xa6\xe9{z\xe3q  
5\xa7\xe8",a=2,l=0,b=17;while(x&&  
(l++,a^x))a=2*a^a/128*29;return l  
:b?k[l:b]^k[b+l/b]^b:k[l/b]^188;}
```

- This claim and this fact **cannot** be reconciled.
- In my opinion, the designers of these algorithms **have provided misleading information** for the external analysis of their design.
- Security analysis is hard enough with proper information: **there is no good reason** to complicate it further with wrong data!

⇒ **These algorithms cannot be trusted and I believe they should be deprecated.**

Conclusion

No secret structure was enforced during construction of the S-box. At the same time, it is obvious that for any transformation a lot of representations are possible (see, for example, a lot of AES S-box representations).

vs.

```
p(x){unsigned char*k="Q~rFTDVbpPB  
vdtfRQ\xacp?\xe2>4\xa6\xe9{z\xe3q  
5\xa7\xe8",a=2,l=0,b=17;while(x&&  
(l++,a^x))a=2*a^a/128*29;return l  
?b?k[l?b]^k[b+l/b]^b:k[l/b]^188;}
```

- This claim and this fact **cannot** be reconciled.
- In my opinion, the designers of these algorithms **have provided misleading information** for the external analysis of their design.
- Security analysis is hard enough with proper information: **there is no good reason** to complicate it further with wrong data!

⇒ **These algorithms cannot be trusted and I believe they should be deprecated.**

Thank you!
