Abstract: Accounting for realistic observations errors is a known bottleneck in data assimilation, because dealing with error correlations is complex. Following a previous study on this subject, we propose to use multiscale modelling, more precisely wavelet transform, to address this question. This study aims to investigate the problem further by addressing two issues arising in real-life data assimilation: how to deal with partially missing data (e.g., concealed by an obstacle between the sensor and the observed system); how to solve convergence issues associated to complex observation error covariance matrices? Two adjustments relying on wavelets modelling are proposed to deal with those, and offer significant improvements. The first one consists in adjusting the variance coefficients in the frequency domain to account for masked information. The second one consists in a gradual assimilation of frequencies. Both of these fully rely on the multiscale properties associated with wavelet covariance modelling. Numerical results on twin experiments show that multiscale modelling is a promising tool to account for correlations in observation errors in realistic applications.

Keywords: data assimilation; observation errors; error correlation; multiscale analysis; wavelets; error covariance matrices

1. Introduction

Numerical weather prediction requires the determination of the initial state of the system. Indeed, the true state, at a given moment and in all points of space, is not accessible but required in order to produce forecasts. In order to retrieve an optimal initial condition one uses the so called data assimilation methods that combine information from observations, model equations and their respective error statistics.

Since the late 70s, satellites are a dominant source of information. Errors associated to such data are highly correlated in space, which can be detrimental if this is not properly accounted for. Due to the size of the observation vectors, building and handling corresponding error covariance matrices is not feasible in practice. Because of that most data assimilation systems assume that observations are uncorrelated to each other. This either induces severe mis-specification of error statistics, or makes people using only a fraction of the available observations to ensure this assumption to be valid. Considering the high cost of remote sensing observation, this situation should be avoided.

Fortunately their density in space generally allow for the efficient use of multi-scale transformation, which in turn permit a cheap but good approximation of said error statistics representation. However two main difficulties arise with such approach. First, dealing with partially missing data in one set of observation is not straightforward and requires a special treatment of

32 observation error statistics in the frequency domain. Second, limited to homogeneous spatially
 33 correlated Gaussian observation errors this approach is very efficient. For more complex errors,
 34 however, it can severely damage the convergence properties of the assimilation methods. In this
 35 paper, after a short introduction to the context of general data assimilation (section 2.1) and wavelet
 36 representation of the observation errors (2.2), we present its actual implementation in the main data
 37 assimilation techniques (2.3, 2.4) and discuss in details the aforementioned difficulties (2.5). Proposed
 38 solutions are then implemented on a simple case mimicking a laboratory experiment (presented in
 39 section 2.6), and their performances are discussed in section 3.

40 2. Materials and Methods

41 2.1. General formulation of data assimilation

42 Let \mathcal{M} be a model describing the dynamics of a given system, represented by its state vector \mathbf{x} .
 43 For example, \mathbf{x} might be a vector of temperatures over a grid (discretized area of interest).

$$\frac{\partial \mathbf{x}}{\partial t}(t) = \mathcal{M}(\mathbf{x}(t)), \quad \mathbf{x}|_{t=0} = \mathbf{x}_0 \quad (1)$$

44 where \mathbf{x}_0 is the initial value of the state vector.

45 Data assimilation aims at providing an analysis \mathbf{x}^a which will be used to compute optimal forecasts
 46 of the system's evolution.

47 Such an analysis is produced using various sources of information about the system: observations
 48 (measurements), previous forecasts, past or a priori information, statistics on the data and/or model
 49 errors, and so on.

50 In this paper, we assume that these ingredients are available:

- 51 • the numerical model \mathcal{M} ,
- 52 • a priori information about \mathbf{x}_0 , denoted \mathbf{x}_0^b and called *background state vector*,
- 53 • partial and imperfect observations of the system, denoted \mathbf{y} and called *observation vector*,
- 54 • the observation operator \mathcal{H} , mapping the state space into the observation space,
- 55 • statistical modelling of the background and observation errors (assumed unbiased), by means of
 56 their covariance matrices \mathbf{B} and \mathbf{R} .

57 Data assimilation provides the theoretical framework to produce an optimal (under some
 58 restrictive hypotheses) analysis \mathbf{x}^a using all the aforementioned ingredients. In this work, we will
 59 focus on how to make the most of the observation error statistics information and we will not consider
 60 the background error information. Regarding the observation information, typically, most approaches
 61 can be formulated as providing the best (in some sense) vector in order to minimize the following
 62 quantity, measuring the misfit to the available information:

$$\|\mathcal{H}(\mathbf{x}) - \mathbf{y}\|_{\mathbf{R}}^2 \quad (2)$$

63 where the notation $\|\mathbf{x}\|_{\mathbf{K}}^2$ stands for the Mahalanobis distance; namely, $\|\mathbf{x}\|_{\mathbf{K}}^2 = \mathbf{x}^T \mathbf{K}^{-1} \mathbf{x}$. Some
 64 information about algorithms and methods will be given in following paragraphs. For an extensive
 65 description we refer the reader to the recent book [1].

66 2.2. Spatial error covariance modelling using wavelets

67 Being able to accurately describe the covariances matrices \mathbf{B} and \mathbf{R} is a crucial issue in data
 68 assimilation, as they count as main ingredients in the numerical computation. The \mathbf{B} matrix modelling
 69 has been largely investigated (see e.g., [2,3]). DA works actually using non diagonal \mathbf{R} matrices are
 70 quite few and far between, e.g., [4–6], despite evidence showing that the errors are indeed correlated
 71 [7] and that ignoring it can be detrimental [8,9].

In [5] the authors introduced a linear change of variable \mathbf{A} in order to account for correlated observation errors, while still using a diagonal matrix in the algorithm core. For the sake of clarity we will summarize the approach in the next few lines. If we assume that the observation error ϵ is such that $\epsilon = \mathbf{y} - \mathbf{y}^t$, with $\epsilon \sim \mathcal{N}(0, \mathbf{R})$, \mathbf{y}^t being the true vector (without any error). Then changing variables writes $\beta = \mathbf{A}\epsilon = \mathbf{A}\mathbf{y} - \mathbf{A}\mathbf{y}^t$ and $\beta \sim \mathcal{N}(0, \mathbf{A}\mathbf{R}\mathbf{A}^T)$. Then we carefully choose \mathbf{A} so that the transformed matrix is almost diagonal: $\mathbf{D}_\mathbf{A} = \text{diag}(\mathbf{A}\mathbf{R}\mathbf{A}^T) \simeq \mathbf{A}\mathbf{R}\mathbf{A}^T$. Indeed, we then have the following property:

$$\begin{aligned} \|\mathbf{y} - \mathcal{H}(\mathbf{x})\|_{\mathbf{R}}^2 &= (\mathbf{y} - \mathcal{H}(\mathbf{x}))^T \mathbf{R}^{-1} (\mathbf{y} - \mathcal{H}(\mathbf{x})) \\ &\simeq (\mathbf{y} - \mathcal{H}(\mathbf{x}))^T \mathbf{A}^T \mathbf{D}_\mathbf{A}^{-1} \mathbf{A} (\mathbf{y} - \mathcal{H}(\mathbf{x})) = \|\mathbf{A}\mathbf{y} - \mathbf{A}\mathcal{H}(\mathbf{x})\|_{\mathbf{D}_\mathbf{A}}^2 \end{aligned}$$

After this change of variable, the covariance matrix that will be used in the data assimilation algorithm is therefore $\mathbf{D}_\mathbf{A}$, it is diagonal. At the same time, the covariance information still has some interesting features, if the change of variable \mathbf{A} is carefully chosen.

As an illustration, Figure 1 presents the correlations of the central point with respect to its neighbors for diagonal covariance matrices using various changes of variables: none, change into wavelet space, change into Fourier space, change into curvelet space. This figure was produced using a diagonal correlation matrix \mathbf{D} , then applying the chosen change of variable to obtain $\mathbf{R} = \mathbf{A}\mathbf{D}\mathbf{A}^T$, then plotting the correlation described by \mathbf{R} . We can see in the figure that interesting correlations can be produced with an adequate change of variable. Indeed, all these changes of variables have in common the following fact: they perform a change of basis such that the new basis vectors have supports distributed over multiple neighboring points (contrary to the classical Euclidean basis vector, which are zero except in one point). This fact explains the fact that \mathbf{R} is now non-diagonal.

Let us explain briefly the Fourier, wavelet and curvelet change of variables. For Fourier, the image is decomposed in the Fourier basis:

$$\mathbf{y} = \sum_j \langle \mathbf{y}, \varphi_j \rangle \varphi_j$$

where (φ_j) represent the Fourier basis (e.g., sinusoidal functions) and the index j describes the scale of the j th basis vector (think of j as a frequency). The change of variables consists in describing \mathbf{y} by its coefficients y_j on the basis (φ_j) : $y_j = \langle \mathbf{y}, \varphi_j \rangle$.

Similarly for the wavelets, the decomposition writes

$$\mathbf{y} = \sum_{j,k} \langle \mathbf{y}, \varphi_{j,k} \rangle \varphi_{j,k}$$

where $(\varphi_{j,k})$ represent the wavelet basis (e.g., Haar or Daubechies), where the index j describes the scale of the j th basis vector and k its position in space (think of wavelets as localised Fourier functions). The change of variables (\mathbf{A} , denoted \mathbf{W} for the wavelets) into wavelets space consists in describing \mathbf{y} by its coefficients $y_{j,k}$ on the basis $(\varphi_{j,k})$: $y_{j,k} = \langle \mathbf{y}, \varphi_{j,k} \rangle$. In other words, $\mathbf{W}\mathbf{y}$ is the vector of coefficients $(y_{j,k})_{j,k}$.

This is also similar for the curvelets:

$$\mathbf{y} = \sum_{j,k,l} \langle \mathbf{y}, \varphi_{j,k,l} \rangle \varphi_{j,k,l}$$

where the index l describe the orientation of the basis vector.

Using these changes of variables then allows various observation error modelling:

- Fourier: when the errors change with the scale only
- Wavelets: when the errors change with the scale as well as the position (e.g., for a geostationary satellite whose incidence angle impacts the errors, so that the errors vary depending on the position in the picture)

Figure 1. Correlation of the central pixel with respect to its neighbors. Dark red indicates values close to 1, blue is 0. Panel **a**: true correlation, that we are trying to reproduce. Panel **b**: correlations obtained with the combination of a diagonal matrix and four different changes of variable: none (top left), change into Fourier space (top right), change into wavelet space (bottom left), change into curvelet space (bottom right).

- Curvelets: when the errors change with the scale, the position and the orientation (e.g., when errors are highly non linear and depend on the flow, so that they are more correlated in one direction than another).

In this work, our focus is with wavelet basis, which presents many advantages: there exists fast wavelet transform algorithms (as for Fourier), so the computational cost remains reasonable. Also, contrary to Fourier, wavelets are localised in space and allow errors correlation that are inhomogeneous in space, which is more realistic for satellite data, as well as data with missing zones.

In the next paragraphs we will describe our method in the two classical frameworks of Data Assimilation: variational methods and filtering methods.

2.3. Implementation in variational assimilation

In the framework of variational assimilation, the analysis is set to be the minimizer of the following cost function J , which diagnoses the misfit between the observations and a priori information and their model equivalent, as in (2):

$$J(\mathbf{x}_0) = J^b(\mathbf{x}_0) + J^o(\mathbf{x}_0), \quad \text{where} \quad J^b = \|\mathbf{x}_0 - \mathbf{x}_0^b\|_{\mathbf{B}}^2, \quad J^o = \|\mathcal{H}(\mathbf{x}(\mathbf{x}_0)) - \mathbf{y}\|_{\mathbf{R}}^2$$

where $\mathbf{x}(\mathbf{x}_0)$ is the solution of equation (1), when the initial state is \mathbf{x}_0 . In practice \mathbf{y} stores time-distributed observations, so that it can be written as

$$J^o(\mathbf{x}_0) = \sum_{i \text{ obs. time}} \|\mathcal{H}_i(\mathbf{x}(\mathbf{x}_0)) - \mathbf{y}_i\|_{\mathbf{R}_i}^2$$

where \mathcal{H}_i is the observation operator at time i , \mathbf{y}_i is the observation vector at this time, and \mathbf{R}_i is the observation error covariance matrix.

Using the wavelets change of variables $\mathbf{A} = \mathbf{W}$, we choose a diagonal matrix \mathbf{D}_w (possibly varying with the observation time i , but we omit the index for sake of simplicity), and we set

$$J^o(\mathbf{x}_0) = \sum_{i \text{ obs. time}} \|\mathbf{W}\mathcal{H}_i(\mathbf{x}(\mathbf{x}_0)) - \mathbf{W}\mathbf{y}_i\|_{\mathbf{D}_w}^2 \quad (3)$$

so that the observation error covariance matrix that is actually defined is:

$$\mathbf{R}^{-1} = \mathbf{W}^T \mathbf{D}_w^{-1} \mathbf{W} \quad (4)$$

Meanwhile, the algorithm steps are:

1. Compute the model trajectory $\mathbf{x}(\mathbf{x}_0)$ and deduce the misfits to observation $\mathcal{H}_i(\mathbf{x}(\mathbf{x}_0)) - \mathbf{y}_i$ for all i
2. Apply the change of variable (wavelet decomposition) $\mathbf{W}\mathcal{H}_i(\mathbf{x}(\mathbf{x}_0)) - \mathbf{W}\mathbf{y}_i$
3. Compute the contribution to the gradient for all i : $\nabla J^o = \mathbf{H}^T \mathbf{W}^T \mathbf{D}_w^{-1} (\mathbf{W}\mathcal{H}_i(\mathbf{x}(\mathbf{x}_0)) - \mathbf{W}\mathbf{y}_i)$
4. Descent and update following the minimization process

In this algorithm, we can see that there is no need to form nor inverse \mathbf{R} , the optimization module only sees the diagonal covariance matrix \mathbf{D}_w , so that the minimization can be approached with classical methods like conjugate gradient or quasi Newton. Therefore, the only modification consists in coding the wavelets change of variable and its adjoint. As wavelet transforms are usually implemented using optimized and efficient libraries, the added cost is reasonable [5].

2.4. Implementation in Kalman filtering

In this Section we explain the practical implementation of accounting for correlated observation errors in the Kalman filtering framework. We will briefly recall the main equations of the filters and then explain the adequate alterations to include observation error covariance modelling. We will use the standard notations and algorithms of data assimilation [1,10].

2.4.1. Extended Kalman filter

Using standard notation, the analysis step of the extended Kalman filter writes as follows:

$$\begin{aligned} \mathbf{x}^a &= \mathbf{x}^f + \mathbf{K}(\mathbf{y}^o - \mathcal{H}(\mathbf{x}^f)) \\ \mathbf{K} &= \mathbf{P}^f \mathbf{H}^T (\mathbf{H} \mathbf{P}^f \mathbf{H}^T + \mathbf{R})^{-1} \end{aligned} \quad (5)$$

where \mathbf{x}^a and \mathbf{x}^f are the analysis and forecast state vectors respectively, \mathbf{y}^o is the observation vector, \mathcal{H} is the (possibly nonlinear) observation operator, \mathbf{H} its tangent linearized version, \mathbf{K} the Kalman gain matrix, \mathbf{P}^f the forecast error covariance matrix and \mathbf{R} the observation error covariance matrix.

In order to account for a non diagonal \mathbf{R} while keeping the algorithm easy to implement, let us assume that we define \mathbf{R} as previously by (4), with \mathbf{D}_w a diagonal matrix whose dimension is d , the number of wavelet coefficients (equal to the observation space dimension p). We recall that the wavelet transform \mathbf{W} is orthonormal, we have

$$\mathbf{W}^T \mathbf{W} = \mathbf{I}_d, \quad \mathbf{W}^{-1} = \mathbf{W}^T$$

where \mathbf{I}_d is the identity matrix in dimension $d = p$. Then we can write the Kalman gain matrix as:

$$\mathbf{K} = \mathbf{P}^f \mathbf{H}^T \mathbf{W}^T (\mathbf{W} \mathbf{H} \mathbf{P}^f \mathbf{H}^T \mathbf{W}^T + \mathbf{D}_w)^{-1} \mathbf{W}$$

In this equation, we can see that the algorithm complexity is preserved, up to a change of variable:

- the required matrix inversion $(\mathbf{W} \mathbf{H} \mathbf{P}^f \mathbf{H}^T \mathbf{W}^T + \mathbf{D}_w)^{-1}$ can be expected to be of the same complexity as $(\mathbf{H} \mathbf{P}^f \mathbf{H}^T + \mathbf{R})^{-1}$,

- 158 • two changes of variables, and their inverse, are required, one on the matrix $\mathbf{H}\mathbf{P}^f\mathbf{H}^T$, and one in
 159 the end for the matrix $(\mathbf{W}\mathbf{H}\mathbf{P}^f\mathbf{H}^T\mathbf{W}^T + \mathbf{D}_w)^{-1}$ to get the final Kalman gain.

160 As wavelet transforms are usually implemented using optimized and efficient libraries, we can also
 161 expect the added cost to be affordable.

162 2.4.2. Stochastic ensemble Kalman filter

163 Let us recall the main ingredients of analysis step of the stochastic ensemble Kalman filter, as can
 164 be found in [1] (pages 158–160). The number m stands for the number of members in the ensemble.

- 165 • A set of m perturbed observations is generated to account for the observation error:

$$\text{for } i = 1..m, \text{ compute } \mathbf{y}_i^o = \mathbf{y}^o + \mathbf{u}_i, \quad \text{with } \mathbf{u}_i \sim \mathcal{N}(0, \mathbf{R})$$

- 166 • The \mathbf{Y}_f matrix is computed. First we compute

$$\bar{\mathbf{u}} = \frac{1}{m} \sum_{i=1}^m \mathbf{u}_i$$

167 then the i th column of \mathbf{Y}_f is given by:

$$\left[\mathbf{Y}_f\right]_i = \frac{\mathcal{H}(\mathbf{x}_i^f) - \mathbf{u}_i - (\mathcal{H}(\bar{\mathbf{x}}^f) - \bar{\mathbf{u}})}{\sqrt{m-1}}, \text{ for } i = 1..m$$

- 168 • The Kalman gain matrix is computed:

$$\mathbf{K} = \mathbf{x}^f \mathbf{Y}_f^T (\mathbf{Y}_f \mathbf{Y}_f^T)^{-1}$$

- 169 • The analysis members are computed:

$$\mathbf{x}_i^a = \mathbf{x}_i^f + \mathbf{K} \left[\mathbf{y}_i^o - \mathcal{H}(\mathbf{x}_i^f) \right], \text{ for } i = 1..m$$

170 This algorithm can accommodate the accounting for observation errors correlations using this simple
 171 modification of the very first step (perturbation of the observations), which is the only occurrence of
 172 the \mathbf{R} matrix:

$$\text{for } i = 1..m, \quad \begin{cases} \beta_i \sim \mathcal{N}(0, \mathbf{I}) \\ \mathbf{u}_i = \mathbf{W}^T \mathbf{D}_w^{1/2} \beta_i \\ \mathbf{y}_i^o = \mathbf{y}^o + \mathbf{u}_i \end{cases}$$

173 As we can see, this is quite easy to implement, as \mathbf{D}_w is diagonal, its square root is easily obtained,
 174 and \mathbf{W}^T is the inverse of the wavelet transform, which has to be performed m times (and can be
 175 parallelized), so that the added cost should be negligible.

176 2.4.3. Deterministic ensemble Kalman filter

177 As previously, let us recall the main ingredients of the deterministic Kalman filter (from [1] page
 178 162 and following), and see how it can be adapted to account for a change of variable in wavelet space
 179 for observation error covariance modelling. Let us first take a look at the analysis phase of the filter:

- 180 • Contrary to the stochastic Kalman filter, the \mathbf{Y}_f observation anomalies matrix is not perturbed:

$$\left[\mathbf{Y}_f\right]_i = \frac{\mathcal{H}(\mathbf{x}_i^f) - \bar{\mathbf{y}}^f}{\sqrt{m-1}} \quad \text{for } i = 1..m, \quad \text{with } \bar{\mathbf{y}}^f = \frac{1}{m} \sum_{i=1}^m \mathcal{H}(\mathbf{x}_i^f)$$

- 181 • The analysis is given by

$$\mathbf{x}^a = \bar{\mathbf{x}}^f + \mathbf{K} \left[\mathbf{y}^o - \mathcal{H}(\bar{\mathbf{x}}^f) \right], \text{ for } i = 1..m$$

- 182 • The Kalman gain matrix writes

$$\mathbf{K} = \mathbf{P}^f \mathbf{H}^T \left(\mathbf{H} \mathbf{P}^f \mathbf{H}^T + \mathbf{R} \right)^{-1}$$

- 183 • The analysis anomalies are given by

$$\mathbf{w}^a = \mathbf{Y}_f^T (\mathbf{Y}_f \mathbf{Y}_f^T + \mathbf{R})^{-1} \delta, \quad \text{with } \delta = \mathbf{y}^o - \mathcal{H}(\bar{\mathbf{x}}^f)$$

184 which can be rewritten using an adapted version of the Sherman-Morrison-Woodbury formula:

$$\mathbf{w}^a = (\mathbf{I}_m + \mathbf{Y}_f^T \mathbf{R}^{-1} \mathbf{Y}_f)^{-1} \mathbf{Y}_f^T \mathbf{R}^{-1} \delta = \mathbf{T} \mathbf{Y}_f^T \mathbf{R}^{-1} \delta, \text{ with } \mathbf{T} = (\mathbf{I}_m + \mathbf{Y}_f^T \mathbf{R}^{-1} \mathbf{Y}_f)^{-1}$$

- 185 • And finally, here is the generation of the posterior ensemble:

$$\mathbf{x}_i^a = \bar{\mathbf{x}}^f + \mathbf{X}^f \left(\mathbf{w}^a + \sqrt{m-1} \left[\mathbf{T}^{\frac{1}{2}} \mathbf{U} \right]_i \right)$$

186 where \mathbf{X}^f is a matrix whose columns are the normalized forecast anomalies and \mathbf{U} is an arbitrary
187 orthogonal matrix:

$$[\mathbf{X}^f]_i = \frac{\mathbf{x}_i^f - \bar{\mathbf{x}}^f}{\sqrt{m-1}}, \text{ for } i = 1..m$$

188 The required modifications to include the change of variable \mathbf{W} are twofold:

- 189 1. First, we change variable in the expression $\mathbf{Y}_f^T \mathbf{R}^{-1} \mathbf{Y}_f$:

$$\mathbf{Y}_f^T \mathbf{R}^{-1} \mathbf{Y}_f = \mathbf{Y}_f^T \mathbf{W}^T \mathbf{D}_w^{-1} \mathbf{W} \mathbf{Y}_f = (\mathbf{W} \mathbf{Y}_f)^T \mathbf{D}_w^{-1} (\mathbf{W} \mathbf{Y}_f)$$

190 Here we can see that the matrix inversion still occurs with a diagonal matrix, as before, and we
191 just have to apply the wavelet transform on \mathbf{Y}_f , which is a matrix with m columns, where m is
192 small.

- 193 2. Second, we change variable in the expression $\mathbf{Y}_f^T \mathbf{R}^{-1} \delta$:

$$\mathbf{Y}_f^T \mathbf{R}^{-1} \delta = (\mathbf{W} \mathbf{Y}_f)^T \mathbf{D}_w^{-1} (\mathbf{W} \delta)$$

194 Here the change of variable is done only once on δ the innovation vector. It has been done
195 previously for \mathbf{Y}_f .

196 Notice that the matrix inversion $\mathbf{T} = (\mathbf{I}_m + \mathbf{Y}_f^T \mathbf{R}^{-1} \mathbf{Y}_f)^{-1}$, as well as computing its square-root $\mathbf{T}^{\frac{1}{2}}$,
197 takes place in ensemble subspace, of dimension m , and is therefore efficient even if the change of
198 variable impacted $\mathbf{Y}_f^T \mathbf{R}^{-1} \mathbf{Y}_f$.

199 2.5. Toward realistic applications

200 This approach works well with idealistic academic test cases. In order to go toward realistic
201 applications, several issues need to be sorted out. In this section we address two of them. The first one
202 is quite general and requires the ability to deal with incomplete observations, where part of the signal
203 is missing, either due to sensor failure or external perturbation/obstruction. the second one is more

204 specific to variational data assimilation, where the conditioning of the minimisation, and hence its
 205 efficiency, can be severely affected by complex correlation structure in the observation error covariance
 206 matrix. It is likely to also affect the Kalman Filter, in particular the matrix inversion in the observation
 207 space it requires (e.g in equation 5), but it is yet to be demonstrated.

208 2.5.1. Accounting for missing observations

209 When dealing with remote sensing, reasons for missing observation are numerous, ranging from
 210 a glitch in the acquisition process to an obstacle blocking temporarily one part of the view. This may be
 211 quite detrimental to our proposed approach since it violates the multi-scale decomposition hypotheses.
 212 However, contrary to Fourier, wavelets (and many, if not all, x-lets) have local support that may be
 213 exploited to handle this issue. Note that the same kind of issue can arise in case of complex geometry.
 214 For instance if one observes sea surface temperatures, land is present in the observation, while not
 215 being part of the signal. Somehow it can be treated as missing value.

216 We want to avoid the use of inpainting or any method that introduces more signal, because
 217 managing the error statistic description would be even more complex if more data is generated. Indeed
 218 it would require the estimation of the errors associated to introducing “new” data in the missing zones,
 219 and that we wish to avoid.

220 The idea is therefore to adapt the \mathbf{R} matrix to the available data. Without any change of variable,
 221 the adaptation would be straightforward, as we would just have to apply a projection operator π to
 222 both the data and the \mathbf{R} matrix:

$$\mathbf{y}^o - \mathcal{H}(\mathbf{x}^f) \rightarrow \pi(\mathbf{y}_\pi^o - \mathcal{H}(\mathbf{x}^f)); \quad \mathbf{R} \rightarrow \pi\mathbf{R}\pi^T$$

223 where the projector π maps the full observation space into the subset of the observed points, and
 224 \mathbf{y}_π^o represents the full observation vector (with 0 where there is no available data).

225 When using a change of variable into wavelet space, it is a bit more tricky to perform, as a given
 226 pixel is used to compute many wavelet coefficients. Vice-versa a given wavelet coefficient is based on
 227 several image pixels. As a consequence, if some pixels are missing and others are available, it may
 228 result in “partially observed” wavelet coefficients, as schematized on Figure 2.

Figure 2. Working in wavelet space leads to partially observed wavelets coefficients.

229 Our choice is to still take into account these coefficients (and not discard them, because it
 230 would result in disarding too much information, as a single missing pixel affects numerous wavelet
 231 coefficients), but to carefully tune the diagonal coefficient of the diagonal matrix \mathbf{D}_w .

232 In order to do so, let us consider the impact of missing information. It has two opposite effects:

- 233 • A missing pixel does not have signal nor any error, so we could expect the error variance of the
 234 impacted wavelet coefficient to decrease.

- 235 • A missing pixel leads to more discontinuities in the observed signal, which impacts the small
 236 scale coefficients, this should increase the error statistics (as more local information helps decrease
 237 the local variance, due to averaging effects).

238 To account for both effects, we adjust the variance σ_π^2 (in other words, the coefficients of the diagonal
 239 matrix \mathbf{D}_w) corresponding to coefficients whose support is partially masked as follows:

$$\sigma_\pi^2 = (\sigma^2 + \beta\sigma_a^2) I^2$$

240 where:

- 241 • σ^2 is the original error variance (e.g. given by the data provider);
 242 • $\beta \in [0, 1]$ is multiplied by the variance of the wavelet coefficient without any correlation σ_a : it
 243 accounts to inflating the variance due to missing information (loss of the error averaging effect);
 244 • $I \in [0, 1]$ models the deflation effect, it takes into account the impact of missing pixels on the
 245 considered wavelet coefficient.

246 We will now explain how β and I can be tuned. For the sake of simplicity, let us assume that
 247 our observation lives in a one dimensional space. The observation space is represented by a subset
 248 of \mathbb{Z} , where each number represents a given pixel. Wavelet decomposition consists in computing, at
 249 each given scale, a coarse approximation at that scale, and finer details. Both are decomposed on a
 250 multiscale basis and are therefore represented by their coefficients on the bases. Coarse and details
 251 coefficients are given by a convolution formula:

$$c^{j-1}[n] = \sum_{p \in \mathbb{Z}} h[p - 2n]c^j[p]; \quad d^{j-1}[n] = \sum_{p \in \mathbb{Z}} g[p - 2n]d^j[p]$$

252 where $c^j[n]$ represents the coarse coefficient at scale j at point $n \in \mathbb{Z}$, $d^j[n]$ represents the details
 253 coefficient at scale j at point $n \in \mathbb{Z}$, h and g are functions depending on the chosen wavelets basis, each
 254 of them being equal to zero outside of their support $[n_1; n_2]$. Moreover, g has k vanishing moments,
 255 therefore it is orthogonal to every polynomial of degree up to $k - 1$. As a consequence, if the correlation
 256 is smooth enough (ie. can be well approximated by polynomials of degree smaller than k), then details
 257 coefficients have a very small variance.

258 Computation of I .

259 The deflation percentage I for each coefficient is computed using also a wavelet transform, where
 260 h and g are replaced by constant functions with the same support:

$$h^0[n] = \frac{1}{n_2 - n_1 + 1}; \quad g^0[n] = \frac{1}{n_2 - n_1 + 1}; \quad \forall n \in [n_1; n_2]$$

261 We proceed as follows. First we set the mask corresponding to the missing observation, it is an
 262 observation vector m equals to 1 where the pixel is observed and equal to zero where the pixel is
 263 missing. The wavelet transform of the mask aims to keep track of the impact of any missing pixel
 264 on any given wavelet coefficient. The percentage I is computed for each coefficient $c^j[n]$ and $d^j[n]$ by
 265 induction:

- 266 • At the finest scale j_{max} :

$$\begin{cases} I(c^{j_{max}}[n]) &= \sum_{p \in \mathbb{Z}} h^0[p - 2n]m[p] \\ I(d^{j_{max}}[n]) &= \sum_{p \in \mathbb{Z}} g^0[p - 2n]m[p] \end{cases}$$

- 267 • At the other scales:

$$\begin{cases} I(c^{j-1}[n]) &= \sum_{p \in \mathbb{Z}} h^0[p - 2n]I(c^j[p]) \\ I(d^{j-1}[n]) &= \sum_{p \in \mathbb{Z}} g^0[p - 2n]I(c^j[p]) \end{cases}$$

268 Computation of β .

269 Let us now explain how to compute the inflation coefficient β . As explained previously, as g has
 270 k vanishing moments, small scale coefficients have small variances. However, when using masked
 271 signal, one loses this property. The coefficient β reflect this fact: in the following formula we can see
 272 that β is zero if the first vanishing moment is preserved, and non-zero if not, in order to inflate the
 273 variance of small scales. As before, we compute β by induction. For the finest scale, β is given by:

$$\begin{cases} c_m^j[n] &= \frac{\sum_{p \in \mathbb{Z}} |h[p-2n]| m[p]}{\sum_{p \in \mathbb{Z}} |h[p-2n]|} \\ \beta_m^j[n] &= \left| \frac{\sum_{p \in \mathbb{Z}} g[p-2n] m[p]}{\sum_{p \in \mathbb{Z}} |g[p-2n]| m[p]} \right| \end{cases}$$

274 Indeed, $\sum_{p \in \mathbb{Z}} g[p-2n] m[p] = 0$ means that wavelet still has a 0-th order null moment, even with
 275 missing coefficients, and in that case $\beta = 0$.

276 At the other scales we have:

$$\begin{cases} c_m^{j-1}[n] &= \frac{\sum_{p \in \mathbb{Z}} |h[p-2n]| c_m^j[p]}{\sum_{p \in \mathbb{Z}} |h[p-2n]|} \\ \beta_m^{j-1}[n] &= \left| \frac{\sum_{p \in \mathbb{Z}} g[p-2n] m[p]}{\sum_{p \in \mathbb{Z}} |g[p-2n]| m[p]} c_m^j[p] \right| \end{cases}$$

277 Finally, the variance model is modified as follows for every detail coefficient whose data is
 278 partially missing:

$$\sigma_\pi^2(d^j[n]) = (\sigma^2 + \beta_m^j[n] \sigma_a^2) I(d^j[n])^2$$

279 For approximation coefficient, only the deflation factor is used:

$$\sigma_\pi^2(c^j[n]) = \sigma^2 I(d^j[n])^2$$

280 Indeed, when the error is correlated, the variance of the approximation coefficient σ^2 is much
 281 greater than σ_a^2 . Moreover, h can be seen as a local smoothing operator and therefore correlated errors
 282 do not compensate themselves. Consequently, there is no need for inflation.

283 These modifications give therefore a new diagonal matrix \mathbf{D}_w which takes into account the
 284 occurrence of missing information. Section 3 will present numerical results.

285 2.5.2. Gradual assimilation of the smallest scales

286 As will be shown in the numerical results Section 3 below, another issue can occur with real
 287 data: convergence issues due to the nature of observation errors. Indeed, what our experiments
 288 highlight is that the modelling of observation error correlations using wavelets is well-fitted to spatially
 289 correlated Gaussian noise, in the case of homogeneous correlation. For correlated Gaussian errors
 290 whose correlations are inhomogeneous in space, convergence issues occur to the point that it destroys
 291 the advantage of using wavelets: they do worse than the classical diagonal matrix without correlation.

292 Numerical investigation of the results shows that some sort of aliasing occurs for small wavelet
 293 scales. Indeed, smallest scales are the least affected by the correlated noise, so they are not well
 294 constrained by the assimilation and they tend to cause a divergence when large scales are not well
 295 known either, that is at the beginning of the assimilation iteration process. Removing the smaller scales
 296 altogether is not a suitable solution, as they contain valuable information we still want to use. The
 297 proposed solution is therefore to first assimilate the data without the small scales and then add smaller
 298 scales gradually.

299 Description of the online scale selection method.

300 Let us rewrite the observation cost function given by equation (3):

$$\begin{aligned} J^o(\mathbf{x}_0) &= \sum_{i \text{ obs. time}} \|\mathbf{W}\mathcal{H}_i(\mathbf{x}(\mathbf{x}_0)) - \mathbf{W}\mathbf{y}_i\|_{\mathbf{D}_w}^2 \\ &= \sum_{i \text{ obs. time}} \sum_{s \text{ scale}} \sum_k \frac{|d_{\mathbf{y}_i}^s[k] - d_{\mathcal{H}_i(\mathbf{x})}^s[k]|^2}{\sigma_{s,k}^2} \end{aligned}$$

301 where $d_{\mathbf{y}_i}^s[k]$, for $k \in \mathbb{Z}$, (resp. $d_{\mathcal{H}_i(\mathbf{x})}^s[k]$) represent the wavelet coefficients at scale s of the signal \mathbf{y}_i
 302 (resp. $\mathcal{H}_i(\mathbf{x})$) and the $\sigma_{s,k}^2$ are the associated error variances (corresponding to the diagonal coefficients
 303 of the matrix \mathbf{D}_w).

304 Let us denote by $J_{s,i}^o$ the total cost corresponding to the scale s and observation time i :

$$J_{s,i}^o = \sum_k \frac{|d_{\mathbf{y}_i}^s[k] - d_{\mathcal{H}_i(\mathbf{x})}^s[k]|^2}{\sigma_{s,k}^2}$$

305 We then decide that the information at a given scale is usable only if the cost remain small, e.g.
 306 smaller than a given threshold τ_s , we define the thresholded cost J_{s,i,τ_s}^o by:

$$J_{s,i,\tau_s}^o = \begin{cases} J_{s,i}^o & \text{if } J_{s,i}^o \leq \tau_s \\ \tau_s & \text{otherwise} \end{cases}$$

307 The new observation cost function is then:

$$J_{\tau_s}^o(\mathbf{x}_0) = \sum_{i \text{ obs. time}} \sum_{s \text{ scale}} J_{s,i,\tau_s}^o$$

308 As mentioned before, the same issue could arise when using Kalman Filter type techniques during
 309 the matrix inversion needed when computing the gain matrix. Similar approaches based on iterative
 310 and multi-resolution could be used to sort this out.

311 2.6. Experimental framework

312 Numerical experiments have been performed to study and illustrate the two issues that were
 313 previously highlighted: how to account for covariances with missing observations, and how to improve
 314 the algorithm convergence while still accounting for smaller scale information. This paragraph
 315 describes the numerical setup which has been used.

316 We wish to avoid adding difficulty to these already complex issues, therefore we chose a so-called
 317 *twin experiment* framework. In this approach, synthetic observations are created from a given state of
 318 the system (which we call the "true state", which will serve as reference) and then used in assimilation.

319 The experimental model represents the drift of a vortex on the experimental turntable CORIOLIS
 320 (Grenoble, France), which simulates atmospheric vortices in the atmosphere: the turning of the table
 321 provides an experimental environment which emulates the effect of the Coriolis force on a thin layer
 322 of water. A complete rotation of the tank takes 60 seconds, which corresponds to one Earth rotation.

323 2.6.1. Numerical model

324 A numerical model represents the experiment, using the shallow-water equations on the water
 325 elevation $h(x, t)$ and the horizontal velocity of the fluid $\mathbf{w}(x, t) = (u(x, t), v(x, t))$, where u and v are
 326 the zonal and meridional components of the velocity. The time variable t is defined on an interval
 327 $[t_0, t_f]$, while the space variable x lives in Ω a rectangle in the plane \mathbb{R}^2 . The equations writes:

$$\begin{cases} \partial_t u - (f + \zeta)v + \partial_x B & = -ru + \kappa \Delta u \\ \partial_t v + (f + \zeta)u + \partial_y B & = -rv + \kappa \Delta v \\ \partial_t h + \partial_x(hu) + \partial_y(hv) & = 0. \end{cases}$$

328 The relative vorticity is denoted by $\zeta = \partial_x v - \partial_y u$ and the Bernoulli potential by $B = g^* h + \frac{u^2 + v^2}{2}$,
 329 where g^* is the reduced gravity. The Coriolis parameter on the β -plane is given by $f = f_0 + \beta y$, κ is
 330 the diffusion coefficient and r the bottom friction coefficient. The following numerical values were
 331 used for the experiments: $r = 9.10^{-7}$, $\kappa = 0$, $f_0 = 0.25$, $g = 9.81$ and $\beta = 0.0406$.

332 Additional equations represent the evolution of the tracer concentration (fluorescein):

$$\begin{cases} \partial_t q + \nabla q \cdot \mathbf{w} - \nu_T \Delta q = 0 \\ q(t_0) = q_0. \end{cases} \quad (6)$$

333 where q_0 is the initial concentration of the tracer (assumed to be known), $\nu_T = 10^{-5}$ is the tracer
 334 diffusion coefficient and $\mathbf{w} = (u, v)$ the fluid velocity computed above.

335 2.6.2. Synthetic observations for twin experiments

336 In the twin experiment framework, observations are computed using the model. A known "true state"
 337 is used to produce a sequence of images which constitutes the observations. Therefore, the
 338 observation operator \mathcal{H} is given by:

$$\mathcal{H}(\mathbf{x}_i) = q(t_i). \quad (7)$$

339 where $q(t_i)$ comes from (6).

340 Then assimilation experiments are performed starting from another system state, using synthetic
 341 observations. The results of the analysis can then be compared to the synthetic truth.

342 Unless otherwise stated, the assimilation period will be of 144mn, with one snapshot of passive
 343 tracer concentration every 6mn (24 snapshot in total). A selection of such snapshots is shown in Figure
 344 3.

Figure 3. "True" initial concentration of the passive tracer (left) and noisy observations at initial time, after 90mn, 150mn and 270mn (right)

345 The observations are then obtained by adding an observation error $\mathbf{y} = \mathbf{y}^t + \epsilon$, with $\epsilon \sim \mathcal{N}(0, \mathbf{R})$
 346 and \mathbf{R} a suitably chosen matrix.

347 Our experiments will focus on three different formulations of the observation error covariance
 348 matrix. We will refer as "Pixels" the experiments for which there is no change of variable and
 349 the observation error covariance matrix is equal to $\mathbf{D} = \text{diag}(\mathbf{R})$. "Wavelet" will represent the
 350 experiments with the wavelet change of variable \mathbf{W} and the observation error covariance matrix
 351 $\mathbf{D}_w = \text{diag}(\mathbf{W}\mathbf{R}\mathbf{W}^T)$. Finally, the last set of experiments will proceed as for the wavelets but will adjust
 352 the observation error covariance matrix according to the computations presented in paragraphs 2.5.1
 353 and 2.5.2. The following table sums this up:

Experiment name	Change of variable	Observation error covariance matrix
Pixels	none (identity)	$\mathbf{D} = \text{diag}(\mathbf{R})$
Wavelet	\mathbf{W}	$\mathbf{D}_w = \text{diag}(\mathbf{WRW}^T)$
Wavelet tweaked	\mathbf{W}	\mathbf{D}_w modified according to 2.5.1
Wavelet scale by scale	\mathbf{W}	\mathbf{D}_w modified according to 2.5.2

Table 1. Summary of the experiments description: name, change of variable, observation error covariance matrix

354 3. Results

355 3.1. Accounting for missing observations

356 Figure 4 provides an example of image data with 10% missing observations. It represents three
 357 images from an temporal observation sequence, in which we simulated the presence of a passing cloud.
 358 This sequence has been generated using the experimental model presented above.

Figure 4. Example of an image sequence of the passive tracer concentration with missing observations. Left: first observation in the sequence, right: last observation.

359 This image sequence was then modified by a strong additive and spatially correlated noise (signal
 360 to noise ratio SNR = 14.8 dB). Then we performed many twin data assimilation experiments, while
 361 varying two parameters:

- 362 • the covariance error matrix: diagonal in pixel space, diagonal in wavelet space (no adjustment),
- 363 diagonal in wavelet space and modified according to paragraph 2.5.1 (see Table 1);
- 364 • the percentage of occulted signal: varying from 0 to 18% (with varying cloud sizes).

365 For each experiment, we computed the ratio between the root mean square error for the analysis and
 366 the background:

$$\frac{\text{RMSE}(\text{analysis})}{\text{RMSE}(\text{background})} = \frac{\|(h_0^t, \mathbf{w}_0^t) - (h_0^a, \mathbf{w}_0^a)\|}{\|(h_0^t, \mathbf{w}_0^t) - (h_0^b, \mathbf{w}_0^b)\|}$$

367 where (h_0^t, \mathbf{w}_0^t) , (h_0^a, \mathbf{w}_0^a) and (h_0^b, \mathbf{w}_0^b) represent the true, analysed and background initial states
 368 of the experimental system. This ratio is close to zero when the analysis is much closer to the true
 369 state than the background (which represents the "no assimilation" state), and close to 1 when the
 370 analysis performs poorly. Figure 5 shows the resulting ratios for all the experiments. We can draw the
 371 conclusion that modifying the covariance matrix as proposed allows a considerable improvement from
 372 other methods, as it keeps the error below 20%, even for a widely occulted image sequence, despite
 373 the high noise level.

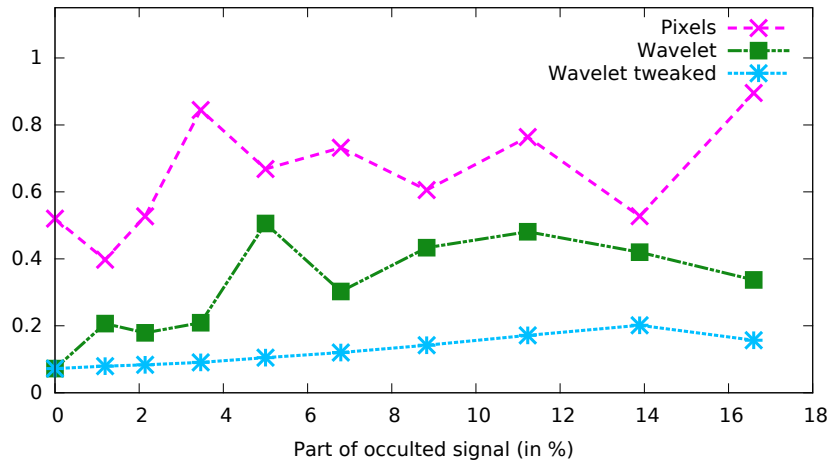

Figure 5. Ratio between the analysed state RMSE and the background RMSE for observations distorted by a strong spatially correlated additive noise, as a function of the percentage of missing pixels. The variable of interest is the velocity v .

374 Figure 6 gives more details for the experiments with 9% occulted signal, as it represents (as
 375 a function of the spatial variable $x \in \Omega \subset \mathbb{R}^2$, see paragraph 2.6.1 for more details) the errors
 376 $v^t(x, 0) - v^a(x, 0)$, where $v^t(x, 0)$ is the true longitudinal velocity at time 0 and $v^a(x, 0)$ is the analysed
 377 longitudinal velocity at time 0. From this figure we can confirm that the modified wavelet covariance
 378 matrix does a much better job in approximating the true state.

Figure 6. Error between the true velocity v and the analysed velocity after assimilation of an observation sequence with strong spatially correlated additive noise, with 9% missing pixels. The color scale ranges from $-0.01m.s^{-1}$ (blue) to $0.01m.s^{-1}$ (red), which amounts to a third of the maximum velocity (ranging from $-0.028m.s^{-1}$ to $0.028m.s^{-1}$). Left: result for the pixel method, middle: wavelet without modification, right: improved wavelet method.

379 3.2. Gradual assimilation of the smallest scales

380 Figure 7 illustrates the issue that we try to tackle using gradual assimilation. This figure presents
 381 the ratio r_k of the residual errors, as a function of the iteration number k :

$$r_k = \frac{\|(h_0^t, \mathbf{w}_0^t) - (h_0^k, \mathbf{w}_0^k)\|}{\|(h_0^t, \mathbf{w}_0^t) - (h_0^b, \mathbf{w}_0^b)\|}$$

382 As before (h_0^t, \mathbf{w}_0^t) and (h_0^b, \mathbf{w}_0^b) represent the true and background initial states of the experimental
 383 system. Index k represents the iteration number (loop index in the assimilation process) and (h_0^k, \mathbf{w}_0^k) is
 384 the initial state vector computed by the assimilation system after k iterations. Both panels of Figure
 385 7 shows the evolution of these ratio as a function of k for the "Pixels" and the "Wavelet" methods for
 386 covariance matrices modelling, as described in Table 1. The difference lies in the actual error that is
 387 added to the observations:

- 388 • on the left panel, the error is as previously described: $\mathbf{y} = \mathbf{y}^t + \epsilon$, with $\epsilon \sim \mathcal{N}(0, \mathbf{R})$, it is spatially
 389 correlated but the correlation is homogeneous in space ;
 390 • on the right panel, we added an inhomogeneously correlated error : $\epsilon = \mathbf{W}^T \mathbf{D}_w^{1/2} \beta$ with $\beta \sim$
 391 $\mathcal{N}(0, \mathbf{I})$.

Figure 7. Ratio of the residual errors as a function of minimisation iterations for both wavelet and pixel methods, in the presence of correlated observation errors. Left: homogeneously correlated error, right: inhomogeneously correlated error.

392 As we can see on the left panel, accounting for correlated observations thanks to the "Wavelet" method
 393 is beneficial for an homogeneously correlated noise, as the error is much decreased than for the "Pixels"
 394 method, for which no error correlation is modelled. However, when the error correlation is not
 395 homogeneous, the "Wavelet" method, despite having the correct error covariance matrix, fails to do
 396 better than the "Pixels" method.

397 To investigate the issue, Figure 8 presents the discrepancy between the background and successive
 398 observations for various time:

$$\|\mathbf{y}_{t_i} - \mathcal{H}(\mathbf{x}_0^b)\|_{\mathbf{X}}^2 \quad \text{for } 0 \leq i \leq 240$$

399 with $\mathbf{X} = \mathbf{D} = \text{diag}(\mathbf{R})$ for Pixels and $\mathbf{X} = \mathbf{D}_w = \text{diag}(\mathbf{WRW}^T)$ for Wavelet. It suggests an issue
 400 probably similar to what we could call aliasing of the smallest scales. Indeed let us examine more
 401 closely this figure.

Figure 8. Discrepancy between the background (no assimilation) concentration trajectory and the successive observations along time. The discrepancy measurement is computed using the norms given by the observation term of the cost function for various methods: pixel (solid blue), classical wavelet (dashed green), wavelet excluding the finest scale (solid red), wavelet excluding the two finest scales (solid black), wavelet excluding the three finest scales (solid pink).

402 On the one hand, the blue line represents this norm for the Pixel case. It starts with a small value
 403 (the only difference comes from the noise) and, as time goes by, the vortex drifts and the difference
 404 with the initial concentration steadily increases. As one would expect, the farther the vortex drift,
 405 the higher the difference with the initial concentration is, all the scales being given the same uncertainties.

406 On the other hand, the wavelet-based norm (in green), shows a steep increase at the beginning,
 407 but then oscillate around a 'plateau'. This happens because, at this point, the norm is really dominated
 408 by the small scales. Indeed, the smallest scales are the least affected by the correlated noise. Therefore
 409 their associated error variances are the smallest (i.e. one trusts more the small scales). As it is the
 410 inverse of the variances that is used as a weight in the norm, it should be expected that they dominate
 411 the norm. However it prevents to discriminate between two large scale signals, when the difference
 412 is too large (when the green curve stop being monotonic), so the minimisation problem becomes
 413 ill-posed.

414 Red, black and purple curves show the same quantity as the green one, but removing the 1, 2 and
 415 3 finest scales in the multi scale decomposition respectively. The problem appears later (i.e. for larger
 416 discrepancies) when removing the finest scales and even disappear for the purple one. This motivates
 417 the introduction of the gradual assimilation of the smallest scales we presented above in paragraph
 418 [2.5.2](#).

419 Figure 9 is similar as the right panel of Figure 7, where we added the "Wavelet scales by scales"
 420 method. The green curve shows the evolution of the residual error for this method, with $\tau_s = 4.5$ for
 421 all s . This value has been chosen to preserve Gaussianity in the retained scales. Indeed, for a Gaussian
 422 signal 99% of the considered population should lie within 3 std dev of the mean (here it is a square
 423 and divided by two, hence 4.5). As we can see, this method clearly improves the above-mentioned
 424 issue, as the convergence is reasonably good and the error improved.

Figure 9. Ratio of the residual error as a function of minimisation iterations in the presence of inhomogeneously correlated observation errors, for three methods: pixels (dashed red), classical wavelet (dotted blue), modified wavelet (dashdotted green).

425 Figure 10 gives more details about how the minimization actually operates. It shows the
 426 contribution to the observation term of the cost function from each activated scale. The coarser
 427 scales are dominating at the very beginning of the minimisation and converge quite quickly (after 10
 428 iterations), then scales 5 and 6 dominate and converge after 100 iterations. Scale 7 appears later and is
 429 gradually assimilated (image by image) and has not fully converged yet after 200 iterations.

Figure 10. Contribution to the observation cost function, in percentage, of each activated scale, as a function of the minimisation iterations. The coarsest scale is the first one, the finest scale is the 7th.

430 4. Discussion

431 In this paper, we addressed an important yet overlooked aspect of data assimilation: how to
 432 account for correlations in observation errors statistics. This question is a known obstacle of operational
 433 assimilation, as it implies technical as well as conceptual difficulties.

434 In this regard, we proposed an extension of the previous study [5], using wavelets transform
435 in order to account for correlated observation errors in variational assimilation as well as Kalman
436 filtering.

437 Keeping in mind the objective of using this methodology for real, operational, data assimilation,
438 we choose to address two difficulties: accounting for missing observations (e.g., passing clouds for
439 ocean color images) and scale-progressive assimilation in order to make the most of the multiscale
440 aspect of the wavelet transform and improve convergence. For these two aspects we developed
441 appropriate methodologies, which proved satisfactory to address both issues.

442 These promising results open new possibilities for accounting for correlated errors in operational
443 data assimilation, e.g. regarding the following applications:

- 444 • Assimilation of the SWOT data (Surface Water and Ocean Topography): SWOT satellite
445 (operational in 2021) has a large swath and will produce altimetric data for the ocean. Because of
446 the swath width, any tiny oscillation of the satellite will have a wide impact on the observation
447 error correlation that are therefore complex (inhomogeneous). The images are supposed to be
448 filtered in order to avoid any problem. Our method could help to fully use the data without
449 filtering out valuable information.
- 450 • Assimilation of ocean color images (imaging phytoplankton, in marine biology and ocean model
451 coupling), for which the images are damaged by passing clouds.
- 452 • Any other application domain with dense observations, correlated errors, partially missing
453 observations...
