Supplemental

S1. Modalities for Experimental Setup

In the following section, we present further details for our experimental setup to generate the real-capture dataset and measure reference friction values.

S1.1. Details of Cloth Material

The details of cloth materials used in our experimental setup for capturing real test data are presented in Table S1. All materials, except silk, match the description of materials used and characterized by Wang et al [32].

Mat. ID	Density	Composition	Correspondence in [32]
MI	0.197	Polyester 50%	Camal Danta Dama
IVI I	0.167	Rayon 50%	Callel Folite Kollia
MO	0.197	Polyester 95%	New Sporkle Sweet
IVIZ	0.167	Spandex 5%	INAVY Sparkle Sweat
M3	0.75	Cotton 100%	11oz Black Denim
		Cotton 65%	
M4	0.207	Polyester 33%	Royal Target
		Spandex 2%	
M5	0.198	Polyester 100%	Pink Ribbon Brown
M6	0.083	Polyester 100%	Tango Red Jet Set
M7	0.15	Polyester 100%	White Dots on Black
M8	0.065	Silk 100%	N/A
мо	0.268	Cotton 95%	Ivory Rib Knit
1017		Spandex 5%	
	Table S1	Experimental Cl	oth Materials

S1.2. Reference Friction Measurement

In order to measure the reference friction coefficient for a material/substrate pair, we employ the inclined plane protocol. As depicted in fig S1, when an object is on an inclined plane, with mass m, gravitational acceleration g, and angle of inclination α , its weight is in equilibrium as long as the tangential to the surface component, $mg\sin(\alpha)$, is equal to the frictional force \vec{Q} and the perpendicular to the surface component, $mg\cos(\alpha)$, is equal to the normal \vec{P} . As the angle α increases the tangential component increases, which remains in equilibrium up to the limit where the frictional force reaches its maximum possible value $\vec{Q} = \mu \vec{P}$. This gives the relation for the friction coefficient $\mu = Q/P = \sin(\alpha)/\cos(\alpha) = \tan(\alpha).$

For each piece of cloth we test the angle at which it slides on every substrate. Then from the angle we compute its tangent and we use this value as a friction coefficient. We test each piece of cloth on various sections of a substrate and do not find a noticeable difference in the slippage angle.

Our resulting measurements of friction coefficient are presented in Tables S2 and S4 in the 'Reference' columns, alongside predictions made by our model. Note that our measurement is the angle of maximum inclination in equilibrium, and as we move the inclined plane with a discrete

Figure S1. Inclined plane principle for frictional characterisation

Figure S2. Multiple reflectance renderings on the substrate

interval $\delta \alpha$, the propagation of the error to the computed parameter μ is given by $\delta \mu \sim \pm \sec(\alpha)^2 \delta \alpha$.

S2. Detailed Results on Real Dataset

The detailed results of evaluating our method on the real dataset are presented below. Table S2 presents friction coefficient predictions of the model, when it has been trained on synthetic data, that has been generated without varying the reflectance of the substrate during rendering (we plot the absolute error from the reference interval in red, black and light blue curves in Figure 6). It can be observed that the model gives fairly good results on substrates that are nonreflective in the real data i.e. Aluminum, Aluminum-PET, Ceramic, and Stainless. Table S3 presents the material predictions for this scenario.

Table S4 presents friction coefficient predictions when the model has been trained with data rendered with multiple reflectance values as presented in Figure S2. The results are shown in green curve in Figure 6, where we plot the absolute error from the reference interval. The results improve significantly on reflective substrates and also improve marginally on non-reflective substrates. Table **\$5** presents the material predictions for this scenario.

An annotated depiction of the experimental setup for producing our real test dataset is presented in Figure S3. Figure S4 shows the experiment with various substrates.
