

Supplemental Material for Left atrial appendage electrical isolation reduces atrial fibrillation recurrences: a simulation study

Ali Gharaviri, PhD; Simone Pezzuto, PhD; Mark Potse, PhD; Sander Verheule, PhD, Giulio Conte, MD, PhD, Rolf Krause, PhD, Ulrich Schotten, MD, PhD, and Angelo Auricchio, MD, PhD.

S1 Computational model of AF

A structurally detailed model of the human atria, extensively described previously¹, was used in this study. The global geometry was reconstructed using magnetic resonance image data of a subject with normal atria. Additional anatomical structures and properties, such as wall thickness heterogeneities, twenty pectinate muscles, Bachmann's Bundle, interatrial bundles, and the crista terminalis, and left atrial appendage trabeculated network were added manually.² One to three layers of fiber orientations manually included in the model based on anatomical studies using a combination of manual editing and computer algorithms.¹ These structures are considered to play a key role in AF initiation and maintenance.^{3,4} Simulations were performed with a second-order accurate finite-difference method⁵ on a hexahedral mesh at 0.2mm resolution including of approximately 5 million nodes. Differential equations for potentials and ion concentrations were integrated with the forward Euler method and gating variables with the Rush-Larsen method⁶ using a time step of 0.01ms. The implementation of the boundary conditions is implicit in the formulation of Saleheen and Ng.⁷ Simulations were performed with a monodomain reaction-diffusion model using the propag-5 software⁸ and run on a Cray XC50 supercomputer with GPU support. The material properties for the atria were set to produce an approximately normal P wave in case of sinus rhythm.² The effective monodomain conductivities along and across the fiber

28 are given in Table S1. The tissue surface to volume ratio was 800 cm^{-1} throughout the atrial
29 myocardium.

30 Ionic currents for each node were described by the Courtemanche-Ramirez-Nattel model.⁹
31 Changes in ionic currents caused by AF were incorporated by setting the conductivities for
32 I_{to} , $I_{Ca,L}$, and I_{K1} at 40%, 35%, and 200% of their normal values, respectively.¹⁰

33 **S2 Fibrosis distribution**

34 Fibrosis patterns similar to those obtained from LGE-MRI were generated with an algorithm
35 that produces spatially-correlated, anatomy-tailored random fields (Figure S1).^{1, 11}

36 The fibrosis was distributed within the atrial wall, while the endocardial bundles remain
37 intact. The spatial distribution of fibrosis was uneven, with patches or island presenting
38 higher degree of fibrosis. Such distribution was based on spatially correlated, anatomy-
39 tailored random fields (Figure S1).^{1, 11, 12} Fibrotic elements were assumed to be electrically
40 active and conductive along the fiber direction and electrically isolated in the transverse
41 direction (Table S1). The fibrosis was modelled in this way to represent the loss of side-to-
42 side electrical connections between atrial muscle bundles found by Spach et al. in fibrotic
43 atrial tissue.¹³ Simulations were performed without fibrosis, with moderate fibrosis, and with
44 severe fibrosis, in which 0%, 50%, and 70% of elements were fibrotic as described earlier.¹

45 **S3 AF initiation in pre- and post-catheter ablations**

46 In order to assess the likelihood of AF initiation, both before and after catheter ablations, 20
47 pacing locations were selected in both atria, including the area between the PVs, left atrium
48 (LA), left atrial appendage (LAA), right atrial appendage (RAA), coronary sinus, superior
49 caval vein (SCV), inferior caval vein (ICV), and right atrium (RA). These points were
50 selected based on reported possible sources of extra-PV ectopic focal activity in AF

51 patients.¹⁴ All pacing points, except the one located on the LAA were located outside the
52 ablated area. As a consequence, in simulations with LAAI the AF initiation rates were
53 corrected by excluding simulations in which pacing point was located in the LAA. In each
54 simulation one pacing point were selected. The stimulation protocol consisted of a 2 seconds
55 incremental pacing from a selected location, in which a train of stimuli with progressive
56 reduction in pacing interval was applied, followed by 3 seconds of simulation with no pacing.

57 **S4 Definition of a successful AF initiation**

58 The outcome of the stimulation protocol was analyzed in terms of the type of self-sustained
59 rhythm after 2 seconds of stimulations. In the presence of no activity, the initiation was
60 considered unsuccessful. Otherwise, a distinction between AF and atrial flutter (AFL) was
61 made, with the latter not being considered a successful AF initiation. To differentiate between
62 AF and AFL conduction patterns, we computed 12-leads ECGs from the simulated atrial
63 electrical activity. To construct the ECGs, the atrial model was incorporated into an
64 inhomogeneous torso model including lungs and intracavitary blood masses. Body surface
65 potentials were simulated using a bi-domain equation solved at 1-mm resolution.²
66 In all 12-lead ECGs, after the pacing periods, we detected positive fibrillation wave peaks
67 and calculated fibrillation cycle length (FCL) as the time interval between two successive F-
68 wave peaks (Figure S2-A). These FCL lengths were used to generate Poincaré plots (Figure
69 S2-B &C). The FCL were described as a vector $FCL = [l_1, l_2, \dots, l_N]$, where l_i is the i th FCL.
70 Each Poincaré plot is composed of the points of l_i on the x -axis versus l_{i+1} on the y -axis.
71 The point cloud dispersion (PCD) in Poincaré plots was used as a sensitive parameter
72 describing the regularity of activations and to differentiate between AFL and AF simulations.
73 PCD were calculated using as an averaged Euclidean distance of each point in a point cloud
74 to the point cloud centroid:

$$PCD = \frac{1}{N-1} \sum_{i=1}^{N-1} \sqrt{(l_i - c_x)^2 + (l_{i+1} - c_y)^2} \quad (1)$$

75 where $C(c_x, c_y)$ is the centroid of the point cloud in Poincaré plot. Finally, by applying an
 76 arbitrary threshold to the PCD we classified AF conduction patterns in simulations from
 77 AFL. All algorithms were developed in Matlab (v. R2016a, Mathworks).
 78 Figure S3 illustrates representative conduction patterns of simulations and corresponding
 79 three-lead ECG in the control group with three different degrees of fibrosis. In the absence of
 80 fibrosis AF was not inducible while in moderate and severe fibrosis the stimulation of the
 81 atria resulted in AF induction. Figure S4 shows activation patterns in PVI + LAAI
 82 simulations and corresponding ECGs without fibrosis, with moderate fibrosis, and with
 83 severe fibrosis. In these examples, AF was inducible only in severe fibrosis but not without or
 84 in moderate fibrosis.

85 **S5 Detection and tracking fibrillation waves**

86 A fibrillation wave was defined as a contiguous volume in which all nodes had
 87 transmembrane voltages above -60mV . The number of waves was calculated at each
 88 millisecond of simulated time.

89 Fibrillation waves were tracked in both time and space, as described in our previous study.¹⁵

90 Briefly, the temporal dynamics of waves can be described by three events:

- 91 • Generation: appearance of a new wave due to a wave breaking up into two or more
 92 waves.
- 93 • Fusion: the fusion of two or more waves into one wave as they merge with each other.
- 94 • Extinction: the extinction of a wave, because either it hits a boundary or runs into
 95 unexcitable tissue.

96 **S6 Statistics**

97 All statistical analyses were performed using GraphPad Prism software version 8.0. All
98 values were expressed as the mean \pm SD. Statistical tests were performed to compare the
99 effect of two parameters, fibrosis levels and ablation patterns, in AF initiation rate, using
100 Two-Way ANOVA followed by post hoc Bonferroni test. A value of $P < 0.05$ was considered
101 significant.

102

103 **Figure legends:**

104 **Figure S1:** Posterior and anterior view of the atria with patchy fibrosis. A) Patchy fibrosis
105 model, 50% fibrotic (anterior view). B) Patchy fibrosis model, 50% fibrotic (posterior view).
106 C) Cross sectional view of the atrial geometry demonstrating fibrosis distribution within the
107 atrial wall.

108 **Figure S2:** Local electrograms recorded during simulated AF episodes at 4 different point on
109 both atria (E1-E4) and 2 ECG leads (II and V1).

110 **Figure S3:** Atrial tachycardia patterns. A) An example of simulated lead II ECG in a
111 simulation with atrial fibrillation conduction pattern. Red stars indicate the positive peak of
112 the fibrillation wave. B) Corresponding Poincaré plot generated from the ECG presented in
113 section A. C) An example of ECGs (Lead I, II, and V1) and corresponding Poincaré plots in a
114 simulation with flutter conduction pattern. D) An example of ECGs and corresponding
115 Poincaré plots in a simulation with a fibrillation conduction pattern.

116 **Figure S4:** AF initiation in control simulations. A) Consecutive snapshots of conduction
117 patterns and corresponding three ECG leads (II, V1, and V3) in control simulations with no,
118 moderate, and severe fibrotic simulations.

119 **Figure S5:** AF initiation in ablation simulations. Series of conduction pattern snapshots in
120 simulations with pulmonary vein isolations accompanied by LAA isolation and their
121 corresponding three ECG leads (II, V1, and V3) without, with moderate, and with severe
122 fibrosis.
