Confluence in UnTyped Higher-Order Theories by means of Critical Pairs

GASPARD FÉREY AND JEAN-PIERRE JOUANNAUD, Université Paris-Saclay, INRIA project Deducteam, Laboratoire de Méthodes Formelles, ENS Paris-Saclay, 91190 France

User-defined higher-order rewrite rules are becoming a standard in proof assistants based on intuitionistic type theory. This raises the question of proving that they preserve the properties of beta-reductions for the corresponding type systems. We develop here techniques that reduce confluence proofs to the checking of critical pairs for higher-order rewrite rules extending beta-reduction on pure lambda-terms. The present paper concentrates on the case where rewrite rules are left-linear and critical pairs can be joined without using beta-rewrite steps. The other two cases will be addressed in forthcoming papers.

Additional Key Words and Phrases: Lambda calculus, Type systems, Church-Rosser property, Confluence, Decreasing diagrams, Ancestor peaks, Critical peaks

ACM Reference Format:

1 INTRODUCTION

The two essential properties of a type theory, consistency and decidability of type checking, follow from three simpler ones: type preservation, strong normalization and confluence. In dependent type theories however, confluence is often needed to prove type preservation and strong normalization, making all three properties interdependent if termination is used in the confluence proof. This circularity can be broken in two ways: by proving all properties together within a single induction [9]; or by proving confluence on untyped terms first, and then successively type preservation, confluence on typed terms, and strong normalization. We develop the latter way here, focusing on untyped confluence.

In Coq [25] and Agda [22], rewrite rules introduced by the user originate from the definition of inductive types of some form. They satisfy a precise format which has been well studied, for which confluence is always satisfied. But Agda and Coq developers have recently announced the development of new versions that would allow user-defined rewrite rules [5], and several on-going developments are already using this facility. User defined rewrite rules are indeed at the heart of Dedukti [7], which has been mostly used so far as a logical framework, user-defined rewrite rules originating then from complex higher-order encodings for which inductive types do not provide enough flexibility. Investigating the preservation of confluence by user-defined rewrite rules in \(\lambda\)-calculus appears therefore to be very timely.

Let \(R\) be the set of user-defined rewrite rules, which come in addition to the \(\beta\)-rule. The rewrite relation underlying the type theory is then generated by both \(R\) and the \(\beta\)-rule. Studying the meta-theory of such a type theory implies investigating the confluence property of \(\beta \cup R\). Since our prime target is Dedukti, which is a calculus without extentionality, we do not consider here the \(\eta\) rule in addition to the \(\beta\)-rule.
There are three main tools for analyzing confluence of a rewrite relation: Newman’s Lemma [20], Hindley-Rosen’s Lemma [11], and van Oostrom’s Theorem which generalizes both previous ones [28]. Since β-reductions are non-terminating in the pure λ-calculus, Newman’s Lemma does not apply. And if the rules have non-trivial critical pairs, then Hindley-Rosen’s Lemma does not apply either. Even the subtle use of Hindley-Rosen’s Lemma allowing for development-closed critical pairs [27] is too restrictive for practical usage. The way out is the use of van Oostrom’s decreasing diagrams [26]. The fact that β-reductions do not terminate for pure λ-terms is no obstacle since we do not rely on termination for showing confluence when using decreasing diagrams. A further reason for considering pure λ-terms is that it is then easy to deduce confluence for any type system, including dependent type systems, for which the rules enjoy type preservation.

Van Oostrom’s theorem is abstract, its application to term rewriting relations conceals many difficulties. Further, neither confluence nor termination are preserved by adding a confluent and terminating set of rewrite rules to a λ-calculus. A counter-example to termination in the simply typed λ-calculus is given in [23]. Numerous counter-examples to confluence in the pure λ-calculus are given in [16]. The problem we address is by no means simple.

Our untyped λ-calculus is intended to fit with the implementation of Dedukti. The format of rules is classical: left-hand sides must be patterns [18, 19], which are extremely useful for describing encodings of a type theory in another, a keen application to us. Considering untyped terms requires some adaptations of the usual higher-order rewriting definitions. In particular, we shall consider that the meta-variables used in rules have an arity which is not fixed, but bounded. These adaptations impact unification: we shall precisely analyze unification of linear untyped patterns and show the existence of most general unifiers computable in linear time.

Our main contribution is that a set \( R \) of rules which is terminating on the set of pure λ-terms and whose left-hand sides are linear patterns, preserves confluence of the λ-calculus if its critical pairs are joinable by using rules in \( R \cup M\eta \), where \( M\eta \) is the extensionality rule for the meta-variables.

This result is then demonstrated with the example of a theory of global states due to Plotkin and Power [24], whose rules have overlapping linear higher-order patterns as left-hand sides. The confluence of this example had indeed been shown already in [10]. Hamana shows first that the (simply) typed rules are terminating, then that the higher-order critical pairs are joinable, using Newman’s Lemma to deduce its confluence. Our method applies independently of the typing system, hence we can deduce that the same example remains confluent when using a dependently typed discipline. As we shall see, the critical pairs are not development closed, hence this result does not follow from existing techniques.

The applicability of our result to Church-style dependent type theories in which abstraction need carrying a type as first argument is not direct, it requires arguing that the confluence of the theory follows from the confluence of its Curry-style type-free version. We will briefly justify the use of our techniques in the case of Church-style PTS’s.

We recall the notions of labeled reductions and decreasing diagrams in Section 2, and describe our higher-order setting in Section 3. Matching and unification of untyped patterns and basic properties of untyped higher-order rewriting are considered in Section 4. Local rewriting peaks are analyzed in Section 5. Our confluence result is stated and proved in Section 6. Related work and applicability of our results is discussed in Section 7. Concluding remarks come last.

2 LABELED REDUCTIONS

2.1 Reductions

Given a binary relation \( \rightarrow \) on terms, called rewriting, we use: \( \leftarrow \) for its inverse, \( \Rightarrow \) for its parallelization, allowing one to rewrite at once several subterms of a given term, when none is a
subterm of another, and \( \rightarrow,\rightarrow\), and \(\leftrightarrow\), for its closures by, respectively, symmetry; reflexivity and transitivity (called derivation); and reflexivity, symmetry and transitivity (called convertibility).

A term \( s \) is in normal form if there is no \( t \) such that \( s \rightarrow t \). We define a normal form for an arbitrary term \( s \) as a term \( t \) in normal form, denoted by \( s_\downarrow \), such that \( s \rightarrow t \). Termination (or strong normalization) is the impossibility of an infinite rewriting sequence \( t_0 \rightarrow t_1 \rightarrow \ldots \rightarrow t_n \rightarrow \ldots \).

Termination guarantees the existence of normal forms for every term. A local peak is a triple of terms \( (s, u, t) \) such that \( s \leftarrow u \rightarrow t \); \( u \) is the source and \( s, t \) are its reducts. Two terms \( s, t \) are joinable if \( s \rightarrow v \leftarrow t \) for some \( v \), making the peak \( s \leftarrow u \rightarrow t \) joinable. The property that every two convertible terms are joinable is called confluence (or Church-Rosser). Confluence guarantees the unicity of normal forms for every term.

When rewriting terminates, it is well-known that the joinability of all local peaks implies the confluence property, this is the so-called Newman’s lemma. When it does not, it is then necessary to strengthen joinability, this is the rôle of decreasing diagrams.

### 2.2 Decreasing diagrams

In the following, we consider rewrite relations all of whose elementary steps are equipped with a label belonging to some well-founded set whose strict partial order is denoted by \( \triangleright \).

**Definition 2.1 (Decreasing diagram [26]).** Given a labeled relation \( \rightarrow \) on an abstract set, we denote by \( DS(l, m) \) the set of decreasing rewrite sequences of the form \( u \overset{L'}{\rightarrow} v \) or \( u \overset{L}{\rightarrow} s \overset{m}{\rightarrow} t \overset{L'}{\rightarrow} v \) such that \( L \) and \( L' \) are sequences of labels that are strictly smaller than, respectively, \( l \) and, \( l \) or \( m \). The steps labeled by \( l, m \) and \( L' \), are called the side steps, facing step and middle steps of the decreasing sequence, respectively.

Given a local peak \( v \overset{l}{\leftarrow} u \overset{m}{\rightarrow} w \), a decreasing (rewrite) diagram is a pair of derivations from \( v \) and \( w \) to some common term \( u' \), belonging to \( DS(l, m) \) and \( DS(m, l) \), respectively.

Decreasing rewrite diagrams are represented in Figure 2 and abbreviated as DDs. Note that a facing step of a decreasing diagram may be missing, its side steps are then absorbed by the middle ones. A more general notion of decreasing diagram appears in [28], we will not need it here.

**Theorem 2.2 ([26]).** A labeled relation is Church-Rosser if all its local peaks have DDs.

Van Oostrom’s theorem generalizes to rewriting modulo an equational theory \( =_E \) in which case the order on labels must be compatible with the equational theory [14]. This is for example the case when rewriting terms of the \( \lambda \)-calculus for which \( a \) conversion is built-in and must be compatible with the chosen definition of reduction over terms. Equational steps are considered to have a minimal label and often ignored.

### 3 Higher-Order Rewriting

Given an untyped \( \lambda \)-calculus generated by a vocabulary made of three pairwise disjoint sets, a signature \( \mathcal{F} \) of function symbols, a set \( \mathcal{X} \) of variables, and a set \( \mathcal{Z} \) of meta-variables, we are interested in the calculus \( \lambda \mathcal{F} \), whose reduction relation extends the \( \beta \)-rule of the underlying \( \lambda \)-calculus by a set \( \mathcal{R} \) of user-defined rewrite rules built over that vocabulary. Were we to analyze the confluence of \( \mathcal{R} \) alone, then, the situation would be similar to the first-order case, at least when left-hand sides of rules are patterns [18]. Unfortunately, confluence of \( \mathcal{R} \cup \beta \) cannot, in general, be deduced from the confluence of its two components.
3.1 Terms in $\lambda\mathcal{F}$

$\lambda\mathcal{F}$ is a mix of the pure $\lambda$-calculus and Klop’s combinatory reduction systems [16], that fits with Dedukti [7]. Terms are those of the pure $\lambda$-calculus enriched with $\mathcal{F}$-headed terms of the form $f(\overline{u})$ with $f \in \mathcal{F}$ and meta-terms of the form $Z[\overline{v}]$ with $Z \in \mathcal{Z}$, where $\overline{u}$ and $\overline{v}$ denote lists of terms.

Only variables can be abstracted over. Elements of the vocabulary have arities, denoted by vertical bars as in $|f|$ or $|Z|$. Variables have arity zero. The grammar of terms is the following:

$$ u, v := x \in \mathcal{X} \mid (u, v) \mid \lambda x. u \mid f(\overline{u}) \mid Z[\overline{v}] \quad \text{where } f \in \mathcal{F}, |\overline{u}| = |f|, Z \in \mathcal{Z} \text{ and } |\overline{v}| \leq |Z| $$

Following usage, we do not duplicate parentheses, writing $f(x \ y)$ for $f((x \ y))$, and use brackets instead of parentheses for meta-variables. It is sometimes convenient to name the head symbol of the expression $(s \ t)$: we use the symbol @ for that purpose throughout the paper. We use the small letters $f, g, h, \ldots$ for function symbols and $x, y, z, \ldots$ for variables, and reserve capital letters $X, Y, Z, \ldots$ for meta-variables. When convenient, a small letter like $x$ may denote any variable in $\mathcal{X} \cup \mathcal{Z}$. Likewise, the letter $f$ may sometimes denote any non-variable symbol, including abstraction and application. We use the notation $\lfloor \ldots \rfloor$ to denote various quantities besides arities of elements of the vocabulary, such as the length of a list, the size of an expression or the cardinality of a set.

Given a list $\overline{u}$, $\overline{u}[m..n]$ denotes the finite sublist $u_m, \ldots, u_n$. Commas in lists are sometimes omitted.

Unlike function symbols and Klop’s meta-variables, meta-variables here have an arity which is not fixed, but bounded, a handy feature used in Dedukti which has several objectives. First of all, the number of dependent arrows in a dependent type $T$ is not fixed, it may depend upon, say, the value of a natural number this type depends upon. However, any occurrence of a meta-variable of type $T$ used in a rewrite rule must have a finite number of arguments, the maximum of these numbers can then be taken as the arity of that meta-variable. This also allows to have implicit arguments in meta-variables, a feature that eases code development. Another use of this facility in Dedukti is to speed up computations by avoiding type-checking terms along rewriting derivations. The pattern matching algorithm, as we shall see in Section 4, requires using the arity of meta-variables instead of their type. Finally, verifying in Dedukti that rewrite rules preserve types is based, as expected, on solving type equality constraints, which in turn requires inferring the arities of the meta-variables that occur in those rules.

Arities extend naturally to all terms, writing $ar(t)$ for the arity of an arbitrary term $t$, by induction on their structure: $ar(\lambda x. t) = 1 + ar(t)$, $ar(X[\overline{f}]) = |X| - |\overline{f}|$ and $ar((u, v)) = ar(x) = ar(f(\overline{u})) = 0$. So, the arity of a term characterizes its potential for creating $\beta$-redexes via applications.

Positions in terms are words over the natural numbers (assuming $|\lambda x. | = 1$), using $·$ for concatenation, $\wedge$ for the empty word, $P/p$ for $\{ q : p-q\in P \}$, $\leq_p$ for the prefix order (above), $\geq_p$ for its inverse (below), $<_p$ and $>_p$ for their strict parts, and $p\#q$ for $(p \not\in_p q \wedge p \not\in_p q)$ (parallel). These orders are extended to sets of positions as follows: $P \geq_p Q$ ($P \geq_p Q$, $P \leq_p Q$, $P <_p Q$, respectively), where $Q$ is a set of parallel positions, iff $\forall p \in P \exists q \in Q$ such that $p \geq_p q$ ($p >_p q$, $q \leq_p q$, $p <_p q$, respectively). Note that $>_p$ is a well-founded partial order on both positions and sets of positions. Finally, concatenation is extended to sets of positions in the natural way. If $P, Q$ are sets of pairwise parallel positions, so is their concatenation.

Given a term $M$, we use $\mathcal{P}os(M)$, $\forall\mathcal{P}os(M)$, $\mathcal{M}Pos(M)$ for its sets of: all positions, positions of free variables, positions of meta-variables, respectively; and $\forall\mathcal{V}ar(M)$, $\forall\mathcal{B}Var(M)$ and $\forall\mathcal{M}Var(M)$ for its sets of: free variables, bound variables and meta-variables, respectively. A term $M$ is ground if $\forall\mathcal{V}ar(M) = \emptyset$, closed if $\forall\mathcal{M}Var(M) = \emptyset$, And linear if $|\mathcal{M}Pos(M)| = |\forall\mathcal{M}Var(M)|$.

Given now a term $M$ and a position $p \in \mathcal{P}os(M)$, we use $M(p)$ for its symbol at position $p$, $M|_p$ for the subterm of $M$ at position $p$, $M[N]_p$ for the term obtained by replacing in $M$ the subterm $M|_p$ by the term $N$. The latter notation extends to sets $P$ of parallel positions in $M[\overline{N}]_P$ or $M[\overline{N}]_P$ in
We say that a variable \( x \in \mathcal{B} \text{Var}(M) \) is bound above \( p \) in \( M \) if \( M|_q = \lambda x. N \) for some \( q <_p p \).

### 3.2 Substitutions

A substitution is a mapping from a finite set of variables and meta-variables to terms, written as \( \sigma = \{ x_1 \mapsto M_1, \ldots, x_n \mapsto M_n \} \), or \( \sigma = \{ \overline{x} \mapsto \overline{M} \} \), where \( \text{ar}(M_i) \geq |x_i| \), which extends to an arity-preserving and capture-avoiding homomorphism on terms as defined next. Let \( \text{Dom}(\sigma) = \{ x_1, \ldots, x_n \} \subseteq \mathcal{X} \cup \mathcal{Z} \) be the domain of \( \sigma \) while \( \text{Ran}(\sigma) = \bigcup_{i=1}^n \text{Var}(M_i) \cup \text{MVar}(M_i) \) is its image. By convention, we write \( \sigma(x_i) \) for \( M_i \). As in \( \lambda \)-calculus, substituting in terms requires renaming bound variables to avoid capturing free ones. Using post-fixed notation, applying a substitution to a term is therefore defined as follows: \( x_i \sigma = M_i; y \sigma = y \) if \( y \notin \text{Dom}(\sigma) \); \( f(\overline{t}) \sigma = f(\overline{t}; \sigma) \); \( (u \ therefore satisfies the condition). Assuming now \( Z \mapsto \lambda \overline{x}. s \in \sigma \), where \( s \) is not an abstraction and \( |\overline{x}| = n \), the additional rule for meta-variables, inspired from Klop’s definition of substitutions in the case of fixed arities [16], is as follows:

- Case 1: \( |\overline{u}| = m \leq n \), then \( Z[\overline{u}]\sigma = \lambda \overline{x}[m+1..n]. s\{\overline{x}[1..m] \mapsto \overline{u}\sigma\} \), hence delaying the replacement of those arguments of \( Z \) that are missing.

- Case 2: \( m > n \): since \( \text{ar}(s) \geq |Z| - |\overline{x}| \geq |\overline{u}| - |\overline{x}| > 0 \), \( s = Y[\overline{t}] \) and \( \overline{u} = \overline{b} \overline{w} \) with \( |\overline{b}| = n \) and \( |Y| - |\overline{t}| \geq |\overline{w}| \). Then \( Z[\overline{u}]\sigma = Y[\overline{t}\{\overline{x} \mapsto \overline{u}\sigma\}, \overline{w}\sigma] \). The result \( t\sigma \) of substituting the term \( t \) is called an instance (of \( t \) and the operation itself an instantiation. The substitution \( \sigma \) is ground (resp., closed) when so are all \( M_i \)'s. By a closed substitution, we often mean a substitution such that \( t\sigma \) is a closed term for all terms \( t \) it is applied to.

A substitution \( \sigma \) can be restricted to or deprived from (meta-)variables in some set \( V \), written \( \sigma|_V \) and \( \sigma\setminus_V \) respectively.

**Example 3.1.** Let \( s = \lambda x. (X[Y, f(x, Y)] g(Y)) \) and \( \sigma = \{ X \mapsto \lambda yzz'. h(z', z), Y \mapsto h(a, a) \} \) where \(|X| = 3 \) and \(|Y| = 0 \). Since \( m = 2 \) and \( n = 3 \), case 1 applies: \( s\sigma = \lambda x. (\lambda z'. h(z', f(x, h(a, a)) g(h(a, a))) \)).

Note the first two arguments of \( X \) are directly substituted in \( \sigma(X) \) while the missing argument creates a \( \beta \)-redex.

Let now \( t = \{ X \mapsto \lambda z. Z[z], Y \mapsto a \} \) where \(|Z| = 3 \). In this case, \( m = 2 \) and \( n = 1 \), hence case 2 applies: \( s\tau = \lambda x. (Z[a, f(x, a)] g(a)) \).

Our definition of substitution ensures the following important property:

**Lemma 3.2.** Arities are non-decreasing under substitution: \( \forall M, \sigma (\text{ar}(M\sigma) \geq \text{ar}(M)) \).

**Proof.** Easy for term constructors. For meta-variables, \( |Z| \leq n + \text{ar}(s) \) by definition.

Case 1: \( \text{ar}(Z[\overline{u}]\sigma) = |Z| - m \leq n + \text{ar}(s) - m \leq (n - m) + \text{ar}(s\{\overline{x}[1..m] \mapsto \overline{u}\sigma\}) \leq \text{ar}(Z[\overline{u}]\sigma) \) by induction hypothesis.

Case 2: \( \text{ar}(Z[\overline{u}]\sigma) = |Z| - m \leq n - m + \text{ar}(s) = -|\overline{w}| + |Y| - |\overline{t}| = \text{ar}(Z[\overline{u}]\sigma) \).

Instantiation extends to lists of terms or to substitutions in the natural way. For example, if \( \sigma(X) = \lambda \overline{x}. u \) then \( (\sigma\sigma)(X) = (\lambda \overline{x}. u)\tau \). Using our post-fixed notation, we write \( u(\sigma\tau) = (u\sigma)\tau = u\sigma\tau \).

Terms compare in the subsumption order, \( t \geq s \) if \( t =_{a\sigma} s \) for some substitution \( \gamma \), whose equivalence \( =_{a} \) defines a bijection between the free variables of \( s, t \), and strict part \( > \) is well-founded.

This well-founded order extends to substitutions in the natural way: \( \tau \geq \sigma \text{ iff } \forall t: t\tau \geq t\sigma \).
which is implied by \( \tau =_{\alpha} \sigma \gamma \) for some \( \gamma \). Given a set \( \Sigma \) of substitutions closed under instantiation, a most general substitution is a substitution \( \theta \in \Sigma \), when it exists, which is minimal w.r.t. subsumption.

### 3.3 Splitting

Given a term \( u \) and a list \( P = \{ p_i \}_{i=1}^n \) of parallel positions in \( u \), we define the term obtained by splitting \( u \) along \( P \) as \( u \downarrow_P = u | Z_1 \mapsto \ ... | Z_n \mapsto | P \) (\( u \) is cut below \( P \)) and its associated substitution by \( \overline{u}^P = \{ Z_i \mapsto \lambda \overline{x}_i. u | p_i \}_{i=1}^n \) (\( u \) is cut above \( P \)), where, for all \( i \in [1, n] \), \( \overline{x}_i \) is the list of all variables of \( u | p_i \) bound in \( u \) above \( p_i \) and \( Z_i \) is a fresh meta-variable of arity (exactly) \( | \overline{x}_i | \). The definition of substitution for meta-variables ensures that \( u \downarrow_P \overline{u}^P = u \), which justifies writing \( u = u | P \_P \) as a familiar shorthand. Note the two kinds of brackets in \( u \downarrow_P .

Our use of splitting in this paper will be systematic unless it alters readability for no good reason. This invention permitted by Klop’s notion of meta-variable, is the only technique we know of which allows to manipulate terms with binders safely, in case renaming of variables needs to take place independently in a term and in its context, as will often be the case here. We do not claim for originality here, although we cannot tell who made use of it first.

### 3.4 Functional reductions

Arrow signs used for rewriting will often be decorated, below by a name, and above by a position \( \rho \) or set of parallel positions \( P \), as in \( s \xrightarrow{p}{\rho} t \) or by a property that this position or set of positions satisfies, as in \( u \xrightarrow{\geq}{\rho} v \) and in \( v = u \xrightarrow{\geq}{\rho} P \) (\( v \) is obtained from \( u \) by normalizing its subterms \( v | p \in P \) with \( R \)).

Two different kinds of reductions coexist in our calculus, functional and higher-order reductions. Both are meant to operate on closed terms. However, rewriting open terms will sometimes be needed, in which case rewriting is intended to rewrite all their closed instances at once.

**Functional reduction** is the relation on terms generated by the rule \( (\lambda x. u) v \longrightarrow u[\lambda x. v] \). The usually omitted \( \alpha \)-index stresses that renaming bound variables, called \( \alpha \)-conversion, is built-in.

The particular case for which \( v \) is a variable is denoted by \( \beta^0 \), a notation introduced by Miller [19]. Instantiating a \( \beta^0 \)-step may yield a full \( \beta \)-step: \( s = (\lambda x. (\lambda y. g(y) x) a) \xrightarrow{1}{\beta^0} (\lambda x. g(x) a) \xrightarrow{\Lambda}{\beta} g(a) \) while \( s \xrightarrow{\Lambda}{\beta} (\lambda y. g(y) a) \xrightarrow{\Lambda}{\beta} g(a) \). This is our main motivation for using Klop’s notion of substitution for meta-variables, whose benefits will appear in the next subsection.

We will also use a particular case of extensionality, for meta-variables only: \( \lambda z.X[\overline{u}, z] =_{M\eta} X[\overline{u}] \) if \( |X| > |\overline{u}| \), \( z \) fresh. When oriented from left to right, \( M\eta \) is terminating and confluent. It has another important property: \( M\eta \)-steps disappear when taking ground instantiations, a key property for us.

**Lemma 3.3.** Let \( \overline{u} \) be a sequence of closed terms, \( z \) a variable such that \( z \notin \text{Var}(\overline{u}) \), \( X \) a meta-variable such that \( |X| > |\overline{u}| \) and \( \sigma \) a closed substitution. Then \( \lambda z.X[\overline{u}, z] \sigma = X[\overline{u}] \sigma \).

**Proof.** Since \( \sigma \) is closed, and \( |X| \geq |\overline{u}| + 1 \), then \( \{ X \mapsto \lambda \overline{x}. v \} \in \sigma \) with \( |\overline{x}| = |\overline{u}| \). We then get \( (\lambda z.X[\overline{u}, z]) \sigma = \lambda z.X[\overline{u}, z] \sigma = \lambda z.v[\overline{x} \mapsto \overline{u} \sigma, z \mapsto z] = \lambda z.v[\overline{x} \mapsto \overline{u} \sigma] = X[\overline{u}] \sigma \).

**Corollary 3.4.** Let \( u, v \) be terms such that \( u =_{M\eta} v \) and \( \sigma \) a closed substitution. Then, \( u \sigma = v \sigma \).

### 3.5 Higher-order reductions

**Higher-order reductions** result from rules whose left-hand sides are higher-order patterns in Miller’s or Nipkow’s sense [18], although they need not be typed.
Definition 3.5 (Pattern). A pre-redex of arity \( n \) in a term \( L \) is an unapplied meta-term \( Z[\overline{x}] \) whose arguments \( \overline{x} \) are \( n \) pairwise distinct variables. A pre-pattern is a \( \beta \)-normal term whose meta-variables all occur in pre-redexes. A pattern is a ground pre-pattern which is neither a pre-redex nor an abstraction, that is, is headed neither by a meta-variable nor by \( \lambda \).

It is important to assume, as does Nipkow, that patterns are \( \beta \)-normal. Note also that patterns are ground: free variables are not needed, one can use meta-variables of arity zero instead. Pre-patterns play an important rôle in pattern matching and unification, since patterns must be deconstructed.

Erasing types from a Nipkow’s pattern yields a pattern in our sense, since his pre-redexes being of base type, they cannot be applied. This restriction is not important until later, when we address the question of matching and unification of patterns.

Observe that pre-redexes in pre-patterns occur at parallel positions, whose set plays a key rôle:

Definition 3.6 (Fringe). The fringe \( F_L \) of a pre-pattern \( L \) is the set of parallel positions of its pre-redexes. We denote by \( \mathcal{FP}(L) = \{ p \in \mathcal{P}(L) : p \notin \mathcal{F}_P F_L \} \) the set of functional positions of the pre-pattern \( L \), which is non-empty if \( L \) is a pattern. We define \( F_R = \{ 1 \cdot 1, 2 \} \) for convenience.

Example 3.7. The term \( L = f(\lambda x y z. g(X[x, y, z], X[x, y])) \) is a pattern. Its pre-redexes are the terms \( X[x, y, z] \) and \( X[x, y] \). Its fringe is the set \( F_L = \{ 1^2, 1^1 \cdot 2 \} \). The term \( f(\lambda x y z. g(X[x, y, z], (a X))) \) is also a pattern, its fringe is the set \( \{ 1^2, 1^1 \cdot 2^1 \cdot 2 \} \). The subterms of a pattern are pre-patterns, such as the subterms \( \lambda x y z. g(X[x, y, z]) \) or \( (a X) \) of the above pattern, the second one being even a pattern. The terms \( f(\lambda x. X[x, x]), f(X[a]), f(X[Y]), f(\lambda x. X) \) and \( f(X Y) \) are not patterns.

Note that the set of functional positions coincides with the usual notion for first-order terms. Since patterns are ground terms, for all pre-redexes \( Z[\overline{x}] = L|_p \) at position \( p \in F_L \) in the pattern \( L \), the variables \( \overline{x} \) are all locally bound above \( p \) in \( L \).

We can now define higher-order rules and rewriting:

Definition 3.8 (Rule). A (higher-order) rule is a triple \( i : L \rightarrow R \), whose (possibly omitted) index \( i \) is a natural number, left-hand side \( L \) is a pattern, and right-hand side \( R \) is a ground \( \beta \)-normal term such that \( \mathcal{MV}ar(R) \subseteq \mathcal{MV}ar(L) \). The rule is left-linear if \( L \) is linear.

So, rules are pairs of (specific) ground terms. They may have meta-variables, but do not admit free variables. This allows to clearly separate the object language (which has no meta-variables), from the meta-language (which has meta-variables). Rules, critical pairs and splittings belong to the meta-language.

Definition 3.9 (Higher-order untyped rewriting). Given a term \( u \), a position \( p \in \mathcal{P}(u) \), and a rule \( i : L \rightarrow R \) then \( u \) rewrites with \( i \) at \( p \), written \( u \xrightarrow{p} i \rightarrow_R v \), or \( u \xrightarrow{L \rightarrow R} v \), iff \( u|_p = L \gamma \) for some substitution \( \gamma \), and \( v = u[R \gamma]_p \). We write \( u \xrightarrow{p} R \rightarrow_R v \) for \( \exists i \in \mathcal{R}, u \xrightarrow{p} i \rightarrow_R v \).

Let us now make our splitting notations fully explicit. Whenever \( u \xrightarrow{p} i \rightarrow_R v \), we have by definition:

- \( u_p = u[X[\overline{x}]]_p \) and \( \overline{\alpha}_p = \{ X \mapsto \lambda \overline{x}. u|_p \} \) with \( \overline{x} \) the variables bound above \( p \) in \( u \) and \( X \) a fresh meta-variable of arity \( |\overline{x}| \).
- \( u = u_p \overline{\alpha}_p = u_p \{ X \mapsto \lambda \overline{x}. u|_p \} = u_p \{ X \mapsto \lambda \overline{x}. L \gamma \} \)
- \( v = u_p \{ X \mapsto \lambda \overline{x}. R \gamma \} \), hence \( u_p = u_p, \overline{\alpha}_p = \{ X \mapsto \lambda \overline{x}. R \gamma \} \) and \( v|_p = R \gamma \).

Example 3.10. Let \( L = \text{der}(\lambda x. \text{times}(A, F[x])) \rightarrow \text{times}(A, \text{der}(\lambda y. F[y])) = R \) and \( \sigma \) the substitution \( \{ A \mapsto 2, F \mapsto \lambda x. x \} \). Then, \( L \sigma = \text{der}(\lambda x. \text{times}(2, x)) \) and \( R \sigma = \text{times}(2, \text{der}(\lambda y. y)) \), thus \( \text{der}(\lambda x. \text{times}(2, x)) \rightarrow \text{times}(2, \text{der}(\lambda y. y)) \). However, \( \text{der}(\lambda x. \text{times}(x, x)) \) is a normal form.
In sharp contrast with Nipkow [18], we observe that we do not need matching modulo \( \beta^0 \), since the corresponding \( \beta^0 \)-steps are now hidden in Klop’s definition of substitution for meta-variables, whose \( \beta \)-steps become \( \beta^0 \)-steps when substituting pre-redexes. We however show in Section 7.1 that our main confluence result applies to Nipkow’s definition: the use of Klop’s definition of substitution for meta-variables can be seen as a technical choice, undoubtedly an important one.

Besides, we do not assume that \( u, v \) is \( \beta \)-normal, or even \( \beta \)-normal up to position \( p \). Two reasons prevent it, \( \beta \)-normal forms may not exist, and we need monotonicity and stability properties:

**Lemma 3.11 (Splitting Above).** Let \( s \xrightarrow{q} t \). Then, \( s \xrightarrow{q} \sigma \) and \( t = s \xrightarrow{\sigma} \).

**Lemma 3.12 (Monotonicity).** Let \( s \xrightarrow{p} t \) and \( u \) a term such that \( q \in \text{Pos}(u) \). Then, \( u[s]_q \xrightarrow{q \cdot p} u[t]_q \).

Monotonicity follows directly from definition and \( u[s]_q \cdot p = s[p] \). Monotonicity extends to several different rewrites under the same context \( u[\_']_Q \), where \( Q \) is a set of parallel positions. Hence \( u[\overline{x} \mapsto \overline{u}] \xrightarrow{\cdot} u[\overline{x} \mapsto \overline{v}] \) if \( \overline{u} \mapsto \overline{v} \), assuming \( \overline{x} \) is a vector of variables only.

Stability is just as easy.

**Lemma 3.13 (Stability).** Let \( s \xrightarrow{p} t \) and \( \sigma \) a substitution. Then, \( s \sigma \xrightarrow{p} t \sigma \).

**Proof.** By definition of higher-order rewriting, \( s[p] = L \gamma \) for some substitution \( \gamma \), and \( t = s[R \gamma]_p \). We have \( s \sigma[p] = s[p] \sigma = L \gamma \sigma \) and \( t \sigma = s[R \gamma]_p \sigma = s \sigma[R \gamma \sigma]_p \) yielding the result. \( \square \)

**Lemma 3.14 (Instantiation).** Let \( \sigma \xrightarrow{R} \tau \) and \( u \) be a term. Then, \( u \sigma \xrightarrow{R} u \tau \).

**Proof.** By induction on \( |u| \).

- \( u = f(\overline{u}) \) with \( f \in F \). By induction hypothesis, \( \overline{u} \sigma \rightarrow \overline{u} \tau \). By monotonicity, \( f(\overline{u} \sigma) \rightarrow f(\overline{u} \tau) \).
- \( u = (u \ w) \) and \( u = \lambda x. v \) are similar to the first case.
- \( u = x \) is straightforward.
- \( u = X[\overline{u}] \) with \( X \notin \text{Dom}(\sigma) \). Similar to the first case.
- \( u = X[\overline{u}], X \mapsto \lambda x \gamma. u' \in \sigma, X \mapsto \lambda x \gamma. v' \in \tau, |\overline{x}| = |\overline{u}|, \) and \( u' \mapsto v' \).

Then \( X[\overline{u}] \sigma = \lambda \gamma. u'[\overline{x} \mapsto \overline{u} \sigma] \) and \( X[\overline{u}] \tau = \lambda \gamma. v'[\overline{x} \mapsto \overline{u} \tau] \). By induction hypothesis, \( \overline{u} \sigma \rightarrow \overline{u} \tau \). Hence \( u \sigma = \lambda \gamma. u'[\overline{x} \mapsto \overline{u} \sigma] \rightarrow \lambda \gamma. u'[\overline{x} \mapsto \overline{u} \tau] = u \tau \) by monotonicity.

- \( u = X[\overline{w}], X \mapsto \lambda x. Y[\overline{x}] \in \sigma \) and \( X \mapsto \lambda x. Y[\overline{t}] \in \tau, \) with \( |\overline{x}| = |\overline{v}| \).

Then \( u \sigma = (Y[\overline{x} \mapsto \overline{u} \sigma] \overline{w} \sigma) \) and \( u \tau = (Y[\overline{x} \mapsto \overline{u} \tau] \overline{w} \tau) \). By induction hypothesis, \( \overline{u} \sigma \rightarrow \overline{u} \tau \) and \( \overline{u} \sigma \rightarrow \overline{w} \sigma \). Hence \( u \sigma \rightarrow \overline{w} \sigma \) by monotonicity. \( \square \)

**Lemma 3.15 (Substitution Lemma).** Let \( u \xrightarrow{R} v \) and \( \sigma \rightarrow \tau \). Then, \( u \sigma \xrightarrow{R} u \tau \).

**Proof.** By Instantiation, \( u \sigma \xrightarrow{R} u \tau \). By Stability, \( u \tau \rightarrow u \tau \). We conclude by transitivity. \( \square \)

### 3.6 Rewrite theories

**Definition 3.16.** A \( \lambda F \)-rewrite theory is a pair \( (F, R) \) made of a user’s signature \( F \) and a set \( R \) of higher-order rewrite rules on that signature, defining the rewrite relation \( \xrightarrow{R} \) of \( \lambda F \) as \( \lambda F \rightarrow_{R \cup \beta u} \). We say that \( \lambda F \) is a left-linear theory if \( R \) is a set of left-linear rewrite rules.

Rewrite theories are used in DEDUKTI [1] to define the conversion rule of the calculus, which, as is customary in PTS’s, is untyped. The rewrite relation implemented in DEDUKTI is indeed the one
we just described, Klop’s notion of substitution for meta-variables being implemented via a priority mechanism.

The main question addressed in this paper is whether a $\lambda F$-rewrite theory is confluent (Church-Rosser), and how to show its confluence by calculating and inspecting critical pairs of some form. Showing this meta-theoretical property of $\lambda F$ will involve rewriting arbitrary terms, and possibly use $\eta$-rewriting steps for its checking. In other words, confluence of $\mathcal{R} \cup \beta$ will not be satisfied on the whole set of terms, but only on the subset of closed terms. We do not need more, of course.

Although we shall focus our attention to left-linear rewrite theories in the sequel, some results hold for non-left linear ones. We shall explicitly mention the left-linearity assumption each time it is needed.

### 3.7 The rewrite theory of global states

Our running example here will be Plotkin’s and Power’s theory of global states for a single location [24]. It is described by two types, $\text{Val}$ for values and $\Lambda$ for states, a unary operation $\text{lk}$ for looking up a state, a binary operation $\text{ud}$ for updating a state, and five higher-order rules which satisfy our format, the meta-variables having arities (unlike in the original article). First, the signature:

\[
\text{lk} : (\text{Val} \rightarrow \Lambda) \rightarrow \Lambda \quad \text{ud} : \text{Val}, \Lambda \rightarrow \Lambda
\]

$\text{lk}(\lambda v.t)$ looks up the state, binds its value to $v$, and continues with $t$ while $\text{ud}(v, t)$ updates the state to $v$, and continues with $t$. Types are given for a better understanding, they do not play any important rôle here. Let us now give the rules, using $U, V, W$ (resp. $X$) (resp. $Y$) (resp. $T$) for meta variables of arity 0 (resp. 1) (resp. 2) (resp. 3). These meta-variables may appear primed when too many of a given arity are needed, as it will be the case when computing critical pairs. This convention will be followed in all examples, throughout the paper.

\[
\begin{align*}
(\text{ll}) \quad & \text{lk}(\lambda w. \text{lk}(\lambda v.Y[v, w])) \rightarrow \text{lk}(\lambda v.Y[v, v]) \\
(\text{lu}) \quad & \text{lk}(\lambda v.\text{ud}(v, X[v])) \rightarrow \text{lk}(\lambda v.X[v]) \quad | \quad \text{lk}(\lambda v.U) \rightarrow U \\
(\text{ul}) \quad & \text{ud}(V, \text{lk}(\lambda v.X[v])) \rightarrow \text{ud}(V, X[V]) \quad | \quad \text{ud}(U, \text{ud}(V, W)) \rightarrow \text{ud}(V, W) \\
\end{align*}
\]

This typed higher-order theory was studied by Hamana, who was interested in its confluence investigated with his Haskell-based analysis tool SOL [10]. Our presentation is a simplification of Hamana’s, in which one rule was actually superfluous. Note that all rules are left-linear.

In this example, all meta-variables take a constant number of arguments, equal to their arity. Using our meta-variables with a bounded arity, we can reformulate this system by eliminating its $\eta$-expansions:

\[
\begin{align*}
(\text{ll}) \quad & \text{lk}(\lambda w. \text{lk}(Y[w])) \rightarrow \text{lk}(\lambda v.Y[v, v]) \\
(\text{lu}) \quad & \text{lk}(\lambda v.\text{ud}(v, X[v])) \rightarrow \text{lk}(X) \quad | \quad \text{lk}(\lambda v.U) \rightarrow U \\
(\text{ul}) \quad & \text{ud}(V, \text{lk}(X)) \rightarrow \text{ud}(V, X[V]) \quad | \quad \text{ud}(U, \text{ud}(V, W)) \rightarrow \text{ud}(V, W) \\
\end{align*}
\]

All these rules, whether from the first or the second set, are left-linear. We will see that their precise formulation, when there are possible variations, impacts their confluence properties.

### 4 Patterns Matching and Unification of Linear Patterns

Computing critical pairs, which play a key rôle in the analysis of overlapping peaks, requires unifying a left-hand side of rules with a subterm of another left-hand side, possibly the same. Since taking a subterm of a pattern may free some variables, an operation called $\lambda$-lifting will be applied so that, finally, two patterns are unified. Checking then their joinability requires rewriting arbitrary terms, possibly having meta-variables, which requires in turn pattern matching arbitrary terms.
against left-hand sides of rules, that is patterns. In both cases, the only variables to be instantiated are meta-variables belonging to patterns. For unification, the range of the unifying substitutions cannot contain free variables, since there are none in patterns, while for matching, the range can be arbitrary. Both algorithms, unification and pattern matching are described by rewrite rules that will deconstruct the pattern(s) to be matched or unified. These deconstructions will transform those patterns into pre-patterns. Therefore, the rules will operate on conjunctions of equations between pre-patterns (for unification) or between a pre-pattern and a term (for matching), a format invariant under rule application, as will be shown.

4.1 Matching and unification problems

The coming definitions do not assume patterns to be linear, but the unification and matching rules do. We discuss briefly how to remove this restriction in conclusion.

Definition 4.1. A (matching or unification) equational problem is a conjunction of elementary equations. An elementary equation is either the constant ⊥ or is of the form \( u = v \) in which \( u \) is a pre-pattern and \( v \) is either a pre-pattern (unification case), or an arbitrary term (matching case).

Given the problem \( P = \bigwedge_i u_i = v_i \), we denote by \( lPVar(P), lMVar(P), rPVar(P), rMVar(P), \) and \( Vар(P) \) its respective sets of left variables \( \bigcup_i Vар(\alpha u_i) \), left meta-variables \( \bigcup_i MVar(\beta u_i) \), right variables \( \bigcup_i Var(\gamma v_i) \), right meta-variables \( \bigcup_i MVar(\delta v_i) \), and all variables \( lPVar(P) \cup rPVar(P) \).

A matching or unification problem \( P \) is ground if \( lPVar(P) = \emptyset \) and \( rPVar(P) = \emptyset \), respectively.

We now define solutions, matches or unifiers, of an equational problem.

Definition 4.2 (Solutions and unifiers). An equational problem whose one elementary equation is \( ⊥ \) has no solution or unifier. Given now an equational problem \( P = \bigwedge_i u_i = v_i \),

1. a substitution \( γ \) is a match (or matching substitution) of \( P \) if \( \forall i : u_i γ = α u_i \);  
2. a substitution \( γ \) is a unifier (or unifying substitution) of \( P \) if \( \forall i : u_i γ = α v_i γ \);  

We use the word solution without qualification when which kind of substitution is meant does not matter or is made clear by the context.

4.2 Matching and unification rules

Definition 4.3. A unification problem \( P \) is linear if no meta-variable occurs more than once in \( P \). A matching problem \( P \) is linear if no meta-variable occurs more than once in the left-hand sides of the elementary equations of \( P \).

In the sequel, we will usually omit \( = α \), and also restrict ourselves to linear equational problems. This is enough for our use of matching and unification since we restrict ourselves to left-linear rewrite rules.

Describing the matching and unification rules requires the following preliminary definition:

Definition 4.4. A free variable \( x \in X \) is protected in a pre-pattern \( u \) if all its occurrences in \( u \) belong to a pre-redex of \( u \), that is, take place below \( E_u \). We denote by \( UVar(u) \) the set of unprotected variables of \( u \).

For an example, \( x \) is protected in \( f(g(X[x]), X) \). It is not protected in \( f(g(X[x]), x) \) because of its second occurrence. Protected variables can be eliminated from a term by appropriately instantiating its meta-variables, while unprotected variables cannot be eliminated. An important known observation to be justified later is that elementary unification problems for which a free variable occurs unprotected on one side, and does not occur at all on the other side have no solution.
Dec-Fun \[ f(\bar{u}) = f(\bar{v}) \rightarrow \land_{i = 1}^{m} u_i = v_i \] if \( f \in \mathcal{F} \cup \mathcal{X} \cup \{\@\} \)

Dec-Abs \[ \lambda x.ru = \lambda y.rv \rightarrow u(x \mapsto z) = v(y \mapsto z) \] with \( z \) fresh

Conflict \[ f(\bar{u}) = g(\bar{v}) \rightarrow \perp \] if \( f, g \in \mathcal{F} \cup \mathcal{X} \cup \{@, \lambda\} \) and \( f \neq g \)

Meta-Abs \[ X[\bar{x}] = \lambda y.rv \rightarrow X[\bar{y}] = v \] if \( X \in \mathcal{Z} \) and \( |X| > |\bar{x}| \)

Fail-Arity \[ X[\bar{x}] = u \rightarrow \perp \] if \( |X| - |\bar{x}| > ar(u) \)

Fail-Protect \[ X[\bar{x}] = u \rightarrow \perp \] if \( \exists z \in \text{Var}(u) \text{ s.t. } z \notin (\bar{x} \cup r\text{Var}(P_0)) \)

Fail-Arity \[ X[\bar{x}] = f(\bar{u}) \rightarrow \perp \] if \( |X| > |\bar{x}| \wedge f \in \{@\} \cup \mathcal{F} \cup \mathcal{X} \)

Fail-Protect \[ X[\bar{x}] = u \rightarrow \perp \] if \( \exists z \in \mathcal{U} \text{Var}(u) \setminus \bar{x} \)

Swap \[ u = Y[\bar{y}] \rightarrow Y[\bar{y}] = u \] if \( u \) is not a pre-redex

Flip \[ X[\bar{x}] = Y[\bar{y}] \rightarrow Y[\bar{y}] = X[\bar{x}] \] if \( |X| - |\bar{x}| > |Y| - |\bar{y}| \)

Drop \[ X[\bar{x}] = u[Y[\bar{y}]]) \rightarrow \]
\[ X[\bar{x}] = u[Z[\bar{z}]) \rightarrow \]
\[ Y[\bar{y}] = Z[\bar{z}] \]

\[
\begin{align*}
\text{if } & \exists \bar{y} \notin \bar{x} \cup \mathcal{BVar}(u) & |X| = |\bar{x}| \text{ if } u(\lambda) \in \mathcal{F} \cup \{\@, \lambda\} \\
& \mathcal{U} \text{Var}(u) \subseteq \bar{x} & |Y| - |\bar{y}| \geq |X| - |\bar{x}| \text{ if } q = \wedge \\
& Z \text{ fresh s.t. } |Z| = |Y| - |\bar{y}| + |\bar{z}| & \end{align*}
\]

Fig. 1. Matching and unification rules for linear equational problems

Pattern matching and unification are described by the rewrite rules given in Figure 1. Rules written in black apply to both matching and unification problems. Rules written in green apply to matching problems only, while rules in blue apply to unification problems only.

Apart from Meta-Abs, the first subset of four black rules treats equations between expressions which are not pre-redexes. Those equations can be decomposed or fail, depending on the respective root symbol of the left-hand and right-hand sides. These rules are just the same as those for first-order unification, with the exception, of course, of Dec-Abs. Note that Dec-Fun removes equations of the form \( x = x \). The rôle of Meta-Abs is to ensure that the arity condition for meta-variables is met by the substitution that will be obtained if the algorithm succeeds.

The second subset of rules is made of failure rules, two green followed by two blue. Failure may come from an arity violation (first or third rule), or from the existence of an unprotected variable (in the case of matching, any variable occurring free in the right-hand side of an equation should occur free in either its left-hand side or in the initial problem).

There are three remaining blue rules for unification that constitute the third subset. When the right-hand side of an equation is a pre-redex, it is moved to the left by Swap if the left-hand side is not a pre-redex, or else by Flip if the left-hand side is lacking more (implicit) arguments than the right-hand side. Drop applies to equations with a pre-redex on the left, in case some free variables, occur protected in the right-hand side while they do not occur on the left-hand side and must therefore be eliminated. Note that the first condition of this rule ensures that it is only fired if the set \( \bar{y} \setminus (\bar{x} \cup \mathcal{BVar}(u)) \) of such variables is non-empty. The following three conditions, in the order they are listed, postpone the application of Drop until Fail-Arity, Fail-Protect and Flip, in this order, can no longer apply.

In the particular case where \( q = \wedge, |X| - |\bar{x}| = |Y| - |\bar{y}| \) and \( \bar{x} \subseteq \bar{y} \) then Drop applies to \( X[\bar{x}] = Y[\bar{y}] \) and produces \( X[\bar{x}] = Z[\bar{x}] \wedge Y[\bar{y}] = Z[\bar{z}] \) which could be improved in an implementation with a special instance of Drop to produce \( Y[\bar{y}] = X[\bar{x}] \) only, as does Flip.
Note that the set of rules can easily be transformed into a deterministic algorithm as no two rules apply to the same equation, except (i) two different (blue or green) failure rules, which does not hamper determinism since they deliver the same result, ⊥; (ii) Meta-Abs and each of the failure rules but Fail-Arity, in which case the considered failure rule still applies after Meta-Abs.

4.3 Examples

Before proving properties of these matching and unification rules, we show below examples of reduction sequences using the unification rules that are useful for the reader’s understanding. All four examples transform a unification problem into one in normal form.

**Example 4.5.** Let us illustrate some rules, using meta-variables according to our convention.

\[
\begin{align*}
  & f(\lambda z.X[z]) = f(\lambda z.z) \xrightarrow{\text{Dec--Fun}} \lambda z.X[z] = \lambda z.z \xrightarrow{\text{Dec--Abs}} X[z] = z \\
  & f(\lambda z.X) = f(\lambda z.z) \xrightarrow{\text{Dec--Fun}} \lambda z.X = \lambda z.z \xrightarrow{\text{Dec--Abs}} X = z \xrightarrow{\text{Fail-Protect}} \bot \\
  & f(\lambda y.f(U)) = f(X) \xrightarrow{\text{Dec--Fun}} \lambda y.f(U) = X \xrightarrow{\text{Dec--Abs}} X = \lambda y.f(U) \xrightarrow{\text{Meta-Abs}} X[y] = f(U) \\
  & f(Y) = f(\lambda y.f(U)) \xrightarrow{\text{Dec--Fun}} Y = \lambda y.f(U) \xrightarrow{\text{Meta-Abs}} Y[y] = f(U) \xrightarrow{\text{Fail-Arity}} \bot \\
  & T = \lambda y.Y[y] \xrightarrow{\text{Meta-Abs}} T[y] = Y[y] \xrightarrow{\text{Flip}} Y[z, x] = T[y, z] \xrightarrow{\text{Drop}} Y[z, x] = Z[z] \wedge T[y, z] = Z[z]
\end{align*}
\]

*Drop* applies here to an elementary equation in which there are extra variables on both sides, eliminating, perhaps surprisingly, both problems at once: the two generated equations have a pre-redex on the left-hand side which contains all free variables occurring on the other side.

We now show examples of matching and unification problems that will be useful later when computing the critical pairs of the theory of global states. We will not do all computations needed later on, only a few interesting ones originating from the first or second versions of that theory:

**Example 4.6.** We consider here two matching problems based on the second set of rules of the theory of global states. Firstly, matching the term \(1k(\lambda w.ud(w, X'[w]))\) against the left-hand side \(1k(\lambda w.ud(w, X'[w]))\) of rule (lu):

\[
\begin{align*}
  & 1k(\lambda w.ud(w, X[w])) = 1k(\lambda w.ud(w, X'[w])) \xrightarrow{\text{Dec--Fun}} \lambda w.ud(w, X[w]) = \lambda w.ud(w, X'[w]) \\
  & \xrightarrow{\text{Dec--Abs}} ud(w, X[w]) = ud(w, X'[w]) \xrightarrow{\text{Dec--Fun}} w = w \wedge X[w] = X'[w] \xrightarrow{\text{Dec--Fun}} X[w] = X'[w]
\end{align*}
\]

Secondly, matching the term \(1k(\lambda w.1k(\lambda w.\upsilon))\) against the left-hand side of rule (ll):

\[
\begin{align*}
  & 1k(\lambda w.1k(\lambda w.\upsilon)) = 1k(\lambda w.1k(\lambda w.\upsilon)) \xrightarrow{\text{Dec--Fun}} \lambda w.1k(\lambda w.\upsilon) = \lambda w.1k(\lambda w.\upsilon) \\
  & \xrightarrow{\text{Dec--Abs}} 1k(\lambda w.\upsilon) = 1k(\lambda w.\upsilon) \xrightarrow{\text{Dec--Fun}} Y[\upsilon] = \lambda w.\upsilon \xrightarrow{\text{Meta-Abs}} Y[\upsilon, w] = \upsilon
\end{align*}
\]

This equation is in normal form as the left-hand side is a pre-redex of the same arity, 0, as the right-hand side whose set of free variables is a subset of the pre-redex arguments.

**Example 4.7.** We consider here first, three unification problems using rules of the first set of rules of the theory of global states. The first unifies the left-hand sides of rules (ll) and (l):

\[
\begin{align*}
  & 1k(\lambda w.\upsilon) = 1k(\lambda w.\upsilon) \xrightarrow{\text{Dec--Fun}} \lambda w.1k(\lambda w.\upsilon) = \lambda w.\upsilon \\
  & 1k(\lambda w.\upsilon) = U \xrightarrow{\text{Swap}} U = 1k(\lambda w.\upsilon) \xrightarrow{\text{Drop}} U = 1k(\lambda w.\upsilon) \wedge Y[w, \upsilon] = Z[\upsilon]
\end{align*}
\]

(where \(Z\) is a fresh variable of arity 1, since \(|Y| = 2\) in (ll))
Now, we consider the unification of the left-hand sides of rules (l₁) and (l₂):

\[ 1k(\lambda v. ud(v, X[v])) = 1k(\lambda v. U) \rightarrow Dec-Fun \lambda v. ud(v, X[v]) = \lambda v. U \rightarrow Dec-Abs ud(v, X[v]) = U \rightarrow U = ud(v, X[v]) \rightarrow \perp \]

since v occurs unprotected as first argument of ud in ud(v, X[v]), making unification fail, which therefore rules out a potential critical pair.

Finally unification of the left-hand sides of (l₁) with a subterm of the left-hand side of (ul₁):

\[ 1k(\lambda v. U) = 1k(\lambda v. X[v]) \rightarrow Dec-Fun \lambda v. U = \lambda v. X[v] \rightarrow Dec-Abs U = X[v] \rightarrow U = Z \land X[v] = Z \]

(where Z is a fresh variable of arity 0, since |X| = 1 in (ul₁))

We now carry out the same three computations using the second set of rules of the theory of global states. For the first:

\[ 1k(\lambda w. 1k(Y[w])) = 1k(\lambda w. U) \rightarrow Dec-Fun \lambda w. 1k(Y[w]) = \lambda w. U \rightarrow Dec-Abs 1k(Y[w]) = U \rightarrow U = 1k(Y[w]) \rightarrow U = 1k(Z) \land Y[w] = Z \]

(where Z is a fresh variable of arity 1, since |Y| = 2 in (ll₁))

The second computation is exactly the same. We move to the third:

\[ 1k(\lambda v. U) = 1k(X) \rightarrow Dec-Fun \lambda v. U = X \rightarrow X = \lambda v. U \rightarrow Meta-Abs X[v] = U \]

We observe that the computations from the second set of rules are identical in the failure case, but slightly different in the other two. We will see later the impact on the unifying substitutions.

### 4.4 Soundness

We now go on studying the matching/unification rules. First, we verify that the rules operate on equation problems (linearity will be considered later):

**Lemma 4.8.** Assume that an equational problem P rewrites to P’ by using one of the matching/unification rules. Then, P’ is an equational problem.

**Proof.** All rules preserve the property that pre-redexes are never applied. \(\square\)

A difficulty in defining soundness is that not all rules preserve the set of solutions: consider the equation \(\lambda x. X = \lambda x. x\), in which \(|X| = 0\), which yields the new equation \(X = x\) by Dec-Abs. The latter equation has for matching or unifying solution the substitution \(\gamma = \{X \mapsto x\}\), which is not a solution of the original equation since, for matching, \((\lambda x. X)\gamma = \lambda y. x\) for some fresh \(y\) and \(\lambda y. x \neq \lambda x. x\), and for unification, \((\lambda x. X)\gamma = \lambda y. x\) for some fresh \(y\) while \((\lambda x. x)\gamma = \lambda x. x \neq \lambda x. y\).

To solve this problem, we need to make precise why some solutions need not be considered, so that a failure rule can eventually apply to the above equation \(X = x\). For matching, the domain and range of a matching solution of an equational problem \(P\), can be restricted without loss of generality to \(MV\var{P}\) and \(rMV\var{P}\) respectively. Assuming groundness of \(P\) does not help making these restrictions stronger. For unification, similar restrictions are less straightforward, and groundness makes their justification easier:

**Lemma 4.9.** If a ground unification problem \(P\) has a unifier \(\gamma\), then there exists a ground unifier \(\sigma\) more general than \(\gamma\), such that \(\text{Dom}(\sigma) \subseteq MV\var{P}\).

**Proof.** Showing that \(\text{Dom}(\sigma) \subseteq MV\var{P}\) is straightforward, we therefore assume that \(\gamma\) satisfies that property, and prove groundness by induction on the number of variables in \(\text{Ran}(\gamma)\).

- Base case: \(\text{Ran}(\gamma) = \emptyset\), then \(\sigma = \gamma\).
• Induction step: let \( x \) be a variable in \( \text{Ran}(\gamma) \), and \( X \) a fresh meta-variable such that \( |X| = 0 \). Let \( \tau \) be the substitution such that \( Y \mapsto s\{x \mapsto X\} \in \tau \) iff \( Y \mapsto s \in \gamma \). Let \( t \) be an arbitrary term. Then \( ty = t\tau(x \mapsto x) \), which is easily shown by induction on \( t \). Hence \( \tau \) is more general than \( \gamma \). Now, \( u\tau = u\gamma(x \mapsto X) = v\gamma(x \mapsto X) = v\tau \), hence \( \tau \) is a unifier of \( P \). By induction hypothesis, there exists a ground unifier \( \sigma \) smaller than \( \tau \), hence smaller than \( \gamma \) by transitivity of subsumption, which satisfies both our requirements. \( \square \)

Patterns are ground terms, hence matching a pattern against an arbitrary term or unifying two patterns are ground equational problems. In the sequel, we denote by \( P_0 \) an arbitrary equational problem of either type. The solutions to be considered are therefore those of \( P_0 \).

This leads us to the following definitions for soundness of matching:

**Definition 4.10.** Given a ground matching problem \( P_0 \), a matching substitution \( \gamma \) of a matching problem \( P \) is **adequate** for \( P_0 \) if \( \text{Dom}(\gamma) \subseteq \text{IMVar}(P_0) \) and \( \text{Ran}(\gamma) \subseteq r\text{MVVar}(P_0) \cup r\text{Var}(P_0) \). A matching rule is **sound** w.r.t. \( P_0 \), if it preserves the matching substitutions that are adequate for \( P_0 \).

**Definition 4.11.** Given a ground unification problem \( P_0 \), a unifying substitution \( \gamma \) of a unification problem \( P \) is **adequate** for \( P_0 \) if \( \text{Dom}(\gamma) \subseteq \text{MVVar}(P_0) \) and \( \text{Ran}(\gamma) \subseteq \mathbb{Z} \). A unification rule is **sound** w.r.t. \( P_0 \) if it preserves the unifying substitutions that are adequate for \( P_0 \).

Obviously, preservation of all matching substitutions, or all unifying substitutions, implies soundness of a matching or unification rule, respectively.

**Lemma 4.12.** Dec-Fun and Conflict preserve all solutions.

**Lemma 4.13.** Dec-Abs preserves all solutions.

**Proof.** We carry out the proof for the case of unification. \( \gamma \) is a solution of \( \lambda x.u = \lambda x.v \) iff
\[(\lambda x.u)\gamma = (\lambda x.v)\gamma \iff (\lambda x.u(x \mapsto z))\gamma = (\lambda x.v(x \mapsto z))\gamma \quad \text{where} \quad z \text{ is a fresh variable, iff} \quad (u(x \mapsto z))\gamma = (v(x \mapsto z))\gamma, \]
since the fresh variable \( z \) does not belong to \( \text{Ran}(\gamma) \), hence does not need be renamed in order to push the substitution \( \gamma \) inside the abstractions. \( \square \)

We continue with the arity-checking rules, using the property that arities are non-decreasing under substitution:

**Lemma 4.14.** Meta-Abs preserves all solutions.

**Proof.** Assume that \( |X| > |\overline{X}| \). Let be the elementary unification problems \( X[\overline{X}] = \lambda y.v \) and \( X[\overline{X}y] = v \). Without loss of generality, we assume that \( y \not\in \overline{X}. \) Let \( |X| = n \) and \( |\overline{X}| = m \), hence \( n > m \).

Let \( \sigma = \{ X \mapsto \lambda \overline{X}[1..p].s \} \) where \( p \leq m \) and \( s \) is not an abstraction. Then, \( s \) must be headed by a meta-variable \( Y \) such that \( |Y| \geq n - p > 0 \) to satisfy the arity constraint of a substitution, hence \( \sigma = \{ X \mapsto \lambda \overline{X}[1..p].Y[\overline{Y}] \} \) for some \( \overline{Y}. \) \( X[\overline{X}]\sigma \) is then a term headed by \( Y \), which cannot be equal modulo renaming to \( \lambda y.v \). Therefore, \( \sigma \) cannot be a solution of the equation \( X[\overline{X}] = \lambda y.v \).

A substitution \( \sigma \) solution of that equation must therefore be of the form \( \{ X \mapsto \lambda \overline{X}{\lambda y}.y.s \} \), where \( ar(s) \geq 0 \). Then, \( X[\overline{X}]\sigma = s \) and \( (\lambda y.v)\sigma = v\sigma \), hence \( \sigma \) is a solution of the equation \( X[\overline{X}y] = \lambda y.v \) iff \( \sigma \) is a solution of the equations \( X[\overline{X}] = v \), which ends the proof. \( \square \)

**Lemma 4.15 (Fail-Arity).** The matching problem \( X[\overline{X}] = u \) has no solution if \( |X| < |\overline{X}| > ar(u) \).

**Proof.** By non-decreasingness Lemma 3.2, \( ar(X[\overline{X}]\sigma) \geq ar(X[\overline{X}]) > ar(u) \). \( \square \)

**Lemma 4.16 (Fail-Arity).** The unification problem \( X[\overline{X}] = f(\overline{u}) \) has no solution if \( |X| > |\overline{X}| \) and \( f \in \mathcal{F} \cup \{ @ \} \cup X \).

**Proof.** Again, \( ar(X[\overline{X}]\sigma) \geq ar(X[\overline{X}]) > 0 = ar(f(\overline{u})\sigma) = ar(f(\overline{u})) \), since \( x\sigma = x \) when \( f \in X \). \( \square \)

---

We now move to the case where extra variables occur in right-hand sides, whether protected or not, starting with the two failure rules.

**Lemma 4.17.** *Fail-Protect* preserves all solutions adequate for $P_0$.

**Proof.** Let $u$ be a term containing a variable $z \notin \bar{x}$. A solution $\gamma$ for the matching problem $X[\bar{x}] = u$ must contain $X \mapsto \bar{\gamma}u$, which is not adequate for $P_0$. □

**Lemma 4.18.** *Fail-Protect* preserves all solutions adequate for $P_0$.

**Proof.** Let $X[\bar{x}] = u$ be an elementary unification problem such that $z \in \mathcal{U} \text{Var}(u) \setminus \bar{x}$, and let us assume it has a solution $\gamma$ such that $X \mapsto \bar{\gamma}v \in \gamma$ with $ar(v) \geq |X| - |\overline{\gamma}|$. By definition of a solution, $z \notin \text{Var}(X[\bar{x}]\gamma)$, and $z \notin \text{Dom}(\gamma)$, hence $zy = z$, thus $z \in \text{Var}(uv)$. Since $X[\bar{x}]\gamma$ and $uv$ have different sets of free variables, no $\alpha$-renaming can make them equal, contradicting our assumption that $\gamma$ is a solution.

**Lemma 4.19 (Drop).** Let $E$ be the unification problem $X[\bar{x}] = u[Y[\overline{\gamma}]]q$ and $P$ the unification problem $X[\bar{x}] = u[Z[\overline{\gamma}]]q \wedge Y[\overline{\gamma}] = Z[\overline{\gamma}]$, where $\overline{\gamma} = \overline{\gamma} \cap (\bar{x} \cup B \text{Var}(u))$ and $Z$ is a fresh variable of arity $|Y| - |\overline{\gamma}| + |\overline{\gamma}|$. Then $\gamma$ is a solution of $E$ iff there exists a solution $\gamma'$ of $P$ such that $\gamma = \gamma'[Z]$.

**Proof.** Assume first that $\gamma'$ is a solution of $P$. Then, $X[\bar{x}]\gamma' = u[Z[\overline{\gamma}]][q]q'$ by definition of a substitution and the fact that $u[Z[\overline{\gamma}]]q$ is a pre-pattern. Since $Z[\overline{\gamma}]\gamma' = Y[\overline{\gamma}]\gamma'$, it follows that $X[\bar{x}]\gamma' = u[Z[\overline{\gamma}]]q\gamma' = u[Y[\overline{\gamma}]]q\gamma'$, hence $\gamma'[Z]$ is a solution of $E$.

Conversely, let $\gamma = \{X \mapsto \bar{\lambda}\overline{x}.w. Y \mapsto \lambda\overline{\gamma}\lambda\overline{x}.w'\}$ be a solution of $E$ such that $Z \notin \text{Dom}(\gamma)$. We can extend $\gamma$ as $\gamma'$ by defining $\gamma' = \gamma \cup \{Z \mapsto \lambda\overline{\gamma}. Y[\overline{\gamma}]\gamma\}$. Note that $\gamma'[Z]$ is ground and closed since $\gamma$ is a solution, implying that $\lambda\overline{\gamma}. Y[\overline{\gamma}]\gamma$ is ground and closed. Then, $Z[\overline{\gamma}]\gamma' = Y[\overline{\gamma}]\gamma = Y[\overline{\gamma}]\gamma'$, hence $\gamma'$ is a solution of the equation $Y[\overline{\gamma}] = Z[\overline{\gamma}]$. Further, $\gamma'$ is a solution of the equation $X[\bar{x}] = u[Z[\overline{\gamma}]]q$ by the same token as before, hence $\gamma'$ is a solution of $P$.

We can now conclude:

**Lemma 4.20.** The matching/unification rules are terminating and sound.

**Proof.** Termination of the matching rules is clear. For unification, we interpret an equational problem by the multiset of interpretations of its elementary equations, so that it is enough to show that the interpretation of each elementary equation generated by a unification rule is strictly less than the interpretation of its left-hand side. An elementary equation $u = v$ is interpreted by the quadruple $\langle m, n, p, q \rangle$, where $m$ is the size of the equation from which all pre-redexes have been removed, $n = 1$ if $u$ is not a pre-redex otherwise 0, and $p = 1$ if $ar(u) > ar(v)$ otherwise 0, and $q$ is the number of variables occurrences in $v$. It is easy to see that all rules but the last three generate elementary equations whose interpretation has a strictly smaller first component. Now, *Swap, Flip, Drop* decrease respectively their second, third, fourth component without changing their previous ones. In the case of *Drop*, this follows from the easy property that $\overline{\gamma} \subseteq \overline{\gamma}$.

Soundness follows from: from Lemma 4.12 for *Dec-Fun*, Lemma 4.13 for *Dec-Abs*, Lemma 4.14 for *Meta-Abs*; Lemma 4.15 for *Fail-Arity*; Lemma 4.17 for *Fail-Protect*; Lemma 4.16 for *Fail-Arity*; and Lemmas 4.18 for *Fail-Protection*; commutativity of equality for *Swap* and *Flip*; and Lemmas 4.19 and 4.9 for *Drop*. □

### 4.5 Solved forms

We now give the characterization of equational problems in normal form for those rules:

**Definition 4.21 (Solved forms).**

---

(1) An equation $u = v$ is in arity-solved form if $u$ is a pre-redex $X[\vec{x}]$ such that $ar(v) \geq |X| - |\vec{x}|$; 
(2) An equational problem is in solved form if it is either the constant $\bot$, or a conjunction
\[
\land X_i[\vec{x}_i] = v_i \text{ of equations in arity-solved form such that for all } i, VVar(v_i) \subseteq \vec{x}_i \text{ and for all } i, j, X_i \notin M\text{Var}(v_j) \text{ and for all } i \neq j, X_i \neq X_j.
\]

Lemma 4.22.

(1) An equation is in arity-solved form iff it is irreducible by all rules but Fail-Protect, Fail-Protect, Drop and Meta-Abs;
(2) Drop and Meta-Abs preserve arity-solved forms.

Proof. (1) The only if case being clear, let us assume that no rule other than Fail-Protect, Fail-Protect, Drop and Meta-Abs can apply to $u = v$. Necessarily $u = X[\vec{x}]$ otherwise one of the Dec rules, Conflict or Swap rules would apply. Assuming $|\vec{x}| < |X|$, then $v$ must be some pre-redex $Y[\vec{y}]$ otherwise Meta-Abs, Fail-Arity or Fail-Arity would apply. Because Flip does no apply by assumption, we conclude that $|X| - |\vec{x}| \leq |Y| - |\vec{y}|$, hence $u = v$ is in arity-solved form.

(2) The case of Meta-Abs follows from the definition of arity. Consider now Drop. If $q = \Lambda$, then $|X| - |\vec{x}| \leq |Y| - |\vec{y}| = |Z| - |\vec{z}|$ and the first generated equation is in arity-solved form. Otherwise $|X| = |\vec{x}|$. The first generated equation is in arity-solved form, as was the input equation. The second generated equation is in arity-solved form because $|Z| - |\vec{z}| = |Y| - |\vec{y}|.$

Lemma 4.23. All rules preserve the following two properties of a unification problem $P$:

(1) For all equations $u = v \in P$ not in arity-solved form, all meta-variables in $M\text{Var}(u) \cup M\text{Var}(v)$ are linear in $P$.
(2) For all equations $X[\vec{x}] = v \in P$ in arity-solved form, the meta-variable $X$ is linear in $P$ and for all pre-redexes $Z[\vec{z}]$ in $v$, either the meta-variable $Z$ is linear in $P$ or $\vec{z} \subseteq \text{Var}(v) \cup \vec{x}$.

Proof. All rules but Meta-Abs, Fail-protect and Drop preserve linearity of elementary equations, hence both properties (1) and (2) are preserved in that case. The case of Meta-Abs and Fail-Protect is clear. We are left with Drop which operates on equations in arity-solved form. From (2), non-linear meta-variables in right-hand sides are applied to locally bound or left-hand side variables, which prevents the application of Drop in that case. On the other, any application of Drop to linear meta-variable produces equations that satisfy the property since $\vec{z} \subseteq \vec{y}$ and $\vec{z} \subseteq \vec{x} \cup B\text{Var}(u)$.

Lemma 4.24. Let $P$ be a linear (matching or unification) equational problem: its normal form is in solved form.

Proof. Let $Q$ be the normal form of $P$. By Lemma 4.22 (1), all equations in $Q$ are in arity-solved form. By Lemma 4.23 (2), pre-redexes in their left-hand sides are linear in $Q$. We are left proving that for all $X[\vec{x}] = u \in Q$, $\text{Var}(v) \subseteq \vec{x}$. Assume it is not the case, and let $y \in \text{Var}(v) \setminus \vec{x}$. Either $y$ occurs protected and Drop applies, or else Fail-Protect applies, contradicting the assumption that $Q$ is in normal form.

Lemma 4.25. Solved forms of equational problems are computed in linear time.

Proof. First, note that the matching and unification rules check a fixed number of symbols belonging to the head of the left-hand and right-hand side of each equation belonging to a given equational problem in turn. It is therefore enough to show that the total number of matching or unification steps is linear in the size of the problem. Finally, because meta-variables appear linearly in a given equational problem, it is enough to consider every elementary equation separately.

The set of rules common to unification and matching applies to an elementary equation $u = v$ a number of times bounded by $|FP\text{os}(u)|$, and yields a number of elementary equations whose
whole size is bounded by $|u| + |v|$. Failure rules may apply only once. This concludes the case of matching, we continue with the remaining unification rules. Swap and Flip may apply only once to a given equation, and leave the size of the problem invariant. Finally, the conditions for applying Drop ensure that no other rule will ever apply after any sequence of Drops. Further the total number of applications of Drop to a given equation is bounded by the number of protected variables to be eliminated, hence by its size. This shows that the whole unification process is linear. □

4.6 Matching solutions and unifiers

We are left extracting matching substitutions and most general unifiers from equational problems in solved form. The case of a matching solved form follows quite easily:

**Lemma 4.26.** A matching solved form $P = \land_i X_i[\overline{x_i}] = v_i$ has a matching solution $\text{match}(P) = \{X_i \mapsto \lambda \overline{x_i}.a_i\}_i$, which is unique up to the equivalence $=_{\alpha \cup \eta}$.

**Proof.** It is clear that match($P$) is a matching solution. Let $\gamma = \{X_i \mapsto \lambda \overline{x}_i.t_i\}_i$ be another matching solution. If $|\overline{x}_i| \geq |\overline{x}_j|$, then necessarily $(X_i[\overline{x}_i])\gamma =_a v_j = (X_i[\overline{x}_i])\sigma$. As noted after the definition of a matching solution, $\text{Ran}(\gamma) \cap \overline{x} = \emptyset$, hence $\sigma(X_i) =_a \gamma(X_i)$. Otherwise $\overline{x}_i = \overline{x}_j\gamma$ and $t_j = \gamma[\overline{u}]$ such that $(X_i[\overline{x}_i])\gamma = \gamma[\overline{u}, \overline{y}_i]$ and $t_i = \gamma[\overline{u}]$, hence $\sigma(X_i) = \lambda \overline{x}_i\lambda \overline{y}_i.\gamma[\overline{u}, \gamma[\overline{y}_i]] =_a v_i$. Therefore, $\sigma(X_i) = \lambda \overline{x}_i\lambda \overline{y}_i.\gamma[\overline{u}, \gamma[\overline{y}_i]] = \sigma(\gamma)\gamma(X_i).

**Example 4.27.** We continue here the calculations of Example 4.6.

Consider the first matching solved form obtained, $X[w] = X'[w]$, whose corresponding matching solution is therefore $\{X \mapsto \lambda w.X'[w]\}$. We can therefore rewrite the term $1k(\lambda w.ud(w, X'[w]))$ with rule (lu), resulting in the term $1k(\lambda w.X'[w])$.

Note that $\{X \mapsto X'\}$ is another matching solution which is $\eta$-equivalent to the previous one. Using that solution yields the reduct $1k(X')$ which is again $\eta$-equivalent to the previous one.

For the second matching problem, the reader can verify that the matching solution becomes $\lambda vw.Y'[v, w]$ and therefore $1k(\lambda v.1k(Y'[v, w]))$ rewrites to $1k(\lambda v.Y'[v, v])$.

**Lemma 4.28.** A unification solved form $P = \land_i X_i[\overline{x}_i] = v_i$ has a most general unifier $\text{mgu}(P) = \{X_i \mapsto \lambda \overline{x}_i.\alpha_i\}_i$, which is unique up to the equivalence $=_{\alpha \cup \eta}$.

**Proof.** Let $\sigma$ be $\text{mgu}(P)$. We need to show that $\sigma$ is a unifier, that it is most general, and that it is unique up to equivalence.

By definition of a unification solved form, $\text{MVar}(v_i) \cap \text{Dom}(\sigma) = \emptyset$ and $\text{Var}(v_i) \subseteq \overline{x}_i$. Hence $\sigma$ is ground as required, and $X_i[\overline{x}_i]\sigma = v_i = v_i\sigma$. Therefore, $\sigma$ is a unifier of $P$.

Let $\theta$ be a unifying solution. For all $i$, $X_i[\overline{x}_i]\theta = v_i\theta = (X_i[\overline{x}_i])\sigma\theta = X_i[\overline{x}_i](\sigma\theta)$. Since $\theta$ is ground, $X_i\theta = X_i(\sigma\theta)$. And for all $Y \in \text{Dom}(\theta) \setminus \text{Dom}(\sigma)$, $Y\theta = Y(\sigma\theta)$, hence $\theta = \sigma\theta$.

Finally, let $\tau$ be another most general unifier. We assume $\text{Dom}(\tau) \subseteq \text{iMVar}(P)$ and prove $\sigma =_{\alpha \cup \eta} \tau$ from $X_i[\overline{x}_i]\sigma = X_i[\overline{x}_i]\tau$ as in the proof of Lemma 4.26.

**Example 4.29.** We continue here the calculations of Example 4.7. Consider first the two solved forms obtained when unifying the left-hand sides of rules belonging to the first set of rules of the theory of global states. First, for the rules (ll) and (l), we get the solved form $U = 1k(\lambda v.Z[v]) \land Y[w, v] = Z[v]$ where $|Z| = 1$. The most general unifier is therefore $\{U \mapsto 1k(\lambda v.Z[v]), Y \mapsto \lambda w.Z[v]\}$. Then, for the rules (lu) and (l), we get the solved form $U = Z \land X[v] = Z$, where $|Z| = 1$, hence the mgu is $\{U \mapsto Z, X \mapsto \lambda v.Z\}$.

Moving now to the unifications between the same rules of the second set, we got as solved forms $U = 1k(Z) \land Y[w] = Z$ which yields the mgu $\{U \mapsto 1k(Z), Y \mapsto \lambda w.Z\}$, and $X[v] = U$ which yields the mgu $X \mapsto \lambda v.U$. These mgus differ slightly: the first two are the same up to extensionality of the meta-variables; the other two differ in a different but more usual way, the use of an extra variable that can be dispensed with. Altogether, the second set of rules yields more economic mgus.
Pattern matching and unification of linear patterns is therefore quite easy: first, reduce the initial equational problem to solved form. Then extract the matching substitution or the most general unifier from the solved form. Therefore:

**Theorem 4.30.** The matching problem results in a single matching substitution when it succeeds, computable in linear time and space. The unification problem results in a single (up to \( \alpha \cup M\eta \)) most general solution when it succeeds, computable in linear time and space.

Note that there is no mention of types in this algorithm. A natural question is whether the most general solution is typed when two linear patterns get unified, and whether it coincides with the one obtained when unifying dependently typed linear patterns.

5 LOCAL PEAKS IN REWRITE THEORIES

From now on, by a local peak, we mean one using terms and rewrite steps in \( \lambda \mathcal{F} \). In particular, the terms must be closed.

Rewrite theories have two kinds of local peaks, **homogeneous** ones, between functional or between higher-order reductions, and **heterogeneous** ones, which mix both kinds of reductions. We analyze here which local ancestor peaks, whether homogeneous or heterogeneous, enjoy **decreasing diagrams for free** and which do not. Results that do not rely on the left-linearity of the rewrite rules, nor on orthogonal functional reductions, may use a formulation more general than necessary so as to be usable in more general contexts.

5.1 Decreasing diagrams for free

A key property of plain first-order rewriting is that there are three possible kinds of local peaks depending on the respective positions of the rewrites that define them. This property generalizes trivially to higher-order rewrites with our definition of set of functional positions for patterns:

**Lemma 5.1.** Given terms \( s, t \) such that \( s \xrightarrow{p} u \xrightarrow{q} q \xrightarrow{p} t \), there are three possibilities: (i) \( p \# q \) (disjoint peak case); (ii) \( q \geq p \cdot F_L \) or \( p \geq q \cdot F_G \) (ancestor peak case); and (iii) \( p \cdot q \) with \( o \) with \( o \in \mathcal{F}Pos(G) \) or \( q \cdot p \cdot o \) with \( o \in \mathcal{F}Pos(L) \) (overlapping peak case).

In the case of plain rewriting, two non-overlapping rewrite steps issuing from a same term commute, a major component of any confluence proof. When the steps occur at disjoint positions, this property, which holds for any monotonic relation, remains true for rewriting modulo a theory, hence all disjoint peaks have decreasing diagrams for free. This is not the case when the steps occur at positions such that one is an ancestor of the other, because the modulo part of the above rewrite may interact with the rewrite below. Our definition of higher-order rewriting, however, enjoys a similar property, because the fringe of a rewrite step protects positions below it.

In the coming lemmas, "AP" stands for **ancestor peak**, and the prefix "L" for **linear**. In next lemma, "A" stands for above, the \( \beta \)-step being above a higher-order rewrite step.

**Lemma 5.2 (AP\( \beta \lambda \)).** Let \( u \) be a term, \( p, q \in Pos(u) \) such that \( q \geq p \cdot F_L \) and \( s \xrightarrow{p} u \xrightarrow{q} \beta \ x \xrightarrow{R} t \). Then \( s \xrightarrow{Q} \frac{p}{j} \beta \ x \xrightarrow{R} t \) for some set \( Q \) of parallel positions of \( s \) such that \( Q \geq p \) \( p \).

**Proof.** By assumption, \( u_\rho = s_\rho = L_\rho \cdot u_\rho = (\lambda x. M N) \), and \( s_\rho = M \sigma \), where \( \sigma = \{ x \mapsto N \} \). There are two cases:

The case where \( q = p \cdot q \cdot q \) and \( t_\rho = (\lambda x. M P) \) with \( N \xrightarrow{q} P \). This requires several \( j \)-steps at the parallel positions of \( x \) in \( M \). Then \( s = u[M \sigma]_\rho \xrightarrow{p} \beta \ x \xrightarrow{R} t \)
Otherwise, \( q = p \cdot 1^2 \cdot q' \), that is, \( M[q'] = u_q \xrightarrow{j} t_q \). Then, \( s = u[M\sigma[u_q\sigma][q']]_p \). By Lemma 3.13, \( u_q\sigma \xrightarrow{j} t_q\sigma \), hence, by Lemma 3.12, \( s = u[M\sigma[t_q\sigma][q']]_p \). On the other hand, \( t|_p = (\lambda x. P N) \), where \( P = M[t_q]q' \), therefore \( t = u[(\lambda x. P N)]_p \xrightarrow{j} u[P\sigma]_p = u[M\sigma[t_q\sigma][q']]_p. \) □

The case of a local peak \( s^p \xrightarrow{i} u \xrightarrow{j} t \), where the higher-order rewrite step with \( i : L \rightarrow R \) takes place above another step belonging to \( R \cup \beta \), a situation called (LAP\( \mathcal{P} \mathcal{R} \Lambda \)), is shown at Figure 3. As indicated by the name (LAP\( \mathcal{R} \Lambda \)), left-linearity is essential here. The proof requires an important preliminary result:

**Lemma 5.3 (Preservation).** Let \( u \xrightarrow{p}{i : L \rightarrow R} v \) with \( L \linear \) and \( q \in \mathcal{P}\text{os}(u) \) such that \( q \geq_p p \cdot F_L \). Then \( u_q = u[Z\bar{z}]_q \xrightarrow{p}{i} w \) for some \( w \), where \( \bar{z} \) is the list of variables bound above \( q \) in \( u \), \( Z \) fresh, \( |Z| = |\bar{z}| \), and \( v = w\bar{w}' = w[Z \mapsto \lambda \bar{z}. u_q] \).

**Proof.** By definition of splitting, \( u = t \tau \), where \( t = u_q = u[Z\bar{z}]_q \) and \( \tau = \bar{w}' = \{Z \mapsto \lambda \bar{z}. u_q\} \).

Since \( q \geq_p p \cdot F_L \), then \( q = p \cdot o \cdot q' \), where \( o \in F_L \) is the position of a pre-redex in \( L \). Hence \( L_\alpha = X[\bar{x}] \) for some meta-variable \( X \) and variables \( \bar{x} \) bound above \( o \) in \( L \).

By definition of higher-order rewriting, \( u|_p = L\gamma \) for some substitution \( \gamma \) and we call \( M = u|_{p \cdot o} \).

We have \( M = (L\gamma)|_o = L_\alpha y = X[\bar{x}]\gamma \).

Let now \( \theta \) be the substitution identical to \( \gamma \) except for the meta-variable \( X \) for which \( \theta(X) = \lambda x. M[Z\bar{z}]_q \).

We have \( X[\bar{x}]\theta \tau = M[u_q]_q \gamma = M[M[Z\bar{z}]_q \gamma = M = X[\bar{x}]\gamma \), since \( L \) is linear, the only occurrence of the meta-variable \( X \) in \( L \) is at position \( p \cdot o \) and therefore \( L\gamma = L\theta \tau \).

Since \( L \) is linear, there is a single pre-redex containing the meta-variable \( X \). As a consequence, \( L\theta = u|_p[X[\bar{x}]\theta]|_o = u|_p[(M[Z\bar{z}]_q \gamma)\theta u|_p[u|_{p \cdot o}[Z\bar{z}]_q \gamma])_o = u|_p[Z\bar{z}]_q \gamma \), and therefore \( u_q = u[L\theta]_p \).

By definition of higher-order rewriting, \( L\theta \xrightarrow{\Lambda}{i : L \rightarrow R} \theta \), and by monotonicity, \( u_q \xrightarrow{p}{i} u[R\theta]_p = w \).

By definition of higher-order rewriting again, \( v = u[R\theta \tau]_p = u[R\theta \tau]_p = (u[R\theta]_p \tau = w\bar{w}' \). □

Preservation extends easily to a set of pairwise parallel positions \( Q \geq p \cdot F_L \) by induction on \( Q \).

**Lemma 5.4 (LAP\( \mathcal{R} \Lambda \)).** Let \( R \) be a left-linear rewrite system, \( i : L \rightarrow R \subseteq \mathcal{R} \), \( j \subseteq \mathcal{R} \cup \beta \), \( u \) be a term, and \( p, q \in \mathcal{P}\text{os}(u) \) such that \( q \geq_p p \cdot F_L \) and \( s^p \xrightarrow{i} u \xrightarrow{j} t \). Then, \( s \xrightarrow{\geq_p p}{j} u \xrightarrow{j} t \).

**Proof.** Splitting \( u \) at \( q \) yields \( u = u \sigma \), where \( u\sigma = \{Z \mapsto \lambda \bar{z}. u_q\} \) is preserving since \( u_q \) cannot be an abstraction by definition of a pattern and is normal as a subterm of \( u|_p \). By assumption, \( u_q \xrightarrow{j} t_q \), and by monotonicity, \( \sigma(Z) = \lambda \bar{z}. u_q \xrightarrow{j} \lambda \bar{z}. t_q \). Let \( \tau \) be \( \sigma \) with the exception \( \tau(Z) = \lambda \bar{z}. t_q \). Then \( \sigma \xrightarrow{j} \tau \) and by Lemma 3.12, \( u = u \sigma \xrightarrow{j} u \sigma \tau = t \). By Lemma 5.3, \( u \xrightarrow{j} w \) for some \( w \) such that \( s = w \sigma \). By Lemma 3.15, \( u = w \sigma \xrightarrow{j} w \tau \). The result follows. □

### 5.2 Critical peaks

Higher-order critical pairs have been introduced in [21], [18]. As always, a critical peak is created by overlapping a left-hand side of rule \( G \) with the subterm of a left-hand side \( L \) at some position \( p \).

Note that a critical peak is not local in our sense, since it may involve meta-variables. A further problem is that \( L|_p \) may have free variables that are bound above \( p \) in \( L \). In order to restore the dependencies of the meta-variables of \( L|_p \) upon these free variables, Nipkow introduces a lifting
operation. Our lifting operation differs slightly from his, we do not keep the outside abstractions but lift instead terms with respect to a set of fresh variables, which we find more convenient:

**Definition 5.5 (Lifting).** Given a term \( L \) and a list \( \overline{x} \) of pairwise different variables such that \( \text{Var}(L) \cap \overline{x} = \emptyset \), we call lifting of \( L \) with respect to \( \overline{x} \), denoted by \( L \uparrow \overline{x} \), the term \( L \sigma_\overline{x} \), where
\[
\sigma_\overline{x} = \{ Y \mapsto Y' | \overline{x} : Y \in M \text{Var}(L), Y' \text{ fresh}, |Y'| = |Y| + |\overline{x}| \}.
\]

**Example 5.6.** Consider the left-hand-side \( L = \text{ud}(V, 1k(X)) \) of the rule (ul). The lifting of \( L \) with respect to the variable \( x \) gives the term \( L \uparrow x = \text{ud}(V'[x], 1k(X'[x])) \), using the substitution
\[
\sigma_x = \{ V \mapsto V'[x], X \mapsto X'[x] \}.
\]

Lifting increases by \( \overline{x} \) the list of arguments of all meta-variables occurring in \( L \), whose name is changed to a fresh one. Lifting has the following properties that justify its use:

**Lemma 5.7.** Given a term \( L \) and a list \( \overline{x} \) of pairwise different variables such that \( \text{Var}(L) \cap \overline{x} = \emptyset \),

1. If \( L \) is: (i) a pre-pattern, then so is \( L \uparrow \overline{x} \); (ii) ground, then so is \( \lambda \overline{x} L \uparrow \overline{x} \).
2. If \( L \uparrow \overline{x} \emptyset = t \), then there exists \( \sigma \) such that \( L = t \sigma \) and \( \text{Ran}(\sigma) \subseteq \text{Ran}(\emptyset) \cup \overline{x} \);
3. If \( L = t \), then there exists \( \emptyset \) such that \( L \uparrow \overline{x} \emptyset = t \) and \( \text{Ran}(\emptyset) = \text{Ran}(\sigma) \setminus \overline{x} \).

**Proof.** (1): by definition. (2) \( \sigma = \sigma_L \emptyset \). (3) If \( \sigma = \{ Y_i \mapsto v_i \} \) then take \( \emptyset = \{ Y'_i \mapsto \lambda \overline{x}.v_i \} \).

We can now define untyped higher-order critical peaks:

**Definition 5.8.** Let \( i : L \to R \) and \( j : G \to D \) be rules in \( \mathcal{R} \), \( o \in \mathcal{FP}os(L) \) and \( \text{Var}(L|_o) = \overline{x} \) such that the equation \( \lambda \overline{x}.L|_o = \lambda \overline{x}.G|_o \uparrow \overline{x} \) has a most general solution \( \sigma \). Then, \( R \sigma \mapsto \lambda i \sigma \uparrow o \text{L} \sigma \uparrow j \text{D} \sigma \sigma_{\overline{x}} \uparrow o \) is a critical peak of \( j \) onto \( i \) at position \( o \). Its associated critical pair is \( \langle R \sigma, L \sigma \uparrow \overline{x} \sigma \rangle_o \).

The definition of critical peaks asserts the existence of a rewrite from a term to a lifted term, we must therefore verify that this rewrite does exist:

**Proof.** Since \( o \in \mathcal{Pos}(L), (L \sigma)|_o = L|_o \sigma = G|_o \uparrow \overline{x} \sigma = (G|_o \sigma) \sigma = G(\sigma_L \uparrow \overline{x} \sigma) = \text{D}(\sigma_L \uparrow \overline{x} \sigma) = (\text{D}\sigma_L \sigma) \sigma = \text{D}\sigma_L \sigma \).

We conclude that \( L \sigma \mapsto \lambda i \sigma \uparrow o \text{L} \sigma \uparrow j \text{D} \sigma \sigma_{\overline{x}} \uparrow o \) by monotonicity.

**Example 5.9.** Consider the overlap between the rules (ll) and (l) at position \( o = 1 \cdot 1 \) of the left-hand side of (ll). We need to unify the left-hand-side \( 1k(\lambda w.U) \) of (l) with the subterm \( 1k(Y[w]) \).

In order to account for the variable \( w \) which is bound above \( o \) but occurs below \( o \), the left-hand side of the inner rule, (l), is lifted with respect to \( w \), which yields the term \( 1k(\lambda w.U[w]) \).

Unification returns the most general substitution \( \emptyset = \{ Y \mapsto \lambda w.U[w] \} \). A peak originates from \( 1k(\lambda w.1k(\lambda w.U[w])) \) has therefore two reducts, \( 1k(\lambda w.Y[w,w]) \) and \( 1k(\lambda w.U[w]) \) using (ll) at the root and (l) at position 11 respectively.

Nipkow considers instead unification of the terms \( \lambda \overline{x}.L|_o = \lambda \overline{x}.G|_o \uparrow \overline{x} \). Note that this problem has the same ground solutions as the one we consider, since the latter can be obtained from the former by applying Meta-Abs \( |\overline{x}| \)-times. This is why it is not necessary to keep the lifting abstractions explicitly in the lifted term.

Our definition makes sense: since \( o \in \mathcal{FP}os(L), \) then \( o <_p F_L \), and therefore, \( o \in \mathcal{FP}os(L \sigma) \).

Using standard techniques, we then get the analog of Nipkow’s critical pair lemma developed for the case of simply typed higher-order rewrite rules:

**Lemma 5.10 (Critical peak lemma).** Assume \( s \mapsto t \) is an overlapping peak of rule \( j : G \to D \) onto rule \( i : L \to R \) at position \( o \in \mathcal{FP}os(L) \) such that \( q = p \cdot o \). Then there is a critical peak \( s' \mapsto t' \) and a closed substitution \( \emptyset \) such that \( u' \emptyset = u|_p \), \( s' \emptyset = s|_p \) and \( t' \emptyset = t|_p \).
Proof. By definition of higher-order rewriting, there exists some substitutions \( \gamma \) and \( \sigma \) such that
\[
L_Y = u|_\rho, \quad G_G = u|_q = (L_Y)|_o, \quad s = u[\rho|_\sigma] = t = u[D\sigma]|_q.
\]
Let \( \overline{x} \) be the set of variables bound above \( o \) in \( L \). We cannot merge \( \gamma \) and \( \sigma \) into a substitution that can be applied to \( L \) as the \( \overline{x} \) variables may occur in \( \text{Ran}(\sigma) \). However, by Lemma 5.7, there exists \( \sigma' \) such that \( G_G^{\overline{x}} \sigma' = (L_Y)|_o \). Since \( \sigma' \) and \( \gamma \) have disjoint domains we can define \( \gamma' = \gamma\sigma' \) and have both \( L_Y' = u|_\rho \) and \( G_G^{\overline{x}} \gamma' = (L_Y')|_o = u|_q \).

Besides, since \( o \in \mathcal{FP}os(L) \) and \( \text{Ran}(\gamma') \cap \overline{x} = \emptyset \) we have \( (L_Y')|_o = L_o y' \). Therefore, \( y' \) is a solution of the equation \( L|_o = G_G^{\overline{x}} \). Let \( \omega \) be its most general unifier, and \( \theta \) the closed substitution such that
\[
\omega\theta = y'.
\]
The critical peak is \( s' = R_\omega \Lambda_i L_\omega = u' = L_\omega [G_G^{\overline{x}} \omega|_o \circ \circ L_\omega [D\sigma]|_o] = t|_\rho \). We check that \( s'\theta = R_\omega \theta = R_Y = Y = u|_\rho \) and \( t'\theta = L_Y[D\sigma]|_o = u|_\rho[D\sigma]|_o = t|_\rho \). \( \square \)

5.3 Orthogonal functional reductions

The confluence proof will not be based on using \( \beta \)-rewrites, nor parallel \( \beta \)-rewrites, but, as in Tait’s confluence proof of the \( \lambda \)-calculus, orthogonal \( \beta \)-rewrites (called parallel reductions in [2]). Our definition is essentially Tait’s, but makes the rewriting positions explicit.

To this end, we first define the product of sets of positions:

**Definition 5.11.** Given a set of parallel positions \( P \) and a family \( \{Q_p\}_{p \in P} \) of sets of positions not containing \( \Lambda \), we define the orthogonal product \( P \otimes Q \) as the set \( P \cup \bigcup_{p \in P} p \cdot Q_p \).

**Lemma 5.12.** Given a set of positions \( O \) there exist a unique set of parallel positions \( P \subseteq O \) and family \( \{Q_p\}_{p \in P} \) of sets of positions not containing \( \Lambda \) such that \( O = P \otimes Q \).

**Proof.** \( P = \{p \in O \mid \forall q \in O, p \neq q\} \) is the set of minimal positions of \( O \), and \( Q_p = \{q \neq \Lambda \mid p \cdot q \in O\} \).

\( P \) is called the parallel part of \( O \), written \( \overline{O} \), while \( \bigcup_{p \in P} p \cdot Q_p \) is called the residual part of \( O \), written \( \overline{O} \). Note that \( O = O \cup \overline{O}, \overline{O} >_P O \) and that whenever \( O \neq \emptyset, O \neq \emptyset \) and \( \overline{O} \subset O \).

**Definition 5.13 (Orthogonal reductions).** Orthogonal \( \beta \)-rewriting, written \( u \overset{O}{\beta} \rightarrow v \), is the smallest reflexive relation on terms such that \( u \overset{\overline{O}}{\beta} \rightarrow s \) and \( s \overset{O}{\beta} \rightarrow u \) imply \( u \overset{\overline{O}}{\beta} \rightarrow v \).

The alternative choice of rewriting first at positions in \( O \), instead of first in \( \overline{O} \), would yield a more complex calculation for \( O \), explaining our formulation of Tait’s parallel rewriting definition.

Note that orthogonal rewriting contains parallel rewriting. Furthermore it is easy to show that our definition of orthogonal reduction coincides with Tait’s parallel rewriting. This follows from the property: \( t \overset{P}{\beta} u \overset{Q}{\beta} v \) implies \( t \overset{P \circ Q}{\beta} v \) if \( \forall p \in P, \forall q \in Q, q \not\geq_P p \), which is easily proved by induction on \( P \).

We shall need several well-known properties of (Tait’s) orthogonal \( \beta \)-reductions: monotonicity, stability, commutation with any other monotonic rewrite relation, and strong confluence. Besides the following properties will be needed for the coming analysis of orthogonal ancestor peaks.

**Lemma 5.14.** Assume \( q \in \mathcal{P}os(u) \) and \( O = P \cup Q \cup R \subseteq \mathcal{P}os(u) \) with \( P \geq q \), \( q \geq_R q \) and \( R \preceq_P q \).

Then \( u \overset{O}{\beta} v \) if and only if \( u \overset{P}{\beta} \overset{Q}{\beta} \overset{R}{\beta} v \).

**Proof.** It suffices to notice that \( \overset{P}{\beta} \) preserves \( Q \) and \( R \) and \( \overset{Q}{\beta} \) preserves \( R \). \( \square \)
Lemma 5.15. \((\lambda x. M \ N) \xrightarrow{\beta} t\) with \(\Lambda \in O\) if and only if \(O = \{\Lambda\} \cup 11 \cdot P \cup 2 \cdot Q, M \xrightarrow{\beta} M', N \xrightarrow{\beta} N'\) and \(t = M'\{x \mapsto N'\}\).

Proof. By definition using the fact that \(\overline{O} \geq_{\beta} \overline{O} \cdot F_\beta\), since the left-hand side of the \(\beta\)-rule does not overlap itself at a strict subterm. □

5.4 Orthogonal decreasing diagrams for free

We investigate here the linear ancestor peak properties of orthogonal \(\beta\)-reductions. Unlike the “above case”, the “below case” listed first follows easily from preservation.

Lemma 5.16 (LAPOb). Given a set \(R\) of left-linear higher-order rules, let \(s \xleftarrow{q} u \xrightarrow{\beta} t\) for some set \(R\) such that \(s \xleftarrow{q} u \xrightarrow{\beta} t\). Then, \(\exists \sigma \in \Delta\).

Proof. Since patterns are \(\beta\)-normal, \(O \geq_{\beta} Q \cdot F_L\), and from the extension of Lemma 5.3 to sets of pairwise parallel positions, \(u \xrightarrow{q} v\) for some \(v\) such that \(s = v', u = v\). By definition of orthogonal rewriting, \(v = \overline{\sigma}\) for some \(\sigma\) such that \(t = u'.\overline{\sigma}\). We conclude that \(s = s', u = u'\overline{\sigma}\), and by stability, \(t = u'.\overline{\sigma}\).

The “above case” does not need the left-linearity assumption.

Lemma 5.17 (APOA). Given a set \(R\) of higher-order rules, let \(s \xleftarrow{p} u \xrightarrow{\beta} t\), where \(\forall p \in P, p \not\geq_{\beta} q\).

Then \(s \xrightarrow{Q'} v \xleftarrow{P} t\) for some set \(Q'\) of parallel positions of \(s\) such that \((P \cup \{q\})\) is rigid in \(s\). Besides \(s = u'\overline{\sigma}\), \(v = u'\sigma\) and \(t = u'\sigma\) such that \(u \xrightarrow{q} u', u' \xrightarrow{R} \sigma\).

Note that \(Q'\) is a set of positions in \(s\), hence the condition \((P \cup \{q\})\) is rigid in \(s\) makes sense.

Carrying out the proof requires the following definition:

Definition 5.18. A non-empty set of parallel positions \(Q \subseteq Pos(u)\) is said to be rigid in \(u\) if there exists \(q \leq_{\beta} Q\) such that \(\Var(u|_Q) \subseteq \Var(u|_q)\).

If \(Q\) is rigid in \(u\), we can always choose \(q = \text{glb}(Q)\), the greatest lower bound of \(Q\) w.r.t. \(\beta\), whose existence follows from well-foundedness of \(>_{\beta}\).

Note also that a position \(q \in Pos(u)\) is a singleton set of rigid positions in \(u\).

Example 5.19. If \(u = \lambda x.f.(\lambda y.y, \lambda z.x)\), then \{11, 12\} and \{11, 121\} are rigid in \(u\) while \{111, 121\} is not since \(\Var(u|_{111}) = \{y\} \not\subseteq \Var(u|_1) = \{x\}\).

We can now prove a formulation of Lemma (APOA) which is more general, so as to be possibly reused in further work.

Proof. We prove the more general result with \(u \xrightarrow{Q} v\), with \(P \not\geq_{\beta} Q\), for some set \(Q\) of parallel rigid positions of \(u\). We then conclude that \(s \xrightarrow{Q'} v\) for some set \(Q'\) of parallel positions of \(s\) such that \((P \cup Q) \leq_{\beta} Q'\)
We prove the result by induction on the set of positions $P$ using the well-founded multiset extension $\geq_{mul}$ of the size ordering on positions (a set is of course a multiset).

If $P$ or $Q$ is empty, the result is trivial. Otherwise, there are two cases depending whether $\Lambda \in P$.

If $\Lambda \notin P$, then $u = f(\Xi)$ and $f(\Xi) \overset{P}{\Rightarrow} f(\Xi) \overset{Q}{\Rightarrow} f(\Xi)$ with $s_1 \overset{P_i}{\Rightarrow} u_1 \overset{Q_i}{\Rightarrow} t_1$. Since $Q$ is rigid in $u$, then $Q_1$ is obviously rigid in $u_1$. Note further that in case two different subsets $Q_1$ and $Q_2$ are non-empty, $\text{glb}(Q) = \Lambda$ and $\text{Var}(u_1|Q_1) \subseteq \text{Var}(u)$, the latter property being preserved by rewriting. Since $P_1 <_{mul} P$, by induction hypothesis, $s_1 \overset{Q_i}{\Rightarrow} u_1 \overset{Q_i}{\Rightarrow} t_1$, where $P_1 \cup Q_1 \leq_P Q_1'$. The orthogonal $\beta$-steps can be grouped together into $v \overset{P}{\Rightarrow} t$. For the $R$-steps, let $Q' = \bigcup_i i \cdot Q_i'$, hence $s = f(\Xi) \overset{Q}{\Rightarrow} f(\Xi) = v$. From $P_1 \cup Q_1 \leq_R Q_1'$ we deduce $P \cup Q \leq_R Q_1'$, which concludes this case.

If $\Lambda \in P$, then $u = (\lambda x. M N) P$ and $P = \{\Lambda\} \cup P'$, $P' = 1 \cdot P_1 \cup 2 \cdot P_2$ and $Q = 1 \cdot Q_1 \cup 2 \cdot Q_2$, where $P_1, Q_1 \in \mathcal{P}(\text{os}(M))$ and $P_2, Q_2 \in \mathcal{P}(\text{os}(N))$ such that $M_w \overset{P_1}{\Rightarrow} M_{Q_1} \overset{P_2}{\Rightarrow} M_{Q_2}$. Since $P_1, Q_1 \in \mathcal{P}(\text{os}(M))$ and $P_2, Q_2 \in \mathcal{P}(\text{os}(N))$ such that $M_w \overset{P_1}{\Rightarrow} M_{Q_1} \overset{P_2}{\Rightarrow} M_{Q_2}$.

If $P \cup Q = \{\Lambda\}$, we only need to show that $s \overset{Q'}{\Rightarrow} v \overset{R}{\Rightarrow} t$ for some $Q'$ and $v$ yet to be defined. There are two cases, depending whether $Q_2 = \emptyset$, the first one being itself split into two:

1. $Q_2 \neq \emptyset$, a case depicted at Figure 4. Let $w = (\lambda x. M N) w \overset{P'}{\Rightarrow} u \overset{Q}{\Rightarrow} t$. Since $P' \not\geq_R P$ and $P' <_{mul} P$, by induction hypothesis, $w \overset{Q}{\Rightarrow} (\lambda x. M N_0) \overset{P'}{\Rightarrow} t$. Hence $M_w \overset{Q}{\Rightarrow} M_0$ and $N_w \overset{Q}{\Rightarrow} N_0$.

(a) $Q_1 \neq \emptyset$, hence $\text{glb}(Q) = \Lambda$. Since $Q$ is a rigid set of positions in $u$, no variable bound above $Q_1$ in $u$ can occur in $M|\{Q_1\}$. It follows that $x \notin \text{Var}(M|\{Q_1\})$ and furthermore that $\beta$-reductions at $P_1$ do not instantiate terms at $Q_1$, and therefore $x \notin \text{Var}(M|\{Q_1\})$. By repeated applications of monotonicity Lemma 3.12, it follows that $s = M_w\{x \mapsto N_0\} \overset{Q}{\Rightarrow} M_0\{x \mapsto N_0\}$, where $Q' = Q_1' \cup \{o \cdot Q_2' : M_w|o = x\}$ is a set of parallel positions.

(b) $Q_1 = \emptyset$. Then $M_0 = M_w$ and $s \overset{Q}{\Rightarrow} M_0\{x \mapsto N_0\}$, where $Q' = \{o \cdot Q_2' : M_w|o = x\}$ is a set of parallel positions.

Since $t \overset{R}{\Rightarrow} v = M_0\{x \mapsto N_0\}$, we can conclude in both cases.

2. $Q_2 = \emptyset$, hence $N_0 = N$, a case depicted in Figure 5. This time, the variable $x$ may occur below the $R$-redexes in $M$, but there are no redexes in $N$. We split the orthogonal step into three parts:

$$u = (\lambda x. M N) \overset{2 \cdot P_1}{\Rightarrow} (\lambda x. M N_w) = w \overset{\Lambda}{\Rightarrow} M\{x \mapsto N_w\} \overset{P_1}{\Rightarrow} M_0\{x \mapsto N_w\} = s$$

rewrites at $1 \cdot Q_1 \neq 2 \cdot P_2$, $(\lambda x. M N) \overset{Q}{\Rightarrow} (\lambda x. M_{T} N_w) \overset{2 \cdot P_2}{\Rightarrow} (\lambda x. M_{T} N) = t$. By stability Lemma 3.13 used at all positions in $Q_1$, $M\{x \mapsto N_w\} \overset{Q}{\Rightarrow} M\{x \mapsto N_w\} \overset{\Lambda}{\Rightarrow} (\lambda x. M_{T} N_w)$.

Since $P \not\geq_P Q$, then $P_1 \not\geq_P Q_1$. Besides, since $Q$ is rigid in $u$ and $Q_2 = \emptyset$, then $Q_1$ must be rigid in $M$ and since substitutions do not capture variables, $Q_1$ is rigid in $M\{x \mapsto N_w\}$. We can therefore apply the induction hypothesis to $M_0\{x \mapsto N_w\} \overset{P_1}{\Rightarrow} M\{x \mapsto N_w\} \overset{Q}{\Rightarrow} M\{x \mapsto N_w\}$, which gives $s = M_0\{x \mapsto N_w\} \overset{Q}{\Rightarrow} M'\{x \mapsto N_w\} \overset{P_1}{\Rightarrow} M_0\{x \mapsto N_w\} = v$, where $P \cup Q \geq_P Q'$.
We can now address the problem of confluence of a higher-order rewrite theory $\lambda F$.

We assume given a set $\mathcal{Rll}$ of left-linear rewrite rules, and will consider the case where the relation generated by $\mathcal{Rll}$ is terminating. The other rewrite relations to be considered are $=_\alpha$ and $\beta$. For $\beta$, we shall need orthogonal reductions, as previously defined, introduced by Tait under the name of parallel reductions for showing confluence of the $\lambda$-calculus.

**Theorem 6.1.** Let $\mathcal{Rll}$ be a terminating, left-linear rewrite system whose critical pairs are all joinable with $\mathcal{Rll} \cup \alpha \cup M\eta$. Then $\lambda F$ is confluent.

**Proof.** Let $\rightarrow = \rightarrow_{\mathcal{Rll}} \cup \otimes \Rightarrow_{\mathcal{Rll}} \beta$. The relations $\rightarrow_{\mathcal{Rll}}$ and $\rightarrow_{\lambda F}$ verify the assumptions of the following basic property: assume $\langle 1 \rangle \subseteq 2 \subseteq 1$ and then Church-Rosser of $\rightarrow_{\mathcal{Rll}}$ implies Church-Rosser of $\rightarrow_{\lambda F}$. We will therefore apply van Oostrom’s decreasing diagram method to the relation $\rightarrow_{\lambda F}$ and conclude that $\rightarrow_{\lambda F}$ is confluent on the set of closed terms. To this end, we use for labels ordered pairs defined as follows: $\langle 0, u \rangle$ for $u \rightarrow_{\lambda F} v$; and $\langle 1, \bot \rangle$ for $u \otimes v$, $\bot$ being a “don’t care” constant. Labels are compared lexicographically, the first argument in the order on natural numbers, the second in the order $\rightarrow_{\lambda F}$, $\bot$ being chosen minimal.

We now show that all local peaks have decreasing diagrams.

Let $s \rightarrow_{\mathcal{Rll}} u \rightarrow_{\lambda F} t$ be an arbitrary local peak, where $s, u, t$ are closed terms, and $P, Q$ are either a set of orthogonal positions (for $\beta$) or a single position (for $\mathcal{Rll}$).

1. First, rewrite steps of monotonic relations always commute when $P \# Q$, yielding a DD.

We are now left with all peaks for which $\neg (P \# Q)$, which we consider in turn:

1. Orthogonal $\beta$-reductions are known to be joinable in at most one step from each side, hence $s \otimes \Rightarrow_{\mathcal{Rll}} v \otimes \Rightarrow_{\mathcal{Rll}} t$ for some $P’, Q’, v, a DD$. (2) $s \leftarrow_{\mathcal{Rll}} u \rightarrow_{\lambda F} t$. Orthogonal $\beta$-reductions are known to be joinable in at most one step from each side, hence $s \otimes \Rightarrow_{\mathcal{Rll}} v \otimes \Rightarrow_{\mathcal{Rll}} t$ for some $P’, Q’, v, a DD$. (3) $s \leftarrow_{\mathcal{Rll}} u \rightarrow_{\lambda F} t$. Orthogonal $\beta$-reductions are known to be joinable in at most one step from each side, hence $s \otimes \Rightarrow_{\mathcal{Rll}} v \otimes \Rightarrow_{\mathcal{Rll}} t$ for some $P’, Q’, v, a DD$. (4) $s \leftarrow_{\mathcal{Rll}} u \rightarrow_{\lambda F} t$. Orthogonal $\beta$-reductions are known to be joinable in at most one step from each side, hence $s \otimes \Rightarrow_{\mathcal{Rll}} v \otimes \Rightarrow_{\mathcal{Rll}} t$ for some $P’, Q’, v, a DD$. (5) $s \leftarrow_{\mathcal{Rll}} u \rightarrow_{\lambda F} t$, where $i : L \rightarrow R \in \mathcal{Rll}$. The proof of this case is shown in Figure 6.

From Lemma 5.14 we have $s \leftarrow_{\mathcal{Rll}} u \leftarrow_{\mathcal{Rll}} u$ with $O = P \cup Q \cup R$ such that $P \# q$, $Q \geq_p q$, and $R <_p q$. Besides, since $u(q) \in F$, then $q \notin O$ and $Q >_p q$. By commutation we easily get...
We therefore cannot apply our theorem to the untyped theory of global states as it is. However, it is
this subset contains all typed terms, for whatever type discipline is considered for which
\( \vdash \) taking 
\( \beta \)
val
By Lemma 5.1, all cases have been considered, we are therefore done.

Note that the last case in the proof is actually a generalization of (APO\( \Lambda \)) and (LAPO\( \bar{B} \)) to an
arbitrary local peak between \( \beta \)- and \( \\beta ll \)-rewrites, which we could have been singled out.

**Example 6.2.** SOL [10] shows the confluence of the theory of global states for the case of simple
types with prenex polymorphism. We show below that it is confluent for any type discipline. To this
end, we need to show first that its untyped version is terminating, and then, that the critical pairs
are joinable. Unfortunately, it is not terminating, as exemplified by the following reduction with
\( \ul \): taking \( V = 1k(\lambda v.v) \) and \( X = \lambda v.v \), we get \( \text{ud}(1k(\lambda v.v), 1k(\lambda v.v)) \to \text{ud}(1k(\lambda v.v), 1k(\lambda v.v)) \).

We therefore cannot apply our theorem to the untyped theory of global states as it is. However, it is
easy to see that, in the absence of \( \beta \)-reduction, \( \ul \) is the only troublesome rule, since it duplicates
its meta-variable \( V \). In the typed version of the theory of global states, the meta-variable \( V \) inhabits
\( \text{Val} \), a possibly infinite set of values that can’t contain expressions built from \( 1k \) and \( \text{ud} \), hence
preventing from any infinite reduction using rules in the theory.

We therefore show confluence of the rules for a subset of expressions for which the rules can be
shown terminating. Several such subsets can be considered. An easy one is to keep some typing,
\( 1k : (\text{Val} \to * ) \to * \) and \( \text{ud} : \text{Val} \to * \), where * denotes the whole set of expressions so obtained.
This subset contains all typed terms, for whatever type discipline is considered for which \( \text{Val} \) is that
base type. The set of rules can then be proved terminating on that subset of terms by interpreting a
term \( s \) by the natural number \( m + n \), where \( m \) and \( n \) are the number of occurrences of \( 1k \) and \( \text{ud} \) in \( s \), respectively. Since all meta-variables in the rules have elements of type * as arguments, the
\( \beta \)-reductions associated to their instantiation can’t increase the number of \( 1k \) and \( \text{ud} \), hence all
rules have a strictly decreasing interpretation, implying termination.

We are left with verifying the joinability of critical pairs of the obtained set of rules. Because
the first argument of \( \text{ud} \) belongs to a subset of expressions which is left unknown, we will have
to make sure that in any critical pairs, and in their reducts when showing joinability, no terms is
generated for which the first argument of \( \text{ud} \) is not in that set. The rules being typed, this should
indeed be the case if all unification rules preserve typing, which is indeed the case provided all
fresh variables and meta-variables used are assigned the appropriate type.

These computations are presented inside individual boxes. In the upper middle of each box
appear two left-hand sides of rules whose superposition is inside braces. The upper left-hand side
is displayed in red, the lower one in blue. In case lifting is needed, this happens with the 3rd to 7th
critical pairs, the new bound variables originating from the upper red rule that are added as new
arguments to the meta-variables of the inner blue rule appear in red – we have not changed the
meta-variable name, as in the definition of lifting. Next comes the most general unifier, then the
colored right-hand sides, then the reduced right-hand sides, and finally the joinability verification
itself, sometimes just an equality test. Colored rule names label the arrows.

The most general unifiers obtained when computing the critical pairs of the theory of global
states described at Section 3.7 are not identical for both choices of rules, although very similar
since they capture the same sets of ground instances. The joinability computations are not identical
for both sets either, since they depend upon the number of arguments of the meta-variables in the
right-hand sides of the rules. Actually, all right-hand sides are the same except for \( \ul \), this will
impact four critical pairs only. Our choice for making the calculations is the second set.
\[
\begin{align*}
\text{ud}(V, \{ & \lambda v. U \} ) \\
\text{ud}(V, X[V]) \sigma & = \text{ud}(V, U) \\
\text{ud}(V, U) & = \text{ud}(V, U) \\
\end{align*}
\]
want to encode the properties of our own notion of rewriting which are critical for developing our results. Finally, encoding our setting into either HRS or HORS would break the monotonicity and stability of our notion of higher-order rewriting in their notion is certainly possible but not exactly trivial.

One main reason is that we always insist, in Dedukti, donk’s higher-order rewriting systems (HORS, [29]), and then encode our setting within theirs. One may wonder why we did not consider a well-known setting, like Klop’s combinatory reduction systems (CRS, [16]) or Nipkow’s higher-order rewriting (HRS), or van Oostrom and van Raamsdonk’s higher-order rewriting systems (HORS, [29]), and then encode our setting within theirs. One main reason is that we always insist, in Dedukti, in using shallow encodings, hence do not want to encode the \( \lambda \)-calculus itself as a higher-order calculus in such a setting. Further, our notion of meta-variable has a fixed arity but may have missing arguments, which is unusual: encoding our notion of higher-order rewriting in their notion is certainly possible but not exactly trivial. Finally, encoding our setting into either HRS or HORS would break the monotonicity and stability properties of our own notion of rewriting which are critical for developing our results.

Hence, most critical pairs are just joinable, with two exceptions: the second is joinable modulo \( M\eta \), and the 6th is joinable modulo \( \alpha \)-renaming. Note that all terms involved in these computations satisfy the typing restriction required for termination of the rules. It follows that the theory of global states for a single location preserves confluence of the \( \beta \)-rule in the subset of pure \( \lambda \)-calculus that satisfy the typing restriction. Note also that only the first and third critical pairs are (trivially) development closed. The 7th is not development closed either, despite the fact that there is a single rewrite from the appropriate side of the critical pair, but the rewrite position is not below the overlap occurrence.

### 7 IMPACT AND RELATED WORK

One may wonder why we did not consider a well-known setting, like Klop’s combinatory reduction systems (CRS, [16]) or Nipkow’s higher-order rewriting (HRS), or van Oostrom and van Raamsdonk’s higher-order rewriting systems (HORS, [29]), and then encode our setting within theirs. One main reason is that we always insist, in Dedukti, in using shallow encodings, hence do not want to encode the \( \lambda \)-calculus itself as a higher-order calculus in such a setting. Further, our notion of meta-variable has a fixed arity but may have missing arguments, which is unusual: encoding our notion of higher-order rewriting in their notion is certainly possible but not exactly trivial. Finally, encoding our setting into either HRS or HORS would break the monotonicity and stability properties of our own notion of rewriting which are critical for developing our results.
We address, in this last section, an important remaining question. To which kind of dependent type theories do our results apply? In particular, do they apply to the previous settings?

7.1 Relationship to Nipkow’s higher-order rewriting

Nipkow’s rewriting assumes terms to be simply typed, but it can be easily extended to other typing disciplines. The major requirement is indeed that β-reduction is strongly normalizing as well as η-expansion. The latter is obtained by restricting its application to functionally typed terms (which can be obtained in our case by controlling the arity of expressions).

Assuming a subset \( T \) of the set of terms that satisfies these assumptions, we denote by \( u_π^γ \) and \( u_π^γ ρ \), the \( β \)-normal form, the \( η \)-expanded form and the \( β \)-normal \( η \)-expanded form, respectively, possibly omitting indices and exponents when convenient.

A rule “à la Nipkow” assumes \( η \)-expanded left-hand side patterns and \( η \)-expanded right-hand sides, as well as fully applied meta-variables of arity zero. To have both Nipkow’s rewriting relation and ours defined in our setting, the pre-redex \((X \bar{x})\) in a Nipkow’s pattern will correspond in our syntax to the pre-redex \(X[x]\) in which \( |X| = |\bar{x}| \). It follows that a rule will have two different writings dubbed Klop and Nipkow, respectively. We will denote by \( R_{kp} \) the set of higher-order Klop rules, corresponding to a set \( R_{nw} \) of Nipkow rules, which must therefore be in \( η \)-expanded form.

In the Nipkow case, because meta-variables have arity zero, Klop’s notion of substitution is nothing but the usual higher-order substitution. The meaning of the same expression \( Lσ \) for some left-hand side of rule \( L \) will therefore depend on whether the rule \( L \rightarrow R \) belongs to \( R_{nw} \) or \( R_{kp} \); the equality \( u = Lσ \) when \( L \) is a Klop left-hand side of rule becomes \( u = ρ_0 \ L ‘σ’ \) for the corresponding Nipkow left-hand-side of rule \( L’ \). The same applies to unification of left-hand sides.

We now make these remarks formal:

Definition 7.1. \( u \xrightarrow{p} v \) for \( L \rightarrow R \in R_{nw} \) iff \( u = u_π^γ \), \( u|_p = ρ_0 \ Lσ \) for some \( β \)-normal \( η \)-expanded substitution \( σ \) and \( v = u[Rσ]_p^γ \).

We write \( u \xrightarrow{p} v \) when \( u \xrightarrow{p} v \) for some \( L \rightarrow R \in R_{nw} \). As it is known that \( η \)-expanded forms are closed under β-reduction and substitution, we have:

Lemma 7.2. If \( u \xrightarrow{p} R_{nw} v \) then \( u = u_π^γ \) and \( u \xrightarrow{p} R_{kp} \ β \rightarrow v = v_π^γ \).

Lemma 7.3. For all \( u \in T \) such that \( u \xrightarrow{p} R_{nw} v \) and \( v \in T \), \( u_π^γ \xrightarrow{p} R_{nw} v_π^γ \).

Proof. We have \( u = [Lσ]_p = \bar{u}^p(Z \mapsto λ\bar{z}.Lσ) = \bar{u}^p γ \) and \( v = u[Rσ]_p = \bar{u}^p(Z \mapsto λ\bar{z}.Rσ) = \bar{u}^p θ \) with \( γ \rightarrow θ \). Since \( L \) is a pattern \( (Lσ) \downarrow L(σ) \downarrow \) and since it cannot be an abstraction we have, \( u_π^γ = ((\bar{u}^p γ) \downarrow) \uparrow (\bar{u}^p (γ) \downarrow) \uparrow \xrightarrow{R_{nw}} (\bar{u}^p (Z \mapsto λ\bar{z}.R(σ) \downarrow)) \uparrow = v_π^γ \) \( \square \)

Corollary 7.4. If \( u \xrightarrow{p} R_{nw} v \) then \( u_π^γ \xrightarrow{p} R_{nw} v_π^γ \).

Lemma 7.5. Assume a rewrite system \( R \) such that \( \xrightarrow{β} \cup \xrightarrow{β} \) is Church-Rosser. Then \( \xrightarrow{β} \cup \xrightarrow{β} \) is Church-Rosser on \( β \)-normal \( η \)-expanded terms of \( T \).

Proof. Assume \( u \xrightarrow{β} R_{nw} \cup β \xrightarrow{β} v \). Then by Lemma 7.3, \( u = u_π^γ \), \( v = v_π^γ \) and \( u \xrightarrow{β} R_{nw} \cup β \xrightarrow{β} v \). By assumption, \( u \xrightarrow{β} R_{kp} \cup β \xrightarrow{β} R_{kp} \) and by Corollary 7.4, \( u \xrightarrow{β} R_{nw} \cup β \xrightarrow{β} v \). \( \square \)

Theorem 7.6. Assume $R$ is a left-linear system such that all critical pairs are joinable using $\longrightarrow_{\text{kp}}$ and $R$ is strongly normalizing. Then $\longmapsto_{\text{ll}}$ is Church-Rosser on $\beta$-normal $\eta$-expanded terms of $T$.

Proof. $\longrightarrow_{\text{R}}$ satisfies the hypotheses of Theorem 6.1. We conclude that $\longrightarrow_{\beta} \cup \longrightarrow_{R}$ is Church-Rosser and by Lemma 7.5, $\longmapsto_{\text{ll}}$ is too on $\beta$-normal $\eta$-expanded terms of $T$. $\square$

This result is of course not really surprising, since it is known to hold for various type systems for which $\beta$-reductions terminate, in which case $T$ is the set of typable terms. What’s new here is only that we abstract from a particular typing discipline.

7.2 Modularity of higher-order confluence

In [30], van Oostrom and van Raamsdonk show that higher-order rewriting enjoys Toyama’s modularity property when rules are left-linear: the union of two confluent higher-order linear rewriting systems (in their sense) that have no non-trivial critical pairs is confluent. This suggests an alternative way for proving that $\mathcal{R}_{\text{ll}} \cup \beta$ is confluent: first, encode $\beta$ as a (linear) higher-order rewriting system made of one rule $\text{beta} : \text{app}(\text{lam}(\lambda x. X[x]), U) \rightarrow X[U]$. It is well-known that this encoding is a faithful (simply typed) encoding of the lambda-calculus [16]. Assuming now a higher-order rewriting system $\mathcal{R}_{\text{ll}}$ in our sense, that is, in particular, left-linear and having no abstraction as left-hand side, then $\mathcal{R}_{\text{ll}}$ and $\text{beta}$ have no critical pair. Assuming now that the result of van Oostrom and van Raamsdonk applies, we could deduce the confluence property of the union from the confluence of $\text{beta}$ (a well-know fact) and of $\mathcal{R}_{\text{ll}}$. Now, it is easy to deduce the confluence property of $\mathcal{R}_{\text{ll}}$ from our assumptions: since $\mathcal{R}_{\text{ll}}$ is terminating, it suffices to prove its local confluence, which follows from Lemmas 5.1, 5.4, 5.10, 3.12 and 3.13, the last two being used to show that the joinability of critical pairs can be lifted to all overlapping peaks, as is done in the proof of Theorem 6.1.

It would therefore make sense to show that the modularity result of van Oostrom and van Raamsdonk applies to our setting. Note however that our technique is more informative: it tells us more precisely how local confluence diagrams are decreasing via the order used on proofs [15, 17].

7.3 Applicability to theories with annotated abstractions

Although one could fear that the present setting becomes too specific for a wide application, we believe that this is not the case, and that it can be used to show confluence of rewrite rules in several dependent type theories without difficulty, as well as for other, related rewrite relations, as we have shown with Nipkow’s higher-order rewriting.

In some dependent type theories, such as Martin-Löf Type Theory, abstractions need to be annotated in order to guarantee typing properties such as decidability of type checking. Our setting supports type annotations through encodings, for instance using a dedicated symbol $a \in X$ and considering $\lambda x : A.t$ to be syntactical sugar for $a(A, \lambda x.t)$ or $\lambda x.a(A, t)$. In the first case, the $\beta$ rule itself becomes a rewrite rule headed with the $a$ symbol which is not only non-terminating, preventing the use of our criteria, but also defies its very purpose which was based on the study of the interactions between the first-class $\beta$ reduction and well-behaved rewrite rules. In the second case $\beta$ reduction leaves a dangling “a” symbol which can freeze further use of the $\beta$ rule, for instance as in $((\lambda x : B.\lambda y : A.x) \; u) = ((\lambda x.a(B, \lambda y.a(A, x)) \; u) \rightarrow (a(B, \lambda y.a(A, u))) \; t)$ which is no longer a $\beta$-redex and requires some annotation erasure to proceed. This type erasure cannot simply be stated as an extra rewrite rule as it needs to be controlled: $\lambda x : A.t$ and $\lambda x : B.t$ should remain convertible only if $A$ and $B$ are.
Note that in some dependently typed systems, such as the Pure Type Systems [4] or the Calculus of Inductive Constructions [3], type erasure was proven to be safe and allows faster conversion check of well-typed terms. It is our understanding however that properties of the type system are critical to ensure this irrelevance of type annotation which can only be used for computation optimizations once the type system has been proven to be well-behaved, which usually requires to prove first the confluence of (annotated) reduction. As we study confluence on untyped terms, we cannot rely on this kind of type erasure.

Our solution would be to simply extend the definition of terms to add a type annotation to the syntax of abstractions. This requires to redefine the $\beta$ rule while keeping it first-class. In particular, the fringe $F_\beta = \{11, 12, 2\}$ is extended, orthogonal reduction may occur simultaneously in the body and the annotation of an abstraction, the unification and matching algorithm need to take the annotation into account. All properties of our development remain true in this extended setting, in particular: $\otimes \Rightarrow \beta$ still has the diamond property, the definition of patterns keeps forbidding overlap between rewrite rules and $\beta$-redexes which is the key property for our theorem, commutation lemmas such as Lemma 5.2 (LAP$\beta$A), Lemma 5.4 (LAPR$A$), Lemma 5.16 (LAPO$B$) and Lemma 5.17 (APOA). This is the approach taken in the (submitted) PhD thesis of the first author and in a recent work of ours addressing the same confluence problem in case the user’s higher-order rewrite rules are not left-linear.

8 CONCLUSION

Confluence of first-order rewrite rules is well understood, in both the terminating and non-terminating cases. Confluence of left-linear higher-order rules on simply-typed $\lambda$-terms is well understood too [18]. This is true as well of confluence of first-order rules in presence of $\beta$-reductions for any type discipline for which $\beta$ is terminating [6].

A dependently typed system, as we have seen, imposes the use of meta-variables whose arity is not fixed, a need which is not encountered in non-dependent type systems. Our language of untyped expressions must therefore cope with that peculiarity, and include meta-variables whose number of arguments can vary. This makes the use of existing frameworks difficult, as we have argued in Section 7. This paper includes therefore our own variant of an untyped $\lambda$-calculus, and a notion of substitution for meta-variables inspired from Klop’s combinatory reduction systems which makes the definition of higher-order rewriting surprisingly simple and easy to manipulate.

In this paper, we have described a condition on critical pairs which ensures preservation of confluence in the untyped $\lambda$-calculus by a set $Rll$ of rewrite rules whose left-hand sides are left-linear patterns: if $Rll$ is terminating and the critical pairs of $Rll$ are joinable by rules of $Rll$, modulo $\alpha$-renaming and extensibility for meta-variables. The $\beta$-rule itself, on the other hand, cannot be used to join the critical pairs. In that case, confluence can be obtained by joining nested critical pairs, as will be shown in a forthcoming paper. This other result does not subsume the present one, since nested critical pairs may be infinitely many, as is the case with the theory of global states for a unique location [8], for which four infinite families of critical pairs are generated whose joinability uses a proof by (a simple) induction.

In order to define critical pairs, we had to unify left-linear patterns, where patterns are specific untyped $\lambda$-terms whose definition ensures that erasing types from a simply-typed pattern in Miller’s sense yields a pattern in our sense. Untyped patterns enjoy most general unifiers, in the same way as Miller’s patterns do. Note that unification here looks purely syntactic, thanks to a definition of substitution which incorporates $\beta$-reductions. The linearity restriction is useful to simplify the resolution of equational problems, but not essential.
One may wonder whether considering parallel higher-order critical pairs could improve our results. The difficulty here is that one of the decreasing diagrams for free, Lemma 5.4, breaks down. It can of course be repaired, at the price of imposing that meta-variables do not occur nested in one another in the right-hand sides of the rules. This restriction looks very strong. However, any expression such as \( X[Y] \) can be transformed into \( (X \cdot Y) \), hence eliminating the nesting. There is of course a general transformation that will eliminate all nestings, making the use of parallel rewriting (and therefore parallel critical pairs) look attractive. The problem however, is that right-hand sides such as \( (X \cdot Y) \) may result in the use of \( \beta \)-steps to join the critical pairs, hence the joinability diagrams would not be decreasing. This may or may not happen. It is certainly possible to exhibit examples for which this transformation would work. We have not encountered such a natural example so far.

The case of non-left-linear rules is not touched at all here, it is indeed much more difficult since adding such rules to the untyped \( \lambda \)-calculus results, in general, in losing confluence, as shown by Klop [16]. We however show in another forthcoming paper that for all Klop’s counter-examples, confluence is preserved on appropriate subsets of \( \lambda \)-terms, hence showing a way to get around this difficulty. Of course, the presence of non-left-linear patterns requires adding appropriate rules for matching and unification, but that’s the easy part of the problem.

Acknowledgments: to Frédéric Blanqui for useful remarks, Gilles Dowek for many discussions, Jiaxiang Liu for reading an earlier draft, Vincent van Oostrom for his many suggestions and corrections to that earlier draft, as well as the referees for their many relevant questions about the first version of the manuscript, which lead us to improve our framework substantially.
