**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

# Observational Equality: Now For Good

LOÏC PUJET, Inria, France

NICOLAS TABAREAU, Inria, France

Building on the recent extension of dependent type theory with a universe of definitionally proof-irrelevant types, we introduce  $\text{TT}^{\text{obs}}$ , a new type theory based on the setoidal interpretation of dependent type theory.  $\text{TT}^{\text{obs}}$  equips every type with an identity relation that satisfies function extensionality, propositional extensionality, and definitional uniqueness of identity proofs (UIP). Compared to other existing proposals to enrich dependent type theory with these principles, our theory features a notion of reduction that is normalizing and provides an algorithmic canonicity result, which we formally prove in AGDA using the logical relation framework of Abel et al. Our paper thoroughly develops the meta-theoretical properties of  $\text{TT}^{\text{obs}}$ , such as the decidability of the conversion and of the type checking, as well as consistency. We also explain how to extend our theory with quotient types, and we introduce a setoidal version of Swan’s Id types that turn it into a proper extension of MLTT with inductive equality.

CCS Concepts: • **Theory of computation** → **Type theory**.

Additional Key Words and Phrases: type theory, dependent types, rewriting theory, confluence, termination

## 1 INTRODUCTION

Dependent type theories and in particular MLTT, as originally developed by Martin-Löf [1975], provide an adequate framework for developing constructive mathematics and certifying software. A core aspect of MLTT is the coexistence of two distinct notions of equality: a *definitional* equality that records the equations automated by the system, and a *propositional* equality that is a type internal to the system and thus can be used to do equational reasoning. However, the propositional equality of MLTT lacks some extensionality principles that pervade mathematical reasoning, such as function extensionality (funext). Since they are generally considered desirable, these principles are sometimes added as axioms, but doing so results in a system with weaker computational properties.

Throughout the years, several options to obtain a more extensional version of propositional equality while preserving computation have been explored. The most successful lines of work can be roughly divided into two groups: the ones using an observational equality, and the ones using a cubical equality. Both notions build on the following fundamental idea: in order to obtain sufficient extensionality principles, the behavior of equality in a given type should be explicitly specified for every type instead of using a single definition that is parametric over the types.

The work on observational equality originated from the study of the setoid model of type theory [Altenkirch 1999; Hofmann 1995], and a first attempt at a proper type theory that supports an observational equality satisfying funext has been proposed in [Altenkirch et al. 2007]. In these systems, observational equality equips every type with a setoid structure. This setoidal equality satisfies the uniqueness of identity proofs (UIP), which states that all proofs of an equality are equal; in other words, equality is proof irrelevant.

POPL, 2022, jsp

. ACM ISBN 978-x-xxxx-xxxx-x/YY/MM.

50 The other line of work is more recent and takes its roots in the formulation of the univalence  
 51 axiom [Kapulkin and Lumsdaine 2018; Univalent Foundations Program 2013], which gives a new  
 52 meaning to the equality between types: two types are equal when they equivalent. This can be  
 53 understood as an extensionality principle for the universe of types. In their search for a compu-  
 54 tational interpretation of univalence, Cohen et al. [2015] developed a notion of cubical equality,  
 55 which satisfies funext and univalence, but is incompatible with UIP.

56 Thus, observational equality and cubical equality are two diverging directions for providing  
 57 propositional equality with more extensionality. Altenkirch et al. [2016]; Capriotti [2017]; Voevodsky  
 58 [2013] advocate that the two solutions are actually complementary and can be integrated to a single  
 59 system with two universe hierarchies, one that satisfies univalence and the other that satisfies UIP.  
 60 While cubical type theory has been thoroughly investigated and even implemented in the AGDA  
 61 proof assistant Vezzosi et al. [2019], observational equality has not reached a comparable level  
 62 of maturity. Recent attempts to design a type theory based on observational equality are either  
 63 lacking an algorithm for type checking Sterling et al. [2019], or restricted to a single universe and  
 64 having computational properties only up to a conjecture Altenkirch et al. [2019]. Indeed, the latter  
 65 relies on computation in an enriched version of MLTT that features a universe of definitionally  
 66 proof-irrelevant types (noted hereafter  $\Omega_i$ ) as recently proposed by Gilbert et al. [2019], along with  
 67 a proof-irrelevant identity type that supports a strong eliminator. This theory has not been justified  
 68 yet, and it has even been shown not to be normalizing in presence of impredicativity Abel and  
 69 Coquand [2020].

70 In this paper, we define  $\text{TT}^{\text{obs}}$ , the first extension of  $\text{MLTT} + \Omega_i$  with an observational equality  
 71 that satisfies UIP, funext and propext, and supports quotient types and countably many universes  
 72 —with a proof of normalization and canonicity formalized in AGDA.<sup>1</sup> Firstly, we remark that this  
 73 theory can only be derived in a system with some level of cumulativity, as it is required for certain  
 74 computation rules to be well-typed. This makes explicit some difficulties that do not show up in  
 75 previous works. Second, we remark that our version of observational equality can be equipped  
 76 with two elimination principles: a notion of type cast (or coercion) for proof relevant types, and  
 77 the standard eliminator of MLTT for proof irrelevant types, thus making all the setoidal structure  
 78 derivable from the standard eliminator. Funext and propext are obtained by specifying the right  
 79 computation rules for observational equality whereas UIP is obtained for free by interpreting  
 80 observational equality in  $\Omega$ .

81 The proof of normalization and canonicity is based on the use of logical relations defined in  
 82 AGDA using induction-recursion as initially developed by Abel et al. [2018] and later extended  
 83 to  $\Omega$  by Gilbert et al. [2019]. Compared to previous work on formalized normalization proofs,  
 84 we have added the support for a cumulative hierarchy with two universes, and we make a clear  
 85 distinction between inhabitants of proof-irrelevant types, which have no computational behavior,  
 86 and inhabitants of proof relevant types, which do. This key change allows us to add new principles  
 87 in  $\Omega$  without having to supply them with a computational behavior, trivializing for instance the  
 88 management of higher coherences of the cubical interpretation. In counterpart for this added  
 89 flexibility, normalization does not directly imply canonicity anymore, and a separate proof of  
 90 consistency of the theory is required to derive canonicity. This proof is done by defining a model  
 91 for  $\text{TT}^{\text{obs}}$ , but as consistency is the only consequence that we need from the existence of a model,  
 92 the model can be defined in an extensional setting.

93 To illustrate the simplicity of extending  $\text{MLTT} + \Omega$  to  $\text{TT}^{\text{obs}}$ , we have implemented a simple version  
 94 in AGDA using rewrite rules, as recently introduced by Cockx et al. [2021] (file [setoid\_rr.agda]).

96 <sup>1</sup>The formalization is available at <https://github.com/CoqHott/logrel-mltt/>, references to a particular file are done using  
 97 [myfile.agda] which directly points to the corresponding file on github.

Fig. 1. Syntax of  $\mathbb{T}\mathbb{T}^{\text{obs}}$ 

110  
111  
112  
113  
114 *Plan of the paper.* In Section 2, we present the syntax and typing rules of  $\mathbb{T}\mathbb{T}^{\text{obs}}$ , focusing on its  
115 notions of conversion and reduction. Then in Section 3, we develop the logical relation framework,  
116 and the model from which we derive consistency. This shows normalization, canonicity and  
117 decidability of typechecking for  $\mathbb{T}\mathbb{T}^{\text{obs}}$ . In Section 4, we explain how to extend  $\mathbb{T}\mathbb{T}^{\text{obs}}$  to support  
118 quotient types, box types and squash types, as well as the standard identity type of MLTT, while  
119 preserving meta-theoretical properties.

## 120 2 A TYPE THEORY WITH OBSERVATIONAL EQUALITY

121  $\mathbb{T}\mathbb{T}^{\text{obs}}$  has two cumulative hierarchies of universes. The first one, which we write  $\mathcal{U}_i$  (where  $i$  is  
122 a natural number), is the usual universe hierarchy of Martin-Löf type theory. The second family,  
123 which we write  $\Omega_i$ , is the family of *definitionally proof-irrelevant types*, which means that any two  
124 inhabitants of a type  $A : \Omega_i$  are convertible. This corresponds to the two hierarchies presented  
125 in Gilbert et al. [2019] and implemented in AGDA, except that we also introduce some cumulativity  
126 features that will prove useful when interpreting equality in the universe of propositions and for  
127 dependent function types. Having a proof-irrelevant hierarchy of types seems to be crucial to  
128 interpret an extensional equality that satisfies UIP. Indeed, it trivializes all of the higher coherences  
129 that naturally arise when considering proofs of equality between equalities, and provides a canonical  
130 inhabitant for the type that encodes UIP, which is simply given by reflexivity.

### 132 2.1 Syntax of $\mathbb{T}\mathbb{T}^{\text{obs}}$

133  
134 The syntax of the sorts, contexts, terms and types of  $\mathbb{T}\mathbb{T}^{\text{obs}}$  is specified in Fig. 1. The theory features  
135 cumulative dependent functions (noted  $\Pi_{s,i}^j(x : A). B$ ) with  $\eta$ -equality, natural numbers, as well  
136 as proof-irrelevant dependent sums (noted  $\exists(x : A). B$ ), a proof-irrelevant empty type (noted  $\perp$ )  
137 and unit type (noted  $\top$ ). When  $B$  does not depend on  $A$ , we write  $A \rightarrow B$  instead of  $\Pi(x : A). B$ ,  
138 and  $A \wedge B$  instead of  $\exists(x : A). B$ . The capture-avoiding substitution of a variable  $x$  in a term  $A$  by  
139 the term  $t$  is noted  $B[x := t]$ .  $\mathbb{T}\mathbb{T}^{\text{obs}}$  can also be extended with more primitives such as quotients  
140 or general inductive types, but we defer the treatment of those to Section 4 to better focus on the  
141 treatment of equality in the theory.

142 Compared to MLTT with proof irrelevant types, there are two fundamental new ingredients in  
143  $\mathbb{T}\mathbb{T}^{\text{obs}}$ . The first is a proof-irrelevant observational equality type  $t \sim_A u$  that encodes equality of  $t$   
144 and  $u$  at type  $A$ , together with a term  $\text{refl}(t)$  that witnesses reflexivity of this equality. The second  
145 is an operation that casts a term  $t$  from a type  $A$  to another type  $B$  according to a proof of equality  $e$   
146 between  $A$  and  $B$ , which is noted  $\text{cast}(A, B, e, t)$ . This operation comes with a witness  $\text{castrefl}(A, t)$

that casting between a type  $A$  and itself does nothing. Note that since observational equality is proof irrelevant, any proof of equality between  $A$  and  $A$  is convertible to  $\text{refl}(A)$ . The theory also features a generic transport  $\text{transp}(t, B, u, t', e)$  when  $A$  and  $B$  are proof irrelevant.

Observational equality is quite different from the usual Martin-Löf Identity Type, which is an inductive type that computes via the  $J$ -eliminator. Instead, observational equality  $t \sim_A u$  should be understood as an eliminator that reduces the type  $A$  to its weak head normal form, and then reduces by pattern-matching on it, much like the path type from Cubical Type Theory. In particular, the reduction rules for observational equality between two dependent products, or two types in  $\Omega_i$  provide us with function extensionality and propositional extensionality by definition.

## 2.2 Typing Rules of $\text{TT}^{\text{obs}}$

The typing rules of  $\text{TT}^{\text{obs}}$  are presented in Fig. 2. They are based on four kinds of judgments:  $\vdash \Gamma$  (well-formedness of a context),  $\Gamma \vdash t :^{s,i} A$  (typing of a term),  $\Gamma \vdash t \equiv u :^{s,i} A$  (convertibility of terms), and  $\Gamma \vdash t \Rightarrow u :^i A$  (weak-head reduction of relevant terms). To avoid clutter, we will omit the  $^{s,i}$  annotations that denote the sort and level of a type as that can generally be inferred from the context.<sup>2</sup> Similarly, we will often omit the annotations on the dependent function type and simply write  $\Pi(x : A). B$ ; except when the annotations are explicitly required to understand a rule. In all the judgments,  $s$  denotes either  $\mathcal{U}$  or  $\Omega$ .

*Generic rules and universes.* Rules **CTX-NIL**, **CTX-CONS** and **VAR** describe the usual formation of contexts and typing of variables. Rule **CONV** stipulates that type checking is done modulo conversion of types. The formation rule for universes (Rule **UNIV**) states that both  $\mathcal{U}_i$  and  $\Omega_i$  are relevant types. It is natural for  $\Omega$  to be proof-relevant, since its inhabitants are types which are not convertible to one another despite being proof-irrelevant.

*Dependent products.* The formation of dependent products between a domain and a codomain that have different sorts and universe levels is allowed. The resulting type has the same relevance as the codomain, and a universe level that is higher than both the level of the domain and the level of the codomain (Rule **PI-FORM**). The sort of the domain and the levels of both the domain and the codomain are collected as annotations to the dependent function type for the convenience of the type checking algorithm. Note that the introduction of cumulativity in the formation of dependent products is a necessary complication of  $\text{TT}^{\text{obs}}$  as the rules that provide us with propositional extensionality and function extensionality can only be well-typed in the presence of cumulativity.

Rules **FUN** and **APP** are the usual rules of  $\lambda$ -abstraction and application. Note that the sort and level annotation are implicit as they can be inferred from the premises.

*Existential types.*  $\text{TT}^{\text{obs}}$  features proof-irrelevant dependent sums. They are required to describe the behavior of observational equality between two dependent function types. We do not need them to be cumulative so we keep the formation rule as simple as possible ( **$\exists$ -FORM**).

We give a negative presentation of dependent sums with one introduction rule (Rule **PAIR**) and two projections (Rules **FST** and **SND**). Note that because of proof irrelevance, the negative and positive presentations are completely equivalent, and we do not need any rule to account for the computational behavior of projections, nor  $\eta$ -equality. This is because any well-typed equality between two inhabitants of a proof-irrelevant type is proven by reflexivity (modulo Rule **CONV**).

*Natural numbers.* Strictly speaking, all inductive types could be excluded from the core of  $\text{TT}^{\text{obs}}$ , and be considered as extensions. However, we decided to treat the example of natural numbers as we feel it is both very simple and a good illustration.

<sup>2</sup>The interested reader may look at the AGDA formalization where all annotations have been made explicit.

Fig. 2.  $\text{TT}^{\text{obs}}$  Typing Rules

The type  $\mathbb{N}$  comes with a formation rule **N-FORM**, constructors **0** (Rule **ZERO**) and **S** (Rule **SUC**) and an elimination/induction principle given by Rule **N-ELIM**. Since we do not require cumulativity for the type of natural numbers, we decided to only allow it in the lowest universe  $\mathcal{U}_0$ , but it could be made to inhabit all relevant universes without added difficulty. Extensions to other inductive types and quotient types are presented in Section 4.

*Empty and Unit type.* To encode respectively the true equalities and the absurd equalities,  $\text{TT}^{\text{obs}}$  features the unit type  $\top$  and the empty type  $\perp$ . Besides its formation rule (Rule **⊥-FORM**), the

empty type comes with an elimination principle (Rule  $\perp$ -ELIM) that can eliminate it into both proof-irrelevant and proof-relevant types. In MLTT with a proof irrelevant universe hierarchy, this constitutes the unique connection between the proof-irrelevant and relevant types. This means that the only way to use information from a proof-irrelevant term to build a proof-relevant term is by using a proof of  $\perp$ , which amounts to proving that actually we are in an inaccessible branch or impossible case. In  $\mathbb{T}^{\text{obs}}$  however, there is another very different way of using proof irrelevant information to build a proof relevant term, by transporting (or casting) along a proof of equality.

The unit type on the other hand only requires a formation rule (Rule  $\top$ -FORM) and a constructor  $*$  (Rule  $\top$ -INTRO). It does not require an eliminator, since the usual one can be derived from proof irrelevance. Equivalently, we could have defined the unit type as  $\perp \rightarrow \perp$ . Note that both the unit type and the empty types are made cumulative, that is because they are used as terminal cases for the computation of observational equality, which can live at any level.

*Setoid equality and Type Casts.* A central feature of  $\mathbb{T}^{\text{obs}}$  is that every proof-relevant type comes equipped with a proof-irrelevant equality type, noted  $t \sim_A u$  (Rule EQ-FORM) and a canonical way to inhabit it, by the reflexivity term  $\text{refl}(t)$  (Rule REFL). It is not necessary to equip proof-irrelevant types with a propositional equality, as two terms would always be propositional equal by reflexivity. As we will see in the definition of reduction (Fig. 4), the equality type of  $\mathbb{T}^{\text{obs}}$  should not be seen as a type constructor like the identity type of MLTT, but rather as a type eliminator that computes on its type argument and possibly on its two end points.

For this equality type to be of any use, we need to be able to eliminate it as well. The usual  $J$ -eliminator defined in MLTT can be defined in our context, but if the predicate is proof-relevant, there will be no hope for the eliminator to compute on reflexivity: since equality types are proof irrelevant, there is no reduction of equality proofs, and we cannot do pattern matching on the equality proof either. In order to avoid this issue, we restrict the use of  $J$  to proof-irrelevant predicates only, and note it  $\text{transp}$  (Rule TRANSPORT- $\Omega$ ). Note that in this setting, the non-dependent version of the eliminator would be enough, as one can prove the contractibility of singletons for free thanks to proof-irrelevance [Univalent Foundations Program 2013]. Using  $\text{transp}$ , we can derive the usual groupoid laws provided by the  $J$  eliminator, and we note  $e^{-1}$  for the inverse of  $e$ ,  $e \cdot e'$  for the transitivity, and  $\text{ap } f e$  for the preservation of equality by non-dependent function.

To deal with elimination of equality in a proof relevant context, we introduce a cast primitive that handles transport between two propositionally equal proof relevant types. Note that our cast operation also applies to proof-irrelevant types (Rule CAST). This is unnecessary as Rule TRANSPORT- $\Omega$  subsumes this case, but it will allow us to write more uniform reduction rules. The term  $\text{cast}(A, B, e, t)$  is an eliminator that reduces the types  $A$  and  $B$  in weak-head normal form, then reduces by pattern-matching on their head constructors. This will be explained in more detail in the next section. When applied to reflexivity,  $\text{cast}$  does not compute as the identity function, but this equality is propositionally admissible as witnessed by  $\text{castrefl}$  (Rule CAST-REFL).

### 2.3 Conversion and Reduction to Weak-Head Normal Forms

Conversion (Fig. 3) subsumes reduction (RED-CONV),  $\eta$ -equality of functions (Rule  $\eta$ -EQ), and proof-irrelevance (Rule PROOF-IRRELEVANCE). It is also closed under reflexivity, symmetry, transitivity and congruence. Note that  $\eta$ -equality does not need to be defined when the codomain is in  $\Omega$ , because of proof-irrelevance. Congruence rules are standard.

Fig. 4 describes the reduction in  $\mathbb{T}^{\text{obs}}$ . Note that since reduction is typed, one needs to add a rule for type conversion (Rule CONV-RED). Reduction features the usual notion of  $\beta$ -reduction (Rule  $\beta$ -RED), which corresponds to the computation rule of application (the eliminator of dependent

functions) applied to a  $\lambda$ -term (the constructor of dependent functions). Similarly, rules **N-ELIM-ZERO** and **N-ELIM-SUC** describe the two computation rules of the eliminator of  $\mathbb{N}$ , one for each constructor of  $\mathbb{N}$ .

As mentioned previously, the equality type and type cast operation of  $\mathbb{T}^{\text{obs}}$  are eliminators, and thus must come with their computation rules. Since  $t \sim_A u$  is an eliminator for the universe, it needs rules for every type constructor. Rule **EQ-FUN** is the computation rule for dependent functions which stipulates that two functions are equal when they are pointwise equal, thus naturally providing  $\mathbb{T}^{\text{obs}}$  with function extensionality. Rule **EQ- $\Omega$**  says that two proof irrelevant types are equal when they are logically equivalent, thus providing  $\mathbb{T}^{\text{obs}}$  with propositional extensionality. Note that cumulativity is required for this reduction rule to preserve typing, as the types  $A$  and  $B$  live in a universe below  $A \sim_{\Omega_i} B$ .

There are three reduction rules for equality in  $\mathcal{U}$ . Rule **EQ-UNIV** stipulates that when the two endpoints are both  $\mathbb{N}$  or the same universe, the equality holds, which is captured by the fact that it reduces to the unit type. Rule **EQ-UNIV- $\neq$**  says that when the two end points do not have the same head  $\text{hd}$ , the equality does not hold, which is captured by the fact that it reduces to the empty type. The function  $\text{hd } A$  is simply equal to  $\mathbb{N}$  or  $s_i$  when  $A$  is the type of natural numbers or a universe respectively, and is defined as  $(\Pi, s, i, j)$  when  $A$  is the type  $\Pi_{s,i}^j(x : A). B$ . The third rule (Rule **EQ- $\Pi$** ) says that two dependent function types are equal when their domain are equal, and their codomain are pointwise equal (as type families) up to the equality on their domain. As for Rule **EQ- $\Omega$** , this rule is well-typed only in presence of cumulativity.

There are four rules for equality in  $\mathbb{N}$ , corresponding to every possible normal forms of the endpoints. Equality holds when both endpoints are  $0$  (Rule **EQ-ZERO**), computes to the equality of arguments when both endpoints are successors (Rule **EQ-SUC**), and does not hold otherwise (Rules **EQ-ZERO-SUC** and **EQ-SUC-ZERO**). This concludes the reduction rules for equality.

We can now turn to the description of the computation rules for type cast, which only need to be defined when the types are compatible—otherwise the cast will be stuck.<sup>3</sup> Casting from  $\mathbb{N}$  to  $\mathbb{N}$  is defined by recursion to be the identity on constructors (Rules **CAST-ZERO** and **CAST-SUC**), and casting a type from a universe to the same universe is the identity<sup>4</sup> (Rule **CAST-UNIV**). Finally, casting between two dependent products is more involved: it produces a new function by casting back and forth the argument and return value of the original function (Rule **CAST- $\Pi$** ).

For our definition of reduction to be complete, we need to add rules that reduce the scrutinees of eliminators to *weak-head normal form* (whnf), so the eliminator can then reduce by case analysis on the whnf. Weak-head normal forms correspond to relevant terms that can *not* be reduced (Fig. 5). They are either terms with a constructor in head position, or a neutral term, which correspond to the

<sup>3</sup>An alternative design would be to reduce to an elimination on the proof of equality which in this case has type  $\perp$ .

<sup>4</sup>We could also define it by recursion. It is not clear whether it makes any significant difference.

stuck terms that can not exist in an empty context. Neutral terms are either variables, eliminators applied to another neutral term, or obtained from an inhabitant of  $\perp$ . In  $\mathbb{T}\mathbb{T}^{\text{obs}}$ , inhabitants of a proof-irrelevant type are never considered as whnf, as there is no notion of reduction of proof-irrelevant terms. Substitution rules that implement reduction of scrutinees to weak-head normal form are standard.

### 3 METATHEORETICAL PROPERTIES

In order for a type theory to be a reasonable candidate for implementation in a proof assistant, it is desirable to have some control over its behavior and its semantics. There is a wide variety of properties we can ask of a type theory; we will describe four of them and prove they apply to  $\text{TT}^{\text{obs}}$ .

*Consistency.* A theory is called consistent if it is impossible to use it to derive a contradiction. It goes without saying that this property is of utmost importance if one wants to build interesting mathematics. When proving a theory consistent, one should pay some attention to the meta-theory where reasoning takes place, as a consistency result is really a reduction of the consistency of the theory to the consistency of the meta-theory.

*Normalization.* If a type theory features reduction rules, one may want to make sure that by repeatedly applying said rules, all terms eventually reach a normal form that cannot be reduced further. One says that the reduction strategy is normalizing.

*Canonicity.* A term belonging to a type is called canonical when it can be explicitly built up using the constructors of that type. For instance, an inhabitant of the type  $\mathbb{N}$  of natural numbers is canonical if it is an explicit numeral. If all terms of type  $\mathbb{N}$  in an empty context normalize to a canonical form, then the theory is said to enjoy canonicity for natural numbers.

*Decidability of Type Checking.* Finally, in order to implement a type theory in a proof assistant, it is desirable to have an algorithm that, given a context  $\Gamma$  and terms  $t$  and  $A$ , decides whether  $t$  is an inhabitant of  $A$  in context  $\Gamma$ . This ensures users that when they find a proof for a statement, the proof assistant can automatically check that their proof is correct.

In this section, we will prove these four properties for  $\text{TT}^{\text{obs}}$ . We first present our extension of the logical relations framework developed by Abel et al. [2018] and later extended to  $\Omega$  by Gilbert et al. [2019]. The framework provides a proof of normalization and canonicity from consistency, as well as decidability of conversion and thus decidability of type checking. It has been formalized in the AGDA development. Then, to get consistency and therefore canonicity, we develop a model of  $\text{TT}^{\text{obs}}$  in a constructive set theory that supports inductive-recursive definitions and one Grothendieck universe.

#### 3.1 Normalization and Canonicity from Consistency

We now explain the proof by reducibility as initially formalized in AGDA by Abel et al. [2018] and extended to  $\Omega$  by Gilbert et al. [2019]. The proof starts from untyped syntax [Untyped.agda], with syntactical operations such as weakening and substitution, which are used to define typing judgments [Typed.agda]. Abel et al. [2018] also identify the weak head normal forms: define a neutral term to be a term that has a variable in head position, which blocks reduction. Weak head normal forms are then defined to be either neutral terms or terms that have a constructor in head position. This is the notion that we extended to  $\text{TT}^{\text{obs}}$  in Fig. 5.

From there, Abel et al. [2018] use induction-recursion to define a Kripke logical relation that exhibits the structure and properties of well-typed terms, and implies weak-head normalization.

442	$\Gamma \Vdash_{\ell} A$	A is a reducible type at level $\ell$ in context $\Gamma$
443	$\Gamma \Vdash_{\ell} A \equiv B$	A and B are reducibly equal types at level $\ell$ in context $\Gamma$
444	$\Gamma \Vdash_{\ell} t : A$	t is a reducible term at level $\ell$ of type A in context $\Gamma$
445	$\Gamma \Vdash_{\ell} t \equiv u : A$	t and u are reducibly equal terms at level $\ell$ of type A in context $\Gamma$

446

447

448

449

Fig. 6. The four judgments of the logical relation

450

The proof builds up to the *fundamental lemma*, which states that any well-typed term is reducible by induction on the typing derivation. Abel et al. [2018] prove this for a dependent type theory with dependent functions, natural numbers and one universe. Gilbert et al. [2019] extends it with one universe of definitionally proof irrelevant types.

451

452

453

In our work, we added support for two cumulative universe levels, existential types, proof irrelevant axioms, setoid equality and cast. This doubles the size of the proof, getting it up to 20,000 lines of Agda code.

454

455

456

Our most novel contribution to the proof is our treatment of proof-irrelevant types. Even though the theory studied by Gilbert et al. [2019] features proof-irrelevant types, their reducibility proof extends reduction rules to the inhabitants of these types, and the normalization result applies to them too. From this, Gilbert et al. [2019] derive an easy proof of consistency: any proof of  $\perp$  in an empty context will reduce to a weak head normal form, and the only weak head normal forms that can inhabit  $\perp$  are neutral terms. But since there are no variables in the empty context, neutral terms cannot exist, so  $\perp$  has no inhabitant in the empty context.

457

458

459

460

461

462

463

However, this strategy is not applicable in our setting: it seems difficult to devise reduction rules for some terms that we postulated, such as `castrefl`, so that they reduce to a normal form. Therefore we have dropped the notion of reduction rules for inhabitants of proof-irrelevant types in  $\mathbb{T}^{\text{obs}}$ , and only prove normalization for proof-relevant types. We argue that this is more faithful to the philosophy of proof irrelevance, and results in a proof that is completely agnostic about the proof irrelevant content of the theory—we could postulate any consistent proof-irrelevant axiom and the normalization proof would carry through.

464

465

466

467

468

469

470

Of course, this means that consistency and canonicity do not follow from normalization anymore. The reason is simple: since we gave up any kind of control on the proof-irrelevant terms, we are forced to consider them as neutral. This also adds neutrals to the proof-*relevant* world, as  $\perp$ -elim can build inhabitants of proof-relevant types from inhabitants of  $\perp$ . Therefore, we need consistency of  $\mathbb{T}^{\text{obs}}$  to show canonicity.

471

472

473

474

475

476

### 3.2 Definition of the Logical Relation

477

478

479

480

In this section, we define the (Kripke) logical relation that we used [*LogicalRelation.agda*], closely following Abel et al. [2018]. For pedagogical reasons, we will present a somewhat informal version of the logical relation, and refer the interested reader to the formalization.

481

482

483

484

485

486

487

488

489

The logical relation is indexed by a level  $\ell$ , which reflects the predicative nature of the universe hierarchies: we first define reducibility at level 0 to characterize judgments that do not mention any universe, then we use this relation to define reducibility at level 1 for judgments that mention  $\mathcal{U}_0$  at most, and so on. Therefore, the whole definition is done by induction on  $\ell$ . While our formal proof only features three levels, we describe a full proof with levels that range over  $\mathbb{N}$  as this does not add significant complexity to the argument. The logical relation features four kinds of judgments presented in Fig. 6. As is customary in reducibility proofs [Girard 1972], these judgments imply normalization, are closed under weak head expansion, and are verified by all neutral terms. The judgment  $\Gamma \Vdash_{\ell} A$  is defined inductively, while the three others are simultaneously defined

490

by recursion on a derivation of  $\Gamma \Vdash_\ell A$ . Thus, these judgments technically depend on the specific derivation of  $\Gamma \Vdash_\ell A$ , but since two different derivations will give rise to equivalent judgments we freely ignore this dependence.

We now present the six cases in the inductive definition  $\Gamma \Vdash_\ell A$ , together with the definition of the other three judgments.

*Neutral Types.*

$$\frac{\Gamma \vdash A \Rightarrow^* N : s_i \quad \text{neutral } N}{\Gamma \Vdash_\ell A}$$

This rule states that  $A$  is reducible to a neutral type:  $\Gamma \vdash A \Rightarrow^* N : s_i$  means that  $A$  reduces to a neutral term  $N$  in a finite number of steps (possibly zero), and that both  $A$  and  $N$  are of type  $s_i$  in context  $\Gamma$ . When  $A$  is reducible to a neutral type, we define:

- $\Gamma \Vdash_\ell A \equiv B$  if there is a neutral term  $M$  such that  $\Gamma \vdash B \Rightarrow^* M : s_i$  and  $\Gamma \vdash N \equiv M : s_i$ .

If  $A$  is a proof-relevant type, then we also define:

- $\Gamma \Vdash_\ell t : A$  if there is a neutral term  $n$  such that  $\Gamma \vdash t \Rightarrow^* n : N$ .
- $\Gamma \Vdash_\ell t \equiv u : A$  if there are neutral terms  $n, m$  such that  $\Gamma \vdash t \Rightarrow^* n : N$  and  $\Gamma \vdash u \Rightarrow^* m : N$ , and  $\Gamma \vdash n \equiv m : N$ .

If  $A$  is a proof-irrelevant type, then we define instead:

- $\Gamma \Vdash_\ell t : A$  if  $\Gamma \vdash t : A$ .
- $\Gamma \Vdash_\ell t \equiv u : A$  if  $\Gamma \vdash t : A$  and  $\Gamma \vdash u : A$ .

More generally, inhabitants of proof-irrelevant types are always reducible when they are well-typed.

*Universes.*

$$\frac{\Gamma \vdash A \Rightarrow^* s_i : \mathcal{U}_j \quad i < \ell}{\Gamma \Vdash_\ell A}$$

When  $A$  is reducible to a universe, we define:

- $\Gamma \Vdash_\ell A \equiv B$  if  $\Gamma \vdash B \Rightarrow^* s_i : \mathcal{U}_j$ .
- $\Gamma \Vdash_\ell t : A$  if there is a normal form  $t'$  such that  $\Gamma \vdash t \Rightarrow^* t' : s_i$ , and  $\Gamma \Vdash_i t$  (which is already defined by induction hypothesis, since  $i < \ell$ ).
- $\Gamma \Vdash_\ell t \equiv u : A$  if there are normal forms  $t', u'$  such that  $\Gamma \vdash t \Rightarrow^* t' : s_i$  and  $\Gamma \vdash u \Rightarrow^* u' : s_i$ , and  $\Gamma \Vdash_i t, \Gamma \Vdash_i u$ , and  $\Gamma \Vdash_i t \equiv u$ .

*Natural Numbers.*

$$\frac{\Gamma \vdash A \Rightarrow^* \mathbb{N} : \mathcal{U}_i}{\Gamma \Vdash_\ell A}$$

When  $A$  is reducible to  $\mathbb{N}$ , we define:

- $\Gamma \Vdash_\ell A \equiv B$  if  $\Gamma \vdash B \Rightarrow^* \mathbb{N} : \mathcal{U}_i$ .
- $\Gamma \Vdash_\ell t : A$  if there is a normal form  $t'$  such that  $\Gamma \vdash t \Rightarrow^* t' : \mathbb{N}$  and  $\Gamma \Vdash_{\mathbb{N}} t'$ , which is inductively defined by

$$\frac{}{\Gamma \Vdash_{\mathbb{N}} 0} \quad \frac{\Gamma \Vdash_{\mathbb{N}} t}{\Gamma \Vdash_{\mathbb{N}} S t} \quad \frac{\Gamma \vdash n : \mathbb{N} \quad n \text{ is neutral}}{\Gamma \Vdash_{\mathbb{N}} n}$$

- $\Gamma \Vdash_\ell t \equiv u : A$  if there are normal forms  $t', u'$  such that  $\Gamma \vdash t \Rightarrow^* t' : \mathbb{N}$  and  $\Gamma \vdash u \Rightarrow^* u' : \mathbb{N}$ , and  $\Gamma \Vdash_{\mathbb{N}} t' \equiv u'$ , which is inductively defined by

$$\frac{}{\Gamma \Vdash_{\mathbb{N}} 0 \equiv 0} \quad \frac{\Gamma \Vdash_{\mathbb{N}} t \equiv u}{\Gamma \Vdash_{\mathbb{N}} S t \equiv S u} \quad \frac{\Gamma \vdash n \equiv m : \mathbb{N} \quad n, m \text{ are neutral}}{\Gamma \Vdash_{\mathbb{N}} n \equiv m}$$

540 *Dependent Function Types.*

$$\frac{\Gamma \vdash A \Rightarrow^* \Pi(x : F). G : s_k \quad \Gamma \vdash F : s'_i \quad \Gamma, x : F \vdash G : s_j \quad \forall \Delta \rho. \Delta \Vdash_\ell F[\rho] \quad \forall \Delta \rho. \Delta \Vdash_\ell a : F[\rho] \Longrightarrow \Delta \Vdash_\ell G[\rho, a]}{\forall \Delta \rho. \Delta \Vdash_\ell a : F[\rho] \Longrightarrow \Delta \Vdash_\ell b : F[\rho] \Longrightarrow \Delta \Vdash_\ell a \equiv b : F[\rho] \Longrightarrow \Delta \Vdash_\ell G[\rho, a] \equiv G[\rho, b]} \begin{array}{l} i \leq k \\ j \leq k \end{array}$$

$$\Gamma \Vdash_\ell A$$

This rule states that  $A$  is reducible to a dependent function type. We introduced quite a bit of notation here.  $\Longrightarrow$  is implication in the meta theory, *i.e.*, the theory of AGDA.  $\forall \Delta \rho$  is a meta-theoretical quantification on an arbitrary well-formed context  $\Delta$  and a weakening  $\rho$  that turns  $\Delta$  into  $\Gamma$ . Applying such a weakening on the free variables of a term  $F$  that is a well-typed in context  $\Gamma$  results in a term  $F[\rho]$  that is well-typed in context  $\Delta$ . Given a term  $G$  in the extended context  $\Gamma, x : F$  and a term  $\Delta \vdash a : F[\rho]$ , we can apply  $\rho$  on the free variables of  $G$  except for  $x$  to get a term in  $\Delta, x : F[\rho]$ , and then substitute  $x$  with  $a$  to get a term in  $\Delta$ . The result is noted  $G[\rho, a]$ .

When  $A$  is reducible to a dependent function type, we define:

- $\Gamma \Vdash_\ell A \equiv B$  if there are terms  $F'$  and  $G'$  such that
  - $\Gamma \vdash B \Rightarrow^* \Pi(x : F'). G' : s_k$  and  $\Gamma \vdash \Pi(x : F). G \equiv \Pi(x : F'). G' : s_k$
  - $\forall \Delta \rho. \Delta \Vdash_\ell F[\rho] \equiv F'[\rho]$
  - $\forall \Delta \rho. \Delta \Vdash_\ell a : F[\rho] \Longrightarrow \Delta \Vdash_\ell G[\rho, a] \equiv G'[\rho, a]$ .

If  $A$  is a proof-relevant type, then we also define:

- $\Gamma \Vdash_\ell t : A$  if there is a normal form  $t'$  such that
  - $\Gamma \vdash t \Rightarrow^* t' : \Pi(x : F). G$
  - $\forall \Delta \rho. \Delta \Vdash_\ell a : F[\rho] \Longrightarrow \Delta \Vdash_\ell t'[\rho] a : G[\rho, a]$
  - $\forall \Delta \rho. \Delta \Vdash_\ell a : F[\rho] \Longrightarrow \Delta \Vdash_\ell b : F[\rho] \Longrightarrow \Delta \Vdash_\ell a \equiv b : F[\rho] \Longrightarrow \Delta \Vdash_\ell t'[\rho] a \equiv t'[\rho] b : G[\rho, a]$
- $\Gamma \Vdash_\ell t \equiv u : A$  if there are normal forms  $t', u'$  such that
  - $\Gamma \vdash t \Rightarrow^* t' : \Pi(x : F). G$  and  $\Gamma \vdash u \Rightarrow^* u' : \Pi(x : F). G$
  - $\Gamma \vdash t' \equiv u' : \Pi(x : F). G$
  - $\Gamma \Vdash_\ell t : A$  and  $\Gamma \Vdash_\ell u : A$
  - $\forall \Delta \rho. \Delta \Vdash_\ell a : F[\rho] \Longrightarrow \Delta \Vdash_\ell t'[\rho] a \equiv u'[\rho] a : G[\rho, a]$ .

If  $A$  is a proof-irrelevant type, then we define instead:

- $\Gamma \Vdash_\ell t : A$  if  $\Gamma \vdash t : \Pi(x : F). G$ .
- $\Gamma \Vdash_\ell t \equiv u : A$  if  $\Gamma \vdash t : \Pi(x : F). G$  and  $\Gamma \vdash u : \Pi(x : F). G$ .

*Existential types.* The definition of a type  $A$  reducible to an existential type is similar to those for dependent function types, and the same holds for the notion of reducibly equal types. However, the definition of judgments for terms is much simpler: as existential types are proof-irrelevant we only ask them to be well-typed.

- $\Gamma \Vdash_\ell A \equiv B$  if there are terms  $F'$  and  $G'$  such that
  - $\Gamma \vdash B \Rightarrow^* \exists(x : F'). G' : \Omega_k$  and  $\Gamma \vdash \exists(x : F). G \equiv \exists(x : F'). G' : \Omega_k$
  - $\forall \Delta \rho. \Delta \Vdash_\ell F[\rho] \equiv F'[\rho]$
  - $\forall \Delta \rho. \Delta \Vdash_\ell a : F[\rho] \Longrightarrow \Delta \Vdash_\ell G[\rho, a] \equiv G'[\rho, a]$ .
- $\Gamma \Vdash_\ell t : A$  if  $\Gamma \vdash t : \exists(x : F). G$ .
- $\Gamma \Vdash_\ell t \equiv u : A$  if  $\Gamma \vdash t : \exists(x : F). G$  and  $\Gamma \vdash u : \exists(x : F). G$ .

584 *Empty type.*

$$\frac{\Gamma \vdash A \Rightarrow^* \perp : \Omega_i}{\Gamma \Vdash_\ell A}$$

When  $A$  is reducible to the empty type, we define:

- $\Gamma \Vdash_{\ell} A \equiv B$  if  $\Gamma \vdash B \Rightarrow^* \perp : \Omega_i$ .
- $\Gamma \Vdash_{\ell} t : A$  if  $\Gamma \vdash t : \perp$ .
- $\Gamma \Vdash_{\ell} t \equiv u : A$  if  $\Gamma \vdash t : \perp$  and  $\Gamma \vdash u : \perp$ .

We do not have to add a case for  $\top$ , since it can be encoded as  $\perp \rightarrow \perp$ . There is no case for  $t \sim_A u$  either, because setoid equality is not a type constructor, but rather a type eliminator that does pattern matching on  $A$  and its two endpoints  $t$  and  $u$ . Consequently, the only whnfs of the form  $t \sim_A u$  are neutral, and are handled by the rule for proof-irrelevant neutral types.

*Embedding.*

$$\frac{\Gamma \Vdash_{\ell} A}{\Gamma \Vdash_{\ell'} A} \ell < \ell'$$

This case ensures that the logical relation is monotonic with respect to the level.

### 3.3 The fundamental lemma

Before stating the fundamental lemma for the logical relation, which basically amounts to completeness of the logical relation with respect to the typing relation, we establish the correctness of logical relation, which is called the escape lemma by [Abel et al. \[2018\]](#).

LEMMA 3.1 (ESCAPE LEMMA). *Given  $\Gamma \Vdash_{\ell} A$ ,*

- (1)  $\Gamma \vdash A : s$ .
- (2) *If  $\Gamma \Vdash_{\ell} A \equiv B$  then  $\Gamma \vdash A \equiv B : s$ .*
- (3) *If  $\Gamma \Vdash_{\ell} t : A$  then  $\Gamma \vdash A : s$ .*
- (4) *If  $\Gamma \Vdash_{\ell} t \equiv u : A$  then  $\Gamma \vdash t \equiv u : A$ .*

PROOF. Straightforward induction on the logical relation. □

We can now state the completeness of the logical relation, a.k.a. the fundamental lemma [[Fundamental.agda](#)]. We state it here in a simple form but the proof, done by induction on the typing derivation, requires us to generalize the induction hypothesis to consider reducibility under an arbitrary reducible substitution. This is achieved, in [[Abel et al. 2018](#)] as well as in our formalization [[Substitution.agda](#)], by defining the notion of validity, but we deliberately ignore this technicality in the rest of the section.

LEMMA 3.2 (FUNDAMENTAL LEMMA).

- (1) *If  $\Gamma \vdash t : A$ , then there is a  $\ell$  such that  $\Gamma \Vdash_{\ell} A$  and  $\Gamma \Vdash_{\ell} t : A$ .*
- (2) *If  $\Gamma \vdash t \equiv u : A$ , then there is a  $\ell$  such that  $\Gamma \Vdash_{\ell} A$  and  $\Gamma \Vdash_{\ell} t \equiv u : A$ .*

The fundamental lemma is proved by induction on the typing derivations. For most of the rules, the proof is roughly the same as in [[Abel et al. 2018](#); [Gilbert et al. 2019](#)]*—*with simplified proofs for inhabitants of proof-irrelevant types. The proof relies heavily on reflexivity, symmetry and transitivity of the reducible equality, stability of reducibility under reducible type conversion, reducibility of neutral terms, and the fact that reducibility is stable by weak-head expansion. Our extension to a cumulative hierarchy of universes and to proof-irrelevant existential quantification requires numerous changes, but these do not pose any major difficulty*—*albeit the proof is by no means trivial, as the arguments have to be spelled out in excruciating detail. We now focus on the two main typing derivation introduced by  $\text{TT}^{\text{obs}}$ , Rules **EQ-FORM** and **CAST**. Those two cases are the consequence of the following lemmas.

LEMMA 3.3 (REDUCIBILITY OF CAST). *For all levels  $\ell_1, \ell_2, \ell_3, \ell_4$ , in a well formed context  $\Gamma$ , if:*

- (1)  $\Gamma \Vdash_{\ell_1} A$  and  $\Gamma \Vdash_{\ell_2} A'$  and  $\Gamma \Vdash_{\ell_1} A \equiv A'$

- 638 (2)  $\Gamma \Vdash_{\ell_3} B$  and  $\Gamma \Vdash_{\ell_4} B'$  and  $\Gamma \Vdash_{\ell_3} B \equiv B'$   
 639 (3)  $\Gamma \vdash e : A \sim_s B$  and  $\Gamma \vdash e' : A' \sim_s B'$   
 640 (4)  $\Gamma \Vdash_{\ell_1} t : A$  and  $\Gamma \Vdash_{\ell_2} t' : A'$  and  $\Gamma \Vdash_{\ell_1} t \equiv t' : A$

641 then  $\Gamma \Vdash_{\ell_3} \mathbf{cast}(A, B, e, t) : B$  and  $\Gamma \Vdash_{\ell_3} \mathbf{cast}(A, B, e, t) \equiv \mathbf{cast}(A', B', e', t') : B$ .

642  
 643 **PROOF.** The proof is by case analysis on the reducibility proofs of  $A, A', B, B'$ . If one of these  
 644 proofs is introduced by embedding, then we recursively apply the lemma on the embedded proof.  
 645 Thus, it suffices to prove the lemma when all reducibility proofs correspond to a normal form. From  
 646 the proofs of reducible equality, one obtains that the reducibility proofs of  $A$  and  $A'$  (resp.  $B$  and  $B'$ )  
 647 are introduced by the same rule. Then, if one of the normal forms is neutral, or if the normal forms  
 648 of  $A$  and  $B$  have different head constructors, then  $\mathbf{cast}(A, B, e, t)$  and  $\mathbf{cast}(A', B', e', t')$  are neutral  
 649 and easily seen to be reducible. Therefore, it suffices to prove the lemma when all the reducibility  
 650 proofs are introduced by the same rule. We now detail the case of dependent products, as it is the  
 651 most interesting.

652 We know that  $A$  reduces to a term of the form  $\Pi(x : F_A). G_A$ , as do  $A', B, B'$ . Therefore, we know  
 653 that  $\mathbf{cast}(A, B, e, t)$  reduces to  $\lambda(a' : F_B). \mathbf{cast}(G_A[x := a], G_B[x := a'], \mathbf{snd}(e) a', t a)$  where  $a$  is a  
 654 shorthand for  $\mathbf{cast}(F_B, F_A, \mathbf{fst}(e)^{-1}, a')$ , and  $\mathbf{cast}(A', B', e', t')$  reduces similarly. By the weak head  
 655 expansion lemma, it suffices to prove that these normal forms are reducible, and reducibly equal  
 656 at type  $\Pi(x : F_B). G_B$ —that is, applying them to a reducible term  $a'$  under any weakening results  
 657 in reducible terms that are reducibly equal, and applying the first to two reducibly equal terms  
 658 produce new reducibly equal terms.

659 To prove the first obligation, we first recursively apply the lemma to  $\mathbf{cast}(F_B, F_A, \mathbf{fst}(e)^{-1}, a')$   
 660 so that we obtain reducibility of  $a$ , and then recursively apply it to  $\mathbf{cast}(G_A[x := a], G_B[x :=$   
 661  $a'], \mathbf{snd}(e) a', t a)$ . The other two obligations are proved in the exact same manner.  $\square$

662  
 663 **LEMMA 3.4 (REDUCIBILITY OF ID IN THE UNIVERSE).** *For all levels  $\ell_1, \ell_2, \ell_3, \ell_4$ , in a well formed*  
 664 *context  $\Gamma$ , if:*

- 665 (1)  $\Gamma \Vdash_{\ell_1} A$  and  $\Gamma \Vdash_{\ell_2} A'$  and  $\Gamma \Vdash_{\ell_1} A \equiv A'$   
 666 (2)  $\Gamma \Vdash_{\ell_3} B$  and  $\Gamma \Vdash_{\ell_4} B'$  and  $\Gamma \Vdash_{\ell_3} B \equiv B'$

667 then  $\Gamma \Vdash_{\ell_{\max}} A \sim_s B$  and  $\Gamma \Vdash_{\ell_{\max}} A \sim_s B \equiv A' \sim_s B'$  where  $\ell_{\max} = \max(\ell_1, \ell_2, \ell_3, \ell_4)$ .

669 **PROOF.** The proof is by case analysis on the reducibility proofs of  $A, A', B, B'$ . As in the proof of  
 670 Lemma 3.3, we reduce the proof to introduction rules that correspond to the same kind of normal  
 671 form. Most cases are straightforward, the difficult case being again the dependent products.

672 From reducibility proofs,  $A$  reduces to a term of the form  $\Pi(x : F_A). G_A$ , and so for  $A', B$  and  
 673  $B'$ . Thus, we know that  $A \sim_s B$  reduces to  $\exists(e : F_A \sim_{\mathcal{U}} F_B). \Pi(a' : F_B). G_A[x := a] \sim_{\mathcal{U}} G_B[x := a']$   
 674 where  $a$  is a shorthand for  $\mathbf{cast}(F_B, F_A, \mathbf{fst}(e)^{-1}, a')$ , and  $A' \sim_s B'$  reduces similarly. By the weak  
 675 head expansion lemma, it suffices to prove that the first normal form is reducible, and reducibly  
 676 equal to the second one. We do this by applying reducibility of  $\mathbf{cast}$  to get reducibility of  $a$ , and  
 677 then doing recursive calls on  $F_A \sim_{\mathcal{U}} F_B$  and  $G_A[x := a] \sim_{\mathcal{U}} G_B[x := a']$  under the appropriate  
 678 weakenings and substitutions.  $\square$

679  
 680 **LEMMA 3.5 (REDUCIBILITY OF ID).** *For all levels  $\ell_1, \ell_2$ , in a well formed context  $\Gamma$ , if:*

- 681 (1)  $\Gamma \Vdash_{\ell_1} A$  and  $\Gamma \Vdash_{\ell_2} A'$  and  $\Gamma \Vdash_{\ell_1} A \equiv A'$   
 682 (2)  $\Gamma \Vdash_{\ell_1} t : A$  and  $\Gamma \Vdash_{\ell_2} t' : A'$  and  $\Gamma \Vdash_{\ell_1} t \equiv t' : A$   
 683 (3)  $\Gamma \Vdash_{\ell_1} u : A$  and  $\Gamma \Vdash_{\ell_2} u' : A'$  and  $\Gamma \Vdash_{\ell_1} u \equiv u' : A$

684 then  $\Gamma \Vdash_{\ell_1} t \sim_A u$  and  $\Gamma \Vdash_{\ell_1} t \sim_A u \equiv t' \sim_A u'$ .

687 PROOF. By case analysis on  $A$  and  $A'$ . The most difficult case is the universe, and is handled by  
 688 Lemma 3.4. The case of dependent products requires doing recursive calls on the domain and the  
 689 codomain, as in the previous lemmas.  $\square$

690 These lemmas constitute the bulk of the proof: they occupy approximately 5,000 lines of Agda  
 691 code and most of the time required to check the whole proof is spent on them.

692 COROLLARY 3.6 (NORMALIZATION). *A direct consequence of the fundamental lemma is that any*  
 693 *well-typed term has a weak-head normal form.*

694 Another direct consequence of the fundamental lemma is that any closed term of type  $\mathbb{N}$  reduces  
 695 to a whnf of type  $\mathbb{N}$ . Thus, to conclude canonicity, we just need to know that there is no neutral term  
 696 of type  $\mathbb{N}$  in an empty context. Unfortunately, as the notion of reduction is absent for terms of proof-  
 697 irrelevant types, and in particular for the empty type, this cannot be proven by induction on the  
 698 syntax of the neutral terms. However, assuming consistency of  $\text{TT}^{\text{obs}}$  (proved in Section 3.5), or in  
 699 other words that there is no closed term of type  $\perp$ , we can derive canonicity of  $\text{TT}^{\text{obs}}$  [*Canonicity.agda*].

### 702 3.4 Decidability of typing

703 We first need to show that the conversion judgment is decidable. This is done by defining an  
 704 algorithmic version of the conversion of two terms  $t$  and  $u$  which basically amounts to computing  
 705 the whnf of  $t$  and  $u$ , comparing their head, and applying the algorithm recursively if necessary  
 706 [*Conversion.agda*]. Correctness of this algorithmic conversion is easily obtained, as the rules used are  
 707 special cases of the conversion judgement [*Soundness.agda*]. Then, we can show that algorithmic  
 708 conversion is also complete by replaying the fundamental lemma with a definition of the logical  
 709 relation that uses algorithmic conversion instead of typed conversion [*Completeness.agda*]. To do so,  
 710 the main difficulty is to show that algorithmic conversion is reflexive, symmetric and transitive. In  
 711 our formal proof, we follow Abel et al. [2018] in factoring the two instances of the fundamental  
 712 lemma by defining a generic interface for both algorithmic conversion and typed conversion, and  
 713 using this interface in the definition of the logical relation [*EqualityRelation.agda*].

714 Then, to get decidability of type checking, we can simply rely on the work of Lennon-Bertrand  
 715 [2021] on bidirectional type-checking, which defines an algorithmic version of type-checking  
 716 provided that the theory enjoys subject reduction and decidability of conversion.

### 718 3.5 Consistency: The Setoid Model

719  $\text{TT}^{\text{obs}}$  is designed to describe the behavior of constructive setoids. In order to justify this claim, we  
 720 build a model of  $\text{TT}^{\text{obs}}$  where every context and proof-relevant type is interpreted as a setoid in  
 721 a constructive set theory with induction-recursion [Aczel 1978], following the seminal proof of  
 722 Hofmann [1995]. Then, by interpreting  $\text{TT}^{\text{obs}}$  in this model, we can prove the following theorem,  
 723 which is the central missing piece of the metatheory of  $\text{TT}^{\text{obs}}$ :

724 THEOREM 3.7 (CONSISTENCY OF  $\text{TT}^{\text{obs}}$ ). *There is no inhabitant of  $\perp$  in the empty context.*

725 We work in a constructive set theory that supports inductive-recursive definitions and one  
 726 Grothendieck universe. While it would be more satisfying to use a constructive type theory, as in  
 727 the normalization proof, it is significantly more challenging. This is because the interpretation of  
 728 the syntax in our model is only defined on well-typed terms, but should not depend on the typing  
 729 derivation. While properly establishing this in a typed context is non-trivial, the added flexibility  
 730 of set theory makes the task straightforward. We will write  $\mathbb{N}$  for the set of natural numbers in our  
 731 meta-theory,  $(x \in A) \rightarrow B(x)$  for dependent functions and  $(x \in A) \times B(x)$  for dependent products.

732 We define a *setoid* to be a *carrier* set  $A$  and a *setoid equality* predicate on  $A \times A$  that is reflexive,  
 733 symmetric and transitive, which we write  $\approx$ . Alternatively, we can define setoids to be small  
 734

categories such that morphism sets are subsingletons, and every morphism is invertible. We will make use of both perspectives, and use the notation  $a \approx b$  to mean either the proposition or the corresponding subsingleton. Given two setoids  $A$  and  $B$ , we write  $A \rightarrow_s B$  for the set of functions that preserve setoid equality. This set inherits a natural setoid structure from pointwise setoid equality.  $A \leftrightarrow_s B$  denotes the set of setoid equivalences, which are pairs of setoid functions in both directions that cancel. Given  $e \in A \leftrightarrow_s B$ , the induced function from  $A$  to  $B$  is simply noted  $e$ , while the other direction is noted  $e^{-1}$ .

The setoid equivalence turns the (large) set of all small setoids  $\text{Setoid}$  into a *groupoid*, or in other words a category where all morphisms are invertible. Given any setoid  $A$ , this allows us to define dependent setoids as functions from  $A$  to  $\text{Setoid}$  that send setoidal equalities to setoid equivalences, in a way that is compatible with composition and identity. Then, given a setoid  $A$  and a dependent setoid  $B : A \rightarrow_s \text{Setoid}$ , we write  $(x \in A) \rightarrow_s B(x)$  for the setoid of dependent functions, with pointwise equality. We also form a setoid  $\text{Prop}$  by using the set of subsingletons as the carrier, with logical equivalence as the equality.

The central object in the setoid model is a dual hierarchy of small setoids  $U_i$  and  $\Omega_i$ , which contain codes for the setoids and propositions that can be constructed in  $\text{TT}^{\text{obs}}$ . We build these universes of codes using induction-recursion: we define the sets  $U_i$  and  $\Omega_i$  by induction, and we simultaneously use recursion on them to define interpretation functions  $\text{el} : U_i \rightarrow \text{Setoid}$  and  $\text{val} : \Omega_i \rightarrow \text{Prop}$ , setoid equality on  $U_i$  and  $\Omega_i$ , as well as proofs that  $\text{el}$  and  $\text{val}$  preserve that setoid equality. All of this is done under an external induction on  $i$  and is given in Fig. 7.

We have omitted quite a few bureaucratic proofs from this definition, such as the reflexivity, symmetry and transitivity of  $\approx$ , or the fact that  $\text{el-eq}$  is compatible with reflexivity and transitivity. We also freely make use of the fact that equality is decidable on integers.

With this, we obtain two families of setoids  $U_i$  and  $\Omega_i$ , along with a dependent setoid  $\text{el} : U_i \rightarrow_s \text{Setoid}$  and a setoid function  $\text{val} : \Omega_i \rightarrow_s \text{Prop}$ . This construction turns the category of setoids and setoid functions into a *universe category* in the sense of Voevodsky [2015]. Our model is a contextual category/C-system built from this universe category. In the following, we describe the construction of the setoid model without assuming familiarity with contextual categories.

We now use  $U_i$  and  $\Omega_i$  to define the types and the terms of the setoid model. From now on, we will write  $s$  to mean either  $U$  or  $\Omega$  and we will also write  $c_\Pi$  for any of  $c_{\Pi\Omega\Omega}$ ,  $c_{\Pi\Omega U}$ ,  $c_{\Pi U\Omega}$  and  $c_{\Pi U U}$ . Given a setoid  $\Gamma$ , a *semantic type* of level  $i$  over  $\Gamma$  is simply a setoid function  $\Gamma \rightarrow_s s_i$ . We write these sets as  $\text{Ty}_{s,i} \Gamma$ . Then, given a semantic type  $A$  over  $\Gamma$ , we define the set of *semantic terms* of type  $A$  to be the setoidal dependent product  $(x \in \Gamma) \rightarrow_s \text{el } A(x)$ . We note this set  $\text{tm } A$ .

The contexts of our model are setoids which are inductively built from the terminal setoid as sequences of types:

$$\begin{array}{l} \text{Con} ::= \bullet : \text{Con} \\ | \rightarrow\_ : (\Gamma \in \text{Con}) \rightarrow \text{Ty}_{U,i} \Gamma \rightarrow \text{Con} \quad (\forall i \in \mathbb{N}) \\ | \rightarrow\_ : (\Gamma \in \text{Con}) \rightarrow \text{Ty}_{\Omega,i} \Gamma \rightarrow \text{Con} \quad (\forall i \in \mathbb{N}) \end{array}$$

Being telescopes of setoids, inhabitants of  $\text{Con}$  have an obvious interpretation as setoids: the elements of  $\Gamma \in \text{Con}$  are dependent lists of inhabitants for all of the types and propositions in  $\Gamma$ , and the setoid equality is inherited from pointwise setoid equality of lists.

We have all of the required blocks to get the structure of a category with families [Dybjer 1996] and thus a model of MLTT.

### 3.6 Interpreting $\text{TT}^{\text{obs}}$ in the Setoid Model

We now describe how to interpret the judgments of  $\text{TT}^{\text{obs}}$  in the setoid model where: (i) a well-formedness judgment  $\vdash \Gamma$  will be interpreted as a setoid in  $\text{Con}$  (ii) a type judgment  $\Gamma \vdash A : s_i$  will

785	$U_i ::= c_N : U_i$	
786	$\quad   c_{\Pi U U} : (A \in U_j) \rightarrow (el A \rightarrow_s U_k) \rightarrow U_i$	where $j, k < i$
787	$\quad   c_{\Pi \Omega U} : (A \in \Omega_j) \rightarrow (el A \rightarrow_s U_k) \rightarrow U_i$	where $j, k < i$
788	$\quad   c_U : \{j \in \mathbb{N} \mid j < i\} \rightarrow U_i$	
789	$\quad   c_\Omega : \{j \in \mathbb{N} \mid j < i\} \rightarrow U_i$	
790	$\Omega_i ::= c_\perp : \Omega_i$	
791	$\quad   c_{\Pi U \Omega} : (A \in U_j) \rightarrow (el A \rightarrow_s \Omega_k) \rightarrow \Omega_i$	where $j, k < i$
792	$\quad   c_{\Pi \Omega \Omega} : (A \in \Omega_j) \rightarrow (el A \rightarrow_s \Omega_k) \rightarrow \Omega_i$	where $j, k < i$
793	$\quad   c_\exists : (A \in \Omega_i) \rightarrow (el A \rightarrow_s \Omega_i) \rightarrow \Omega_i$	
794	$el : U_i \rightarrow \text{Setoid}$	
795	$el c_N := N$	$val : \Omega_i \rightarrow \text{Prop}$
796	$el (c_{\Pi U U} A B) := (x \in el A) \rightarrow_s el B(x)$	$val c_\perp := \perp$
797	$el (c_{\Pi \Omega U} A B) := (x \in val A) \rightarrow el B(x)$	$val (c_{\Pi U \Omega} A B) := (x \in el A) \rightarrow_s val B(x)$
798	$el (c_U j) := U_j$	$val (c_{\Pi \Omega \Omega} A B) := (x \in val A) \rightarrow val B(x)$
799	$el (c_\Omega j) := \Omega_j$	$val (c_\exists A B) := (x \in val A) \times val B(x)$
800	$\_ \approx \_ : U_i \rightarrow U_i \rightarrow \text{Prop}$	
801	$c_N \approx c_N := \top$	
802	$c_{\Pi U U} A B \approx c_{\Pi U U} A' B' := (e \in A \approx A') \times ((x \in el A) \rightarrow_s B(x) \approx B'(el\text{-eq } e x))$	when $j = j'$ and $k = k'$
803	$c_{\Pi \Omega U} A B \approx c_{\Pi \Omega U} A' B' := (e \in A \approx A') \times ((x \in val A) \rightarrow B(x) \approx B'(val\text{-eq } e x))$	when $j = j'$ and $k = k'$
804	$c_U j \approx c_U j' := j = j'$	
805	$c_\Omega j \approx c_\Omega j' := j = j'$	
806	$\_ \approx \_ := \perp$	otherwise
807	$\_ \approx \_ : \Omega_i \rightarrow \Omega_i \rightarrow \text{Prop}$	
808	$A \approx B := val A \Leftrightarrow val B$	
809	$el\text{-eq} : (A \in U_i) \rightarrow (B \in U_i) \rightarrow A \approx B \rightarrow el A \leftrightarrow_s el B$	
810	$el\text{-eq } c_N c_N e := (x \mapsto x, x \mapsto x)$	
811	$el\text{-eq } (c_{\Pi U U} A B) (c_{\Pi U U} A' B') e := (f \mapsto (x \mapsto el\text{-eq } (e.2 (el\text{-eq}^{-1} e.1 x)) (f (el\text{-eq}^{-1} e.1 x))))$	
812	$\quad , f \mapsto (x \mapsto el\text{-eq}^{-1} (e.2 (el\text{-eq } e.1 x)) (f (el\text{-eq } e.1 x))))$	
813	$el\text{-eq } (c_{\Pi \Omega U} A B) (c_{\Pi \Omega U} A' B') e := (f \mapsto (x \mapsto el\text{-eq } (e.2 (val\text{-eq}^{-1} e.1 x)) (f (val\text{-eq}^{-1} e.1 x))))$	
814	$\quad , f \mapsto (x \mapsto el\text{-eq}^{-1} (e.2 (val\text{-eq } e.1 x)) (f (val\text{-eq } e.1 x))))$	
815	$el\text{-eq } (c_U j) (c_U j) e := (x \mapsto x, x \mapsto x)$	
816	$el\text{-eq } (c_\Omega j) (c_\Omega j) e := (x \mapsto x, x \mapsto x)$	
817	$val\text{-eq} : (A \in \Omega_i) \rightarrow (B \in \Omega_i) \rightarrow A \approx B \rightarrow val A \Leftrightarrow val B$	
818	$val\text{-eq } A B e := e$

Fig. 7. The Setoid Model

be interpreted as a semantic type over the interpretation of  $\Gamma$  (iii) a typing judgment  $\Gamma \vdash t : A$  will be interpreted as a semantic term of the corresponding semantic type (iv) a convertibility judgment  $\Gamma \vdash t \equiv u : B$  will be interpreted as meta-theoretical equality of the interpretations of  $t$  and  $u$ . Since reduction is contained in convertibility, the model will necessarily interpret reduction as equality—it is not fine enough to distinguish the two notions.

Our interpretation is defined by induction on the syntax of the terms, following Hofmann [1993]. The context interpretation turns a syntactical context  $\Gamma$  into a setoid  $[\Gamma] \in \text{Con}$ . The type

$$\begin{aligned}
834 \quad \llbracket \mathcal{U}_i \rrbracket_{\Gamma} x &:= c_{\cup} i \\
835 \quad \llbracket \Omega_i \rrbracket_{\Gamma} x &:= c_{\Omega} i \\
836 \quad \llbracket \Pi(y : F). G \rrbracket_{\Gamma} x &:= c_{\Pi} (\llbracket F \rrbracket_{\Gamma} x) (y \mapsto \llbracket G \rrbracket_{\Gamma, y:F} x, y) \\
837 \quad \llbracket \lambda(y : F). t \rrbracket_{\Gamma} x &:= y \mapsto (\llbracket t \rrbracket_{\Gamma, y:F} x, y) \\
838 \quad \llbracket t u \rrbracket_{\Gamma} x &:= (\llbracket t \rrbracket_{\Gamma} x) (\llbracket u \rrbracket_{\Gamma} x) \\
839 \quad \llbracket \mathbb{N} \rrbracket_{\Gamma} x &:= c_{\mathbb{N}} \\
840 \quad \llbracket 0 \rrbracket_{\Gamma} x &:= 0 \\
841 \quad \llbracket S t \rrbracket_{\Gamma} x &:= S (\llbracket t \rrbracket_{\Gamma} x) \\
842 \quad \llbracket \mathbb{N}\text{-elim}(P, t_0, t_S, n) \rrbracket_{\Gamma} x &:= \mathbb{N}\text{-elim}(\text{el} \circ (\llbracket P \rrbracket_{\Gamma} x), \llbracket t_0 \rrbracket_{\Gamma} x, \llbracket t_S \rrbracket_{\Gamma} x, \llbracket n \rrbracket_{\Gamma} x) \\
843 \quad \llbracket \exists(y : F). G \rrbracket_{\Gamma} x &:= c_{\exists} (\llbracket F \rrbracket_{\Gamma} x) (y \mapsto \llbracket G \rrbracket_{\Gamma, y:F} x, y) \\
844 \quad \llbracket \langle t, u \rangle \rrbracket_{\Gamma} x &:= (\llbracket t \rrbracket_{\Gamma} x, \llbracket u \rrbracket_{\Gamma} x) \\
845 \quad \llbracket \text{fst}(t) \rrbracket_{\Gamma} x &:= (\llbracket t \rrbracket_{\Gamma} x).1 \\
846 \quad \llbracket \text{snd}(t) \rrbracket_{\Gamma} x &:= (\llbracket t \rrbracket_{\Gamma} x).2 \\
847 \quad \llbracket \perp \rrbracket_{\Gamma} x &:= c_{\perp} \\
848 \quad \llbracket \perp\text{-elim}(A, t) \rrbracket_{\Gamma} x &:= \perp\text{-elim}(\text{el}(\llbracket A \rrbracket_{\Gamma} x), \llbracket t \rrbracket_{\Gamma} x) \\
849 \quad \llbracket t \sim_A u \rrbracket_{\Gamma} x &:= \llbracket t \rrbracket_{\Gamma} x \approx \llbracket u \rrbracket_{\Gamma} x \quad \text{in } \text{el}(\llbracket A \rrbracket_{\Gamma} x) \\
850 \quad \llbracket \text{refl}(t) \rrbracket_{\Gamma} x &:= e_{\text{refl}} \\
851 \quad \llbracket \text{transp}(t, G, u, t', e) \rrbracket_{\Gamma} x &:= \text{val-eq} \\
852 \quad \llbracket \text{cast}(A, B, e, t) \rrbracket_{\Gamma} x &:= \text{el-eq}(\llbracket A \rrbracket_{\Gamma} x, \llbracket B \rrbracket_{\Gamma} x, \llbracket e \rrbracket_{\Gamma} x, \llbracket t \rrbracket_{\Gamma} x) \\
853 \quad \llbracket \text{castrefl}(A, t) \rrbracket_{\Gamma} x &:= e_{\text{id}}
\end{aligned}$$

Fig. 8. Interpretation of  $\text{TT}^{\text{obs}}$  in the Setoid Model

interpretation turns a syntactical context  $\Gamma$  and a syntactical term  $A$  into an element  $\llbracket A \rrbracket_{\Gamma} \in \text{tm } \mathbf{U}_i$  for some  $i$ . The term interpretation turns a syntactical context  $\Gamma$  and a syntactical term  $t$  of type  $A$  into an element  $\llbracket t \rrbracket_{\Gamma} \in \text{tm} (\text{el} \circ \llbracket A \rrbracket_{\Gamma})$ .

The reader might notice that the type interpretation is really an instance of the term interpretation. This is to be expected, since  $\text{TT}^{\text{obs}}$  features Russel-style universes, that do not separate types and terms. As we cannot hope for every syntactical term to have an interpretation, we define the interpretation as *partial* functions from the syntax to the model. In the definition by recursion, we consider that whenever a term reduces to an expression that does not make sense, the interpretation is not defined. It is possible to prove that the interpretation function is total when restricted to the well-typed terms afterwards.

The interpretation of contexts is given by  $\llbracket \bullet \rrbracket := 1$  and  $\llbracket \Gamma, x : A \rrbracket := \llbracket \Gamma \rrbracket, \text{el} \circ \llbracket A \rrbracket_{\Gamma}$  and variables are interpreted as projections:

$$\begin{aligned}
869 \quad \llbracket x \rrbracket_{\Gamma, x:A} (x_1, \dots, x_n) &:= x_n \\
870 \quad \llbracket x \rrbracket_{\Gamma, y:A} (x_1, \dots, x_n) &:= \llbracket x \rrbracket_{\Gamma} (x_1, \dots, x_{n-1})
\end{aligned}$$

Then, the interpretation of the basic theory is not too surprising. Since terms correspond to setoid functions, we define them by their behavior when applied to an arbitrary  $x \in \llbracket \Gamma \rrbracket$ . This is defined in the first part of Fig. 8. Finally, to interpret observational equality and its `cast` operation, we use the setoid structure of the universe: where  $e_{\text{refl}}$  is obtained from the reflexivity of setoid equality, and  $e_{\text{id}}$  is obtained from the behavior of `el-eq` on reflexivity.

In order to prove the soundness of our interpretation, we need to extend it to weakenings and substitutions between contexts: Assume  $\Gamma$  and  $\Delta$  are a syntactical contexts, and  $A$  and  $t$  are syntactical terms. In case  $\llbracket \Gamma, x : A, \Delta \rrbracket$  and  $\llbracket \Gamma, \Delta \rrbracket$  are well-defined, let  $\pi_A$  be the projection:

$$\begin{aligned}
880 \quad \pi_A : \llbracket \Gamma, x : A, \Delta \rrbracket &\rightarrow_s \llbracket \Gamma, \Delta \rrbracket \\
881 \quad (x_{\Gamma}^{\vec{x}}, x_A, x_{\Delta}^{\vec{x}}) &\mapsto (x_{\Gamma}^{\vec{x}}, x_{\Delta}^{\vec{x}}).
\end{aligned}$$

In case  $\llbracket \Gamma, \Delta[x := t] \rrbracket$  and  $\llbracket \Gamma, x : A, \Delta \rrbracket$  are well-defined, we define the setoid function  $\sigma_t$  by:

$$\begin{aligned} \sigma_t : \llbracket \Gamma, \Delta[x := t] \rrbracket &\rightarrow_s \llbracket \Gamma, x : A, \Delta \rrbracket \\ (\vec{x}_\Gamma, \vec{x}_\Delta) &\mapsto (\vec{x}_\Gamma, \llbracket t \rrbracket_\Gamma, \vec{x}_\Delta). \end{aligned}$$

LEMMA 3.8 (WEAKENING).  $\pi_A$  is the semantic counterpart to the weakening of  $A$ : for all terms  $u$ , when both sides are well defined, we have:

$$\llbracket u \rrbracket_{\Gamma, x:A, \Delta} = \llbracket u \rrbracket_{\Gamma, \Delta} \circ \pi_A$$

LEMMA 3.9 (SUBSTITUTION).  $\sigma_t$  is the semantic counterpart to the substitution by  $t$ : for all terms  $u$ , when both sides are well defined, we have:

$$\llbracket u[x := t] \rrbracket_{\Gamma, \Delta[x:=t]} = \llbracket u \rrbracket_{\Gamma, x:A, \Delta} \circ \sigma_t$$

THEOREM 3.10 (SOUNDNESS OF THE SETOID MODEL).

- (1) If  $\vdash \Gamma$  then  $\llbracket \Gamma \rrbracket \in \text{Con}$ .
- (2) If  $\Gamma \vdash A : s_i$  then  $\text{el} \circ \llbracket A \rrbracket_\Gamma \in \text{Ty}_{s_i} \Gamma$ .
- (3) If  $\Gamma \vdash t : A$  then  $\llbracket t \rrbracket_\Gamma \in \text{tm}(\text{el} \circ \llbracket A \rrbracket_\Gamma)$ .
- (4) If  $\Gamma \vdash t \equiv u : A$  then  $\llbracket t \rrbracket_\Gamma = \llbracket u \rrbracket_\Gamma$

PROOF. By induction on the typing derivations. □

Consistency of  $\text{TT}^{\text{obs}}$  (Theorem 3.7) follows immediately from the soundness theorem: any inhabitant of  $\perp$  in the empty context is interpreted as a setoid function from the one-element setoid to the empty setoid, but no such function exists.

## 4 EXTENSIONS TO QUOTIENTS, ID TYPES AND INDUCTIVE TYPES

So far, we have defined and studied a minimal version of  $\text{TT}^{\text{obs}}$ . In this section, we consider several extensions of the theory. In regular MLTT, adding a type generally means giving rules for type formation, introduction, elimination and computation of the eliminator. In our case, we also need to provide computation rules for equality of types, equality of terms, and cast. These extensions have not been formalized in the companion AGDA development.

### 4.1 Quotient Types

Quotients are a ubiquitous construction in mathematics, and one that is famously difficult to handle smoothly in MLTT. The usual way to handle quotients is *via* setoids, but since this structure is not built in MLTT, all the functions between setoids, all the predicates, etc... have to be supplemented with equality preservation lemmas—which appears to be quickly unmanageable.

In  $\text{TT}^{\text{obs}}$  however, every type is already a setoid and every term preserves the setoid equality by construction. This is a very comfortable setting for quotients, that can thus be added to the theory—provided the relation that induces the quotient is proof-irrelevant. This can be seen as a limitation, as noticed by Sterling et al. [2019], as it is generally impossible to extract proof-relevant information from equality in the quotient type. This is in contrast with the development of higher inductive types in the cubical setting [Coquand et al. 2018]. On the other hand, the positive consequence of this limitation is that the elimination principle of the quotient types is fairly easy to manipulate in  $\text{TT}^{\text{obs}}$ .

Quotient types are defined on a type  $A$  equipped with an equivalence relation on  $A$

$$\frac{\begin{array}{l} \Gamma \vdash A : \mathcal{U}_i \quad \Gamma \vdash R : A \rightarrow A \rightarrow \Omega \quad \Gamma \vdash R_r : \Pi(x : A). R x x \\ \Gamma \vdash R_s : \Pi(x, y : A). R x y \rightarrow R y x \quad \Gamma \vdash R_t : \Pi(x, y, z : A). R x y \rightarrow R y z \rightarrow R x z \end{array}}{\Gamma \vdash A/(R, R_r, R_s, R_t) : \mathcal{U}_i}$$

Since the proofs of reflexivity, symmetry and transitivity appear everywhere but are proof-irrelevant, we will generally omit them in the assumptions of the rules, and write  $A/R$  instead of  $A/(R, R_r, R_s, R_t)$ . The only constructor of quotient types is the canonical projection: from an element  $t$  of  $A$ , one obtains an element  $\pi(t)$  of  $A/R$  that is whnf, and equality between two canonical projections reduces to  $R$ .

$$\frac{\Gamma \vdash t : A}{\Gamma \vdash \pi(t) : A/R} \quad \frac{\Gamma \vdash t : A \quad \Gamma \vdash u : A}{\Gamma \vdash \pi(t) \sim_{A/R} \pi(u) \Rightarrow R t u : \Omega_i}$$

The definition of `cast` between two quotient types reduces when the casted term is a canonical projection.

$$\frac{\Gamma \vdash e : A/R \sim_{\mathcal{U}} A'/R' \quad \Gamma \vdash t : A}{\Gamma \vdash \text{cast}(A/R, A'/R', e, \pi(t)) \Rightarrow \pi(\text{cast}(A, A', \text{fst}(e), t)) : A/R'}$$

Observational equality between two quotient types reduces to equality of the (proof-relevant part of the) telescopes that define each quotient:

$$\frac{\Gamma \vdash A : \mathcal{U}_i \quad \Gamma \vdash R : A \rightarrow A \rightarrow \Omega \quad \Gamma \vdash A' : \mathcal{U}_i \quad \Gamma \vdash R' : A' \rightarrow A' \rightarrow \Omega}{\Gamma \vdash A/R \sim_{\mathcal{U}} A'/R' \Rightarrow \exists (e : A \sim_{\mathcal{U}} A'). \Pi(x y : A). R x y \sim_{\Omega} R \text{cast}(A, A', e, x) \text{cast}(A, A', e, y) : \Omega_i}$$

The eliminator for quotient types encodes the universal property of quotients: to construct a function out of a quotient  $A/R$ , it suffices to give a function  $t_\pi$  out of  $A$  such that if  $R x y$ , then their images under  $t_\pi$  are equal.

$$\frac{\Gamma \vdash B : A/R \rightarrow s_i \quad \Gamma \vdash t_\pi : \Pi(x : A). B \pi(x)}{\Gamma \vdash t_\sim : \Pi(x, y : A). \Pi(e : R x y). (t_\pi x) \sim_{B \pi(x)} \text{cast}(B \pi(y), B \pi(x), B e^{-1}, t_\pi y) \quad \Gamma \vdash u : A/R} \\ \Gamma \vdash \text{Q-elim}(B, t_\pi, t_\sim, u) : B u$$

The eliminator for quotient types has the obvious computation rule

$$\frac{\Gamma \vdash B : A/R \rightarrow s_i \quad \Gamma \vdash t_\pi : \Pi(x : A). B \pi(x)}{\Gamma \vdash t_\sim : \Pi(x, y : A). \Pi(e : R x y). (t_\pi x) \sim_{B \pi(x)} \text{cast}(B \pi(y), B \pi(x), B e^{-1}, t_\pi y) \quad \Gamma \vdash u : A} \\ \Gamma \vdash \text{Q-elim}(B, t_\pi, t_\sim, \pi(u)) \Rightarrow t_\pi u : B(\pi(u))$$

There are also reduction rules that reduce terms to a weak head normal form under equality (of the form  $A/R \sim_{\mathcal{U}} X$ , and  $x \sim_{A/R} y$ ,  $\pi(a) \sim_{A/R} y$ ), and similarly for `cast` and quotient elimination, as well as new congruence rules.

We now turn to the proof that the metatheoretical properties of  $\text{TT}^{\text{obs}}$  are preserved by the addition of quotient types. More explicitly, we extend the logical relation framework and its fundamental lemma, as well as the setoid model, to quotient types. From there, we can replay our proofs of consistency, normalization, canonicity and decidability.

*Reducibility.* We first extend the reducibility proof to quotient types. Since they add a new family of types in normal form, we need to add a case to the logical relation:

$$\frac{\Gamma \vdash A \Rightarrow^* A'/(R, R_r, R_s, R_t) : \mathcal{U}_i \quad \Gamma \vdash A' : \mathcal{U}_i \quad \forall \Delta \rho. \Delta \Vdash_{\ell} A'[\rho] \quad \Gamma \Vdash_{\ell} R : A' \rightarrow A' \rightarrow \Omega \quad \Gamma \vdash R_r : \Pi(x : A'). R x x \\ \Gamma \vdash R_s : \Pi(x, y : A'). R x y \rightarrow R y x \quad \Gamma \vdash R_t : \Pi(x, y, z : A'). R x y \rightarrow R y z \rightarrow R x z}{\Gamma \Vdash_{\ell} A}$$

Given a type  $A$  reducible to a quotient type, we define:

- $\Gamma \Vdash_{\ell} A \equiv B$  if there are terms  $B', Q, Q_r, Q_s, Q_t$  such that
  - $\Gamma \vdash B \Rightarrow^* B'/(Q, Q_r, Q_s, Q_t) : \mathcal{U}_i$
  - $\forall \Delta \rho. \Delta \Vdash_{\ell} A'[\rho] \equiv B'[\rho]$
  - $\Gamma \Vdash_{\ell} R \equiv Q : A' \rightarrow A' \rightarrow \Omega$ .

- $\Gamma \Vdash_{\ell} t : A$  if there is a normal form  $t'$  such that  $\Gamma \vdash t \Rightarrow^* t' : A'/R$  and  $\Gamma \Vdash_Q t'$ , which is defined by

$$\frac{\Gamma \Vdash_{\ell} t : A' \quad \Gamma \vdash n : A'/R \quad n \text{ is neutral}}{\Gamma \Vdash_Q \pi(t) \quad \Gamma \Vdash_Q n}$$

- $\Gamma \Vdash_{\ell} t \equiv u : A$  if there are normal forms  $t', u'$  such that  $\Gamma \vdash t \Rightarrow^* t' : A'/R$  and  $\Gamma \vdash u \Rightarrow^* u' : A'/R$ , and  $\Gamma \Vdash_Q t' \equiv u'$ , which is inductively defined by

$$\frac{\Gamma \Vdash_{\ell} t \equiv u : A' \quad \Gamma \vdash n \equiv m : A'/R \quad n, m \text{ are neutral}}{\Gamma \Vdash_Q \pi(t) \equiv \pi(u) \quad \Gamma \Vdash_Q n \equiv m}$$

Then, the proof of the fundamental lemma can be extended to handle the new typing rules, as well as the new cases of logical relation.

*Interpretation in the Model.* The type Setoid of setoids is naturally closed under quotients. Indeed, given a setoid  $A$ , providing  $A$  with a relation  $R : A \times A \rightarrow_s \text{Prop}$  that is reflexive, symmetric and transitive is exactly the same thing as defining an equivalence relation on the carrier set of  $A$  that extends setoidal equality. Then,  $A/R$  is simply defined as a setoid having  $A$  for its carrier set, and the relation  $R$  as its setoidal equality. One can then easily show that  $A/R$  satisfies the universal property of a mathematical quotient, which tells us that this construction is the right candidate to interpret our quotient types.

However, our universe hierarchy  $\mathbf{U}_i$  is not closed under quotients, since its elements are inductively built from  $\mathbf{N}$ , universes and function types. Therefore, we need to modify our inductive-recursive definition to account for them. In the definition of  $\mathbf{U}_i$ , we add a constructor

$$\begin{aligned} c_Q & : (A : \mathbf{U}_i) \\ & \rightarrow (R : \text{el } A \rightarrow_s \text{el } A \rightarrow_s \Omega_i) \\ & \rightarrow (R_r : (x : \text{el } A) \rightarrow_s \text{val } (R \ x \ x)) \\ & \rightarrow (R_s : (x \ y : \text{el } A) \rightarrow_s \text{val } (R \ x \ y) \rightarrow \text{val } (R \ y \ x)) \\ & \rightarrow (R_t : (x \ y \ z : \text{el } A) \rightarrow_s \text{val } (R \ x \ y) \rightarrow \text{val } (R \ y \ z) \rightarrow \text{val } (R \ x \ z)) \\ & \rightarrow \mathbf{U}_i \end{aligned}$$

In the definition of  $\text{el}$ , our new constructor is handled as follows:

$$\text{el } (c_Q \ A \ R \ R_r \ R_s \ R_t) := (\text{el } A) / (\lambda x \ y. \text{val } (R \ x \ y))$$

In the definition of the setoidal equality on  $\mathbf{U}_i$ :

$$c_Q \ A \ R \ R_r \ R_s \ R_t \approx c_Q \ A' \ R' \ R'_r \ R'_s \ R'_t := (e : A \approx A') \times ((x \ y : A) \rightarrow_s R \ x \ y \approx R' \ (\text{el-eq } e \ x) \ (\text{el-eq } e \ y))$$

and all of the other cases that involve  $c_Q$  and a different constructor reduce to  $\perp$ . We also need to update the definition of  $\text{el-eq}$ :

$$\text{el-eq } (c_Q \ A \ R \ R_r \ R_s \ R_t) \ (c_Q \ A' \ R' \ R'_r \ R'_s \ R'_t) \ e := (\lambda x. \text{el-eq } A \ A' \ e.1 \ x, \lambda x. \text{el-eq}^{-1} \ A \ A' \ e.1 \ x)$$

Finally, the reader can check that we can extend the proofs of reflexivity, symmetry and transitivity for  $\approx$  on  $\mathbf{U}_i$ , as well as the proofs that  $\text{el-eq}$  is compatible with reflexivity and transitivity. This defines a new universe that is closed under quotient type formation. We let the reader check that the interpretation of the syntax that defines quotients can be done in this extended universe  $\mathbf{U}_i$ .

## 4.2 Id Types

The reader may wonder if  $\text{TT}^{\text{obs}}$  extends Martin-Löf type theory with inductive types: that is, whether a judgment of MLTT is a judgment in the proof-relevant fragment of  $\text{TT}^{\text{obs}}$ . Our rules handle the universe hierarchy, dependent products, the natural numbers in the exact same way. But there are some difficulties with Martin-Löf identity type inductive equality, and more generally with indexed inductive types.

The first idea that might come to the reader's mind is to use the proof equality types of  $\mathbb{T}^{\text{obs}}$  to interpret the  $I$ -types of MLTT. Sure enough, proof irrelevance will provide us with more definitional equalities than what we require. However, we need to explain how we interpret the  $J$  eliminator for proof-relevant predicates.

It is not too hard to design a term that satisfies the correct typing rule, for instance, the term

$$\frac{\Gamma \vdash t : A \quad \Gamma \vdash B : \Pi(x : A). t \sim_A x \rightarrow \mathcal{U}_j \quad \Gamma \vdash A : \mathcal{U}_i \quad \Gamma \vdash b : B \text{ refl}(t) \quad \Gamma \vdash t' : A \quad \Gamma \vdash e : t \sim_A t'}{\Gamma \vdash \text{cast}(B \text{ refl}(t), B t' e, \text{eq}(A, t, u, t', e), b) : B t' e}$$

where

$$\text{eq}(A, t, B, u, t')e := \text{transp}(t, \lambda(x : A). \lambda(e' : t \sim x). B \text{ refl}(A) \sim B x e', \text{refl}(B \text{ refl}(A)), t', e).$$

But the computational behavior is not preserved: in general, this term will not reduce to  $u$  when we substitute  $t' = t$  and  $e = \text{refl}(t)$ . It might do when  $B$  is a closed term, but it certainly will not if  $B$  is a neutral term. More generally, there is no hope to interpret  $I$ -types as proof-irrelevant types:  $I$ -types compute by doing reduction and pattern-matching on the equality proof, which cannot happen in a proof-irrelevant context.

A very similar problem was encountered by Cohen et al. [2015] in Cubical Type Theory with equality defined using the `Path` type, and solved by Swan [2016]. Following his ideas, we introduce `Id`-types:

$$\frac{\Gamma \vdash A : \mathcal{U}_i \quad \Gamma \vdash t : A \quad \Gamma \vdash u : A}{\Gamma \vdash \text{Id}(A, t, u) : \mathcal{U}_i} \quad \frac{\Gamma \vdash A : \mathcal{U}_i \quad \Gamma \vdash t : A}{\Gamma \vdash \text{Idrefl}(t) : \text{Id}(A, t, t)} \quad \frac{\Gamma \vdash e, e' : \text{Id}(A, t, u)}{\Gamma \vdash e \sim_{\text{Id}(A, t, u)} e' \Rightarrow \top : \Omega_i}$$

$$\frac{\Gamma \vdash t : A \quad \Gamma \vdash B : \Pi(x : A). \text{Id}(A, t, x) \rightarrow s_j \quad \Gamma \vdash u : B \text{ Idrefl}(t) \quad \Gamma \vdash t' : A \quad \Gamma \vdash e : \text{Id}(A, t, t')}{\Gamma \vdash J(A, t, B, u, t', e) : B t' e}$$

$$\frac{\Gamma \vdash A : \mathcal{U}_i \quad \Gamma \vdash t : A \quad \Gamma \vdash B : \Pi(x : A). \text{Id}(A, t, x) \rightarrow s_j \quad \Gamma \vdash b : B \text{ Idrefl}(t)}{\Gamma \vdash J(A, t, B, b, t, \text{Idrefl}(t)) \Rightarrow u : B \text{ Idrefl}(t)}$$

These rules mimic the behavior of inductive  $I$ -types, quotiented so they contain only one inhabitant up to propositional equality. Observational equality between two identity types is defined as equality of the telescopes of arguments, as for the quotient type:

$$\frac{\Gamma \vdash A : \mathcal{U}_i \quad \Gamma \vdash t : A \quad \Gamma \vdash u : A \quad \Gamma \vdash A' : \mathcal{U}_i \quad \Gamma \vdash t' : A' \quad \Gamma \vdash u' : A'}{\Gamma \vdash \frac{\text{Id}(A, t, u) \sim_{\mathcal{U}} \text{Id}(A', t', u') \Rightarrow \exists(e : A \sim_{\mathcal{U}} A'). \text{cast}(A, A', e, t) \sim_{A'} t' \wedge \text{cast}(A, A', e, u) \sim_{A'} u' : \Omega_j}}$$

We may hope to define computation rules for `cast` by simply reducing the equality proof to a weak head normal form, and then commuting `cast` with the head constructor like we did for other positive types. However, we quickly run into a problem:

$$\frac{\Gamma \vdash A, A' : \mathcal{U}_i \quad \Gamma \vdash t : A \quad \Gamma \vdash t, u : A' \quad \Gamma \vdash e : \text{Id}(A, t, t) \sim \text{Id}(A', t', u')}{\Gamma \vdash \text{cast}(\text{Id}(A, t, t), \text{Id}(A', t', u'), e, \text{Idrefl}(t)) \Rightarrow ? : \text{Id}(A', t', u')}$$

We cannot reduce this term to `Idrefl`, because  $t'$  and  $u'$  are not convertible in general— $e$  only provides us with a propositional equality  $t' \sim_{A'} u'$ . In order to fix this, we add a term `Idpath`( $e$ ) that turns any inhabitant of  $e : t \sim_A u$  into an inhabitant of `Id`( $A, t, u$ ).

$$\frac{\Gamma \vdash A : \mathcal{U}_i \quad \Gamma \vdash t : A \quad \Gamma \vdash u : A \quad \Gamma \vdash e : t \sim_A u}{\Gamma \vdash \text{Idpath}(e) : \text{Id}(A, t, u)}$$

Then, the computation rule for cast on  $\text{Idrefl}(t)$  can be defined as:

$$\frac{\Gamma \vdash A, A' : \mathcal{U}_i \quad \Gamma \vdash t : A \quad \Gamma \vdash t', u' : A' \quad \Gamma \vdash e : \text{Id}(A, t, t) \sim \text{Id}(A', t', u')}{\Gamma \vdash \text{cast}(\text{Id}(A, t, t), \text{Id}(A', t', u'), e, \text{Idrefl}(t)) \Rightarrow \text{Id}(A', t', u') : \text{Id}(A', t', u') \\ \text{Idpath}(\text{fst}(\text{snd}(e))^{-1} \cdot \text{snd}(\text{snd}(e)))}$$

We also need to account for this additional constructor in reduction rules:

$$\frac{\Gamma \vdash t : A \quad \Gamma \vdash B : \Pi(x : A). \text{Id}(A, t, x) \rightarrow s_j \quad \Gamma \vdash b : B t \text{Idrefl}(t) \quad \Gamma \vdash t' : A \quad \Gamma \vdash e : t \sim_A t'}{\Gamma \vdash \text{J}(A, t, B, b, t', \text{Idpath}(e)) \Rightarrow \text{cast}(B t \text{Idrefl}(t), B t' \text{Idpath}(e), \text{eqj}(A, t, B, u, t')e, b) : B t' \text{Idpath}(e)}$$

$$\frac{\Gamma \vdash A, A' : \mathcal{U}_i \quad \Gamma \vdash t, u : A \quad \Gamma \vdash e : t \sim_A u \quad \Gamma \vdash t', u' : A' \quad \Gamma \vdash e' : \text{Id}(A, t, t) \sim \text{Id}(A', t', u')}{\Gamma \vdash \text{cast}(\text{Id}(A, t, u), \text{Id}(A', t', u'), e', \text{Idpath}(e)) \Rightarrow \text{Idpath}(\text{fst}(\text{snd}(e'))^{-1} \cdot \text{ap}(\text{cast}(A, A', \text{fst}(e'), -)) e \cdot \text{snd}(\text{snd}(e'))) : \text{Id}(A', t', u')}$$

Along with congruence rules and reduction of the scrutinee of  $J$  and cast, these form the rules for Id types.

*Relation with Setoid Equality.* The introduction rule for  $\text{IdPath}$  proves that  $t \sim_A u$  implies  $\text{Id}(A, t, u)$ . Conversely, if we have an inhabitant of  $\text{Id}(A, t, u)$ , we can get a proof of  $t \sim_A u$  by combining  $J$  to reduce it to the case  $u = t$ , and  $\text{refl}(t)$  to inhabit  $t \sim_A t$ . Since both types are also contractible (for both notions of equality), they are equivalent.

*Reducibility Proof.* In order to fit identity types in the normalization proof, we add another case to the logical relation:

$$\frac{\Gamma \vdash A \Rightarrow^* \text{Id}(A', t, u) : \mathcal{U}_i \quad \Gamma \Vdash_{\ell} A' \quad \Gamma \Vdash_{\ell} t : A' \quad \Gamma \Vdash_{\ell} u : A'}{\Gamma \Vdash_{\ell} A}$$

When  $A$  is reducible to an identity type, we define:

- $\Gamma \Vdash_{\ell} A \equiv B$  if there are terms  $B', t', u'$  such that
  - $\Gamma \vdash B \Rightarrow^* \text{Id}(B', t', u') : \mathcal{U}_i$
  - $\Gamma \Vdash_{\ell} A' \equiv B'$
  - $\Gamma \Vdash_{\ell} t \equiv t' : A'$
  - $\Gamma \Vdash_{\ell} u \equiv u' : A'$ .
- $\Gamma \Vdash_{\ell} e : A$  if there is a normal form  $e'$  such that  $\Gamma \vdash e \Rightarrow^* e' : \text{Id}(A', t, u)$  and  $\Gamma \Vdash_{\text{Id}} e'$ , which is defined by

$$\frac{}{\Gamma \Vdash_{\text{Id}} \text{Idrefl}(t)} \quad \frac{\Gamma \vdash e : t \sim_{A'} u}{\Gamma \Vdash_{\text{Id}} \text{Idpath}(e)} \quad \frac{\Gamma \vdash n : \text{Id}(A', t, u) \quad n \text{ is neutral}}{\Gamma \Vdash_{\text{Id}} n}$$

- $\Gamma \Vdash_{\ell} e \equiv f : A$  if there are normal forms  $e', f'$  such that  $\Gamma \vdash e \Rightarrow^* e' : \text{Id}(A', t, u)$  and  $\Gamma \vdash f \Rightarrow^* f' : \text{Id}(A', t, u)$ , and  $\Gamma \Vdash_{\text{Id}} e' \equiv f'$ , which is inductively defined by

$$\frac{}{\Gamma \Vdash_{\text{Id}} \text{Idrefl}(t) \equiv \text{Idrefl}(t)} \quad \frac{\Gamma \vdash e, f : t \sim_{A'} u}{\Gamma \Vdash_{\text{Id}} \text{Idpath}(e) \equiv \text{Idpath}(f)}$$

$$\frac{\Gamma \vdash n \equiv m : \text{Id}(A', t, u) \quad n, m \text{ are neutral}}{\Gamma \Vdash_{\text{Id}} n \equiv m}$$

Again, the proof of the fundamental lemma can be extended to handle the new typing rules, as well as the new cases of the logical relation.

### 1128 4.3 Box and Squash

1129 Box types embed the proof-irrelevant types into the proof-relevant world. They are useful for  
 1130 a number of constructions: for instance, from a type  $A : \mathcal{U}_i$  and a proof-irrelevant predicate  
 1131  $P : A \rightarrow \Omega_i$ , one can build a *subset type*  $\Sigma(x : A). \Box(P x) : \mathcal{U}_i$  whose inhabitants come with a proof  
 1132 of  $P$ , but retain the computational behavior of inhabitants of  $A$ .

1133 Another typical use of  $\Box$  is to define a singleton type on which it is possible to reason about  
 1134 equality. Indeed, although  $\top$  has only one inhabitant up-to conversion, it is not possible to state  
 1135 this internally as equality on propositions is not defined. However, one can state contractibility of  
 1136 the type  $\Box\top$  and prove it, as it lives in  $\mathcal{U}$ .

1137 Box types can be defined as:

$$\begin{array}{c}
 1139 \frac{\Gamma \vdash A : \Omega_i \quad \Gamma \vdash A : \Omega_i \quad \Gamma \vdash t : A}{\Gamma \vdash \Box A : \mathcal{U}_i} \quad \frac{\Gamma \vdash \diamond t : \Box A}{\Gamma \vdash \diamond t : \Box A} \quad \frac{\Gamma \vdash t, u : \Box A}{\Gamma \vdash t \sim_{\Box A} u \Rightarrow \top : \Omega_i} \quad \frac{\Gamma \vdash A : \Omega_i \quad \Gamma \vdash t : \Box A}{\Gamma \vdash \Box\text{-elim}(t) : A} \\
 1140 \\
 1141 \frac{\Gamma \vdash A, B : \Omega_i}{\Gamma \vdash \Box A \sim_{\mathcal{U}} \Box B \Rightarrow A \sim_{\Omega} B : \Omega_j} \quad \frac{\Gamma \vdash A, B : \Omega_i \quad \Gamma \vdash t : A \quad \Gamma \vdash e : \Box A \sim_{\mathcal{U}} \Box B}{\Gamma \vdash \text{cast}(\Box A, \Box B, e, \diamond t) \Rightarrow \diamond \text{cast}(A, B, e, t) : \Box B} \\
 1142 \\
 1143
 \end{array}$$

1144 Conversely, Squash types embed the proof-relevant world into the proof-irrelevant world.

$$\begin{array}{c}
 1145 \frac{\Gamma \vdash A : \mathcal{U}_i}{\Gamma \vdash \|A\| : \Omega_i} \quad \frac{\Gamma \vdash A : \mathcal{U}_i \quad \Gamma \vdash t : A}{\Gamma \vdash |t| : \|A\|} \\
 1146 \\
 1147 \frac{\Gamma \vdash A : \mathcal{U}_i \quad \Gamma \vdash P : \|A\| \rightarrow \Omega_j \quad \Gamma \vdash t_A : \Pi(x : A). P |x| \quad \Gamma \vdash t : \|A\|}{\Gamma \vdash \text{S-elim}(P, t_A, t) : P t} \\
 1148 \\
 1149
 \end{array}$$

1150 It is not very difficult to check that we can extend the logical relation, as well as Lemmas 3.3 and 3.4  
 1151 so that they handle Box types and Squash types. Likewise, we can extend the setoid model and its  
 1152 interpretation function, and obtain that these additions preserve the metatheoretical properties of  
 1153  $\top\top^{\text{obs}}$ .

### 1154 4.4 Other Standard Inductive Types

1156 So far, we have explained how to integrate integers and the identity type to  $\top\top^{\text{obs}}$ , but it is not  
 1157 difficult to integrate  $\Sigma$ -types as well. The rules for  $\Sigma$ -types are similar to the rules for  $\exists$ -types,  
 1158 except for the fact that the types live in  $\mathcal{U}$ , which means that we also need to define equality and  
 1159 cast on  $\Sigma$ -types. We note  $(a; b)$  for pairs in  $\Sigma$ -types to distinguish them from pairs in  $\exists$ -types.

$$\begin{array}{c}
 1160 \text{EQ-PAIR} \\
 1161 \frac{\Gamma \vdash a : A \quad \Gamma \vdash a' : A \quad \Gamma \vdash b : B[x := a] \quad \Gamma \vdash b' : B[x := a'] \quad e' := \text{ap } B e}{\Gamma \vdash (a; b) \sim_{\Sigma AB} (a'; b') \Rightarrow \exists(e : a \sim_A a'). \text{cast}(B[x := a], B[x := a'], e', b) \sim_B b' : \Omega_i} \\
 1162 \\
 1163 \\
 1164
 \end{array}$$

$$\begin{array}{c}
 1165 \text{EQ-}\Sigma \\
 1166 \frac{\Gamma \vdash A, A' : s_i \quad \Gamma, x : A \vdash B : s'_j \quad \Gamma, x : A' \vdash B' : s'_j \quad a := \text{cast}(A', A, e^{-1}, a')}{\Gamma \vdash \frac{\Sigma(x : A). B \sim_{\mathcal{U}k} \Sigma(x : A'). B' \Rightarrow \exists(e : A \sim_{\mathcal{U}i} A'). \Pi(a' : A'). B[x := a] \sim_{\mathcal{U}j} B'[x := a']}{j \leq k} : \Omega_i} \\
 1167 \\
 1168 \\
 1169
 \end{array}$$

$$\begin{array}{c}
 1170 \text{CAST-}\Sigma \\
 1171 \frac{\Gamma \vdash e : \Sigma(x : A). B \sim_{\mathcal{U}} \Sigma(x : A'). B' \quad \Gamma \vdash a : A \quad \Gamma \vdash b : B[x := a] \quad a' := \text{cast}(A, A', \text{fst}(e), a)}{\Gamma \vdash \frac{\text{cast}(\Sigma(x : A). B, \Sigma(x : A'). B', e, (a; b)) \Rightarrow (a'; \text{cast}(B[x := a], B[x := a'], \text{snd}(e), b))}{: \Sigma(x : A'). B'} \\
 1172 \\
 1173
 \end{array}$$

1174 We conjecture that the reduction of equality and cast for any indexed inductive types as defined in  
 1175 CIC can be described, although we leave the general construction for future work.

## 5 RELATED AND FUTURE WORK

Compared to [Altenkirch et al. 2007], the most important ingredient in  $\text{TT}^{\text{obs}}$  is the use of definitional proof irrelevance. This added flexibility in computations allows our recursors to enjoy proper computational behavior on open terms, and it also lets us seamlessly treat universe hierarchies. Moreover, the normalization proof for OTT relies on a normalization conjecture for a different theory, unlike the normalization proof for  $\text{TT}^{\text{obs}}$ .

In [Altenkirch et al. 2019], the authors define a setoid model in  $\text{MLTT} + \Omega$ . Then, they interpret a version of  $\text{MLTT}$  with proof-irrelevant identity types that support  $\text{propext}$  and  $\text{funext}$  in their model, thereby providing a computational interpretation of these principles. However, handling universes in their model requires some additions to  $\text{MLTT} + \Omega$ , and the resulting theory is only conjectured to be normalizing. In contrast to this,  $\text{TT}^{\text{obs}}$  is a full-fledged type theory and does not require any external model to compute.

Compared to  $\text{XTT}$  [Sterling et al. 2019], the strengths of  $\text{TT}^{\text{obs}}$  are a normalization strategy that exhibits canonicity, as well as a full proof that conversion and typing are decidable. These properties allow us to present a concrete implementation of our system in a proof assistant. In  $\text{XTT}$  however, Sterling et al. show that typing cannot be decidable, as there is no way to deduce  $A \sim A'$  and  $B \sim B'$  from a proof of  $A \times B \sim A' \times B'$ . In order to fix this shortcoming, they suggest adding a “typecase” operator to  $\text{th}$  theory, but argue against it since it forces the universe to be closed, thereby severely constraining the possible semantics. In  $\text{TT}^{\text{obs}}$ , we obtain the injectivity of type constructors from the behavior of observational equality in the universe. These rules somewhat constrain the semantics—for instance, we cannot interpret  $\text{TT}^{\text{obs}}$  in set theory using a Grothendieck universe as the interpretation of  $\mathcal{U}$ —but our universe remains open to the addition of arbitrary types.

Finally, our setoidal adaptation of Swan’s Id types [Swan 2016] turns  $\text{TT}^{\text{obs}}$  into a proper extension of  $\text{MLTT}$ , which realizes UIP,  $\text{funext}$  and  $\text{propext}$  while enjoying algorithmic canonicity. To the best of our knowledge, this is a new result.

The natural next step of our work is to implement  $\text{TT}^{\text{obs}}$  inside  $\text{COQ}$ ,  $\text{LEAN}$  or  $\text{AGDA}$ , which should not be too difficult as all of them already feature a proof-irrelevant universe of propositions. The main missing ingredient for a concrete implementation is a general description of the reduction of equality and cast on arbitrary indexed inductive types, as explained in Section 4.4.

Another interesting line of work is the marriage of  $\text{TT}^{\text{obs}}$  with cubical type theory in a 2-level type theory setting [Altenkirch et al. 2016; Capriotti 2017; Voevodsky 2013], which could lead to an implementation of  $\text{TT}^{\text{obs}}$  in the cubical extension of  $\text{AGDA}$  [Vezzosi et al. 2019].
