HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Device-Independent Quantification of Quantum Resources

Motivation and Goals

- Quantum resources (states, measurements, channels, ...) provide advantages that can be operationally quantified
- Quantifying a given resource typically requires well characterised states and/or measurements to probe the resource
- What resources can be characterised in a **device independent** way?
- Goal:** use techniques from self-testing to **certify and quantify any resourceful object** in a black-box setting

Quantum Resources

We consider resources with convex free sets:

- States:** entanglement, steerability, non-Gaussianity, magic, ...
- Measurements:** incompatibility, non-projective-simulability, ...
- Channels:** non-entanglement-breaking and non-incompatibility-breaking channels, thermal operations, ...

We focus on **channel resources**

- The resourcefulness of Λ w.r.t. a free set F can be quantified with the **generalised robustness**:

$$R_F(\Lambda) = \min_{\tilde{\Lambda}} \left\{ t \geq 0 \mid \frac{\Lambda + t\tilde{\Lambda}}{1+t} \in F \right\}$$

Resource Quantification with Input-Output Games [2]

- $R_F(\Lambda)$ related to operational advantage in an input-output game $\mathcal{G} = (\mathcal{E}, \mathcal{M}, \Omega)$:

$$\begin{aligned} \mathcal{E} &= \{p(x)\rho_x\}_x && \text{(input state ensemble)} \\ \mathcal{M} &= \{M_d\}_d && \text{(a POVM)} \\ \Omega &= \{w_{x,d}\}_{x,d} && \text{(score)} \end{aligned}$$

$$P(\Lambda, \mathcal{G}) = \sum_{x,d} p(x) \omega_{x,d} \text{tr}[\Lambda(\rho_x) M_d] \quad (\text{payout})$$

- For well-normalised input-output games, payout a resource can give is directly related to its robustness:

$$1 + \mathcal{R}_F(\Lambda) = \max_{\mathcal{G}} P(\Lambda, \mathcal{G})$$

- Device dependent:** Must trust \mathcal{E} and \mathcal{M} !

Self-testing [3]

Certify exact form of a state and measurements from correlations $p(a, b|x, y)$

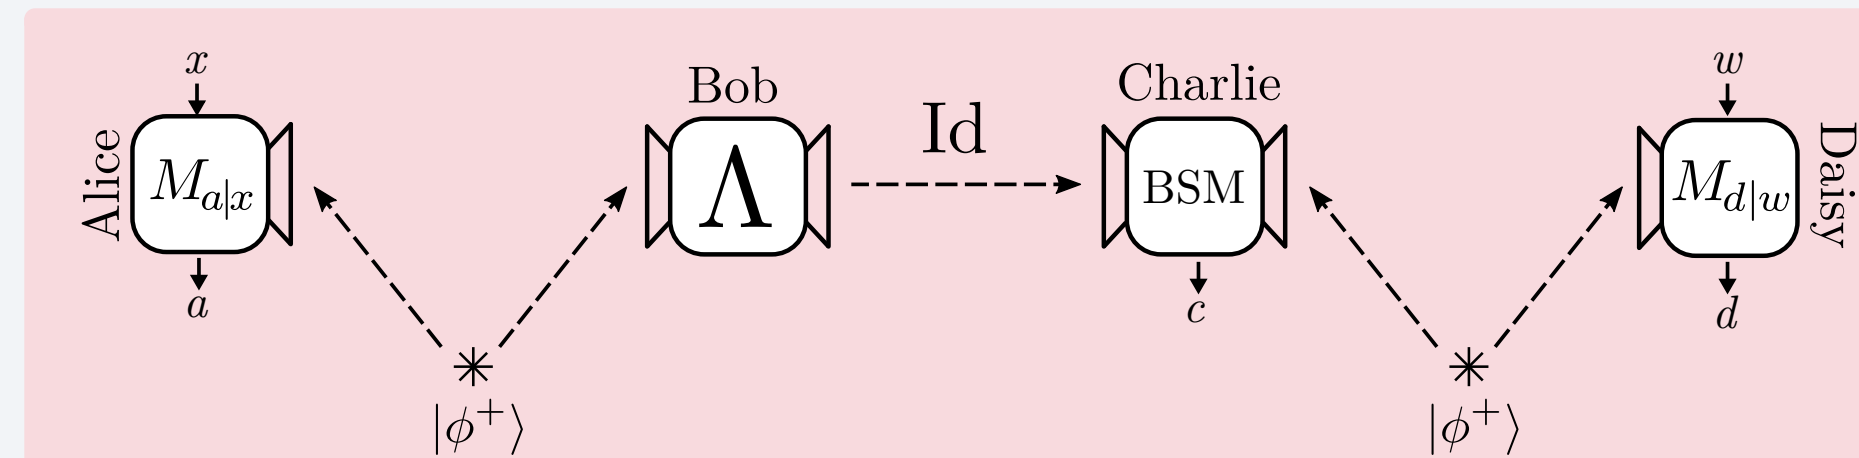

- E.g.: maximal violation of a Bell inequality can certify:
 - $\rho \simeq |\phi^+\rangle\langle\phi^+|$, Alice and Bob measure Pauli X, Y, Z
- Certification up to local isometries and complex conjugate

Reference Scenario & Protocol

Use self-testing to characterise, device-independently:

- remote preparation of pure states $\{\rho_x\}_x$
- arbitrary measurement $\{M_d\}_d$

- On input x , Alice remotely prepares ρ_x for Bob by performing a suitable measurement on her share of $|\phi^+\rangle^{AB}$.
- Bob applies Λ to ρ_x and sends $\Lambda(\rho_x)$ to Charlie via the identity channel Id .
- Charlie performs a Bell-state measurement (BSM) on $\Lambda(\rho_x)$ and his share of $|\phi^+\rangle^{CD}$, teleporting to Daisy the state $\sigma_c \Lambda(\rho_x) \sigma_c^\dagger$.
- Daisy measures $\{M_{d|w}\}_d = \{\sigma_w M_d \sigma_w^\dagger\}_d$ on the teleported state; for $w = c$ this is equivalent to measuring $\{M_d\}_d$ on $\Lambda(\rho_x)$.

$$P(\Lambda, \mathcal{G}) = \sum_{x,d} p(x) \omega_{x,d} \sum_{c,w} \frac{1}{p(0|x)} p(0, c, d|x, w) \delta_{c,w}$$

Device-independent Quantification Protocol

Add extra inputs to self-test (up to local isometries):

- Maximally entangled states ρ^{AB} and ρ^{CD}
- Pauli X, Y, Z measurements for Alice and Daisy
- Identity channel Ξ^{BC}
- Bell-state measurement for Charlie

Quantification Statement

- The statistics on “quantification rounds” give the payoff $P(\Lambda^{\text{ext}}, \mathcal{G})$ of an **effective (extractable) channel**

$$\Lambda^{\text{ext}} = h_{00} \Lambda_{00}^{\text{ext}} + h_{11} \tilde{\Lambda}_{11}^{\text{ext}}$$

- $\tilde{\Lambda}_{11}^{\text{ext}}(\rho) = \Lambda_{11}^{\text{ext}}(\rho^*)^*$ (conjugate channel)
- $\Lambda_{ii}^{\text{ext}}$ can be extracted with local isometries from the physical effective channel $\mathcal{T}^{C \rightarrow D} \circ \Xi^{BC} \circ \Lambda$ from Bob to Daisy and takes into account “junk states” ξ_{ii} arising during extraction
- Λ_{00} and Λ_{11} differ in junk states arising from self-testing (indistinguishability of correlated Alice-Daisy conjugation)
- DI certification that we can extract a channel with payout $P(\Lambda^{\text{ext}}, \mathcal{G})$ on \mathcal{G}

Relation to Physical Channel

For “well-behaved” resources:

- Resource certification:** If Λ is resourceless, so is Λ^{ext}
- Quantification bound:** $P(\Lambda^{\text{ext}}, \mathcal{G}) \leq \max_{\mathcal{G}'} P(\Lambda, \mathcal{G}')$
 - i.e., $R_F(\Lambda^{\text{ext}}) \leq R_F(\Lambda)$

Resource must satisfy certain preconditions:

- Can’t be increased by local unitaries
- Insensitive to channel conjugation
- Unaffected by attaching extra DOFs that measurements are trivial on

Examples

- Non-entanglement-breaking and non-incompatibility-breaking channels are faithfully quantified in this way
- Can be significantly simplified for state or measurement resources
 - E.g., input-output games \rightarrow state-discrimination games
 - Complements known DI certification of all entangled states [4]
- We likewise obtain a fully black-box certification of any sets of incompatible measurements

Conclusions and Open Questions

- DI **certification** of any* resourceful channel
- Correlations **quantify** the resourcefulness of implemented channel
- Causal network structure of protocol important to its success
- Full characterisation of which resources can be quantified in this way?
