Abstract

We present normalization for intuitionistic combinatorial proofs (ICPs) and relate it to the simply-typed lambda-calculus. We prove confluence and strong normalization. Combinatorial proofs, or “proofs without syntax”, form a graphical semantics of proof in various logics that is canonical yet complexity-aware: they are a polynomial-sized representation of sequent proofs that factors out exactly the non-duplicating permutations. Our approach to normalization aligns with these characteristics: it is canonical (free of permutations) and generic (readily applied to other logics). Our reduction mechanism is a canonical representation of reduction in sequent calculus with closed cuts (no abstraction is allowed below a cut), and relates to closed reduction in lambda-calculus and supercombinators. While we will use ICPs concretely, the notion of reduction is completely abstract, and can be specialized to give a reduction mechanism for any representation of typed normal forms.

1 Introduction

The sequent calculus was introduced by Gentzen [7] as a meta-calculus, to describe the construction of proofs in natural deduction, the object-calculus. The sequent calculus has good proof-theoretic properties, such as isolating the cut-rule as the distinction between normal and non-normal proofs and avoiding the ad-hoc construction of open and closed assumptions. However, it features many permutations, that relate different ways of constructing the same natural deduction proof. This is a problem for proof normalization in particular, since permutations come to dominate the cut-elimination process.

When Girard introduced Linear Logic [8], it was naturally expressed in sequent calculus, which defined clear and natural meta-level operations for proof construction. But there was no object-level calculus to which these applied, and which might capture its computational content. Constructing one became the project of proof nets [8, 10, 16, 12], with the aim of canonicity: proof nets aim to represent sequent proofs canonically, modulo permutations.

Combinatorial proofs, first developed for classical propositional logic by Hughes [14], continue the tradition of proof nets with a refined aim, called local canonicity [15]. The issue is that permutations may duplicate subproofs; to factor them out then generally causes an exponential blowup of the representation. Figure 1 illustrates such a permutation. The idea of local canonicity is to give a complexity-sensitive, polynomial representation of sequent proofs, modulo the non-duplicating permutations. This is achieved in combinatorial proofs by a clean separation of the logical content (the logical rules of a sequent proof) and the structural content (the structural rules, contraction and weakening), each captured in a distinct part of a combinatorial proof. Sequent calculi are generally unable to stratify proofs in this way, but it
Figure 1 A duplicating permutation. Intuitionistic sequent calculus, as we will use it, has exactly one duplicating permutation, illustrated here. Permuting the contraction rule $c$ and the implication-left rule $\Rightarrow L$ duplicates the subproof on the left. Iterating the permutation gives exponential growth. It is instructive to consider the translation to natural deduction, which unfolds along this permutation and does indeed grow exponentially.

is a natural form of decomposition in deep inference [26]. Beyond classical propositional logic, combinatorial proofs have been given for intuitionistic propositional logic [13], first-order classical logic [17, 18], relevance logics [2], and modal logics [3].

We are interested in the question: what is a natural and general notion of composition for combinatorial proofs? In this paper we consider the intuitionistic case, Intuitionistic Combinatorial Proofs (ICPs) [13], where the question is particularly pertinent due to the Curry–Howard correspondence with typed lambda-calculi.

Our aim has been twofold: 1) to implement sequent-calculus reduction canonically (i.e. without permutations), and 2) to ensure our notion of reduction is sufficiently abstract that it will (plausibly) generalize to combinatorial proofs more widely.

Our solution is a notion of composition in conjunction-implication intuitionistic logic that is canonical for sequent calculus normalization, in the sense that permutations on cuts are factored out. Reduction operates on trees of normal forms, where edges represent cuts, giving a simple and natural structure that may easily generalize to other logics. A reduction step on a given edge is determined by how the attached nodes may sequentialize, not by their internal structure. Consequently, the reduction mechanism is abstract in the sense that it is agnostic about the actual contents of nodes, which can be any representation of normal forms.

1.1 Composition

Composition of proofs in intuitionistic sequent calculus is by the following cut-rule, followed by cut-elimination. We would like to transport this operation to combinatorial proofs.

We identify two prominent approaches for similar composition operations in the literature (our classification is not intended to be comprehensive, only helpful in setting out similarities):

Internal rewriting. An object-calculus may support non-normal forms and rewrites internally. In the $\lambda$-calculus, composition creates a redex, which is then beta-reduced. Likewise, many notions of proof net admit an explicit notion of cut, as a node or as a cut-link connecting dual formulae, that is eliminated by rewriting [10, 15], giving rise to the interaction nets paradigm [23].

Direct composition. For an object calculus that admits only normal forms, composition may be computed by a single-shot operation. Examples are the Geometry of Interaction paradigm, which computes a normal form via the execution formula [9]; game semantics, which composes strategies by interaction + hiding [1, 21]; the evaluation of cut-nets in ludics [11]; and various notions of proof net where composition is a form of relational composition over links [16, 12, 19]. Observe that object-level proofs become an invariant for sequent-calculus cut-elimination.
Based on prior art, one may readily imagine what either approach would involve for ICPs. For internal rewriting, an ICP may be constructed over a sequent that includes internal cut-formulas as special antecedents \( A \Rightarrow A \) (marked below by underlining), introduced by a cut as analogous to a \( \Rightarrow_L \) rule, and eliminated by rewriting. One may transport sequent-calculus cut-elimination to this setting by identifying sub-proofs of ICPs, via kingdoms [4].

\[ \Gamma, A_1 \Rightarrow A_1, \ldots, A_n \Rightarrow A_n \vdash B \]

For direct composition, ICPs may be interpreted as games with sharing [13], for which the interaction + hiding approach can be explored. Both these approaches are interesting and deserve to be investigated, and we may do so in future. However, they will inevitably require some intricate combinatorics, and are not likely to generalize across combinatorial proofs.

Here, we describe a normalization method for ICPs that is simple, natural, and achieves both our main objectives: 1) it is effectively a permutation-free implementation of sequent calculus cut-elimination, and 2) it is sufficiently abstract that it is likely to generalize well.

Technically, ICPs will form the nodes of a combinatorial tree, connected by edges that represent cuts. Combinatorial trees are then reduced by cut-elimination, following the reduction in sequent calculus. Interestingly, this approach fits neither of the above categories well, and instead suggests to identify a third category:

**External rewriting.** An object calculus without internal composition may be extended by a secondary structure, which is then evaluated by rewriting. The prime example is supercombinators [20, 25], where normalization takes place on a tree of normal-form \( \lambda \)-terms (restricted to having no abstractions inside applications).

There are interesting parallels between our combinatorial trees and supercombinators, which we explore in Section 7. In addition, we will connect ICP normalization to closed reduction in \( \lambda \)-calculus [6], via a novel explicit-substitution calculus.

## 2 Intuitionistic Combinatorial Proofs

We give a concise inductive definition of ICPs; see [13] for a full treatment including an informal introduction and a geometric definition. For the purposes of this paper, it would also be sufficient to view ICPs as sequent proofs modulo permutations.

We work in conjunction–implication intuitionistic logic. **Formulas** \( A, B, C \) are given by the grammar below, where \( P, Q \) are propositional atoms. A **context** \( \Gamma, \Delta \) is a multiset of formulas and a **sequent** \( \Gamma \vdash A \) is a context with a formula.

\[ A, B, C ::= P \mid A \land B \mid A \Rightarrow B \]

An ICP for a formula \( A \) will be a graph homomorphism \( f : G \to [A] \) consisting of:

- an **arena** \([A]\), a graph representing the formula \( A \) modulo the non-duplicating isomorphisms of symmetry, associativity, and currying;

\[ A \land B \sim B \land A \quad A \land (B \land C) \sim (A \land B) \land C \quad (A \land B) \Rightarrow C \sim A \Rightarrow (B \Rightarrow C) \]

- a **linked arena** \( \bar{G} \), a proof net in IMLL (intuitionistic multiplicative linear logic) over an arena rather than a formula, to represent the **logical** rules of the sequent calculus;

- a **skew fibration** \( f \), a graph homomorphism from \( G \) to \([A]\) representing the **structural** rules of contraction and weakening.

We define each component inductively. An arena will be a DAG (directed acyclic graph) \( G = (V_G, \to_G) \) with vertices \( V_G \) and edges \( \to_G \subseteq V_G \times V_G \). We indicate the **root vertices** of \( G \) (those without outgoing edges) by \( R_G \). Consider the following two operations: a **sum** of
two graphs $G + H$ is their disjoint union, and a **subjunction** $G owtie H$ is a disjoint union that in addition connects all the roots of $G$ to the roots of $H$.

\[
G + H = (V_G \uplus V_H, \rightarrow_G \uplus \rightarrow_H)
\]

**subjunction:** $G \bowtie H = (V_G \uplus V_H, \rightarrow_G \uplus \rightarrow_H \uplus (R_G \times R_H))$

> **Definition 1.** An **arena** is a graph $G$ constructed from single vertices by $(\uplus)$ and $(\bowtie)$, with an $L$-labelling $\ell : V_G \rightarrow L$ assigning each vertex a label from a set $L$. The arena $[A]$ of a formula $A$ is given inductively by: $[P]$ is a single vertex labelled $P$, and

\[
[A \land B] = [A] + [B] \quad [A \lor B] = [A] \bowtie [B].
\]

Note that arenas are linear in the size of formulas, and while they factor out symmetry, associativity, and currying, they do not factor out distributivity.

\[
[A \Rightarrow (B \land C)] \neq [(A \Rightarrow B) \land (A \Rightarrow C)]
\]

An ICP will be an **arena morphism**: a map $f : G \rightarrow [A]$ given by an underlying function on vertices $f : V_G \rightarrow V_{[A]}$ that preserves edges, roots, and the equivalence given by labelling, i.e. if $\ell_G(v) = \ell_G(w)$ then $\ell_{[A]}(f(v)) = \ell_{[A]}(f(w))$. We will construct arena morphisms inductively, which guarantees these conditions. For $g : G \rightarrow [A]$ and $h : H \rightarrow [B]$ we have the operations

\[
\text{implication: } g \rightarrow h : G \bowtie H \rightarrow [A] \bowtie [B]
\]

\[
\text{sum: } g + h : G + H \rightarrow [A] + [B]
\]

\[
\text{contraction: } [g, h] : G + H \rightarrow [A]
\]

where each case is given by the union of the underlying functions on vertex sets: for implication and sum, $g + h : (V_G \uplus V_H) \rightarrow (V_{[A]} \uplus V_{[B]})$, and for contraction $g \cup h : (V_G \uplus V_H) \rightarrow V_{[A]}$. In addition, we use the following constructions, where $\emptyset$ is the empty graph.

| axiom: $1_{P,Q} : [P] \rightarrow [Q]$ |
| weakening: $\emptyset_{[A]} : \emptyset \rightarrow [A]$ |

The axiom is the trivial map from one singleton arena (with vertex labelled $P$) to another (with vertex labelled $Q$). Weakening is the empty morphism. Note that because arenas are non-empty, in isolation it is not an arena morphism, but we will use it only in the context of an implication, sum, or contraction, so that this is not an issue.

We write $f :: A$ for $f : G \rightarrow [A]$. To construct ICPs from sequent proofs we use **sequents** of arena morphisms (and weakenings), that represent a single arena morphism as follows.

\[
k_1 : A_1, \ldots, k_n : A_n \vdash f :: B \iff (k_1 + \ldots + k_n) \circ f :: (A_1 \land \ldots \land A_n) \Rightarrow B
\]

We refer to $f$ and the $k_i$ as ports, where $k_i$ is an antecedent and $f$ the consequent, and we write $\varphi :: \Gamma$ for the context $k_1 :: A_1, \ldots, k_n :: A_n$.

> **Definition 2.** An intuitionistic combinatorial proof (ICP) of a formula $A$ is an arena morphism $f :: A$ constructed by the sequent calculus of Figure 2.

Figure 3 gives examples of ICPs, with corresponding types and $\lambda$-terms (the translation will be made formal in Section 8). Figure 4 gives non-examples of ICPs.

For clarity, an axiom 1 generates the ICP below.

\[
1 :: P \vdash 1 :: P = \begin{array}{c}
\end{array}
\]

We call the subgraph $\begin{array}{c}
\end{array}$ a link, where the side condition $(\ast)$ in Figure 2 requires that every link receives a different label $\begin{array}{c}
\end{array}$, $\begin{array}{c}
\end{array}$, etc. Vertices are equivalent if they have the same label, and ICPs as arena morphisms preserve equivalence by construction.
\[ \frac{1 \vdash P \vdash P}{\phi \vdash \Gamma \vdash f : B} \quad \frac{\phi \vdash \Gamma, k : A, l : A \vdash f : B}{\phi \vdash \Gamma, [k, l] : A \vdash f : B} \quad c^t \]

\[ \frac{\phi \vdash \Gamma, k : A : C \vdash f \vdash B}{\phi \vdash \Gamma, k + l : A \land B \vdash f \vdash C \land R} \quad \frac{\phi \vdash \Gamma, k \vdash f : A \vdash B}{\phi \vdash \Gamma \vdash f : B \land L} \]

- **Figure 2** Inductive construction of ICPs. (*): Each instance of 1 is given a distinct label in the source arena. (†): For c we require \( k, l \neq \emptyset \). (‡): For \( \land L \) we require \( k \neq \emptyset \). (§): Theorem 3 (Local canonicity). Two sequent proofs construct the same ICP if and only if they are equivalent modulo non-duplicating formula-isomorphisms and rule permutations.

To *decompose* an ICP, the unary rules \( \land L, \Rightarrow R, c, w \) apply whenever the given port is of the right kind, respectively \( k + l, k \vdash f, [k, l], \) and \( \emptyset \). The binary rules \( \land R, \Rightarrow L \) apply only when the ICP can be split into two without breaking up any links in the source graph. We write \( \phi \mid | \psi \) when the sources of \( \phi \) and \( \psi \) do not share any labels; then the rules \( \land R, \Rightarrow L \) as given in Figure 2 apply in reverse exactly when respectively \( \phi, f \mid | \psi, g \) and \( \phi, f \mid | k, \psi, g \). We call a port *open* if the ICP can be decomposed along it, and *closed* otherwise.

We refer to [13] for a geometric definition of ICPs, where the equivalence with the inductive definition given here is a theorem. We recall the following from [13].

To decompose an ICP, the unary rules \( \land L, \Rightarrow R, c, w \) apply whenever the given port is of the right kind, respectively \( k + l, k \vdash f, [k, l], \) and \( \emptyset \). The binary rules \( \land R, \Rightarrow L \) apply only when the ICP can be split into two without breaking up any links in the source graph. We write \( \phi \mid | \psi \) when the sources of \( \phi \) and \( \psi \) do not share any labels; then the rules \( \land R, \Rightarrow L \) as given in Figure 2 apply in reverse exactly when respectively \( \phi, f \mid | \psi, g \) and \( \phi, f \mid | k, \psi, g \). We call a port *open* if the ICP can be decomposed along it, and *closed* otherwise.

We refer to [13] for a geometric definition of ICPs, where the equivalence with the inductive definition given here is a theorem. We recall the following from [13].
### Normalization Without Syntax

**Figure 5** Composition of combinatorial proofs into combinatorial trees. a) The sequent calculus cut-rule. b) Presenting ICP sequents as nodes of a tree, with antecedent ports above and consequent port below a central line. c) Connecting both nodes by an edge, represented by a dashed line, to form a tree.

#### 3 Composition of combinatorial proofs

Combinatorial proofs represent normal forms: the sequent calculus for constructing them, in Figure 2, does not have a cut-rule (Figure 5a). What is expected is a notion of composition, of an ICP for \( \Gamma \vdash A \) and one for \( A, \Delta \vdash B \) into one for \( \Gamma, \Delta \vdash B \).

We give a direct interpretation of composition by taking ICPs as the nodes of a tree, connected by cuts as edges; see Figure 5, where solid lines represent the nodes in the tree and the dashed lines the edges. We formalize this construction as a notion of **combinatorial tree**, which we will then proceed to reduce. The nature of reduction will make it desirable to have constants available.

> **Definition 4** (Combinatorial tree). A **combinatorial tree** \( t :: C \) with conclusion formula \( C \) is an inductive tree consisting of either:

- a **premise** \( \varphi :: \Gamma \), representing (the arena of) \( C \), or
- a **constant** \( c :: C \) where \( C = P_1 \Rightarrow \ldots \Rightarrow P_n \Rightarrow P \) (\( n \geq 0 \)), or
- a **node** \( k_1 :: A_1, \ldots, k_n :: A_n \vdash f :: C \) with a sequence of **subtrees** \( t_1 :: A_1 \ldots t_n :: A_n \), written:

\[
\begin{array}{c}
 t_1 :: A_1 \\
 \ldots \\
 t_n :: A_n \\
 f :: C
\end{array}
\]

For a concrete example, Figure 7 gives a reduction featuring various combinatorial trees. We abbreviate \( t :: C \) to \( t \), and write \( \tau :: \Gamma \) for a **forest** \( t_1 :: A_1 \ldots t_n :: A_n \) (where \( \Gamma = A_1, \ldots, A_n \)). Edges connecting \( \tau \) to antecedents \( \varphi = k_1, \ldots, k_n \) are drawn like a single dashed edge, rendering the above tree as (a) below. We indicate a forest of premises by \( * :: \Gamma \), as in (b), and denote the premises of a tree \( t \) by \( *t \). A tree for the sequent \( \Gamma \vdash A \) is one \( t :: A \) with \( *t = \Gamma \). We visually identify the premises of a tree by a double dashed edge, as in (c) below for \( s \) with \( *s = A, \Delta \). Then (d) is the result of replacing \( *::A \) in \( s \) by a tree \( t \) for \( \Gamma \vdash A \), imitating the cut rule of Figure 5.

\[
\begin{array}{c}
 \varphi :: \Gamma \\
 f :: C
\end{array}
\]

\[
\begin{array}{c}
 \varphi :: \Gamma \\
 f :: C
\end{array}
\]

\[
\begin{array}{c}
 \varphi :: \Gamma \\
 f :: C
\end{array}
\]

\[
\begin{array}{c}
 \varphi :: \Gamma \\
 f :: C
\end{array}
\]

The reduction rules will essentially be those of sequent calculus, but now in a setting that is free of permutations. Observe that while combinatorial trees involve a good amount of notation, the notion of a tree of normal forms is in fact highly conceptual. For reduction, the particular use of ICPs is secondary, and any representation of normal forms would do, since the reduction rules are determined entirely by the **sequentialization** or **decomposition** of nodes.

> **Definition 5** (Reduction). Reduction of combinatorial trees is by the rules in Figure 6.
We will assume that constants represent primitives of base type, such as integers and booleans, and functions over base types, such as addition. We extend the reduction rule \( \Rightarrow \) to the latter case as below; an example instance would be where \( c \) is the integer 7 and \( c' \) is a squaring function, with the resulting constant \( c'' \) the integer 49.

3.1 Reduction examples

We illustrate reduction with an example analogous to the following lambda calculus reduction, applying the Church numeral two \( \lambda f.\lambda x. f(fx) : (N \Rightarrow N) \Rightarrow N \Rightarrow N \) to the squaring function constant \( S : N \Rightarrow N \) and the integer constant 3 : \( N \Rightarrow N \).

\[(\lambda f.\lambda x. f(fx)) S 3 \rightarrow (\lambda x. S(x)) 3 \rightarrow S(S3) \rightarrow S9 \rightarrow 81\]

The combinatorial proof \textit{two} corresponding to the Church numeral is the penultimate one displayed in Figure 3. Below, from left to right, we have: numeral two in compact form; two in sequent form; two as a node in a combinatorial tree; and the combinatorial tree representing \((\lambda f.\lambda x. f(fx)) S 3\).

\[(\lambda n.\lambda f.\lambda x. f(nfx)) applied to Church zero \( \lambda f.\lambda x. x \), the squaring function \( S : N \Rightarrow N \) and 4, to yield 16.

\[(\lambda n.\lambda f.\lambda x. f(nfx)) \ (\lambda f.\lambda x. x) \ S \ 4 \rightarrow 16\]

The ICP reduction is shown in Figure 7.
The reduction rules $[\land]$, $[\Rightarrow]$ apply only when the two ports involved are both open (this is what the side-conditions on the reduction rules entail). We briefly show that this does not lead to a deadlock. In a combinatorial tree, a port is extremal if it is connected to a premiss or the consequent of the root node, otherwise internal.

**Lemma 6 (Progression).** For a combinatorial tree $t$ with at least one edge, if no extremal port is open, then a reduction step applies.

The progression lemma illustrates a limitation of the normalization process: reduction may become deadlocked if an extremal port remains open. This is closely related to weak reduction in the $\lambda$-calculus, which does not reduce under an abstraction, though note it is not the same: internal reduction in a combinatorial tree is allowed, and may still be possible, when the root node is an abstraction. As with weak reduction, this is no limitation in practice: we expect a real program to be of base type, and without free variables (the premisses of a combinatorial tree). In that case the progression lemma guarantees we will not reach a deadlock. This explains also the reason to include constants: without them it is impossible to create a combinatorial tree of base type with no premisses, as it would logically be unsound.

To reduce any combinatorial tree, we combine reduction with sequentialization. This enables us to reduce open extremal ports, by interpreting them as sequent rules. We add a special axiom (icp), given below, to the cut-free sequent calculus. It incorporates a combinatorial tree $t$ for $\Gamma \vdash A$ as a sub-proof of $\Gamma \vdash A$. A proof in this calculus is a hybrid proof.

```
t:: A  (icp)
```

The reduction rules $[ax]$, $[\land]$, and $[\Rightarrow]$ apply directly to hybrid proofs, since they preserve the premisses and conclusion of a combinatorial tree. The rules $[c]$ and $[w]$ duplicate or delete...
premisses; to accommodate this in hybrid proofs, contraction or weakening rules are added. The resulting rules are the last two in Figure 8, which gives the rules needed for strong reduction.

> **Definition 7** (Hybrid reduction). **Hybrid proof reduction** is the rewrite relation on hybrid proofs generated by the rules \([\text{ax}], [\text{[Ax]}], [\Rightarrow] \) in Figure 6 plus the rules in Figure 8.

Progression (Lemma 6) gives the following.

> **Lemma 8** (Hybrid progression). If a hybrid proof contains an (icp) axiom, a hybrid reduction step applies.

A normal form of a hybrid proof is then a regular, cut-free sequent proof. This may directly be used to construct an ICP, to obtain fully general ICP normalization. The effect of embedding a combinatorial tree in a hybrid proof is akin to normalization-by-evaluation [5]: it provides an environment that supplies sufficient arguments to any function (it is an applicative context), and other similar services, to ensure continued reduction.

For the remainder of this paper, we will use the rules in Figure 8 on combinatorial trees in isolation, without reference to the surrounding hybrid proof.

### 5 Confluence and strong normalization

Combinatorial-tree reduction is confluent and strongly normalizing. In this section we will consider only local confluence, which demonstrates the intricacies arising from the local

![Figure 8 Hybrid sequentialization and reduction rules](image-url)
canonicity property of ICPs. Strong normalization is stated here, and proved in Appendix C; confluence then follows from local confluence and strong normalization.

The reduction rules for ICPs interact in several intricate ways. Not only can a single node have multiple redexes along different edges, even a single edge may reduce in more than one way. This is due to the multiple ways an arena morphism can be composed inductively, which factor out the formula equivalences of associativity, symmetry, and currying, as well as the interaction of conjunction with contraction. Concretely, we have the following equations:

\[
\begin{align*}
  f + g &= g + f \\
  \emptyset + \emptyset &= \emptyset \\
  f + (g + h) &= (f + g) + h \\
  [k, \emptyset] &= k \\
  (k + l) \circ f &= k \circ (l \circ f) \\
  [k_1, k_2] + [l_1, l_2] &= [k_1 + l_1, k_2 + l_2]
\end{align*}
\]

We recognize two kinds of critical pairs:

- **Single-edge** when multiple reduction steps apply to a single cut-edge, due to the above equations;
- **Single-node** when multiple reduction steps on distinct edges split the same node.

The single-node critical pairs are similar to those of the \(\lambda\)-calculus and proof nets, and these converge accordingly; we give the diagrams in Appendix B. The single-edge critical pairs are new and delicate. We resolve them in Figure 9. For convenience we introduce the notation \(s + t\), below. In the first four diagrams we depict only the ports and subtrees involved, and in the last diagram we use a different colouring scheme to identify ports across diagrams.

\[
\begin{align*}
  t + s &= \alpha \beta \psi \\
  f + g &= \alpha \beta \psi \\
  k + (l + m) &= (k + l) + m \\
  [k_1, k_2] + [l_1, l_2] &= [k_1 + l_1, k_2 + l_2] \\
  (k + l) \circ f &= k \circ (l \circ f) \\
  [k_1 + l_1, k_2 + l_2] &= [k_1 + l_1, k_2 + \emptyset]
\end{align*}
\]

\[ \Rightarrow \text{Proposition 9. Reduction \(\rightarrow\) is locally confluent.} \]

\[ \text{Proof. By Figure 9 and Figures 11–13 in Appendix B.} \]

\[ \Rightarrow \text{Theorem 10 (Strong normalization). Combinatorial-tree reduction is strongly normalizing.} \]

\[ \text{Proof. See Appendix C.} \]

### 6 Combinatory lambda-calculus

To further illustrate the reduction process, we connect ICPs to the \(\lambda\)-calculus, via an explicit-substitution \(\lambda\)-calculus that we call the **combinatory \(\lambda\)-calculus**. The calculus is a Curry–Howard interpretation of sequent calculus, of the kind studied by Graham-Lengrand [24]. We include constants \(c\) to match those of combinatorial trees.

\[ \Rightarrow \text{Definition 11. The combinatorial \(\lambda\)-calculus has normal terms \(N, M\), patterns \(p, q\), and terms \(S, T\) given by the following grammars.} \]

\[
\begin{align*}
  N, M &::= x \mid \langle N, M \rangle \mid \lambda p. N \mid N[p \leftarrow x.M] \\
  p, q &::= x \mid \langle p, q \rangle \\
  S, T &::= c \mid N[p_1 \leftarrow T_1, \ldots, p_n \leftarrow T_n]
\end{align*}
\]
The binding variables $\text{bv}(p)$ of $p$ and the free variables $\text{fv}(N)$ of $N$ are as follows; in
$\text{fv}(N[p \leftarrow x M])$ we require that $\text{fv}(N) \cap \text{bv}(p) \neq \emptyset$, and in $(p, q)$ that $\text{bv}(p) \cap \text{bv}(q) = \emptyset$.

- $\text{bv}(x) = x$
- $\text{bv}((p, q)) = \text{bv}(p) \cup \text{bv}(q)$
- $\text{fv}(\lambda p. N) = \text{fv}(N) - \text{bv}(p)$
- $\text{fv}(N[p \leftarrow x M]) = (\text{fv}(N) - \text{bv}(p)) \cup \{x\} \cup \text{fv}(M)$

In $\lambda p. N$, $N[p \leftarrow x M]$, and $N[p_1 \leftarrow T_1, \ldots, p_n \leftarrow T_n]$ the variables in the patterns $p$ and $p_i$ bind
in $N$. The construction $N[p \leftarrow x M]$ is a shared application, with a variable $x$ as function and
the term $M$ as argument, where the pattern $p$ may bind variables with multiple occurrences
in $N$. The condition that $\text{bv}(p)$ and $\text{fv}(N)$ must intersect means at least one variable becomes
bound; this corresponds to the condition $(!)$ on the rule $\Rightarrow L$ for ICPs in Figure 2 (that the
consequent of a left-implication must not be introduced by weakening). The construction
$[p_1 \leftarrow T_1, \ldots, p_n \leftarrow T_n]$ is an environment, and corresponds to attaching the subtrees to a
node in a combinatorial tree. We abbreviate it by $[e]$, or $[p_1 \leftarrow T_1, e]$, etc.

- Definition 12. Figure 10 gives the (non-deterministic) translation from ICPs to simply-
typed, normal terms of the combinatorial $\lambda$-calculus. We extend it to combinatorial trees as
follows: $\Rightarrow$ is the identity on constants, and if

$$k_1, \ldots, k_n, \varphi \vdash f \quad \Rightarrow \quad p_1 : A_1, \ldots, p_n : A_n, \Delta \vdash N : B$$

and if $t_i \Rightarrow \Gamma_i \vdash A_i$ (with $t_i \neq \ast$) for all $i \leq n$, then
The shared applications \([p \mapsto xM]\) of the combinatory \(\lambda\)-calculus are subject to permutations, creating an equivalence \(\sim\) on terms. We define it below, where we abbreviate \([p \mapsto xM]\) by \([a]\), with \(bv(a) = bv(p)\) and \(fv(a) = \{x\} \cup fv(M)\).

\[
\begin{align*}
(N[a], M) & \sim (N, M[a]) \quad bv(a) \cap fv(M) = \emptyset \\
(N, M[a]) & \sim (N, M)[a] \quad bv(a) \cap fv(N) = \emptyset \\
\lambda p_M(N[a]) & \sim (\lambda p_N)[a] \quad bv(p) \cap fv(a) = \emptyset \\
N[p \mapsto xM][a] & \sim N[p \mapsto xM][a] \quad bv(a) \cap fv(N) = \emptyset \\
N[a][b] & \sim N[b][a] \quad bv(b) \cap fv(a) = \emptyset, bv(a) \cap fv(b) = \emptyset
\end{align*}
\]

The above equivalence factors out sequent calculus permutations. We will further assume combinatory \(\lambda\)-terms equivalent modulo the formula-isomorphisms (symmetry, associativity, and currying). These are factored out simply by considering patterns modulo these rules, but there is a catch: patterns and pairs are connected through cuts, or explicit substitutions, and laws must be applied to both simultaneously. We show an example with currying to demonstrate that a full definition is intricate, and leave it implicit.

\[
N[z \mapsto x(P, Q)][x \mapsto \lambda p, \lambda q, M] \sim N[z \mapsto yQ][y \mapsto xP][x \mapsto \lambda p, \lambda q, M]
\]

With the above equivalence on terms, a direct corollary of local canonicity, Theorem 3, is the following.

> **Proposition 13.** Combinatorial trees canonically represent typed combinatory \(\lambda\)-terms:

\[
S \sim T \iff \exists t. t \vdash S \land t \vdash T
\]

We reduce combinatory \(\lambda\)-terms modulo the equivalence \(\sim\). We write \(\{T/x\}\) for the substitution of \(x\) by \(T\), and if the patterns \(p, q\) are isomorphic as trees and \(bv(p) \cap bv(q) = \emptyset\) then \(q/p\) is the substitution induced by

\[
\{(q_1, q_2)/\{p_1, p_2\}\} = \{q_1/p_1\}\{q_2/p_2\}.
\]

> **Definition 14.** Reduction of combinatory \(\lambda\)-terms modulo \(\sim\) is by the following rules, where:

\([e_P]\) and \([e_Q]\) bind only in \(P\) respectively \(Q\); in \((\Leftarrow)\) we require \(x \notin fv(P) \cup fv(Q)\); in \((\Rightarrow)\) we require \(bv(q) \cap fv(N) \neq \emptyset\); and in \((\wedge)\) that \(bv(p) \cap fv(N) = \emptyset\).

\[
\begin{align*}
N[x \mapsto y][e, e'] & \rightarrow^1 N[y/x][e, e'] \\
N[p, q] & \mapsto (P, Q)[e_P, e_Q], e \\
& \rightarrow^\Leftarrow N[p \mapsto P[e], q \mapsto Q[e]], e \\
P[p \mapsto x][e_Q, x \mapsto \lambda q, N[e, e_P]] & \rightarrow^\Rightarrow P[p \mapsto N[q \mapsto Q[e]], e, e_P] \\
N[p, q][p \mapsto T, e] & \mapsto N[q \mapsto T, p \mapsto T, e] \\
N[p \mapsto T, e] & \mapsto N[e]
\end{align*}
\]
Comparing the reduction rules with the corresponding ones for ICPs in Figure 6, together with Proposition 13, gives:

\[ \begin{align*}
  t & \xrightarrow{\text{[x]}} s \\
  T & \xrightarrow{\text{[x]}} S
\end{align*} \]

The comparison with \( \lambda \)-calculus allows us to make a further observation. ICP normalization is a form of closed reduction \([6]\) (there called weak reduction), where a redex \((\lambda x.N)M\) may not be reduced if \( M \) contains free variables that are bound by the surrounding context. This has the enormous benefit to implementation that alpha-conversion becomes unnecessary. Our construction of combinatory trees is even stronger: it is impossible to construct such a redex, or to produce one by reduction. This can be observed from the combinatory \( \lambda \)-calculus, which does not support abstraction at the level of terms \( T \), only at the level of normal terms.

Abstraction on terms can be introduced as a defined operation, called \textit{lambda-lifting} \([22]\). The analogous operation on ICP combinatory trees would be a transformation

\[ \begin{align*}
  \star : A & \star : \Gamma \\
  t : B & \Rightarrow t' : A \Rightarrow B
\end{align*} \]

We can perform it by abstracting over \( \star : A \) locally, in the node where it resides, and transform every node on the path from there to the root as follows,

\[ \begin{align*}
  k : C & \phi \\
  f : D & \phi \\
  i : k : A = C & \phi \\
  i : f : A = D
\end{align*} \]

where the port \( k : C \) is that on the path to \( \star : A \), and the arena morphism \( i : \Box[A] \rightarrow \Box[A] \) is the identity on \( \Box[A] \). In effect, one is threading the abstraction over \( A \) through the cuts in the tree, rather than adding it as a connection \textit{outside} of them.

By way of example, below is the reduction corresponding to the ICP normalization sequence in Figure 7.

\[ \begin{align*}
  v[x \leftarrow gw][w \leftarrow yz][y \leftarrow ng][n \leftarrow \lambda f.x, g \leftarrow S, z \leftarrow 4] & \rightarrow \ldots \rightarrow v[x \leftarrow gw][w \leftarrow x, g \leftarrow 4], g \leftarrow S \\
  \sim & \vdash v[x \leftarrow gw][w \leftarrow yg][y \leftarrow nz][n \leftarrow \lambda f.x, z \leftarrow 4, g \leftarrow S] \\
  (\Rightarrow) & \vdash v[x \leftarrow gw][w \leftarrow yg][y \leftarrow \lambda f.x, x \leftarrow z, g \leftarrow S, z \leftarrow 4] \\
  (1) & \vdash v[x \leftarrow gw][w \leftarrow yg][y \leftarrow \lambda f.x, x \leftarrow 4], g \leftarrow S, z \leftarrow 4 \\
  (\Rightarrow) & \vdash v[x \leftarrow gw][w \leftarrow h][y \leftarrow \lambda f.x, x \leftarrow 4], g \leftarrow S, h \leftarrow S \\
  (\Rightarrow) & \vdash v[x \leftarrow gw][w \leftarrow x, f \leftarrow h, h \leftarrow S], x \leftarrow 4, g \leftarrow S, \ldots
\end{align*} \]

\section{Supercombinators}

Supercombinators \([20]\) are the basis of an efficient implementation of functional programming \([25]\), used for the Haskell programming language. The main reason for their efficiency is that expressions are compiled into trees (or graphs) over a fixed set of operators, each given as an instruction set that implements the appropriate reduction sequence.

\[ \begin{align*}
  \text{Definition 16. } \textit{Supercombinators} \ C, D \text{ and supercombinator expressions } E_X, F_X, \\
  \text{where } X \text{ is a set of variables, are given by the following grammars.}
\end{align*} \]

\[ 
C, D ::= \lambda x_1 \ldots \lambda x_n, E_{\{x_1, \ldots, x_n\}} \quad E_X, F_X ::= x \in X \mid C \mid F_X E_X
\]
The set \( X \) restricts which variables may occur free in a supercombinator expression, so that each supercombinator is a closed term; we may omit it as superscript for brevity. The grammar for supercombinators \( C \) may be extended to include constants. Reduction is \textit{weak head reduction} on an expression \( E \), as given by the rule below. It applies only at top-level, not in context, and if there are fewer than \( n \) arguments to a supercombinator with \( n \) abstractions, reduction halts.

\[
(\lambda x_1 \ldots \lambda x_n, E) F_1 \ldots F_n F_{n+1} \ldots F_{n+m} \rightarrow E\{F_1/x_1\} \ldots \{F_n/x_n\} F_{n+1} \ldots F_{n+m}
\]

During reduction, substitutions are applied only to the top-level \( E \) expression, and not to supercombinators, which remain fixed. This allows them to be compiled into instruction sets to carry out the appropriate reduction by the rule \( \rightarrow \) above.

Structurally, supercombinators are trees or graphs where each node is a supercombinator \( C \) in which each occurring supercombinator \( D \) is considered as a \textit{pointer} to the node for \( D \). This is highly similar to combinatorial trees, which feature the same tree structure except with ICPs for nodes. The main dissimilarities between supercombinators and combinatorial trees are then as follows.

- Supercombinator reduction is by an abstract machine, where combinatorial-tree reduction is a variant of cut-elimination.
- Supercombinators are trees over \( \beta \)-normal \( \lambda \)-terms where abstractions may not occur under an application, where nodes in combinatorial trees are \( \eta \)-expanded \( \beta \)-normal sequent proofs modulo permutations.

These differences are conceptually shallow, but risk burying a formal comparison in technicalities. We will therefore interpret supercombinators in the combinatory \( \lambda \)-calculus instead (which, mainly, does not require \( \eta \)-expansion), and simulate reduction only up to explicit substitutions.

> Definition 17. The relations \( \triangleright \) and \( \triangleright \triangleright \), defined inductively below, interpret supercombinators respectively supercombinator expressions into the combinatory \( \lambda \)-calculus.

\[
\begin{align*}
E & \triangleright N[e] \\
\lambda x_1 \ldots x_n, E & \triangleright (\lambda x_1 \ldots x_n, N)[e] \\
x & \triangleright x \\
C & \triangleright T \\
E & \triangleright x[a_1] \ldots [a_k][e] \\
EF & \triangleright y[e]/x[N][a_1] \ldots [a_k][e, f]
\end{align*}
\]

Note how this indeed translates a supercombinator to a term \((\lambda x_1 \ldots \lambda x_n, N)[e]\) consisting of a normal form \(\lambda x_1 \ldots \lambda x_n, N\) with a subtree for each occurring supercombinator in the explicit substitutions \([e]\). To simulate reduction, a reduct is translated as follows.

\[
(\lambda x_1 \ldots \lambda x_n, E) F_1 \ldots F_n \triangleright z_n[z_n \leftarrow z_{n-1}]N_1[\ldots][z_1 \leftarrow y]N[\ldots][y \leftarrow (\lambda x_1 \ldots \lambda x_n, M)[e], f_1, \ldots, f_n]
\]

Reduction for this term proceeds as follows.

\[
\begin{align*}
z_n[z_n \leftarrow z_{n-1}]N_1[\ldots][z_2 \leftarrow z_1]N_2[\ldots][z_1 \leftarrow y]N[\ldots][y \leftarrow (\lambda x_1 \ldots \lambda x_n, M)[e], f_1, f_2, \ldots, f_n] \\
(\rightarrow) & \rightarrow z_n[z_n \leftarrow z_{n-1}]N_1[\ldots][z_2 \leftarrow z_1]N_2[\ldots][z_1 \leftarrow (\lambda x_2 \ldots \lambda x_n, M)[x \leftarrow N_1[f_1], e], f_2, \ldots, f_n] \\
(\rightarrow) & \rightarrow z_n[z_n \leftarrow M[x_1 \leftarrow N_1[f_1], \ldots, x_n \leftarrow N_1[f_n], e]]
\end{align*}
\]

The result corresponds to the supercombinator reduct \(E\{F_1/x_1\} \ldots \{F_n/x_n\}\), except that the explicit substitutions \([x_i \leftarrow N_1[f_i]]\) are not evaluated as substitutions. They cannot be: combinatory \( \lambda \)-term reduction does not differentiate between the interpretation of the top-level supercombinator expression \(E\) on which reduction takes place, and which does admit substitutions, and internal subcombinator expressions which do not. We will therefore contend ourselves with the moral equivalence of both reductions.
8 Lambda-calculus

To complete the exposition, we map the combinatory $\lambda$-calculus onto the regular $\lambda$-calculus
with surjective pairing. We have the following terms and rewrite rules, where $i \in \{1, 2\}$.

\[
M, N ::= x \mid \lambda x.N \mid \pi_1 N \mid \langle N, M \rangle \quad (\lambda x.N)M \mapsto_\beta N[M/x] \quad \pi_1 \langle N_1, N_2 \rangle \mapsto_x N_i
\]

The translation from combinatory $\lambda$-terms into $\lambda$-terms is:

\[
\begin{align*}
[x] &= x \\
\lfloor (\langle M, N \rangle) \rfloor &= \lfloor [M], [N] \rfloor \\
\lfloor \lambda p. N \rfloor &= \lambda x. [N][x/p] \\
\lfloor N[p \leftarrow xM] \rfloor &= \lfloor [M][x[N]/p] \rfloor \\
\lfloor N[p_1 \leftarrow T_1, \ldots, p_n \leftarrow T_n] \rfloor &= \lfloor [N][\{T_1\}/p_1] \ldots \{T_n\}/p_n \rfloor
\end{align*}
\]

The combined translation then takes ICP combinatorial trees to $\lambda$-terms. As with the combinatory $\lambda$-calculus, we assume $\lambda$-terms equivalent ($\approx$) modulo formula-isomorphisms (symmetry, associativity, currying). Sequent permutations are already naturally factored out, but at the cost of exponential growth. We will demonstrate this here.

In the combinatory $\lambda$-calculus, the reason that an application must occur in an explicit substitution is precisely that the consequent of a left-implication may have been contracted, the situation highlighted in the introduction:

\[
\begin{array}{c}
\Gamma \vdash \frac{B, B, \Delta \vdash C}{B, \Delta \vdash C} \quad \epsilon \\
\Gamma, A \Rightarrow B, \Delta \vdash C \\
\end{array} \quad \approx_L \\
\begin{array}{c}
\Gamma \vdash \frac{\Gamma \vdash A, B, B, \Delta \vdash C}{\Gamma \vdash A, B, \Gamma, A \Rightarrow B, \Delta \vdash C} \quad \Rightarrow_L \\
\Gamma, A \Rightarrow B, \Gamma, A \Rightarrow B, \Delta \vdash C \\
\end{array} \\
\Gamma, A \Rightarrow B, \Delta \vdash C \quad \epsilon
\]

The corresponding equivalence on combinatory terms is:

\[
N[p/q][p \leftarrow xM] \approx N[q \leftarrow xM][p \leftarrow xM]
\]

(there is $\text{bv}(q) \cap \text{fv}(N) \neq \emptyset$), while both translate to the same $\lambda$-term $[N][x[M]/p]$. Repeated duplication incurred in this way gives rise to exponential growth.

Let strong equivalence $\approx_T$ on combinatory $\lambda$-terms be the equivalence generated by the above and $\sim$. We have the following proposition.

> Proposition 18. For combinatory terms $S, T$, we have

\[
S \approx T \iff [S] = [T]
\]

9 Conclusion

We have given a direct and natural account of normalization for intuitionistic combinatorial proofs. We believe our approach of external rewriting, here manifested in the notion of combinatorial tree, applies much more broadly: in the abstract, what we have are simply trees of normal forms, with the natural reduction rules given by the meta-level sequent calculus. As a generalization of super-combinators, a correspondence we aim to make more precise in future work, we hope that our approach leads to improvements in compiler design. Perhaps the ability to express all normal forms, and the more fine-grained reduction steps, will allow more efficient program transformations, while retaining the benefits of super-combinators.

**A** Proofs for Section 4

**Lemma 6 (restatement).** For a combinatorial tree $t$ with at least one edge, if no extremal port is open, then a reduction step applies.

**Proof.** At first, we ignore constants. If $t$ contains a node that is an axiom $1 \vdash 1$, or a port that is a contraction $[k,l]$ (with $k,l \neq \emptyset$) or a weakening $\emptyset \vdash A$, then a reduction step applies.

Otherwise, all ports are of the forms $1$, $k \mathbin{\downarrow} 1$, and $f + g$. The $[\land, \Rightarrow]$ steps apply if both ports connected by the cut-edge are open. Let $t$ consist of $n$ nodes. By definition, every node has at least one open port, and by assumption it is internal. Then since there are only $n - 1$ edges, at least one edge connects two open ports, and a $[\land]$ or $[\Rightarrow]$ reduction step applies.

To include constants in the argument, we consider $c$ of type $P \Rightarrow A$ as a node with only an open conclusion port. If $c$ is applied to a tree $s :: P$ of base type, we need to reduce this to a constant first (see the reduction rule for constants). We can do so by iterating the argument for the subtree $s$, since its extremal ports are closed (its conclusion must be $1 :: P$ and its premises are also premises of $t$).

**B** Diagrams for Section 5

This section provides Figures 11, 12, 13 demonstrating the property of single-node confluence for the proof of local confluence, Proposition 9.

![Figure 11](image-url) Single-node confluence (1)

**C** Strong normalization

**C.1 Annotated reduction**

While local confluence holds, the interaction of symmetry and associativity with the interchange gives rise to some intricacy, such as in the example below. Each different term rendering of an
Figure 12 Single-node confluence (2)

Figure 13 Single-node confluence (3)
antecedent port \( k \) gives rise to a different reduction sequence of \([\land], [c],\) and \([w]\) steps (and
\([\land \land]\)).

\[
[k_1, l_1] + [k_2, l_2] + [k_3, l_3] = [(k_1 + k_2, l_2) + \emptyset, l_1 + \emptyset + [k_3, l_3]]
\]

More concretely, without the condition that \( k, l \) be non-empty, the reduction step \([c] \) would
create an infinite reduction through the equation \( k = [k, \emptyset] \). While this particular case is
easily ruled out, the equation still rears its head in the third diagram in Figure 9, whose
equation is justified by:

\[
[k_1, k_2] + l = [k_1, k_2] + [l, \emptyset] = [k_1 + l, k_2 + \emptyset]
\]

These equivalences, and in particular the diagram \([\land]/[c]^2\), create a problem for proving strong
normalization (SN). For our proof, we would like to show that infinite reductions are preserved
under non-deleting steps; but this becomes problematic if the commutation of reductions
introduces a \([w]\) step. Clearly, the weakening step in the diagram \([\land]/[c]^2\) should be harmless,
since it reduces a tree that was just duplicated, and any infinite reduction that might be
removed can be simulated in the remaining tree. Formalizing this, however, is delicate.

Our solution is to amend reduction to always introduce the maximal number of copies of
weakened subtrees, so that it is confluent without introducing \([w]\) steps. To map back onto
regular reduction, the superfluous copies may safely be removed. In this way, we separate the
idea that duplicate weakened subtrees may be removed, from other issues.

To obtain the maximal number of copies of weakened subtrees, we annotate a port \( k \) with
the “missing” number of copies \( i \), as \( k' \). Let the \textit{width} \#\( k \) of a port \( k \) be the largest \( n \) for
which \( k = [k_1, \ldots, k_n] \) with \( k_i \neq \emptyset \), where \#\( \emptyset = 0 \). That is, \#\( k \) is the number of connected
components in the source graph \( G = G_1 + \ldots + G_n \) of the arena morphism \( k : G \to [A] \).

A port \( k + \emptyset : A \land B \) of width \#\( k + \emptyset \) = \#\( k \) = \( n \), connected to a subtree \( t + s \), may
generate a maximum of \( n \) weakened copies of \( s \), by preferring the reduction \([c] \) over \([\land]\), and a
minimum of one the other way around. To obtain the same number of copies, we annotate
the reduction rules according to the following equations (with base cases below).

\[
(k + l)^i = k^i + \#l + i + \#k \quad [k, l]^i j = [k^i, l^j]
\]

\[
\emptyset^i = \emptyset \quad 1^0 = 1 \quad (f \diamond k)^0 = f \diamond k \quad (f, k \neq \emptyset)
\]

For instance, if \#\( k \) = \#\( l \) = 1 and \( k, l \neq \emptyset \) then we have:

\[
[k + \emptyset, l + \emptyset] = [k^0 + \emptyset^1, l^0 + \emptyset^1]
\]

\[
= [(k + \emptyset)^0, (l + \emptyset)^0]
\]

\[
= [k + \emptyset, l + \emptyset]^0
\]

\[
= (l, k + [\emptyset, \emptyset])^0
\]

\[
= [k, l]^0 + [\emptyset, \emptyset]^2
\]

\[
= [k^0, l^0] + [\emptyset^1, \emptyset^1] = [k, l] + [\emptyset, \emptyset]
\]

But note that \([\emptyset, \emptyset] = \emptyset\) is not derivable with annotations. While we can’t restrict the
equations themselves in this way, we can restrict the reduction rules accordingly.

\[\textbf{Definition 19.} \textit{Annotated reduction} \to_{\#} \textit{replaces the reduction steps} \[\land\], \[\Rightarrow\], \text{and} \[c] \textit{of}\]
\textit{Figure 6 by those in SonFigure 14}. Hybrid rules \[\land\land]\ and \[\Rightarrow\land]\ are adapted analogously to \[\land\]
and \[\Rightarrow\] respectively. \textit{Annotated rules apply to un-annotated ports by an initial annotation}
with \( i = j = 0 \), while the rules \[1], \[\Rightarrow\], and \[w] \textit{apply through the base-case equations}.

The main point of annotated reduction is to obtain the local confluence diagram \([\land]/[c]\)
in Figure 15. Next, we show that regular and annotated reduction are interchangeable for
proving strong normalization.
We separate reduction into \( \sigma \) and \( \psi \) reductions. \( \sigma \) reduces a node's size, and may only duplicate a subtree but reduces the node it is attached to. The following measure then strictly decreases.

\[ \begin{align*}
\frac{s + t}{(k + l)^{i+j}} & \xrightarrow{[\rho]} \frac{s}{k^i + \#l} ; \frac{t}{l^j + \#k} \\
\frac{s}{[k, l]^{i+j}} & \xrightarrow{[\rho]} \frac{s}{k^i} ; \frac{s}{l^j} \\
\frac{t + s}{(k_1 + l_1, k_2 + l_2)^{j+y}} & \xrightarrow{[\rho]} \frac{t}{[k_1, k_2]^{n_1+n_2}} ; \frac{s}{[l_1, l_2]^{n_1+n_2}} \\
\frac{t + s}{(k_1 + l_1)^{j+y}} & \xrightarrow{[\rho]} \frac{t}{k_1^{n_1}} ; \frac{s}{l_1^{n_1}} \\
\frac{t + s}{(k_2 + l_2)^{j+y}} & \xrightarrow{[\rho]} \frac{t}{k_2^{n_2}} ; \frac{s}{l_2^{n_2}}
\end{align*} \]

\( n_1 = i + \#l_1 \quad n_2 = j + \#l_2 \quad m_1 = i + \#k_1 \quad m_2 = j + \#k_2 \)

**Figure 14** Annotated reduction rules

**Lemma 20.** A tree has an infinite \( \rightarrow \) reduction if and only if it has an infinite \( \rightarrow \# \) reduction.

**Proof.** From left to right, a \( \rightarrow \) reduction can be simulated by a \( \rightarrow \# \) reduction by inserting \([w] \) steps. From right to left, any reduction step \( t \rightarrow \# r \) has an equivalent in \( \rightarrow \) except the following.

\[ \begin{align*}
\frac{s}{[k, \emptyset]^{i+j}} & \xrightarrow{[\rho]} \frac{s}{k^i} ; \frac{s}{\emptyset^j}
\end{align*} \]

Then if \( r \), containing the duplicate subtrees \( s \) as above right, has an infinite reduction inside \( s \), so does \( t \). Otherwise the weakened \( s \) may be removed from \( r \) in a \([w] \) step, while the remaining reduction from \( r \) is still infinite. The infinite \( \rightarrow \# \) reduction may then be simulated by \( \rightarrow \). \( \blacksquare \)

### C.2 Auxiliary reduction

We separate reduction into *implicative* \( [\rho] \) and *auxiliary* \( [\neq] \) \( \approx [1, \&, \wedge, \wedge R, \wedge L, \Rightarrow R, \Rightarrow L] \).

**Lemma 21.** Auxiliary reduction \([\neq]\) is strongly normalizing and confluent.

**Proof.** For SN, observe that 1) all \([\neq]\)-reduction steps preserve or reduce the depth of a combinatorial tree, and 2) the only step that increases the size of the tree is \([c]\), which duplicates a subtree but reduces the node it is attached to. The following measure then strictly decreases.

Let the the *depth* of a node be its longest path to a leaf, and its *size* the sum number of steps in every way of sequentializing it as an ICP. We measure a node as the ordered pair of its depth and its size, and a tree as the multiset over its nodes (ordered in the standard multiset ordering). A normalization step reduces a node’s size, and may only duplicate nodes of smaller depth, so that the overall measure reduces. (Note that the argument works
interchangeably for regular and annotated reduction, using the regular or annotated hybrid rules $[\Lambda L, \Rightarrow R]$ for sequentialization.)

Confluence then follows from local confluence, which is by the convergence of the critical pairs in Figures 9 and 15.

We identify a class of safe reduction steps, which are non-deleting, and guaranteed to reflect SN (if $t \Rightarrow s$ and $s \in SN$, then $t \in SN$).

**Definition 22.** A reduction step is safe, denoted as $t \Rightarrow s$, if it is not a weakening step $[w]$, or if it is a weakening step where the deleted subtree is SN.

\[
\frac{\tau \vdash \varphi \not\vdash A}{f :: B} \quad \frac{\tau \vdash \varphi}{(r \in SN) \quad f :: B}
\]

**Lemma 23 (Safe reduction reflects SN).** If $t \Rightarrow s$ and $s \in SN$ then $t \in SN$.

**Proof.** We assume an infinite reduction in $t$ and find a corresponding one in $s$ to reach a contradiction. Using Lemma 20, we will work with $\Rightarrow_{\#}$ instead of $\Rightarrow$. We will discuss each normalization rule $[1, \land, \Rightarrow, c, w]$; for simplicity we will ignore the hybrid rules $[\ast, \land R, \land L, \Rightarrow R, \Rightarrow L]$ as they behave similarly to their counterparts $[1, \land, \Rightarrow]$.

$\bullet$ $[w]$ Consider the reduction step $t \Rightarrow s$ below.

\[
\frac{\tau \vdash \varphi \not\vdash A}{f :: B} \quad \frac{\tau \vdash \varphi}{(r \in SN) \quad f :: B}
\]

The only reduction step in $t$ where $r$ and $s$ interact is the above, which deletes $r$. Then if $t$ has an infinite reduction, it must either have infinitely many steps in $r$, a contradiction, or infinitely many steps not in $r$, in which case $s$ has an infinite reduction, a contradiction.

$\bullet$ $[1]$ Consider a rewrite sequence of $[1]$ steps $t \Rightarrow s$. An infinite reduction from $t$ must contain infinitely many steps in $[\land, \Rightarrow, c, w]$, since a sequence of $[1]$ (and auxiliary) steps will strictly shrink the tree $t$, and so must be finite. We map the infinite reduction from $t$ onto one from $s$ along the $[1]$ reduction $t \Rightarrow s$, as follows. A $[1]$-sequence commutes with individual $[\land, \Rightarrow, c, w]$ steps as below left. Note that the length of the $[1]$ sequence $t' \Rightarrow s'$ may be longer or shorter than $t \Rightarrow s$ when commuting with $[c]$ respectively $[w]$ steps. The sequence $t \Rightarrow s$ commutes with $[1]$ steps as below right, where the $[1]$ reduction $s \Rightarrow s'$ consists of zero steps if the step $t \Rightarrow t'$ is absorbed in $t \Rightarrow s$ (i.e., the same step occurs in $t \Rightarrow s$), and one step otherwise.

\[
\begin{align*}
&\frac{t \Rightarrow s}{[\land, \Rightarrow, c, w] \quad \downarrow} \quad \frac{t \Rightarrow s}{[\land, \Rightarrow, c, w] \quad \downarrow}
\end{align*}
\]

The above diagrams then map the infinite reduction from $t$, containing infinitely many $[\land, \Rightarrow, c, w]$ steps, onto one from $s$, a contradiction.

$\bullet$ $[\land, \Rightarrow]$ Consider a $[\land, \Rightarrow]$ reduction $t \Rightarrow_{\#} s$. By the confluence diagrams $[\land/\land]$ and $[\Rightarrow/\Rightarrow]^1$ through $[\Rightarrow/\Rightarrow]^3$ in Figures 9 and 11–13 in the appendix it commutes with $[1, \land, \Rightarrow, w]$ steps as below.

\[
\begin{align*}
&\frac{t \Rightarrow s}{[1, \land, \Rightarrow, w] \quad \downarrow} \quad \frac{t \Rightarrow s}{[1, \land, \Rightarrow, w] \quad \downarrow}
\end{align*}
\]
Here, the reduction \( s \rightarrow s' \) is a single step, unless the step \( t \rightarrow t' \) is absorbed in (i.e. the same step occurs in) the reduction \( t \rightarrow s \); then \( s = s' \).

Next, the reduction \( t \rightarrow s \) commutes with a \([c]\) step as below, by the diagram \([\lambda]/[c]\) in Figure 15. The reduction \( s \rightarrow s' \) contains at least one step.

\[
\begin{array}{c}
\text{\( t \rightarrow [\lambda] \)} \\
\downarrow \\
\text{\( t' \rightarrow s' \)}
\end{array}
\]

Then since the \([\lambda] \rightarrow \) reduction \( t \rightarrow s \) may absorb only a finite number of consecutive \([\rightarrow] \rightarrow \) steps, it maps an infinite reduction from \( t \) onto an infinite reduction from \( s \), a contradiction.

• \([c]\) Consider a \([\lambda], [c]\) reduction \( t \rightarrow s \). It commutes with \([1, \rightarrow] \) steps as below left, where \( s \rightarrow s' \) contains at least one step. By the diagrams \([\lambda]/[c]\) and \([\lambda]/[c]\) the relation \([\lambda, c]\) commutes with itself as below right (by Lemma 21 these auxiliary reductions are finite).

\[
\begin{array}{c}
\text{\( t \rightarrow [\lambda, c] \)} \\
\downarrow \\
\text{\( t' \rightarrow s' \)}
\end{array}
\]

\[
\begin{array}{c}
\text{\( t \rightarrow [1, \rightarrow, w] \)} \\
\downarrow \\
\text{\( t' \rightarrow s' \)}
\end{array}
\]

Since \([\lambda, c]\) reduction is SN, the infinite reduction from \( t \) contains an infinite number of \([1, \rightarrow, w]\) steps. Then the corresponding reduction from \( s \) is infinite, a contradiction. 

C.3 Reducibility

We complete the strong normalization proof by abstract reducibility. The reducibility set \([A]\) of a formula \( A \) is the set of combinatorial trees defined as follows.

\[
\begin{align*}
\|P\| & = \text{SN} \\
\|A \Rightarrow B\| & = \{ \star :: A \Rightarrow B \} \cup \left\{ \frac{\tau \cdot \varphi}{k \cdot f :: A \Rightarrow B} \mid \forall s \in \|A\|, \frac{\tau \cdot \varphi}{k \cdot f :: B} \in \|B\| \right\} \\
\|A \land B\| & = \{ \star :: A \land B \} \cup \{ t :: A \land B \mid \exists t_1 \in \|A\|, \exists t_2 \in \|B\|, \rightarrow_{\land} t_1 + t_2 \}
\end{align*}
\]

We write \( \tau \in \|\Gamma\| \) if \( \tau :: \Gamma = t_1 :: A_1, \ldots, t_n :: A_n \) and \( t_i \in \|A_i\| \) for all \( i \leq n \). We establish the standard lemmata.

Lemma 24. \( \|A\| \subseteq \text{SN} \).

Proof of Lemma 24. By induction on \( A \). The case \( \|P\| \) is immediate. For \( \|A \Rightarrow B\| \), let \( t \) be the following tree.

\[
t = \frac{\tau \cdot \varphi}{k \cdot f :: A \Rightarrow B} \in \|A \Rightarrow B\|
\]

Observe that \( \star \in \|A\| \). By definition of \( \|A \Rightarrow B\| \) then

\[
t' = \frac{\tau \cdot \varphi}{k \cdot f :: B} \in \|B\|.
\]

By the inductive hypothesis, \( t' \in \text{SN} \). Since the \([\Rightarrow L]\)-reduction step \( t \rightarrow_{\Rightarrow} t' \) is safe, then \( t' \in \text{SN} \) by Lemma 23.

For \( \|A \land B\| \), let \( t \rightarrow_{\land} t_1 + t_2 \) with \( t_1 \in \|A\| \) and \( t_2 \in \|B\| \). By the inductive hypothesis \( t_1, t_2 \in \text{SN} \). Then \( t_1 + t_2 \in \text{SN} \), and \( t \in \text{SN} \) by Lemma 23.
Lemma 25. If $t_1 :: A \rightarrow_{s} t_2 :: A$ and $t_2 \in \| A \|$ then $t_1 \in \| A \|$.

Proof of Lemma 25. By induction on $A$. The case $\| P \|$ is Lemma 23. For $\| A \Rightarrow B \|$, let

$$\begin{align*}
t_1 &= \frac{\tau_1}{k \vdash f :: A \Rightarrow B} \frac{\varphi_1}{[x]} \frac{\tau_2}{k \vdash f :: A \Rightarrow B} = t_2 \in \| A \Rightarrow B \|.
\end{align*}$$

For any $s \in \| A \|$ we get the corresponding reduction step

$$\begin{align*}
t_3 &= \frac{\tau_1}{f :: B} \frac{s}{k :: A} \frac{\varphi_1}{[x]} \frac{\tau_2}{f :: B} \frac{s}{k :: A} = t_4.
\end{align*}$$

By definition of $\| A \Rightarrow B \|$ we have $t_4 \in \| B \|$, by the inductive hypothesis we have $t_3 \in \| B \|$, and again by definition of $\| A \Rightarrow B \|$ we have $t_1 \in \| A \Rightarrow B \|$.

For $t_2 \in \| A \land B \|$, there are $t_3 \in \| A \|$ and $t_4 \in \| B \|$ such that we have the following reductions.

$$t_1 \rightarrow_{s} t_2 \rightarrow_{s} t_3 + t_4$$

Then $t_1 \in \| A \land B \|$ by definition of $\| A \land B \|$.

Lemma 26. For any tree $t$ for a sequent $\Gamma \vdash B$, we have

$$\forall \sigma \in \| \Gamma \|, \frac{\sigma}{t} \in \| B \|.$$ 

Proof of Lemma 26. By induction on the construction of $t$. We cover a selection of cases, relegate the others to the appendix.

$$t = *$$

We need to show $s \in \| A \|$ for any $s \in \| A \|$, which is immediate.

$$t = \frac{t_1 :: A}{k :: B} \frac{\varphi_1}{\sigma_1} \frac{\sigma_2}{t_2 :: B}$$

We need to show for $t'$ as below left that $t' \in \| B \|$ for any $\sigma_1 \in \| \Gamma_1 \|$ and $\sigma_2 \in \| \Gamma_2 \|$.

$$t' = \frac{\sigma_1}{t_1 :: A}, \frac{\sigma_2}{t_2 :: B} \quad t_1' = \frac{\sigma_1}{t_1 :: A}$$

We apply the inductive hypothesis twice, first on $t_1$ to get $t_1' \in \| A \|$ with $t_1'$ above right, and then on $t_2$ to get $t' \in \| B \|$.

$$t = \frac{\varphi :: \Gamma}{k \vdash f :: A \Rightarrow B}$$

We need to show for $t'$ as below left that $t' \in \| A \Rightarrow B \|$ for any $\sigma \in \| \Gamma \|$. We apply the inductive hypothesis to $t_1$, below centre, which gives that $t_1' \in \| B \|$ for any $r \in \| A \|$ for $t_1'$ as below right.

$$t' = \frac{\sigma}{\varphi :: \Gamma} \frac{\varphi :: \Gamma}{k :: A} \frac{r}{f :: B} \quad t_1' = \frac{\sigma}{\varphi :: \Gamma} \frac{r}{k :: A}$$

By the definition of $\| A \Rightarrow B \|$ then $t' \in \| A \Rightarrow B \|$. 
We need to show for $t'$ as below left that $t' \in \|C\|$, for any $\tau \in \|\Gamma\|$, $s \in \|A \Rightarrow B\|$, and $\rho \in \|\Delta\|$. Let $s$ be as below right.

$$t' = \frac{\tau}{\frac{\sigma}{f : l :: A \Rightarrow B} \ \frac{\rho}{h :: C}}$$

We will apply the inductive hypothesis to $t_1$ and $t_2$ as given below.

$$t_1 = \frac{\tau}{\frac{\phi}{f : A}} \quad t_2 = \frac{\rho}{h :: C}$$

The induction hypothesis for $t_1$ gives us $t'_1 \in \|A\|$ as below left. By definition of $\|A \Rightarrow B\|$ we then get $s' \in \|B\|$ as below centre. Then induction hypothesis for $t_2$ gives us $t'_2 \in \|C\|$ as below right.

$$t'_1 = \frac{\tau}{\frac{\sigma}{f : \phi :: A}} \quad s' = \frac{\rho}{h :: C} \quad t'_2 = \frac{\sigma}{f : \rho :: B} \ \frac{\phi}{h :: C}$$

By Lemma 25 and the below reduction $t' \rightarrow t'_2$ then $t' \in \|C\|$.

$$t' = \frac{\tau}{\frac{\sigma}{f : l :: A \Rightarrow B} \ \frac{\rho}{h :: C}} \ \frac{\phi}{g :: B}$$

We need to show for $t'$ as below that $t' \in \|P\|$ for any $s \in \|P\|$.

$$t' = \frac{\frac{\phi}{f : A}}{1 :: \frac{\phi}{1 :: P}} \ \frac{[\text{3}]}{s}$$

Since $t' \rightarrow s$ as above, we get $t' \in \|P\|$ by Lemma 25.

$$t = \frac{\phi :: \Gamma}{f + g :: A \land B} \ \frac{\psi :: \Delta}{f :: \psi :: \Delta} \ \frac{\phi :: \Gamma}{f + g :: A \land B} \ \frac{\psi :: \Delta}{f :: \psi :: \Delta} \ \frac{f :: A}{f :: A} \ \frac{g :: B}{g :: B} \ \frac{\phi :: \Gamma}{f :: \phi :: \Gamma} \ \frac{\psi :: \Delta}{f :: \psi :: \Delta}$$

We need to show that $t' \in \|A \land B\|$ for $t'$ as below left, for any $\tau \in \|\Gamma\|$ and $\sigma \in \|\Delta\|$. We apply the inductive hypothesis to $t_1$ and $t_2$, as below right,

$$t' = \frac{\tau}{\frac{\phi}{f + g :: A \land B} \ \frac{\sigma}{f :: \phi :: \Gamma} \ \frac{\rho}{g :: B} \ \frac{\phi}{h :: C}}$$

which gives $t'_1 \in \|A\|$ and $t'_2 \in \|B\|$, as below.

$$t'_1 = \frac{\tau}{f :: \phi :: \Gamma} \ \frac{\sigma}{f :: \psi :: \Delta} \quad t'_2 = \frac{\sigma}{f :: \psi :: \Delta} \ \frac{\phi}{h :: C}$$

Since $t' = t'_1 + t'_2$, we have $t' \rightarrow t'_1 + t'_2$ by the empty reduction, and by definition $t' \in \|A \land B\|$.
Let $\tau, \sigma, \psi = \frac{\star}{k : B}$ be an arbitrary combinatorial tree for $\Gamma$. By the above reduction and Lemma 25.

Let $\phi$ be an arbitrary combinatorial tree for $\Gamma$. By Lemma 24, so that the reduction step is safe. Then $s \mapsto \tau, \sigma, \psi = \frac{\star}{k : B}$.

For any $\phi \in \Gamma$, $s_1 \in \|A\|$, and $s_2 \in \|B\|$, there is a reduction as below right, with $s_1 \in \|A\|$, $s_2 \in \|B\|$, gives $t' \in \|C\|$.

The inductive hypothesis for $t_1$ below (with $\phi \in \Gamma$, $s_1 \in \|A\|$, $s_2 \in \|B\|$), gives $t'_1 \in \|C\|$.

Then $t' \in \|C\|$ by the above reduction and Lemma 25.

$t_1 = \frac{\star}{k : B}$ for $\phi \in \Gamma$, $s_1 \in \|A\|$, $s_2 \in \|B\|$, gives $t'_1 \in \|C\|$, and $t' \in \|C\|$.

The inductive hypothesis on $t_1$ below gives $t'_1 \in \|C\|$, and by Lemma 25 then $t' \in \|C\|$.

$t_1 = \frac{\star}{k : B}$ for $\phi \in \Gamma$, $s_1 \in \|A\|$, $s_2 \in \|B\|$, gives $t'_1 \in \|C\|$, and $t' \in \|C\|$.

Combinatorial-tree reduction is strongly normalizing.

Proof. Let $t$ be an arbitrary combinatorial tree for $\Gamma$. Note that $\phi \in \Gamma$, $s \in \|A\|$, and $t \in \|B\|$, gives $t'_1 \in \|C\|$. Then $t' \in \|C\|$ by Lemma 26, and $t \in \|B\|$ by Lemma 24.
