#### Abstract

Symbolic protocol verification generally abstracts probabilities away, considering computations that succeed only with negligible probability, such as guessing random numbers or breaking an encryption scheme, as impossible. This abstraction, sometimes referred to as the perfect cryptography assumption, has shown very useful as it simplifies automation of the analysis. However, probabilities may also appear in the control flow where they are generally not negligible. In this paper we consider a framework for symbolic protocol analysis with a probabilistic choice operator: the probabilistic applied pi calculus. We define and explore the relationships between several behavioral equivalences. In particular we show the need to require randomized schedulers - indeed we exhibit a counter-example to one of the main results in a previous work that relied on non-randomized ones. As in other frameworks that mix both non-deterministic and probabilistic choices, schedulers may sometimes be unrealistically powerful. We therefore consider two subclasses of processes that avoid this problem. When considering purely non-deterministic protocols, as is done in classical symbolic verification, we show that a probabilistic adversary has-maybe surprisingly - a strictly superior distinguishing power for may testing, which, when the number of sessions is bounded, we show to coincide with purely possibilistic similarity. Finally, we consider fully probabilistic protocols and show that trace equivalence corresponds to a notion of may testing with purely probabilistic attackers. We also briefly discuss complexity and automation for these subclasses when the number of sessions is bounded.

## 1 Introduction

Automated symbolic protocol verification, based on the seminal work of Dolev and Yao [DY83], has nowadays reached a level of maturity enabling successful use on complex real-world security protocols, including TLS [BBK17, $\mathrm{CHH}^{+} 17$ ], Signal $\mathrm{CGCD}^{+} 20$, authentication protocols of the 5G standard $\overline{\mathrm{BDH}^{+} 18}$, or EMV's secure payment protocols BST21 to name only a few. In the symbolic model, a non-deterministic, computationally unbounded attacker is assumed to have complete control of the network, being able to intercept any messages, and forge new ones. As a counterpart, cryptography is idealized and the attacker can only use predefined rules to manipulate messages that are represented by terms, e.g. expressed by an equation $\operatorname{dec}(e n c(m, k), k)=m$ stating that a message $m$ encrypted with $k$ can be decrypted with the same key. This treatment of cryptography is in opposition to computational models where we assume a probabilistic polynomial time attacker, messages are represented by bitstrings and assumptions that an arbitrary such attacker has at most negligible probability of breaking a cryptographic primitive. Similarly, in the symbolic model, random values, such as keys or nonces, are chosen freshly from an infinite domain, rather than chosen randomly from a sufficiently large domain. These symbolic abstractions of cryptography and randomness have even been shown sound CKW10] (under rather strong assumptions) and significantly ease the automation of proofs. Hence, symbolic modeling of messages is arguably useful for formally analyzing cryptographic protocols.

However, the above-described abstractions of randomness only apply to the messages, and not to the control flow. Typical examples which crucially rely on randomized control flow are mechanisms for providing anonymity, such as the dining cryptographers protocol [Cha88], Mix-nets Cha81] or Crowds [RR98. In this paper, we will investigate indistinguishability properties, expressed as equivalences in a cryptographic process calculus, the applied pi calculus [ABF17, extended with a probabilistic choice operator. Typically, the testing equivalence expresses that two processes are equivalent if they exhibit the same behaviour when put in parallel with an arbitrary attacker process. Our work presents foundations for a model that (i) extends the scope of symbolic protocol analysis to probabilistic protocols, and (ii) allows to consider non-probabilistic protocols in the presence of a probabilistic attacker. In particular, when we consider purely concurrent processes-without probabilistic behavior-the equivalence we obtain is strictly stronger than the standard testing equivalence on such purely concurrent processes; in other terms, probabilistic adversaries are-for good reasons, as we will argue-more powerful in order to distinguish such processes than the purely concurrent adversaries considered in existing works and tools.

Our contributions. In a first part we introduce a probabilistic applied pi calculus and its semantics, which has similarities to [GLPT07], with two major differences. (i) We express our semantics in terms of general non-deterministic probabilistic transition systems (NPLTS)-also called probabilistic automata in the literature-which allows us to benefit from a large body of existing results on these systems [SL95, PS07, Cas18, BSV19, DVGHM09, Sto02, Eis17. (ii) More importantly, we differ in the way non-determinism is
resolved: unlike GLPT07] we allow for randomized schedulers-rather than choosing one particular non-deterministic choice, we allow the scheduler to choose an arbitrary distribution on the available non-deterministic choices. Next we introduce testing equivalence, and show that unlike in the purely non-deterministic choice, may-testing is strictly stronger than trace equivalence. Finally, we introduce notions of (bi)simulation and observational preorder and equivalence and show that the simulation and observational pre-order, respectively bisimilarity and observational equivalence, coincide for randomized schedulers. We also show that for non-randomized schedulers, these equivalences do not coincide, which provides a counter-example to one of the main results in GLPT07.

A well-known phenomenon [CP10, AAPvR10] in process calculi that are both probabilistic and non-deterministic is the existence of some nonrealistic schedulers that are able to use the internal probabilistic choices done by an agent in order to schedule another agent's non-deterministic choices, i.e., the scheduler leaks the probabilistic choices. Therefore, we study two important subclasses of processes that avoid this phenomenon. First, we consider the classical class of non-probabilistic processes, as in the original applied pi calculus, but in the presence of probabilistic adversaries. We show that, if we additionally bound the number of sessions, may-testing with probabilistic adversaries coincides with the classical, purely possibilistic notion of similarity. This provides a contextual characterization of the notion of similarity which is reminiscent of [DVGHM09] in the setting of CSP. Relying on results from [CKR18], this implies that testing equivalence with probabilistic adversaries is co-NEXPTIME complete for a large class of cryptographic primitives. Second, we consider a class of fully probabilistic processes, which is reminiscent of a probabilistic version of simple processes in CCD13, CC08, and a slight generalization of the processes in CSV17. We next show that trace equivalence as considered in CSV17, is weaker than may-testing, but coincides with a version of may-testing where attacker processes are restricted disallowing replication, parallel, and non-deterministic choice, but allowing probabilistic choices. Finally, we briefly discuss how the algorithm for deciding trace equivalence in the DeepSec verifier CKR18] could be adapted to this fully probabilistic case, providing a more general setting than Bauer et al. [BCSV18] who additionally bound the size of input messages. A thorough treatment of this adaptation and implementation is left for future work. Most of our results are summarized in Figure 1 that depicts the relationship between the different preorders (with similar relations between corresponding equivalences).

$\leq_{-}^{\mathrm{nr}}$ denotes a preorder with non-randomized schedulers.

Figure 1: Summary of the relationship between preorders.

## Part I

## A Probabilistic Applied Pi Calculus

In this first part we present a probabilistic extension of the applied pi calculus. We first introduce its syntax and internal semantics. Then we introduce different equivalences and preorders, and study their relations. We start with the classical may-testing equivalence, which requires to be precise about how non-determinism is resolved. Then we introduce a labelled semantics and the notion of trace equivalence. Unlike in the purely non-deterministic case, trace equivalence is (strictly) weaker than may testing. Finally, we introduce other equivalences and preorders: similarity, bisimilarity and observational preorder/equivalence. We emphasize the need for randomized schedulers; indeed, the use of non-randomized schedulers results into a non-transitive simulation relation.

## 2 Probabilistic Applied $\pi$-calculus

In this paper, we will work with probabilistic applied $\pi$-calculus, the probabilistic variant of applied $\pi$-calculus introduced by Goubault-Larrecq et al. [GLPT07].

### 2.1 Message as terms

We assume an infinite set of names, denoted $\mathcal{N}=\{a, b, \ldots$,$\} . We partition the set \mathcal{N}$ into two disjoint infinite sets $\mathcal{N}_{\text {pub }}$ and $\mathcal{N}_{\text {priv }}$ to respectively represents public and private names. The distinction between public and private names is analogous to the distinction between free and bound names in the original applied pi calculus. We define an infinite set of variables $\mathcal{X}$. Finally we consider a finite set of function symbols with their arity
$\mathcal{F}=\{f / n, g / m, \ldots\}$, called signature. Terms are defined as names, variables, and function symbols applied to other terms. For any $\mathrm{F} \subseteq \mathcal{F}, \mathrm{N} \subseteq \mathcal{N}$ and $\mathrm{V} \subseteq \mathcal{X}$, the set of terms built from N and V by applying function symbols in F is denoted by $\mathcal{T}(\mathrm{F}, \mathrm{N} \cup \mathrm{V})$. We call protocol terms the terms from $\mathcal{T}(\mathcal{F}, \mathcal{N} \cup \mathcal{X})$.

We also suppose that terms are equipped with a binary relation $\doteq$ that expresses that two terms evaluate to the same result, and a predicate $\operatorname{Msg}(\cdot)$ that is intended to hold when evaluation succeeds. We suppose that $\doteq$ is a symmetric and transitive relation that is closed under substitution of names and variables by other terms and application of function symbols and such that for all $a, b \in \mathcal{N}, a=b$ if and only if $a \doteq b . M s g(\cdot)$ is supposed to hold on any names, to be closed under renamings and $t_{1} \doteq t_{2}$ implies that $\operatorname{Msg}\left(t_{1}\right)$ and $\operatorname{Msg}\left(t_{2}\right)$. Finally, we require that $\operatorname{Msg}(t)$ implies $t \doteq t$.

For example, the $\doteq$ relation could capture that $\operatorname{dec}(\operatorname{enc}(m, k), k) \doteq m$ for any $m, k$ modelling that decryption cancels out encryption when the same key $k$ is used and one may define $\operatorname{Msg}(\operatorname{dec}(n, k))$ as false to express that decryption could fail if the ciphertext it is applied to is not an encryption with the matching key.

How $\doteq$ and $\operatorname{Msg}(\cdot)$ are precisely defined is not relevant for the results of this paper and we wish to capture several formalisms. $\doteq$ can for instance be defined by an equational theory, as in the applied pi calculus ABF17] (where $\operatorname{Msg}(\cdot)$ would evaluate to true on any term), defined by a constructor-destructor rewrite system, allowing evaluation to fail when a destructor application does not reduce, as in the DeepSec tool [CKR18], or a combination of these as in the ProVerif tool [Bla16.

### 2.2 Syntax of the process calculus

The syntax for processes is defined as follows:
$P, Q::=$
0
$\operatorname{in}(u, x) ; P$
$\quad \operatorname{out}(u, v) ; P$
$P \mid Q$
$!P$
new $a ; P$
if $u=v$ then $P$ else $Q$
$P+Q$
$P+{ }_{p} Q$
processes
nil
output
input
parallel composition
replication
restriction
conditional
non-deterministic choice
probabilistic choice
where $u, v$ are protocol terms, $x \in \mathcal{X}, a \in \mathcal{N}$ and $p \in] 0 ; 1[$. A process $P$ is closed when all variables in $P$ are bound by an input.

Notation 1. We write $\mathcal{S P}$ for the set of all processes in probabilistic applied $\pi$-calculus, and $\mathcal{M P}$ for the set of all multisets over $\mathcal{S P}$. We sometimes consider syntactic subclasses of these processes. For finite processes, i.e., without replication, we denote these sets by
$\mathcal{S P}{ }^{<\infty}$ and $\mathcal{M} \mathcal{P}^{<\infty}$. For non probabilistic, i.e. purely non-determinisitic processes without $+_{p}$, we write $\mathcal{S P}{ }^{\mathrm{np}}$ and $\mathcal{M} \mathcal{P}^{\mathrm{np}}$ and when considering both restrictions we write $\mathcal{S} \mathcal{P}^{<\infty, \mathrm{np}}$ and $\mathcal{M} \mathcal{P}^{<\infty, n p}$.

### 2.3 Operational semantics

We will now define the semantics of the probabilistic applied $\pi$-calculus. We opt for a different presentation of the semantics than Goubault-Larrecq et al. GLPT07] relying on existing formalisms for transition systems. Moreover, we allow for a more general class of schedulers.

Notation 2. Let $\mathcal{S}$ be any set. We denote by $\mathcal{D}(\mathcal{S})$ the set of all finitely supported probability distributions over $\mathcal{S}$. We denote by $\mathcal{D}^{\leq 1}(\mathcal{S})$ the set of all sub-probability distributions over $\mathcal{S}$ (observe that $\mathcal{D}(\mathcal{S}) \subseteq \mathcal{D}^{\leq 1}(\mathcal{S})$ ). For $p, q \geq 0$, and $D, E$ two sub-distributions, we write $p \cdot D+q \cdot E$ for the measure defined as $(p \cdot D+q \cdot E)(x)=p \cdot D(x)+q \cdot E(x)$. In the particular case where $q=0$, the resulting sub-distribution does not depend on $E$, and we simply write $p \cdot D$ instead of $p \cdot D+0 \cdot E$.

If $D \in \mathcal{D}(\mathcal{S})$, we denote by $\operatorname{supp}(D)$ the support of $D$, i.e. the set of all elements $s \in \mathcal{S}$ such that $D(s)>0$. If $\mathcal{S}^{\prime} \subseteq \mathcal{S}$, we note $D\left(\mathcal{S}^{\prime}\right)=\sum_{s \in \mathcal{S}^{\prime}} D(s)$. Finally, we denote by $\delta_{x}$ the Dirac distribution on $x$.

The operational semantics of processes is defined by a relation between multisets of processes and probability distributions on multisets of processes, denoted $\mathcal{P} \rightarrow_{\tau} \mu$. This relation is defined in Figure 2.

Remark 1. One may note that our calculus offers a non-deterministic choice operator that is resolved internally. This differs from the standard pi-calculus [MPW92] where the non-deterministic choice operator is resolved externally. Even though the original applied pi calculus ABF17] does not contain non-deterministic choice the process $P+Q$ can be encoded as

$$
\text { new } c ;((\text { out }(c, \text { tok }) ; P) \mid(\text { in }(c, \text { tok }) ; Q))
$$

where $c$ and $x$ do not occur in $P$ nor in $Q$. Alternatively, we could have defined + as syntactic sugar.

In the following, we will deal with the operational semantics of our calculus with tools designed for generic probabilistic systems. We choose the notion of non-deterministic probabilistic labelled transition systems (NPLTS) used for instance in BSV19]. A NPLTS allows to represent states that have both internal and external non-deterministic behavior. It can be noted that it coincides with the notion of simple probabilistic automata of Segala et al [SL95].

Notation 3. Let $\mathcal{S}$ be any set. We denote $\mathcal{P}(\mathcal{S})$ for the set of all finite subsets of $\mathcal{S}$. Moreover, we can augment $\mathcal{S}$ with a special element $\star$ will be used to talk about deadlocks, i.e. $\mathcal{S} \cup\{\star\}$.

$$
\begin{align*}
& \mathcal{P} \cup\left\{\{0\} \rightarrow_{\tau} \delta_{\mathcal{P}}\right.  \tag{NuLL}\\
& \mathcal{P} \cup\{\text { if } u=v \text { then } P \text { else } Q\} \rightarrow_{\tau} \delta_{\mathcal{P} \cup\{P\}} \quad \text { if } u \doteq v \quad \text { (THEN) }  \tag{Then}\\
& \mathcal{P} \cup\{\text { if } u=v \text { then } P \text { else } Q\} \rightarrow_{\tau} \delta_{\mathcal{P} \cup\{Q\}} \quad \text { if } u \neq v \quad \text { (ELSE) } \\
& \mathcal{P} \cup\left\{\{\operatorname{out}(u, t) . P, \operatorname{in}(v, x) . Q\} \rightarrow_{\tau} \delta_{\mathcal{P} \cup\{P, Q\{x \mapsto t\}\}} \quad \text { if } \operatorname{Msg}(t) \wedge u \doteq v \quad\right. \text { (Comm) }  \tag{Сомм}\\
& \mathcal{P} \cup\left\{\{P \mid Q\} \rightarrow_{\tau} \delta_{\mathcal{P} \cup\{P, Q\}}\right.  \tag{PAR}\\
& \mathcal{P} \cup\{!P\}\} \rightarrow_{\tau} \delta_{\mathcal{P} \cup\{!P, P\}}  \tag{REPL}\\
& \mathcal{P} \cup\{\text { new } a ; P\} \rightarrow_{\tau} \delta_{\mathcal{P} \cup\left\{\left\{P\left\{a^{\prime} / a\right\}\right\}\right.} \quad \text { where } a^{\prime} \in \mathcal{N}_{\text {priv }} \text { is fresh (NEW) } \\
& \mathcal{P} \cup\{\{P+Q\}) \rightarrow_{\tau} \delta_{\mathcal{P} \cup\{P\}} \\
& \mathcal{P} \cup\left\{\{P+Q\} \rightarrow_{\tau} \delta_{\mathcal{P} \cup\{Q\}}\right. \\
& \mathcal{P} \cup\left\{\left\{P+{ }_{p} Q\right\} \rightarrow_{\tau} p \cdot \delta_{\mathcal{P} \cup\{P\}\}}+(1-p) \cdot \delta_{\mathcal{P} \cup\{Q\}}\right. \\
& \text { (Choice-1) } \\
& \text { (Choice-2) } \\
& \text { (PChoice) }
\end{align*}
$$

Figure 2: Semantics of the calculus

Definition 1 (NPLTS). A NPLTS is a triple $(\mathcal{S}, \mathcal{A}$, trans), where

- $\mathcal{S}$ is a set of states,
- $\mathcal{A}=\mathcal{A}_{\text {int }} \sqcup \mathcal{A}_{\text {ext }}$ is a set of labels, and
- trans : $\mathcal{S} \rightarrow \mathcal{A} \rightarrow \mathcal{P}(\mathcal{D}(\mathcal{S}))$ is a transition function: for each state in $\mathcal{S}$, and each label in $\mathcal{A}, \operatorname{trans}(s)(a)$ is a set of (finitely supported) distributions.

The labels in $\mathcal{A}_{\text {int }}$, respectively $\mathcal{A}_{\text {ext }}$ are called internal, respectively external actions. For $s \in \mathcal{S}, a \in \mathcal{A}$, when $D \in \operatorname{trans}(s, a)$ we write $s \xrightarrow{a} D$ if $a \in \mathcal{A}_{\text {ext }}$ and $s \xrightarrow{\tau} D$ if $a \in \mathcal{A}_{\text {int }}$.

In the rest of this paper, we may define a NPLTS by only its transition function, i.e., we will say that trans : $\mathcal{S} \rightarrow \mathcal{A} \rightarrow \mathcal{P}(\mathcal{D}(\mathcal{S}))$ is the $\operatorname{NPLTS}(\mathcal{S}, \mathcal{A}$, trans). When considering an NPLTS with only one internal action, this action will usually be noted $\tau$, in such a way that $s \xrightarrow{\tau} D$ if and only if $D \in \operatorname{trans}(s, \tau)$.

We now express our operational semantics as a NPLTS, whose only action is the internal action $\{\tau\}$. The need for external actions will become clear in Section 4 , when defining a labelled semantics as a NPLTS $\mathrm{N}^{\ell}$ with an internal action $\tau$, and several external actions that represent adversarial transitions. Moreover, in Section ??, we consider a refinement of both labelled and non-labelled semantics, using several internal actions: an internal action will correspond to an internal action $\tau$ decorated with an annotation visible by the scheduler.

Definition 2. The operational semantics is the NPLTS $\mathrm{N}^{o}=\left(\mathcal{M P},\{\tau\}\right.$, trans $\left.^{\circ}\right)$ where for every $s \in \mathcal{M} \mathcal{P}$, $\operatorname{trans}^{\circ}(s)(\tau)=\left\{D \mid s \rightarrow_{\tau} D\right\}$.

Note that the states of the NPLTS $\mathrm{N}^{o}$ contain all possible multisets of processes and how they are executed. Obviously, $\mathrm{N}^{o}$ is thus an infinite transition system. In examples
illustrating transitions of a multiset of processes $\mathcal{P}$, we only show the relevant fragment of $\mathrm{N}^{o}$ that contains $\mathcal{P}$.

Example 1. The complete execution of the following process $P$ is given in Figure 3.

$$
\left(\operatorname{out}(c, k)+_{1 / 3} \text { out }(c, a)\right) \mid \operatorname{in}(c, x) ; \text { if } x=k \text { then } \operatorname{out}(c, o k)
$$

Figure 3: Semantics of the process $P$ from Example 1

## 3 May Testing Equivalences

### 3.1 Resolving the internal non-determinism

We generically express the way to resolve the internal non-determinism of a NPLTS using the formalism of resolutions: resolving the non-determinism means choosing from the NPLTS, a particular transition system without internal non-determinism. The resulting transition system is called a Reactive Probabilistic Labelled Model and has still external, but no internal, non-determinism. It can be noted that this model is equivalent to Labelled Markov Chains when extended with internal actions.

Definition 3 (RPLTS). A Reactive Probabilistic Labelled Transition System (RPLTS) is a triple ( $\mathcal{S}, \mathcal{A}$, trans), where

- $\mathcal{S}$ is a set of states,
- $\mathcal{A}=\mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}$ a set of labels, and
- trans : $\mathcal{S} \rightarrow\left(\mathcal{A}_{\text {ext }} \rightarrow(\mathcal{D}(\mathcal{S}) \cup\{\star\})\right) \sqcup\left(\mathcal{A}_{\text {int }} \times \mathcal{D}(\mathcal{S})\right)$ is a transition function that assigns to each state in $\mathcal{S}$
- either a function mapping labels in $\mathcal{A}_{\text {ext }}$ to a failure or a distribution over $\mathcal{S}$ (the non deterministic external actions);
- or one unique distribution with its internal label from $\mathcal{A}_{\text {int }}$ (the deterministic internal action).

The states $s \in \mathcal{S}$ such that $\operatorname{trans}(s): \mathcal{A}_{\text {ext }} \rightarrow(\mathcal{D}(\mathcal{S}) \cup\{\star\})$ are called external states, while the ones such that $\operatorname{trans}(s):\left(\mathcal{A}_{\text {int }} \times \mathcal{D}(\mathcal{S})\right)$ are called internal states. Given an RPLTS $R$, we will denote by $\mathcal{S}_{\text {ext }}(R)$ and $\mathcal{S}_{\text {int }}(R)$ the sets of external and internal states of $R$ respectively.

In the particular case of a NPLTS with no external action, resolving the internal nondeterminism results in a system with no non-determinism at all. This is for instance the case of the operational semantics $\mathrm{N}^{\circ}$. Such a purely probabilistic system can be modelled as a reactive probabilistic transition system (that is equivalent to the notion of Markov Chain).

Definition 4 (RPTS). A Reactive Probabilistic Transition System (RPTS) is a pair ( $\mathcal{S}$, trans), where

- $\mathcal{S}$ is a set of states, and
- trans : $\mathcal{S} \rightarrow(\mathcal{D}(\mathcal{S}) \cup\{\star\})$ is a transition function that assigns to each state in $\mathcal{S}$ either a failure token $\star$, or a distribution over $\mathcal{S}$.

We now define resolutions-or schedulers-for a NPLTS that allow to solve the internal, but not external, non-determinism: a resolution describes one of the possible ways of turning an NPLTS into a RPLTS. It means that for each state $s$, a resolution should choose whether $s$ is an internal state or external state; in the first case, a unique pair of an internal action and a post-transition distribution must be chosen; in the second case, for each external action $a$, the resolution must choose a unique distribution $D$ (if it exists) such that $s \rightarrow_{a} D$. It is however slighly more complicated, since the possible existence of cycles in the execution-meaning that from the same state, the scheduler can do successively different choices-lead to the necessity of a correspondance function.

Example 2. There are indeed cycles in the NPLTS $\mathrm{N}^{o}$, because of the replication operator !. For instance, we can consider the following process $P$ :

$$
P:=!Q \quad \text { with } Q:=\operatorname{in}(u, x) \mid(\operatorname{out}(u, 0)+\operatorname{out}(u, 1))
$$

We represent in Figure 4 a fragment of $N^{o}$ containing the state $\{\{P\}$. (Observe that this fragment is not self-contained, in the sense that there exist $\mathrm{N}^{\circ}$-transitions from states in this fragment to states absent from this fragment).

Figure 4: A cycle in $\mathbf{N}^{o}$, from Example 2

Notation 4. Let $\mathcal{S}$ be a set of states and $\Delta \subseteq \mathcal{D}(\mathcal{S})$ be a finite set of probability distributions over $\mathcal{S}$. The convex hull of $\Delta$ is defined as:

$$
\operatorname{conv}(\Delta):=\left\{D \in \mathcal{D}(\mathcal{S}) \mid \exists \alpha_{1}, \ldots, \alpha_{n} \in \mathbb{R} . \exists D_{1}, \ldots, D_{n} \in \Delta . \sum_{i=1}^{n} \alpha_{i}=1 \wedge D=\sum_{i=1}^{n} \alpha_{i} \cdot D_{i}\right\}
$$

Notation 5. Let $\mathcal{S}, \mathcal{S}^{\prime}$ be two sets of states and $f: \mathcal{S} \rightarrow \mathcal{S}^{\prime}$. We define the function $\bar{f}: \mathcal{D}(\mathcal{S}) \rightarrow \mathcal{D}\left(\mathcal{S}^{\prime}\right)$ to be the probabilistic lifting of $f$, where $\bar{f}(D)=\sum_{s \in \mathcal{S}} D(s) \cdot \delta_{f(s)}$.

When obvious from context, we will overload the notation and write $f$ instead of $\bar{f}$.
Definition 5 ([|BSV19 $])$. Let trans : $\mathcal{S} \rightarrow \mathcal{A}_{\text {int }} \sqcup \mathcal{A}_{\text {ext }} \rightarrow \mathcal{P}(\mathcal{D}(\mathcal{S}))$ be a NPLTS. A randomized, respectively non-randomized, resolution for trans is a triple ( $\mathcal{S}^{\prime}$, corr, trans'), where $\mathcal{S}^{\prime}$ is a set of states, corr : $\mathcal{S}^{\prime} \rightarrow \mathcal{S}$ is the correspondence function, and trans' : $\mathcal{S}^{\prime} \rightarrow$ $\left(\mathcal{A}_{\text {ext }} \rightarrow\left(\mathcal{D}\left(\mathcal{S}^{\prime}\right) \cup\{\star\}\right)\right) \sqcup\left(\mathcal{A}_{\text {int }} \times \mathcal{D}\left(\mathcal{S}^{\prime}\right)\right)$ is a RPLTS $R$ such that:
if $s^{\prime} \in \mathcal{S}_{\text {ext }}(R)$ and $\operatorname{trans}^{\prime}\left(s^{\prime}\right)(a)=D$, or $s^{\prime} \in \mathcal{S}_{\text {int }}(R)$ and $\operatorname{trans}^{\prime}\left(s^{\prime}\right)=(a, D)$,
then $\operatorname{corr}(D) \in \operatorname{conv}\left(\operatorname{trans}\left(\operatorname{corr}\left(s^{\prime}\right)\right)(a)\right)$ (randomized), respectively
corr is injective on the support of $D$ and $\operatorname{corr}(D) \in \operatorname{trans}\left(\operatorname{corr}\left(s^{\prime}\right)\right)(a)$ (non-randomized).
Given a NPLTS N we denote by $\mathcal{R}_{\mathrm{r}}(\mathrm{N})$, respectively $\mathcal{R}_{\mathrm{nr}}(\mathrm{N})$, the set of randomized, respectively non-randomized resolutions. Observe that any non-randomized resolution is also a randomized resolution, i.e., $\mathcal{R}_{\mathrm{nr}}(\mathrm{N}) \subset \mathcal{R}_{\mathrm{r}}(\mathrm{N})$.

Remark 2. In the particular case of an NPLTS N that has only one internal action $\tau$, and no external actions, as for instance $\mathrm{N}^{o}$, a resolution is a triple $\mathrm{R}=\left(\mathcal{S}^{\prime}\right.$, corr, trans'), where $\mathcal{S}^{\prime}$ is a set of states, corr : $\mathcal{S}^{\prime} \rightarrow \mathcal{S}$ is the correspondence function, and trans' : $\mathcal{S}^{\prime} \rightarrow$ $\left(\varnothing \rightarrow\left(\mathcal{D}\left(\mathcal{S}^{\prime}\right) \cup\{\star\}\right)\right) \sqcup\left(\{\tau\} \times \mathcal{D}\left(\mathcal{S}^{\prime}\right)\right)$. Recall that for any set $X$, the cardinality of the set $(\varnothing \rightarrow X)$ is 1: by abuse of notation, we denote by $\star$ the unique element of the set

$\left(\varnothing \rightarrow\left(\mathcal{D}\left(\mathcal{S}^{\prime}\right) \cup\{\star\}\right)\right)$. With this notation-and by indentifying any set $X$ to the isomorphic set $\{\tau\} \times X$-we can simply rewrite trans' as:

$$
\text { trans }^{\prime}: \mathcal{S}^{\prime} \rightarrow\{\star\} \sqcup \mathcal{D}\left(\mathcal{S}^{\prime}\right)
$$

To sum up, there are two possibilities when we star from a R-state $s^{\prime} \in \mathcal{S}^{\prime}$ : either the execution stops here (in this case, $\operatorname{trans}\left(s^{\prime}\right)=\star$, and thus $s^{\prime}$ is an external state), or the scheduler chooses the next step (in this case, $\operatorname{trans}\left(s^{\prime}\right) \in \mathcal{D}\left(\mathcal{S}^{\prime}\right)$, and thus $s^{\prime}$ is an internal state). Formally, it means that the N -resolutions are actually RPTSs-the purely probabilistic structure defined in Definition 4. Moreover, we can rewrite the simplified constraints on resolutions given in Definition 5 as follows:

$$
\text { if } \operatorname{trans}^{\prime}\left(s^{\prime}\right)=D
$$

then $\operatorname{corr}(D) \in \operatorname{conv}\left(\operatorname{trans}\left(\operatorname{corr}\left(s^{\prime}\right)\right)(\tau)\right)$ (randomized), respectively
corr is injective on the support of $D$ and $\operatorname{corr}(D) \in \operatorname{trans}\left(\operatorname{corr}\left(s^{\prime}\right)\right)(\tau)$ (non-randomized).
We show in Figure 6 examples of $\mathrm{N}^{o}$-resolutions for the process $P$ from Example 1 and its semantics in Figure 3.

(a) A non-randomized resolution.

(b) A randomized resolution.

Figure 6: Examples of resolutions for process $P$ from Example 1 where the correspondence function corr is the identity. Resolutions in $\mathrm{N}^{\circ}$ correspond to a Markov Chain.

### 3.2 Computing the probability of reaching a barbed state

We first precise when a state of $\mathrm{N}^{o}$, i.e., a multiset of processes, exhibits a barb $c$.
Definition 6. For any public name $c \in \mathcal{N}_{\text {pub }}$, and a multiset of processes $\mathcal{P} \in \mathcal{M} \mathcal{P}$, we say that $\mathcal{P}$ exhibits barb $c$ when there exists a process out $(u, t) . Q$ in $\mathcal{P}$ where $c \doteq u$ and $\operatorname{Msg}(t)$. We denote by $\downarrow c$ the set of all multisets of processes that exhibit the barb $c$.

We formalize here the probability of reaching a state in some set of target states, in a fully probabilistic transition system, i.e., in a transition system where all non-determinisminternal or external-has already been resolved. We first define the probability of reaching such a state in at most $n$ steps, and then we take the probability of reaching them eventually as the limit of the $n$-step reaching probabilities.

Definition 7. Let $R=(\mathcal{S}$, trans) be a $\operatorname{RPTS}, \mathcal{T} \subseteq \mathcal{S}$ a set of states, and $s$ an initial state. For every $n \in \mathbb{N}$ we define the probability of reaching $\mathcal{T}$ from $s$ in at most $n$ steps as:

$$
\begin{aligned}
\operatorname{RProb}_{\bar{R}}^{\leq 0}(s, \mathcal{T}) & = \begin{cases}1 & \text { if } s \in \mathcal{T} \\
0 & \text { otherwise. }\end{cases} \\
\operatorname{RProb}_{\bar{R}}^{\leq n+1}(s, \mathcal{T}) & = \begin{cases}1 & \text { if } s \in \mathcal{T} \\
0 & \text { if } s \notin \mathcal{T} \wedge \operatorname{trans}(s)=\star \\
\sum_{u \in \operatorname{supp}(D)} D(u) \cdot \operatorname{RProb}_{R}^{\leq n}(u, \mathcal{T}) \quad \text { if } s \notin \mathcal{T} \wedge \operatorname{trans}(s)=D\end{cases}
\end{aligned}
$$

We define the probability of reaching $\mathcal{T}$ from $s$ as:

$$
\operatorname{RProb}_{R}(s, \mathcal{T})=\lim _{n \rightarrow+\infty} \operatorname{RProb}_{R}^{\leq n}(s, \mathcal{T})
$$

Note that, as $\operatorname{RProb}_{\bar{R}}^{\leq n}(s, \mathcal{T})$ is an increasing function in $n$ we can replace the limit by the supremum on $n \in \mathbb{N}$.

Notation 6. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}, \operatorname{trans}_{\mathrm{N}}\right)$ be a NPLTS, and $\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $\left._{\mathrm{R}}, \operatorname{trans}_{\mathrm{R}}\right)$ be a resolution for N . Recall that $\widehat{\mathrm{R}}=\left(\mathcal{S}_{\mathrm{R}}, \mathcal{A}\right.$, $\left.\operatorname{trans}_{\mathrm{R}}\right)$ is a RPLTS. From $\widehat{\mathrm{R}}$, we build a RPTS by removing the external actions: we define $\widetilde{\mathrm{R}}=\left(\mathcal{S}_{\mathrm{R}}\right.$, $\left.\operatorname{trans}_{\widetilde{\mathrm{R}}}\right)$ where

$$
\operatorname{trans}_{\widetilde{\mathrm{R}}}(s)= \begin{cases}\star & \text { when } s \in \mathcal{S}_{\text {ext }}(\widehat{\mathrm{R}}) \\ D & \text { when } s \in \mathcal{S}_{\text {int }}(\widehat{\mathrm{R}}) \text { and } \operatorname{trans}_{\mathrm{R}}(s)=\left(a_{i n t}, D\right)\end{cases}
$$

For $\mathcal{T} \subseteq \mathcal{S}_{\mathrm{R}}, s \in \mathcal{S}_{\mathrm{R}}$ and resolution R we write $\operatorname{RProb}_{\mathrm{R}}(s, \mathcal{T})$, respectively $\operatorname{RProb}_{\mathrm{R}}^{\leq n}(s, \mathcal{T})$, for the probability $\operatorname{RProb}_{\tilde{\mathrm{R}}}(s, \mathcal{T})$, respectively $\operatorname{RProb}_{\tilde{\mathrm{R}}}^{\leq n}(s, \mathcal{T})$.

For $\mathcal{T} \subseteq \mathcal{S}_{\mathrm{N}}, s \in \mathcal{S}_{\mathrm{N}}$, and $\mathcal{R} \subseteq \mathcal{R}_{r}(\mathrm{~N})$, we note $\operatorname{RProb}_{\mathcal{R}}(s, \mathcal{T})$, respectively $\operatorname{RProb}_{\mathcal{R}}^{\leq n}(s, \mathcal{T})$, for the probability $\sup \left\{\operatorname{RProb} \operatorname{Pr}_{\mathrm{R}}\left(s^{\prime}, \operatorname{corr}_{\mathrm{R}}^{-1}(\mathcal{T})\right) \mid \mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}, \operatorname{corr}_{\mathrm{R}}, \operatorname{trans}_{\mathrm{R}}\right) \in \mathcal{R}, \operatorname{corr}_{\mathrm{R}}\left(s^{\prime}\right)=s\right\}$, respectively $\sup \left\{\operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(s^{\prime}, \operatorname{corr}_{\mathrm{R}}^{-1}(\mathcal{T})\right) \mid \mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}, \operatorname{corr}_{\mathrm{R}}, \operatorname{trans}_{\mathrm{R}}\right) \in \mathcal{R}, \operatorname{corr}_{\mathrm{R}}\left(s^{\prime}\right)=s\right\}$.

In the following we denote by $\mathcal{R}_{\mathrm{r}}^{o}$ (resp. $\mathcal{R}_{\mathrm{nr}}^{o}$ ) the set of all randomized (resp. nonrandomized) resolutions for $\mathrm{N}^{o}$, i.e., $\mathcal{R}_{\mathrm{r}}^{o}=\mathcal{R}_{\mathrm{r}}\left(\mathrm{N}^{o}\right)$ and $\mathcal{R}_{\mathrm{nr}}^{o}=\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}^{o}\right)$.

### 3.3 Defining May Testing Equivalence

Definition 8 (May testing equivalence). Let $\mathcal{R}$ be a set of resolutions for $\mathrm{N}^{o}$ and $\mathcal{P}, \mathcal{Q} \in$ $\mathcal{M P}$. We say that

$$
\mathcal{P} \leq_{\text {may }}^{\mathcal{R}} \mathcal{Q} \quad \text { iff } \quad \begin{aligned}
& \forall A d v \in \mathcal{M} \mathcal{P} \text { s.t. } f n(A d v) \subseteq \mathcal{N}_{p u b} . \forall c \in \mathcal{N}_{p u b} . \\
& \quad \operatorname{RProb}_{\mathcal{R}}(\mathcal{P} \cup A d v, \downarrow c) \leq \operatorname{RProb}_{\mathcal{R}}(\mathcal{Q} \cup A d v, \downarrow c)
\end{aligned}
$$

We say that $\mathcal{P}, \mathcal{Q}$ are may testing equivalent for $\mathcal{R}$, denoted $\mathcal{P} \approx_{\text {may }}^{\mathcal{R}} \mathcal{Q}$ when both $\mathcal{P} \leq{ }_{\text {may }}^{\mathcal{R}} \mathcal{Q}$ and $\mathcal{Q} \leq_{\text {may }}^{\mathcal{R}} \mathcal{P}$.

We first show that for may-testing, it is sufficient to consider non-randomized resolutions.

Proposition 1. The may testing preorder coincides for randomized and non-randomized resolutions:

$$
\leq_{\text {may }}^{\mathcal{R}_{r}^{o}}=\leq_{\text {maay }}^{\mathcal{R}_{n}^{o}}
$$

The proof of this result is given in Appendix A.
Given that the may testing preorder coincides for randomized and non-randomized resolutions we will simply write $\leq_{\text {may }}$ in what follows.

Remark 3. One alternative definition of probabilistic may testing pre-orders studied in the literature is as follows: $\mathcal{P} \leq^{\prime} \mathcal{Q}$ iff
for all $A d v \in \mathcal{M P}$ s.t. $f n(A d v) \subseteq \mathcal{N}_{p u b}, c \in \mathcal{N}_{p u b}$, resolution R and R -state $s$ s.t. $\operatorname{corr}(s)=\mathcal{P} \mid A d v$,
there exists resolution $\mathrm{R}^{\prime}$ and $\mathrm{R}^{\prime}$-state $s^{\prime}$ such that $\operatorname{corr}^{\prime}\left(s^{\prime}\right)=\mathcal{Q} \mid A d v$ and

$$
\operatorname{RProb}_{\mathrm{R}}\left(s, \operatorname{corr}^{-1}(\downarrow c)\right)=\operatorname{RProb}_{\mathrm{R}^{\prime}}\left(s^{\prime}, \operatorname{corr}^{\prime-1}(\downarrow c)\right)
$$

However, the resulting pre-orders on processes are counter-intuitive: for instance, when we consider the processes $\mathcal{P}:=\operatorname{out}(a, 0)$ and $\mathcal{Q}:=\operatorname{out}(a, 0)+_{1 / 2}\left(\operatorname{out}(a, 0)+_{1 / 2}\right.$ out $\left.(a, 0)\right)$, we can show that $(\mathcal{Q}, \mathcal{P}) \notin \leq^{\prime}$, for both randomized or non-randomized schedulers. Indeed, when we take $A d v=0$, and we see that there exists a resolution R such that $\operatorname{RProb}_{\mathrm{R}}(\mathcal{Q}, \downarrow$ $a)=\frac{1}{2}$, but for every resolution $\mathrm{R}^{\prime}$, it holds that $\operatorname{RProb}_{\mathrm{R}^{\prime}}(\mathcal{P}, \downarrow a)=1$.

## 4 Trace equivalence

As usual in pi calculi, and in the applied $\pi$-calculus in particular we define a labelled semantics. The intent of the labels is to capture adversarial actions and avoid the universal quantification over processes in equivalence definitions.

### 4.1 Labelled semantics

A state in this labeled semantics is defined by associating a multiset of processes with a frame, modeling the knowledge accumulated by the adversary. We also consider a new set of variables $\mathcal{A X}=\left\{\mathrm{ax}_{1}, \mathrm{ax}_{2}, \ldots\right\}$ distinct from $\mathcal{X}$ that will act as pointers to output messages.

Definition 9. An extended process is an ordered pair $(\mathcal{P}, \phi)$, where $\mathcal{P} \in \mathcal{M P}$ and $\phi$ is a ground substitution $\left\{\mathrm{ax}_{1} \mapsto t_{1} ; \ldots ; \mathrm{ax}_{n} \mapsto t_{n}\right\}$ such that $\mathrm{ax}_{i} \in \mathcal{A} \mathcal{X}, t_{i} \in \mathcal{T}(\mathcal{F}, \mathcal{N})$ and $\operatorname{Msg}\left(t_{i}\right)$ for $1 \leq i \leq n$.

We denote by $\mathcal{S} \mathcal{P}_{\ell}$ the set of all extended processes (and use $\mathcal{S P}_{\ell}^{<\infty}, \mathcal{S P}_{\ell}^{\mathrm{np}}$ and $\mathcal{S P}_{\ell}^{<\infty, \mathrm{np}}$ for subclasses as before).

A recipe is a term from $\mathcal{T}\left(\mathcal{F}, \mathcal{N}_{\text {pub }} \cup \mathcal{A X}\right\}$ representing how an attacker can deduce a message.

Notation 7. If $D$ is a distribution over $\mathcal{M} \mathcal{P}$, and $\phi$ a frame, we write $(D, \phi)$ for the distribution over extended processes defined as $(D, \phi)=\sum_{\mathcal{P} \in \operatorname{supp}(D)} D(\mathcal{P}) \cdot \delta_{(\mathcal{P}, \phi)}$.

We now define the NPLTS $\mathrm{N}^{\ell}$ for the labelled semantics. The only internal action is $\{\tau\}$, and we add external actions, that model the interactions with an external environment.

Definition 10. The labelled semantics is the NPLTS $\mathrm{N}^{\ell}=\left(\mathcal{S} \mathcal{P}_{\ell}, \mathcal{A}_{\text {ext }}^{\ell} \sqcup\{\tau\}\right.$, trans $\left.{ }^{\ell}\right)$ where

$$
\text { - } \mathcal{A}_{\text {ext }}^{\ell}=\{\operatorname{in}(\xi, \zeta), \operatorname{out}(\xi, \mathrm{ax}),(\xi \stackrel{?}{=} \zeta),(\xi \stackrel{?}{\neq} \zeta) \mid \xi, \zeta \text { recipes, ax } \in \mathcal{A} \mathcal{X}\}
$$

- $\operatorname{trans}^{\ell}((\mathcal{P}, \phi))(a)=\left\{D \mid(\mathcal{P}, \phi) \rightarrow_{a} D\right\}$ where $\rightarrow_{a}$ is defined by the following rules:

$$
\begin{aligned}
& \text { - }(\mathcal{P}, \phi) \rightarrow_{\tau}(D, \phi) \text { if } \mathcal{P} \rightarrow_{\tau} D \\
& -\left(\{\{\operatorname{in}(u, x) ; P\} \cup \mathcal{P}, \phi) \rightarrow_{i n(\xi, \zeta)} \delta_{(\{P\{\zeta \phi / x\}\} \cup \mathcal{P}, \phi)}\right. \\
& \text { if } u \doteq \xi \phi, \operatorname{Msg}(\zeta \phi) \text { and } \operatorname{vars}(\xi, \zeta) \subseteq \operatorname{dom}(\phi) \\
& -(\{\operatorname{out}(u, t) ; P\} \cup \mathcal{P}, \phi) \rightarrow_{\text {out }\left(\xi, \mathrm{ax}_{n+1}\right)} \delta_{\left(\{P\} \cup \mathcal{P}, \phi\left\{a x_{n+1} \mapsto t\right\}\right)} \\
& \text { if } u \doteq \xi \phi, \operatorname{Msg}(t), \operatorname{vars}(\xi) \subseteq \operatorname{dom}(\phi) \text { and }|\phi|=n \\
& -(\mathcal{P}, \phi) \rightarrow_{(\xi \sim \zeta)} \delta_{(\mathcal{P}, \phi)} \quad \text { if } \operatorname{vars}(\xi, \zeta) \subseteq \operatorname{dom}(\phi) \text { and } \xi \phi \sim \zeta \phi \text { where } \sim \in\{\doteq, \neq\}
\end{aligned}
$$

Note that when we lift $\rightarrow_{\tau}$ to extended processes we suppose that the freshness requirement of a new name $a^{\prime}$ in the (NEW) rule of fig. 2 also applies to the frame $\phi$, i.e., $a^{\prime}$ must not appear in $\phi$. As for the operational semantics, we consider randomized and non-randomized resolutions for $\mathrm{N}^{\ell}$ and denote the corresponding sets of resolutions by $\mathcal{R}_{\mathrm{r}}^{\ell}$, respectively $\mathcal{R}_{\mathrm{nr}}^{\ell}$.

Remark 4. It should be noted that we deal with static equivalence in a different way as done usually in the applied pi-calculus, or implicitly in the probabilistic applied pi-calculus in GLPT07]: indeed, static equivalence is encoded into the NPLTS $\mathrm{N}^{\ell}$ by a countable set of actions-all the tests $(\xi \stackrel{?}{=} \zeta)$ and their negations- instead of just one action testing static
equivalence. The motivation behind this choice is to be able to represent every action from the NPLTS by an elementary push-button action of the adversary. As shown later, this choice has no effect whatsoever on the definition of the simulation pre-orders (or on bisimulation)-see Remark 8 for more details, but it leads to a different notion of trace equivalence, that is closer to may testing equivalence-see Remark 5 .

### 4.2 Trace Preorder

We first define the probability of executing a trace in a resolution. As we are interested in a weak trace preorder, traces are sequences of external actions only. In our definition we will use the previously introduced notation $\operatorname{RProb}_{\mathrm{R}}(s,\{t\})$ : recall that this denotes the probability of reaching state $t$ from state $s$ under resolution R using only internal actions.

Definition 11. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {int }} \sqcup \mathcal{A}_{\text {ext }}\right.$, trans $\left._{\mathrm{N}}\right)$ be a NPLTS. Let $\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $_{\mathrm{R}}$, trans $\left._{\mathrm{R}}\right)$ be a resolution for $\mathrm{N}^{\ell}$. Let $w \in \mathcal{A}_{\text {ext }}{ }^{*}$ be a trace, i.e., a finite word on the alphabet $\mathcal{A}_{\text {ext }}$. For all states $s \in \mathcal{S}_{\mathrm{R}}$, we define the probability of executing $w$ starting from $s$ in R as:

$$
\begin{aligned}
& \operatorname{Prob}_{\mathrm{R}}(s, \epsilon)=1 \\
& \operatorname{Prob}_{\mathrm{R}}(s, a . w)=\sum_{\substack{t \in \mathcal{S}_{\mathrm{R}} \\
\text { s.t. } \exists D \in \mathcal{D}\left(\mathcal{S}_{\mathrm{R}}\right), \text { trans }(t)(a)=D}} \operatorname{RProb}_{\mathrm{R}}(s,\{t\}) \cdot \sum_{s^{\prime} \in \operatorname{supp}(D)} D\left(s^{\prime}\right) \cdot \operatorname{Prob}_{\mathrm{R}}\left(s^{\prime}, w\right)
\end{aligned}
$$

Given a set of resolutions $\mathcal{R} \subseteq \mathcal{R}_{r}(\mathbb{N})$, a state $u \in \mathcal{S}_{\mathrm{N}}$, we denote by $\operatorname{Prob}_{\mathcal{R}}(s, w)$ the maximal probability of executing $w$ from $s$ in $\mathcal{R}$ :

$$
\operatorname{Prob}_{\mathcal{R}}(u, w)=\sup _{\substack{\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}, \operatorname{corr} \\ s \in \mathcal{S}_{\mathrm{R}} \text { s.t.transR }\right) \in \mathcal{R}}} \operatorname{Prorr}_{\mathrm{R}(s)=u}(s, w)
$$

In this work, we are interested mostly by the may paradigm for non-determinism. Observe that nonetheless, we could define must-trace equivalence where we would compute the infimum of probabilities rather than supremum of probabilities in Definition 11 .

Definition 12. Let $\mathcal{R} \subseteq \mathcal{R}_{\mathrm{r}}^{\ell}$ be a set of resolutions for $\mathrm{N}^{\ell}$ and $(\mathcal{P}, \phi),\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \in \mathcal{S} \mathcal{P}_{\ell}$.

$$
(\mathcal{P}, \phi) \leq_{t r}^{\mathcal{R}}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \quad \text { iff } \quad \forall w \in \mathcal{A}_{e x t}^{\ell}{ }^{*} . \operatorname{Prob}_{\mathcal{R}}((\mathcal{P}, \phi), w) \leq \operatorname{Prob}_{\mathcal{R}}\left(\left(\mathcal{P}^{\prime}, \phi^{\prime}\right), w\right)
$$

$(\mathcal{P}, \phi)$ and $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ are trace equivalent for $\mathcal{R}$ if $(\mathcal{P}, \phi) \leq_{t r}^{\mathcal{R}}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ and $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \leq_{t r}^{\mathcal{R}}(\mathcal{P}, \phi)$.

### 4.3 On randomized or non-randomized resolutions

Observe that Definition 12 depends on the class of admissible resolutions under consideration, i.e., whether we restrict ourselves to non-randomized resolutions, or we consider all randomized resolutions. In the following, we show-as we formally state in proposition 2 that these two notions of trace equivalence actually coincide. This result is not surprising: indeed it has for instance been shown in Cas18] (in the restricted setting of strong
trace equivalence and NPLTS with an image-finiteness condition) that trace preordercalled there supremal probability trace pre-order-does not depend on whether we consider all randomized resolutions, or only non-randomized ones. Here, we show the same result for the notion of weak trace pre-order we gave in Definition 12 .

Proposition 2. Let $(\mathcal{P}, \phi)$ and $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ be two extended processes.

$$
(\mathcal{P}, \phi) \leq_{t r}^{\mathcal{R}_{r}^{\ell}}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \quad \text { iff } \quad(\mathcal{P}, \phi) \leq_{t r}^{\mathcal{R}_{n r}^{\ell}}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)
$$

The proof of this result is given in Appendix B.1. In the rest of this paper, as $\leq_{t r}^{\mathcal{R}_{r}^{\ell}}=$ $\leq_{t r}^{\mathcal{R}_{r}^{\ell}}$, we simply denote trace inclusion by $\leq_{t r}$.

Trace preorders is (strictly) weaker than the may testing preorder: it is the sense of Proposition 3 below.

Proposition 3. Let $\mathcal{P}, \mathcal{Q} \in \mathcal{M} \mathcal{P}$ be two processes.

$$
\mathcal{P} \leq_{\text {may }} \mathcal{Q} \quad \Rightarrow \quad(\mathcal{P}, \varnothing) \leq_{t r}(\mathcal{Q}, \varnothing)
$$

Moreover, there exist processes $\mathcal{P}, \mathcal{Q} \in \mathcal{M P}$ such that

$$
(\mathcal{P}, \varnothing) \leq_{t r}(\mathcal{Q}, \varnothing) \text { and } \mathcal{P} \not \leq_{\text {may }} \mathcal{Q}
$$

Proof sketch. We show both points separately.

- Our goal is to show that every trace $w$ can be emulated by an adversary $A d v$. Observe that any trace $w$ can be seen as a (linear) formula in $\mathcal{F}$, where $\mathcal{F}$ is the Henessy-Milner logic from Definition 25. It means that for every ok $\in \mathcal{N}_{p u b}$ such that ok $\notin f n(w)$ and $n \in \mathbb{N}$, we can consider the adversary $A d v_{w, n}^{o k}$ from Definition 27. Recall that we cannot apply directly Lemma 12, because here there can be probabilistic choices inside $\mathcal{P}$. Nonetheless, as long as the formulas considered are traces, we are going to show a generalization of Lemma 12 to probabilistic processes. More precisely, we are going to show: for all trace $w$, for all $\mathcal{P} \in \mathcal{M} \mathcal{P}, \phi \in \mathcal{F}$ with ok $\notin f n(\mathcal{P}, \phi, w)$ :

$$
\begin{equation*}
\operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{\ell}\right)}((\mathcal{P}, \phi), w)=\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}\left(\mathcal{P} \cup\left\{\left\{A d v_{w,|\phi|}^{o k} \phi\right\}, \downarrow o k\right) .\right. \tag{1}
\end{equation*}
$$

We write $\mathcal{I}$ for the set

$$
\mathcal{I}:=\left\{\left(\mathcal{P} \cup\left\{\left\{A d v_{w,|\phi|}^{o k} \phi\right)\right\} \mid(\mathcal{P}, \phi) \in \mathcal{S} \mathcal{P}_{\ell}, w \in \mathcal{A}_{e x t}^{\star}, o k \notin f n(\mathcal{P}, \phi, w)\right\}\right.
$$

Observe that we can write the restriction of $\mathrm{N}^{o}$ to $\mathcal{I}$ using the NPLTS $\mathrm{N}^{\ell^{t r}}$ defined in Definition 33, in the sense where: $\forall s=\mathcal{P} \cup\left\{\left\{A d v_{w,|\phi|}^{o k} \phi\right\}\right\} \in \mathcal{I}: s \xrightarrow{\tau}^{\mathrm{N}} o \mathrm{D}$, if and only if there exists $E$ such that $((\mathcal{P}, \phi), w) \rightarrow_{\mathcal{N}^{e^{t r}}} E$, and $D=\bar{f}(E)$ where $f:\left(\left(\mathcal{P}^{\prime}, \phi^{\prime}\right), w^{\prime}\right) \in$ $\mathcal{S}_{\mathrm{N}^{\operatorname{tr} r}} \mapsto \mathcal{P}^{\prime} \cup\left\{\left\{A d v_{w^{\prime},\left|\phi^{\prime}\right|}^{o o} \phi^{\prime}\right\}\right) \in \mathcal{I}$-see Notation 5 for the meaning of $\bar{f}$. Moreover, a

$$
\begin{aligned}
\mathcal{P} & =\left\{\text { new } k ;\left(P(0)|P(0)| P(1) \mid P_{\text {dec }}\right)\right\} \\
\mathcal{Q} & =\left\{\text { new } k ;\left(P(0)|P(1)| P(1) \mid P_{\text {dec }}\right)\right\}
\end{aligned} \quad \text { and } \quad P(x)=\text { new } r ; \operatorname{out}(c, \operatorname{enc}(x, r, k))
$$

Figure 7: Processes $\mathcal{P}, \mathcal{Q}$ such that $(\mathcal{P}, \varnothing) \leq_{\text {tr }}(\mathcal{Q}, \varnothing)$ and $\mathcal{P} \not \leq_{\text {may }} \mathcal{Q}$
state $\mathcal{P} \cup\left\{\left\{A d v_{w,|\phi|}^{o k} \phi\right\} \in \mathcal{I}\right.$ is in $\downarrow o k$ if and only if $w=\epsilon$. From this observation, we can deduce:

$$
\begin{aligned}
& \operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{\circ}\right)}\left(\mathcal{P} \cup\left\{\left\{A d v_{w,|\phi|}^{o k} \phi\right\}, \downarrow o k\right)\right. \\
& \left.=\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathbb{N}^{\left.\mathrm{e}^{t r}\right)}\right.}((\mathcal{P}, \phi), w),\left\{(s, \epsilon) \mid s \in \mathcal{S} \mathcal{P}_{\ell}\right\}\right) \\
& \left.=\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{\ell t r}\right)}((\mathcal{P}, \phi), w),\{\text { success }\}\right) \text { since } \forall s \in \mathcal{S} \mathcal{P}_{\ell},(s, \epsilon) \xrightarrow{\tau}_{\mathrm{N}^{t^{t r}}} \delta_{\text {success }} .
\end{aligned}
$$

Since we know from Lemma 22 that

$$
\left.\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathbb{N}^{e^{t r}}\right)}((\mathcal{P}, \phi), w),\{\text { success }\}\right)=\operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathbb{N}^{\ell}\right)}((\mathcal{P}, \phi), w)
$$

we conclude that (1) holds. From there, we obtain the result directly by looking at the definition of the may-testing preorder and the trace preorder.

- The fact that may testing is strictly stronger is for instance witnessed by processes $\mathcal{P}, \mathcal{Q}$ in Figure 7.

Remark 5. Observe that-contrary to usual results in the literature, see for instance [CCD13]Proposition 3 holds even for processes non image-finite. This discrepancy comes from our choice of labelled actions for static equivalence (see Remark 44): a trace cannot test directly static equivalence, but can only do a finite numbers of recipe tests.

## 5 Simulation and observational preorders

In this section, we define the simulation and observational preorders on probabilistic picalculus processes and corresponding equivalences. Our definition of simulation preorder is taken from the definition of randomized weak simulation preorder introduced by Segala and Lynch for probabilistic automata [SL95]. Both simulation and observational preorders relie on a weak relation for internal actions which we define as follows, one for randomized and one for non-randomized resolutions.
Definition 13. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}, \operatorname{trans}_{\mathrm{N}}\right)$ be a NPLTS, and $D, E \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$.

- We write $D \xlongequal{\tau} \mathcal{R}_{\mathrm{r}}(\mathrm{N}), E$ when there exists $R=\left(\mathcal{S}_{R}, \operatorname{corr}_{R}, \operatorname{trans}_{R}\right) \in \mathcal{R}_{\mathrm{r}}(\mathrm{N})$, and $D^{\prime}, E^{\prime} \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{R}\right)$ such that $\operatorname{corr}_{R}\left(D^{\prime}\right)=D, \operatorname{corr}_{R}\left(E^{\prime}\right)=E, \operatorname{supp}\left(E^{\prime}\right) \subseteq \mathcal{S}_{\text {ext }}(R)$ and for all $u \in \mathcal{S}_{\text {ext }}(R), E^{\prime}(u)=\sum_{s^{\prime} \in \mathcal{S}_{R}} D^{\prime}\left(s^{\prime}\right) \cdot \operatorname{RProb}_{R}\left(s^{\prime},\{u\}\right)$.
- We write $D \stackrel{\tau}{\Longrightarrow} \mathcal{R}_{\mathrm{nr}}(\mathrm{N}) E$ when there exists $R=\left(\mathcal{S}_{R}, \operatorname{corr}_{R}, \operatorname{trans}_{R}\right) \in \mathcal{R}_{\mathrm{nr}}(\mathrm{N})$, and $D^{\prime}, E^{\prime} \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{R}\right)$ such that $\operatorname{corr}_{R}$ is injective on the support of $D^{\prime}, \operatorname{corr}_{R}\left(D^{\prime}\right)=D$, $\operatorname{corr}\left(E^{\prime}\right)=E, \operatorname{supp}\left(E^{\prime}\right) \subseteq \mathcal{S}_{\text {ext }}(R)$ and for all $u \in \mathcal{S}_{\text {ext }}(R), E^{\prime}(u)=\sum_{s^{\prime} \in \mathcal{S}_{R}} D^{\prime}\left(s^{\prime}\right) \cdot$ $\operatorname{RProb}_{R}\left(s^{\prime},\{u\}\right)$.

Moreover, for all $s \in \mathcal{S}_{\mathrm{N}}, D \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$, and $\mathcal{R} \in\left\{\mathcal{R}_{\mathrm{r}}(\mathrm{N}), \mathcal{R}_{\mathrm{nr}}(\mathrm{N})\right\}$, we write $s \xlongequal{\tau} D$ when $\delta_{s} \xrightarrow{\tau} \mathcal{R} D$.

Observe that in the NPLTS $\mathrm{N}^{\ell}$, even though $s \xrightarrow{\tau} D$ implies that $D$ has finite support, it is possible to have $s \stackrel{\tau}{\Longrightarrow} \mathcal{R} E$, where the sub-distribution $E$ has infinite support.

As we will see below, the non-randomized weak relation ${ }^{\tau} \mathcal{R}_{\text {nr }}(\mathrm{N})$ does not allow to define a robust simulation preorder. However, before defining the simulation preorder, we give a more direct caracterisation of the weak relation $\xlongequal{\tau} \mathcal{R}_{r}(\mathrm{~N})$, without using the notion of resolutions. This caracterisation is more widely used in the literature on probabilistic bisimulation-see e.g. [DVGHM09]-and eases proofs. First, we lift a relation $\rightarrow \subseteq \mathcal{S} \times \mathcal{D}(\mathcal{S})$ to a relation in $\mathcal{D}(\mathcal{S}) \times \mathcal{D}(\mathcal{S})$.

Definition 14. Let $\mathcal{S}$ be a discrete set and $\rightarrow \subseteq \mathcal{S} \times \mathcal{D}(\mathcal{S})$ be a probabilistic reduction relation. We define its lifting $\rightarrow_{r} \subseteq \mathcal{D}^{\leq 1}(\mathcal{S}) \times \mathcal{D}^{\leq 1}(\mathcal{S})$ as

$$
D \rightarrow_{\mathrm{r}} \sum_{i \in I} \alpha_{i} \cdot E_{i}
$$

when $I$ is any countable set, $D=\sum_{i \in I} \alpha_{i} \cdot \delta_{x_{i}}$, and $x_{i} \rightarrow E_{i}$ for all $i \in I$ (observe that it can be that $x_{i}=x_{j}$ even when $i \neq j$ ).

Observe that we can apply Definition 14 above to any NPLTS by considering its probabilistic reduction relation $\xrightarrow{\tau}$. We will do this implicitely in the following.

We are now ready to give an alternative characterisation for the weak reduction relation $\Longrightarrow \mathcal{R}_{r}$, more in line with the tradition in the field of probabilistic simulation. There are a number of equivalent definitions in the literature: we chose here the one given in DVGHM09.

Definition 15. Let $\rightarrow$ be a binary relation in $\mathcal{S} \times \mathcal{D}(\mathcal{S})$ for a discrete set $\mathcal{S}$. We define the relation $\Longrightarrow_{\mathrm{r}} \subseteq \mathcal{D}^{\leq 1}(\mathcal{S}) \times \mathcal{D}^{\leq 1}(\mathcal{S})$ as

$$
D \Longrightarrow_{\mathrm{r}} D^{\prime} \text { if there is an infinite scheme: } \quad \vdots
$$

$$
\begin{array}{ccc}
D & = & D_{0}+D_{0}^{\top} \\
D_{0}^{\rightarrow} \rightarrow_{\mathrm{r}} & D_{1}^{\rightarrow}+D_{1}^{\top} \\
& & \vdots \\
D_{k}^{\rightarrow} & \rightarrow_{\mathrm{r}} & D_{k+1}+D_{k+1}^{\top}
\end{array}
$$

where $D_{k}, D_{k}^{\top}$ are sub-distributions over $\mathcal{S}$ and $D^{\prime}=\sum_{k \in \mathbb{N}} D_{k}^{\top}$.
When starting from the transition relation $\xrightarrow{\tau}$ for a NPLTS $N$, we denote the resulting relations by $\xlongequal{\tau}{\underset{r}{r}, \mathrm{~N}}$. When N is clear from the context, we may directly write $\Longrightarrow_{\mathrm{r}}$.

Remark 6. Whenever we have a finite scheme in a similar shape as the infinite scheme asked for in Definition 15, observe that we can always complete it into an infinite scheme, using the fact that $\varnothing \rightarrow \varnothing+\varnothing$-where $\varnothing$ stands for the sub-distribution with empty support, i.e. $\varnothing(x)=0$ for every $x \in \mathcal{S}$. In particular, if we start from a state $(\mathcal{P}, \phi)$ in $\mathrm{N}^{\ell}$ where $\mathcal{P}$ is a process without replication, then every infinite scheme $\delta_{(\mathcal{P}, \phi)}{ }_{\tau}^{\tau} D$ is actually a finite scheme. A simple corollary to this remark is that $\xlongequal{\tau}_{\mathrm{r}}$ is reflexive (by taking $D_{0}^{\top}=D$ and all other distributions being $\varnothing$ ).

We now show in the following statement that the two characterizations, i.e. $\Longrightarrow_{r, N}$ and $\Longrightarrow \mathcal{R}_{r}$, are equal (proof in Appendix C).

Lemma 1. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}}\right)$ be a NPLTS and $D, E \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$.

$$
D \xlongequal{\tau}_{\mathrm{r}} E \text { if and only if } D \Longrightarrow_{\mathcal{R}_{\mathrm{r}}} E
$$

Remark 7. The weak reduction relation $\xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}^{\ell}}$ (and so equivalently ${ }^{\tau}{\mathcal{\mathcal { R } _ { \mathrm { r } }} \mathbf{( \mathrm { N } ^ { \ell } )} \text { ) allows to }}^{\text {( }}$ lose some probabilities in the presence of a replication in our extended processes. Consider the extended process $A=(\{!P\} \cup \mathcal{P}, \phi)$. We have that $\delta_{A} \Longrightarrow_{\mathrm{r}} D$ where $\operatorname{supp}(D)=\{A\}$, $D(A)=p$ and $p$ can be any value smaller than 1 . To show this, we can build the following infinite scheme:

$$
\delta_{A}=D_{0}+D \quad \text { and for all } k \in \mathbb{N}, D_{k} \xrightarrow{\tau} D_{k+1}+\varnothing
$$

with for all $k \in \mathbb{N}, \operatorname{supp}\left(D_{k}\right)=\left\{A_{k}\right\}, A_{k}=(\{!P ; \underbrace{P ; \ldots ; P}_{k \text { times }}\} \cup \mathcal{P}, \phi)$ and $D_{k}\left(A_{k}\right)=1-p$.
On the other hand, as noted in Remark 6, when processes do not contain replication, $\delta_{(\mathcal{P}, \phi)} \xlongequal{\tau} D$ actually corresponds to a finite scheme. Thus, we cannot lose probabilities, i.e. $D$ is a distribution.

### 5.1 Simulation preorder

We are now going to define the notions of probabilistic simulation preorder, similarity and bisimilarity. However, in these definitions, we will only consider the relation ${ }^{\tau}{ }_{\mathrm{r}}$ (or equivalently $\Longrightarrow_{\mathcal{R}_{r}}$ ) and not $\xlongequal{\tau} \mathcal{R}_{n r}$. First, as highlighted for instance in [Eis17, Den05], when considering bisimilarity or similarity on NPLTSs in general, we are forced to consider randomized resolutions, otherwise the resulting relations are not transitive. Note that in GLPT07], they do rely on non-randomized schedulers in their definition of bisimulation. It does not necessarily mean that their relation is not transitive as they focus directly on the semantics of processes. However, we will show in Section 5.3 that bisimulation and observational equivalence do not coincide when using the non-randomized relation $\xlongequal{\tau} \mathcal{R}_{n r}$, hence disproving [GLPT07, Theorem 2]. This reenforces our belief that it is preferable to use randomized schedulers in our definition.

To define the simulation preorder, we need to introduce the lifting of a relation to sub-distributions as follows.

Definition 16 (Lifting of a relation). Let $R$ be a binary relation on a discrete set $\mathcal{S}$. We define the lifting of $R$ to sub-distributions as the binary relation on $\mathcal{D}^{\leq 1}(\mathcal{S})$, denoted $\widehat{R}$, defined as:

$$
D \widehat{R} E \text { when } \forall \mathcal{S}^{\prime} \subseteq \mathcal{S}, D\left(\mathcal{S}^{\prime}\right) \leq E\left(R\left(\mathcal{S}^{\prime}\right)\right)
$$

where $R\left(\mathcal{S}^{\prime}\right)=\left\{s \in \mathcal{S} \mid s^{\prime} \in \mathcal{S}^{\prime} \wedge s^{\prime} R s\right\}$.
We note that this lifting has the following properties:

- if $R$ is reflexive, then $\widehat{R}$ is reflexive as well;
- if $R$ is symmetric then for any $D_{1}, D_{2} \in \mathcal{D}(\mathcal{S})$, i.e., $D_{1}, D_{2}$ are distributions rather than sub-distributions, if $D_{1} \widehat{R} D_{2}$ then $D_{2} \widehat{R} D_{1}$.

The second property is actually not obvious on the current definition. It is however a direct consequence of an alternative, coupling-based characterization of lifting, that can be found under the name of Strassen's theorem for instance in [ABB+18] (it is stated there for proper distributions, instead of sub-distributions, but the generalisation to subdistributions can be easily done by lifting all sub-distributions $D$ over $X$ to proper distributions $D_{\perp}$ over $X \cup\{\perp\}$ where $\perp$ is an arbitrary new element added to represent divergence).

Notation 8. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}}\right)$ be a NPLTS. Let $a \in \mathcal{A}_{\text {ext }}$ and $D, D^{\prime} \in$ $\mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$. We write $D \xrightarrow{a}{ }_{\mathrm{r}} D^{\prime}$ when $D \xlongequal{\tau}{ }_{\mathrm{r}} E_{1}, E_{1} \xrightarrow{a} E_{2}$ and $E_{2}{ }^{\tau}{ }_{\mathrm{r}} D^{\prime}$ for some $E_{1}, E_{2}$.

Similarly, for $a_{1}, \ldots, a_{n} \in \mathcal{A}_{\text {ext }}$ then we write $D \xlongequal{a_{1} \ldots a_{m}}{ }^{r} D^{\prime}$ when $D \xrightarrow{a_{1}} E_{1} \xlongequal{a_{2}}{ }_{\mathrm{r}}$ $\ldots{\stackrel{a_{n-1}}{\Longrightarrow}}_{r} E_{n-1} \xlongequal{a_{n}} D^{\prime}$.

Definition 17. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}}\right)$ be a NPLTS. A relation $R \subseteq\left(\mathcal{S}_{\mathrm{N}} \times \mathcal{S}_{\mathrm{N}}\right)$ is

- a simulation if $s_{1} R s_{2}$ implies that for all $a \in \mathcal{A}_{e x t} \cup\{\tau\}, D_{1} \in \mathcal{D}\left(\mathcal{S}_{\mathrm{N}}\right)$

$$
\text { if } s_{1} \xrightarrow{a} D_{1} \text { then } s_{2} \xrightarrow{a} D_{2}, D_{2} \in \mathcal{D}\left(\mathcal{S}_{\mathrm{N}}\right) \text { and } D_{1} \widehat{R} D_{2}
$$

- a bisimulation if $R$ is a simulation and $R$ is symmetric.

The simulation preorder, denoted $\leq_{\text {sim }}^{\mathrm{N}}$, is the largest simulation and bisimilarity, denoted $\approx_{b i}^{N}$, is the largest bisimulation. We define similarity, denoted $\approx_{s i m}^{N}$, as $\leq_{s i m}^{N} \cap \leq_{s i m}^{N}{ }^{-1}$.

As usual in the field of (bi)simulation, it can be shown that $\leq_{s i m}^{\mathrm{N}}$, respectively $\approx_{b i}^{\mathrm{N}}$, exists [Eis17] and that it is a pre-order, i.e. a reflexive and transitive relation, respectively an equivalence, i.e., a reflexive, symmetric and transitive relation [Sto02].

The following proposition from [Sto02] states that, as usual in the non-probabilistic case, the weak arrow $\stackrel{a}{\Rightarrow}$ can replace the single arrow $\stackrel{a}{\rightarrow}$ in the definition of weak simulation. It is important to observe that this is not the case when we choose non-randomized schedulers (see Section 5.3).

Proposition 4. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}}\right)$ be a NPLTS, and $R$ be the largest binary relation on $\mathcal{S}_{\mathrm{N}}$ such that $s_{1} R s_{2}$ implies that for every $a \in \mathcal{A}_{\text {ext }} \cup\{\tau\}$, if $s_{1} \xlongequal{a} \Longrightarrow_{\mathrm{r}} D_{1}$ then $s_{2} \xrightarrow{a} D_{2}$ and $D_{1} \widehat{R} D_{2}$. We have $R=\leq_{\text {sim }}^{N}$.

Remark 8. Please observe that our choice of labelled actions for static equivalence (see Remark (4) has no impact on the resulting simulation and bisimulation. Indeed, if two $\mathrm{N}^{\ell}$ states $(\mathcal{P}, \phi)$ and $(\mathcal{Q}, \psi)$ are in the simulation pre-order or bisimulation, then $\phi$ is statically equivalent to $\psi$. Indeed, for all $a \in\{\xi \stackrel{?}{=} \zeta, \xi \stackrel{?}{\neq} \zeta, \mathrm{ax} \in, \mathrm{ax} \notin\}, \delta_{(\mathcal{P}, \phi)} \xrightarrow{a} \delta_{(\mathcal{P}, \phi)}$ implies that $\delta_{(\mathcal{Q}, \psi)} \stackrel{a}{\Longrightarrow} D$ and $\delta_{(\mathcal{P}, \phi)} \widehat{\leq_{\text {sim }}^{\ell}} D$. Since neither the $a$ transition or $\tau$ transition modifies the frame, the former indicates that $\delta_{(\mathcal{Q}, \psi)} \stackrel{\tau}{\Longrightarrow} E_{1}, E_{1} \xrightarrow{a} E_{2}$ and $E_{2}{ }^{\tau}{ }_{\mathrm{r}} D$, with for all $\left(\mathcal{Q}^{\prime}, \psi^{\prime}\right) \in \operatorname{supp}\left(E_{1}\right), \psi=\psi^{\prime}$. The former ensures that $\operatorname{supp}\left(E_{1}\right) \neq \varnothing$. Therefore, for all ax, $\xi, \zeta$, if $\xi \stackrel{?}{=} \zeta, \xi \stackrel{?}{\neq} \zeta$, ax $\in$ or ax $\notin$ holds on $\phi$ then it also holds on $\psi$ respectively. It implies that $\phi$ and $\psi$ are statically equivalent.

### 5.2 Observational preorder

Definition 18. The observational preorder $\leq_{o b s}^{\mathcal{R}}$ is the largest relation $R$ on $\mathcal{M P}$ such that $\mathcal{P} R \mathcal{Q}$ implies :

- for all $c \in \mathcal{N}_{p u b}, \operatorname{RProb}_{\mathcal{R}}(\mathcal{P}, \downarrow c) \leq \operatorname{RProb}_{\mathcal{R}}(\mathcal{Q}, \downarrow c)$;
- if $\mathcal{P} \xlongequal{\tau} D$ then $\mathcal{Q} \xlongequal{\tau}_{\mathrm{r}} E$ and $D \widehat{R} E$;
- for all closed $A d v \in \mathcal{M P}$ such that $f n(A d v) \subseteq \mathcal{N}_{p u b},\{A d v\} \cup \mathcal{P} R\{A d v\} \cup \mathcal{Q}$.

The observational equivalence $\approx_{o b s}^{\mathcal{R}}$ is defined by additionally requesting $R$ to be symmetric and in the second bullet point, by requesting both $D \widehat{R} E$ and $E \widehat{R} D$ to hold.

Remark 9. Note that we slightly diverge from the original definition of observational equivalence ABF17] where an evaluation context $C[]$ is of the form

$$
\text { new } n_{1} ; \ldots ; \text { new } n_{k} ;(-\mid A)
$$

In our definition we simply consider a parallel process, and no additional name restriction. However, we prove in Appendix $D$ that these two definitions coincide. Intuitively, restricting names whose scope includes the adversarial process $A$ corresponds to making previously public channels invisible to the attacker at later steps, hence it does not provide additional distinguishing power.

In the following, we show the asymetric counterpart to the result stated in GLPT07] on the coincidence between bisimulation and observational equivalence. The proof can be found in Appendix F.

Proposition 5. Let $\mathcal{P}, \mathcal{Q}$ two processes in $\mathcal{M} \mathcal{P}$.

$$
\mathcal{P} \leq_{o b s}^{\mathcal{R}_{r}} \mathcal{Q} \quad \text { iff } \quad(\mathcal{P}, \varnothing) \leq_{\text {sim }}^{\mathrm{N}^{\ell}}(\mathcal{Q}, \varnothing) \quad \text { and } \quad \mathcal{P} \approx_{o b s}^{\mathcal{R}_{r}} \mathcal{Q} \quad \text { iff } \quad(\mathcal{P}, \varnothing) \approx_{b i}^{\mathcal{N}^{\ell}}(\mathcal{Q}, \varnothing)
$$

### 5.3 Bisimilarity and observational equivalence do not coincide with non-randomized schedulers

Here, we give more details on the different behaviours of (bi)simulation and observational preorder and equivalence, depending on whether we consider randomized or nonrandomized schedulers. In [GLPT07] for instance, non-randomized schedulers are considered in the definition of bisimulation and observational equivalence on the probabilistic applied $\pi$-calculus.

As said earlier, for general NPLTSs, simulation is not transitive when considering non randomized schedulers Eis17]. We show here that even on our specific NPLTS $\mathrm{N}^{\ell}$, simulation is not transitive (Lemma 2. Furthermore, for non-randomized schedulers, bisimulation (resp. simulation) and observational equivalence (resp. preorder) do not coincide (Lemma 3). However, they do coincide for randomized schedulers (Proposition 55). This discrepancy would also arise when comparing observational preorder with a similar definition where we would only require that $\mathcal{P} \xrightarrow{\tau} D$ (rather $\mathcal{P} \xlongequal{\tau} \mathrm{r} D$ implies $\mathcal{Q}{ }_{\mathrm{\tau}}^{\boldsymbol{\tau}} \mathrm{r} E$ and $D \widehat{R} E$. This one-step observational preorder is equivalent to observational preorder for randomized scheduler but not for non-randomized scheduler.

We are going to compare processes with respect to the bisimilarity $\approx_{b i}^{N^{\ell}}$ as well as the observational equivalence with non-randomized schedulers. The definition of these variants with non-randomized resolutions follows Definition 18 but we use $\xlongequal{\tau} \mathcal{R}_{\text {nr }}\left(\mathrm{N}^{\circ}\right)$ instead of $\xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}^{\mathrm{N}}}$. We denote this non randomized bisimularity as $\approx_{b i}^{\mathrm{nr}}$ (and similar for $\leq_{s i m}^{\mathrm{nr}}$, $\approx_{o b s}^{\mathrm{nr}}$ and $\leq_{o b s}^{\mathrm{nr}}$ ).

Lemma 2. $\leq_{s i m}^{\mathrm{nr}}$ is not transitive.
Proof. Consider processes $P, Q$ and $R$ defined in Figure 8. The corresponding fragment of $\mathrm{N}^{\ell}$ is displayed in Figure 8a. We will show that

$$
\left(\{\{P\}, \varnothing) \leq_{\operatorname{sim}}^{\mathrm{nr}}\left(\{ \{ R \} , \varnothing ) \text { and } \left(\{\{R\}, \varnothing) \leq_{\operatorname{sim}}^{\mathrm{nr}}\left(\{ \{ Q \} , \varnothing ) \text { but } \left(\{\{P\}, \varnothing) \mathbb{Z}_{\operatorname{sim}}^{\mathrm{nr}}(\{\{R\}, \varnothing)\right.\right.\right.\right.\right.
$$

We first show that $\left(\{\{P\}, \varnothing) \leq_{\text {sim }}^{\mathrm{nr}}(\{\{R\}, \varnothing)\right.$. Notice that any $\alpha$ transition can easily be matched, i.e. $(\{\{P\}\}, \varnothing) \xrightarrow{\alpha}(\{\{P\}\}, \varnothing)$ and $(\{\{R\}, \varnothing) \xrightarrow{\alpha}(\{\{R\}, \varnothing)$. Furthermore, we have $\left(\{\{P\}, \varnothing) \xrightarrow{\tau} 0.5 \cdot \delta_{(\{\text {out }(a, c)\}, \varnothing)}+0.5 \cdot \delta_{(\{\text {out }(b, c)\}, \varnothing)}\right.$ which can be matched in $(\{\{R\}, \varnothing)$ by using the scheduler displayed in Figure 8 b, i.e. $\left(\{\{R\}, \varnothing) \xrightarrow{\tau} \mathcal{R}_{\mathrm{nr}} 0.5 \cdot \delta_{(\{\text {out }(a, c)\}, \varnothing)}+0.5 \cdot\right.$ $\delta_{(\{\text {out }(b, c)\}, \varnothing)}$. This concludes the proof of $(\{\{P\}\}, \varnothing) \leq_{\operatorname{sim}}^{\mathrm{nr}}(\{\{R\}, \varnothing)$.

It is easy to see that $(\{Q Q\}, \varnothing) \approx_{b i}^{\mathrm{nr}}\left(\left\{\left\{Q^{\prime}\right\}, \varnothing\right)\right.$ and so $\left(\{\{R\}, \varnothing) \leq_{\text {sim }}^{\mathrm{nr}}(\{\{Q\}, \varnothing)\right.$.
Finally, we need to prove that the transition $(\{\{P\}\}, \varnothing) \xrightarrow{\tau} 0.5 \cdot \delta_{(\{\text {out }(a, c)\}, \varnothing)}+0.5 \cdot$ $\delta_{(\{\text {out }(b, c)\}, \varnothing)}$ cannot be simulated in $(\{Q Q\}, \varnothing)$. First one can see for all $d \in\{a, b\}$, for all $\mathcal{P} \in\left\{\{Q\}, \mathcal{P}_{a b}(0.9), \mathcal{P}_{a b}(0.1)\right\},(\operatorname{out}(d, c), \varnothing) \leq_{s i m}^{\mathrm{nr}}(\mathcal{P}, \varnothing)$. Indeed, (out $\left.(d, c), \varnothing\right) \xrightarrow{\text { out }\left(d \mathrm{ax}_{1}\right)}$ $\delta_{(\{0\}, \phi)}$ with $\phi=\left\{\mathrm{ax}_{1} \mapsto c\right\}$ but we can have at best $(\mathcal{P}, \varnothing) \xrightarrow{\text { out }\left(d, \mathrm{ax}_{1}\right)} \mathcal{R}_{\mathrm{nr}} 0.9 \cdot \delta_{(\{0\}, \phi)}$. Thus, the only relevant extended process from $\leq_{\text {sim }}^{\mathrm{nr}}\left(\left(\left\{\operatorname{oout}^{( }(d, c)\right\}, \varnothing\right)\right)$ reachable from $(\{Q Q\}, \varnothing)$ is $\left(\{\{\operatorname{out}(d, c)\}, \varnothing)\right.$ itself. However, we can only have $\left(\{\{Q\}, \varnothing) \xrightarrow{\text { out }\left(d, \mathrm{ax} \mathrm{a}_{1}\right)} \mathcal{R}_{\mathrm{nr}} 0.1 \cdot \delta_{(\{\{o u t(a, c)\}, \varnothing)}+\right.$

For the sake of readability, $\alpha$ stands for all labels $\mathrm{ax}_{i} \notin$, for $i \in \mathbb{N}$ and all labels $\xi \sim \xi^{\prime}$ for all closed recipes $\xi, \xi^{\prime}$ such that $\xi \sim \xi^{\prime}(\sim \in\{\doteq, \neq\})$. Furthermore, let

$$
\begin{aligned}
Q & =\left(\operatorname{out}(a, c)+_{0.9} \operatorname{out}(b, c)\right)+\left(\operatorname{out}(a, c)+_{0.1} \operatorname{out}(b, c)\right) & & R=Q+_{0.5} Q^{\prime} \\
Q^{\prime} & =\text { if } c=c \text { then } Q \text { else } 0 & & P=\operatorname{out}(a, c)+_{0.5} \operatorname{out}(b, c) \\
\mathcal{P}_{a b}(p) & =\left\{\operatorname{out}(a, c)+_{p} \operatorname{out}(b, c)\right\} & &
\end{aligned}
$$

(a) The fragment of $\mathrm{N}^{\ell}$ corresponding to $(\{Q\}, \varnothing)$ and $(\{R\}, \varnothing)$.

(b) The resolution for $\left(\{\{R\}, \varnothing) \xlongequal{\tau} \mathcal{R}_{\text {nr }} 0.5 \cdot \delta_{\text {out }(a, c)}+0.5 \cdot \delta_{\text {out }(b, c)}\right.$.

Figure 8: Fragments of $\mathrm{N}^{\ell}$ showing that $\left(\{\{P\}, \varnothing) \leq_{\operatorname{sim}}^{\mathrm{nr}}\left(\{\{R\}, \varnothing),\left(\{\{R\}, \varnothing) \leq_{\operatorname{sim}}^{\mathrm{nr}}\right.\right.\right.$ $\left(\{\{Q\}, \varnothing)\right.$ but $\left(\{\{P\}, \varnothing) \mathbb{Z}_{s i m}^{\mathrm{nr}}(\{\{Q\}, \varnothing)\right.$
$0.9 \cdot \delta_{(\{\text {out }(b, c)\}, \varnothing)}$ or $\left(\{\{Q\}, \varnothing) \xrightarrow{\tau} \mathcal{R}_{\text {nr }} 0.9 \cdot \delta_{(\{\text {out }(a, c)\}, \varnothing)}+0.1 \cdot \delta_{(\{0 \text { out }(b, c)\}, \varnothing)}\right.$ and both distributions are incomparable with $0.5 \cdot \delta_{(\{\text {out }(a, c)\}, \varnothing)}+0.5 \cdot \delta_{(\{\text {out }(b, c)\}, \varnothing)}$. Hence, $(\{\{P\}\}, \varnothing) \mathbb{E}_{\text {sim }}^{\mathrm{nr}}$ $(\{\{R\}, \varnothing)$.

We now show that for non-randomized schedulers (bi)simularity and observational equivalence, respectively preorder, do not coincide. The processes witnessing this result are a direct counter-example to [GLPT07, Theorem 2].

For readability, given a closed frame $\phi, \alpha(\phi)$ stands for all labels ax $\notin$, for $i>|\phi|$ and ax $_{i} \in$ for $i \leq|\phi|$, and all labels $\xi \sim \xi^{\prime}$ for all closed recipes $\xi, \xi^{\prime}$ such that $\xi \phi \sim \xi^{\prime} \phi(\sim \in\{\doteq, \neq\})$.
(a) The fragment of $\mathrm{N}^{\ell}$ corresponding to $(\{Q\}, \varnothing)$ and $\left.(\{P\}\}, \varnothing\right)$

$$
\begin{aligned}
& \mathcal{P}_{d a}=\operatorname{out}(d, c) ;\left(\operatorname{out}(a, c)+_{0.9} 0\right) \quad \mathcal{P}_{a+}=\left\{\left\{\operatorname{out}(a, c)+_{0.9} 0\right\}\right\} \quad \mathcal{P}_{a}=\{\text { out }(a, c)\} \\
& \left.\mathcal{P}_{d b}=\operatorname{out}(d, c) ;\left(\operatorname{out}(b, c)+_{0.9} 0\right) \quad \mathcal{P}_{b+}=\left\{\operatorname{out}(b, c)+_{0.9} 0\right\}\right\} \quad \mathcal{P}_{b}=\{\{\operatorname{out}(b, c)\} \\
& \phi=\left\{\mathrm{ax}_{1} \rightarrow c\right\} \quad \phi^{\prime}=\left\{\mathrm{ax}_{1} \rightarrow c, \mathrm{ax}_{2} \rightarrow c\right\}
\end{aligned}
$$

(b) The fragment of $\mathrm{N}^{o}$ corresponding to $\{P ;$ in $(d, x) .0\}$ and $\{Q ;$ in $(d, x) .0\}$

Figure 9: Fragments of NPLTS showing $(\{Q Q\}, \varnothing) \approx_{b i}^{n r}\left(\{\{P\}, \varnothing)\right.$ and $\{Q\} \not \mathbb{Z}_{o b s}^{\mathrm{nr}}\{\{P\}$.

Lemma 3. There exist processes $P, Q \in \mathcal{S P}$ such that

$$
(\{Q Q\}, \varnothing) \approx_{b i}(\{\{P\}, \varnothing), \quad(\{Q\}\}, \varnothing) \approx_{b i}^{\mathrm{nr}}\left(\{\{P\}, \varnothing) \quad \text { and } \quad\{Q Q\} \mathbb{Z}_{o b s}^{\mathrm{nr}}\{P\}\right\}
$$

Proof. We consider the following processes:

$$
\begin{aligned}
P & =\operatorname{out}(d, c) ;\left(\operatorname{out}(a, c)+{ }_{0.9} 0\right)+\operatorname{out}(d, c) ;\left(\operatorname{out}(b, c)+_{0.9} 0\right) \\
P^{\prime} & =\text { if } c=c \text { then } P \text { else } 0 \\
Q & =P+_{1 / 2} P^{\prime}
\end{aligned}
$$

We first show that $(\{Q\}, \varnothing) \approx_{b i}^{\mathrm{nr}}(\{\{P\}, \varnothing)$. For readability we ignore intermediate states of the form $\mathcal{P} \cup\{\{0\}$ as, for any $\mathcal{P}$ and $\phi,(\mathcal{P} \cup\{0\}), \phi) \xrightarrow{\tau}(\mathcal{P}, \phi)$ and $(\mathcal{P} \cup\{0\}\}, \phi) \approx_{b i}^{\text {nr }}$ $(\mathcal{P}, \phi)$. Following the notations of Figure 9a, define the binary relation $R$ as the reflexive, symmetric and transitive closure of

$$
\left\{((\{Q Q\}, \varnothing),(\{\{P\}\}, \varnothing)), \quad\left(\left(\{\{P\}, \varnothing),\left(\left\{\left\{P^{\prime}\right\}, \varnothing\right)\right)\right\}\right.\right.
$$

We show that $R$ is a bisimulation. Let $s_{1}, s_{2} \in\left\{(\{\{Q\}, \varnothing),(\{P\}\}, \varnothing),\left(\left\{\left\{P^{\prime}\right\}, \varnothing\right)\right\}\right.$. If $s_{1} \xrightarrow{\alpha(\varnothing)} D$ then $D=\delta_{s_{1}}$ and $s_{2} \xrightarrow{\alpha(\phi)} \mathcal{R}_{\mathrm{nr}} \delta_{s_{2}}$. By definition of $R, \delta_{s_{1}} \widehat{R} \delta_{s_{2}}$. If $s_{1} \xrightarrow{\tau} D$ then we are in one of the following cases:

- $s_{1}=(\{Q Q\}, \varnothing)$ and $D=0.5 \cdot \delta_{(\{P\}, \varnothing)}+0.5 \cdot \delta_{\left(\left\{P^{\prime}\right\}, \varnothing\right)}$, or $s_{1}=\left(\left\{\left\{P^{\prime}\right\}, \varnothing\right)\right.$ and $D=$ $\delta_{(\{P\}, \varnothing)}$. In these cases, $s_{2} \xrightarrow{\tau} \mathcal{R}_{\mathrm{nr}} \delta_{s_{2}}$ and $D \widehat{R} \delta_{s_{2}}$.
- $s_{1}=(\{\{P\}\}, \varnothing)$ and either $D=\delta_{\left(\mathcal{P}_{d a}, \varnothing\right)}$ or $D=\delta_{\left(\mathcal{P}_{d b}, \varnothing\right)}$. As $s_{2} \xlongequal{\tau} \mathcal{R}_{\mathcal{R}_{n r}} \delta_{s_{1}}$ we also have that $s_{2} \xrightarrow{\tau} \mathcal{R}_{\mathrm{nr}} D$ which allows us to conclude by reflexivity of $R$.

All remaining cases are trivial by reflexivity of $R$. The same relation can also be shown to be a witness that $\left(\{\{Q\}, \varnothing) \approx_{b i}(\{\{P\}, \varnothing)\right.$.

Next, we need to show that $\{Q\} \not \mathbb{Z}_{o b s}^{\mathrm{nr}}\{\{P\}$. For this we show that

$$
\{Q ; \operatorname{in}(d, x) .0\} \not \mathbb{Z}_{o b s}^{\mathrm{nr}}\{\{P ; \operatorname{in}(d, x) .0\}
$$

(since $\leq_{o b s}^{\mathrm{nr}}$ is closed under application of an attacker process). For readability we tacitly omit intermediate states of the form $\mathcal{P} \cup\{\{0\}$ as $\mathcal{P} \cup\{0\}\} \xrightarrow{\tau} \mathcal{P}$ and $\mathcal{P} \cup\left\{\{0\} \approx_{o b s}^{\mathrm{nr}} \mathcal{P}\right.$. Consider Figure 9b, We can build a non-randomized scheduler such that

$$
\{Q ; \operatorname{in}(d, x) .0\} \not \stackrel{\tau}{\Longrightarrow}_{\mathcal{R}_{n r}\left(\mathrm{~N}^{o}\right)} D \quad \text { where } \quad D=0.45 \cdot \delta_{\mathcal{P}_{a}}+0.45 \cdot \delta_{\mathcal{P}_{b}}+0.1 \cdot \delta_{\varnothing}
$$

However, there is no distribution $E$ such that $\{\{P ; \operatorname{in}(d, x) .0\}\} \xlongequal{\tau} \mathcal{R}_{\mathrm{nr}\left(\mathrm{N}^{\circ}\right)} E$, and $D \widehat{\leq_{o b s}^{\widehat{n r}}} E$. Indeed, the set S of all $E$ such that $\{P ;$ in $(d, x) .0\}\}{ }_{\tau_{\mathrm{nr}}\left(\mathrm{N}^{\circ}\right)} E$ is
$S=\left\{\delta_{s} \mid s \in\left\{\left\{\{P ; \operatorname{in}(d, x) .0\},\left\{\left\{\mathcal{P}_{d a} ; \operatorname{in}(d, x)\right\},\left\{\left\{\mathcal{P}_{d b} ; \operatorname{in}(d, x)\right\},\left\{\left\{\mathcal{P}_{a+}\right\},\left\{\left\{\mathcal{P}_{b+}\right\}\right\} \cup\left\{F_{a}, F_{b}\right\}\right.\right.\right.\right.\right.\right.$
where $F_{c}=0.9 \cdot \delta_{\left\{\mathcal{P}_{c}\right\}}+0.1 \cdot \delta_{\{0\}} \quad$ for $c \in\{a, b\}$.

Observe-looking at Definition 18 that for any distribution $E$ such that $D \widehat{\leq_{o b s}^{\mathrm{nr}}} E$ it must hold that:

$$
\begin{equation*}
\sum_{s \in \operatorname{supp}(E)} E(s) \cdot \operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(N^{o}\right)}(s, \downarrow c) \geq 0.45 \quad \text { for } c \in\{a, b\} \tag{2}
\end{equation*}
$$

Indeed, we can see that $D \widehat{\leq_{o b s}} E$ implies that:

$$
\begin{array}{rlr}
0.45 & =D\left(\left\{s \mid \operatorname{RProb}_{\mathcal{R}_{n r}}(s, \downarrow c)=1\right\}\right) & \text { for } c \in\{a, b\} \\
& \leq E\left(\leq_{o b s}^{\text {nr }}\left(\left\{s \mid \operatorname{RProb}_{\mathcal{R}_{n r}}(s, \downarrow c)=1\right\}\right)\right) & \text { by definition of } \widehat{R} \\
& \leq E(\{s \mid \operatorname{RProb} \\
& \left.\left.\leq \sum_{s \in \operatorname{supp}(E)}(s, \downarrow c)=1\right\}\right) & \text { by definition of } \leq_{o b s}^{\mathrm{nr}} \\
& E(s) \cdot \operatorname{RProb}_{\mathcal{R}_{\text {nr }}\left(N^{o}\right)}(s, \downarrow c) &
\end{array}
$$

We now use Equation (2) to show that there is no $E \in S$ such that $D \widehat{\leq_{o b s}} E$.

- we see immediately that Equation (2) does not hold for $F_{a}, F_{b}$ as

$$
\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}\left(\mathcal{P}_{i+}, \downarrow j\right)=0.9 \cdot \operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}\left(\mathcal{P}_{i}, \downarrow j\right)=0 \quad \text { for }(i, j) \in\{(a, b),(b, a)\} ;
$$

- by the definition of $\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}^{o}\right)}($, $)$, we see that

$$
\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}\left(\mathcal{P}_{i+}, \downarrow j\right)=\sum_{s \in \operatorname{supp}\left(F_{c}\right)} F_{c}(s) \cdot \operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}(s, \downarrow j)
$$

for $i \in\{a, b\}$ and every barb $j$. Hence, using the previous case, we conclude that Equation (2) does not hold for $\delta_{\mathcal{P}_{a+}}, \delta_{\mathcal{P}_{b+}}$;

- we have that $\operatorname{RProb}_{\mathcal{R}_{\text {nr }}\left(\mathrm{N}^{\circ}\right)}\left(\left\{\mathcal{P}_{d i} ; \operatorname{in}(d, x)\right\}, \downarrow j\right)=\operatorname{RProb}_{\mathcal{R}_{\text {nr }}\left(\mathrm{N}^{\circ}\right)}\left(\mathcal{P}_{i+}, \downarrow j\right)$ for every barb $j$, and $i \in\{a, b\}$, and from there we can conclude using the previous case;
- finally, we have that

$$
\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}(\{\{P ; \operatorname{in}(d, x) .0\}\}, \downarrow j)=\max _{i \in\{a, b\}} \operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}\left(\left\{\left\{\mathcal{P}_{d i} ; \operatorname{in}(d, x)\right\}\right\}, \downarrow j\right)
$$

for every barb $j$, and we conclude using the previous case.
Therefore, $\left\{\{Q\} \not \mathbb{Z}_{o b s}^{\mathrm{nr}}\{\{P\}\right.$.

### 5.3.1 Counter-example to coincidence of bisimulation and abservational congruence in [GLPT07]

Since we defined our operational semantics in a slightly different way as GLPT07, we present below a proof that Lemma 3 also holds in their framework. Their semantics differs from ours in two distinct ways: the first one is simply a presentation issue, since they define
probabilistic executions and schedulers in a different but equivalent way; while the other one consists of minor difference in the semantics of the reduction. Here, we rewrite their definitions in our framework, while keeping their operational semantics, i.e., their one-step reduction relation. This paragraph is not entirely self-contained, but all definitions and notations used here can be found in GLPT07.

Notation 9. We note $\mathcal{P}_{\diamond}$ for the set of extended processes (in the sense of GLPT07), up to static equivalence (again, in the sense of [GLPT07]). We note ${ }_{\rightarrow}^{a} \subseteq \mathcal{P}_{\diamond} \times \mathcal{D}\left(\mathcal{P}_{\diamond}\right)$ for the one-step reduction relation there. For any name $a$, we write $\downarrow^{\diamond} a$ for the set of all extended processes (in the sense of GLPT07]) of the form $C[\bar{a}\langle x\rangle . P]$, where $C$ is an evaluation context (in the sense of [GLPT07]) that does not bind $a$. Whenever, processes are in $\mathcal{P}_{\diamond}$, we also use the syntax of [GLPT07] for outputs and inputs, i.e., $\bar{a}\langle x\rangle$ and $a(x)$ instead of out $(a, x)$ and $\operatorname{in}(a, x)$.

From there, we define two NPLTS $\mathrm{N}_{\diamond}^{o}$ and $\mathrm{N}_{\diamond}^{\ell}$ that translate their operational semantics in our NPLTS based framework.

Definition 19. The set of states of both $\mathrm{N}_{\diamond}^{o}$ and $\mathrm{N}_{\diamond}^{\ell}$ is $\mathcal{P}_{\diamond}$. $\mathrm{N}_{\diamond}^{o}$ 's set of actions is $\{\tau\}$, while $\mathrm{N}_{\diamond}^{\ell}$ 's set of actions is:

$$
\begin{aligned}
\{\tau\} & \cup\{a \mid a \text { labelled actions in GLPT07] }\} \\
& \cup\{? \in E \mid E \text { equivalence class for static equivalence }\} .
\end{aligned}
$$

Observe that there is a direct correspondance between schedulers in the sense of GLPT07, and non-randomized schedulers on $\mathrm{N}_{\diamond}^{\ell}$. We explicit this correspondance in Lemma 4 below.

Lemma 4. Let $P \in \mathcal{P}_{\diamond}, A$ a subset of $\mathcal{P}_{\diamond}$, and $p \in[0,1]$.

- there exists a scheduler $F$ (in the sense of [GLPT07]) such that $\operatorname{Prob}_{P}^{F}(A)=p$ if and only if there exists $\mathrm{R} \in \mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\diamond}^{\ell}\right)$, and $s^{\prime}$ with $\operatorname{corr}_{\mathrm{R}}\left(s^{\prime}\right)=P$ such that

$$
\operatorname{RProb}_{\mathrm{R}}\left(s^{\prime}, \operatorname{corr}_{\mathrm{R}}^{-1}(A)\right)=p
$$

- there exists a scheduler $F$ (in the sense of [GLPT07]) such that $\operatorname{Prob}_{P}^{F}(\alpha, A)=p$ if and only if there exists $D$ such that
- there exists a scheduler $F$-in the sense of GLPT07] such that $\operatorname{Prob}_{P}^{F}\left(\tau^{\star} \alpha \tau^{\star}, A\right)=p$ if and only if there exists $\mathrm{R} \in \mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\diamond}^{\ell}\right)$, and $s$ with $\operatorname{corr}_{\mathrm{R}}(s)=P$ such that

$$
\sum_{u \in \mathcal{S}_{e x t}(\mathrm{R}) \mid \operatorname{trans}_{\mathrm{R}}(u)(a) \neq \star} \operatorname{RProb}_{\mathrm{R}}(s,\{u\}) \cdot \sum_{v} \operatorname{trans}_{\mathrm{R}}(u)(a)(v) \cdot \operatorname{RProb}_{\mathrm{R}}\left(v, \operatorname{corr}_{\mathrm{R}}^{-1}(A)\right)=p
$$

Using the correspondance in Lemma 4, the counter-example proof below can be followed using either original definitions in GLPT07], or the NPLTS based view of the present paper.

Notation 10. Let $R$ be an equivalence relation on $\mathcal{P}_{\diamond}$, and $P \in \mathcal{P}_{\diamond}$.

- For any scheduler $F$, we denote by $w_{F, P}$ the function that to any equivalence class $E$ of $R$ associates $\operatorname{Prob}_{P}^{F}(E)$ and for any $T \in \mathcal{P}_{\diamond}$, we note $\mathcal{H}_{T}$ for the set of the different possible $w_{F, T}$ for any scheduler $F$.
- For any action $\alpha$, scheduler $F$, we denote by $w_{F, P}^{\alpha}$ the function that to an any equivalence class $E$ of $R$ associates $\operatorname{Prob}_{P}^{F}\left(\tau^{\star} \alpha \tau^{\star}, E\right)$. For any $T \in \mathcal{P}_{\diamond}$, we note $\mathcal{H}_{T}^{\alpha}$ for the set of the different possible $w_{\mathrm{R}, s}^{\alpha}$ for $\operatorname{corr}_{\mathrm{R}}(s)=T$.

Using Notation 10, we can rewrite the definitions of both observational congruence and bisimulation in GLPT07:

Lemma 5. An observational congruence on $\mathcal{P}_{\diamond}$ in the sense of GLPT07 is a symmetric relation $R$ on $\mathcal{P}_{\diamond}$ such that $\mathcal{P} R \mathcal{Q}$ implies:

- $\mathcal{H}_{\mathcal{P}}=\mathcal{H}_{\mathcal{Q}}$
- for all closing evaluation context $C, C[\mathcal{P}] R C[\mathcal{Q}]$.

We denote by $\approx_{o b s}^{\diamond}$ the largest observational congruence on $\mathcal{P}_{\diamond}$.
Lemma 6. A bisimulation on $\mathcal{P}_{\diamond}-$ in the sense of GLPT07 is a symmetric relation $R$ on $\mathcal{P}_{\diamond}$ such that $\mathcal{P} R \mathcal{Q}$ implies:

1. $\mathcal{H}_{\mathcal{P}}=\mathcal{H}_{\mathcal{Q}}$;
2. if $\mathcal{P}{\xrightarrow{a} \mathcal{R}_{\text {nr }}\left(\mathbb{N}_{\delta}^{\ell}\right)} D$ with $a \neq \tau$, then there exists $h \in \mathcal{H}_{\mathcal{Q}}^{a}$ such that for every equivalence class $E$ of $R, h(E)=D(E)$

We denote by $\approx_{b i}^{\diamond}$ the largest bisimulation on $\mathcal{P}_{\diamond}$.
Lemma 7. There exist extended processes $Q_{1}, Q_{2} \in \mathcal{P}_{\diamond}$ such that $Q_{1} \approx_{b i}^{\diamond} Q_{2}$ and $Q_{1} \not \boldsymbol{*}_{o b s}^{\diamond}$ $Q_{2}$.

Proof. We slightly change the processes used in the proof of Lemma 3, to account for the change in the one-step reduction relation. We define $Q_{1}, Q_{2} \in \mathcal{P}_{\diamond}$ as:

$$
\begin{aligned}
P & =\bar{a}\langle c\rangle \cdot\left(\bar{d}\langle c\rangle \cdot \overline{b_{1}}\langle c\rangle+\bar{d}\langle c\rangle \cdot \overline{b_{2}}\langle c\rangle\right) \\
P^{\prime} & =\text { if } c=c \text { then } P \text { else } 0 \\
Q_{1} & =\bar{a}\langle c\rangle \cdot P \oplus_{1 / 2} \bar{a}\langle c\rangle \cdot P^{\prime} \\
Q_{2} & =\bar{a}\langle c\rangle \cdot P
\end{aligned}
$$

We first show that $Q_{1} \approx_{b i}^{\diamond} Q_{2}$, using the relevant fragment of $\mathrm{N}_{\diamond}^{\ell}$ represented in Figure 10a. We are going to show that the relation $R$ defined as the reflexive, transitive and symmetric closure of $\left\{\left(Q_{1}, Q_{2}\right),\left(Q_{2}, \bar{a}\langle c\rangle . P^{\prime}\right),\left(P, P^{\prime}\right)\right\}$ is a bisimulation on $\mathcal{P}_{\diamond}$ in the sense of Lemma 6. What are the equivalence classes of $R$ ? They consist of

$$
C_{0}:=\left\{Q_{1}, Q_{2}, \bar{a}\langle c\rangle . P^{\prime}\right\} \quad C_{1}:=\left\{P, P^{\prime}\right\} \quad C_{T}=\{T\} \text { for all other extended processes } T
$$

We now show that $R$ is a bisimulation by considering all (non-identical) pairs in $R$, and we show that the conditions of Lemma 6 hold. Let be $\left(U_{1}, U_{2}\right) \in R$, with $U_{1} \neq U_{2}$ (if $U_{1}=U_{2}$, it is obvious that both conditions in Lemma 6 hold).

- We first check Condition 1 in Lemma 6. We can see using Figure 10a that for every $U \in\left\{U_{1}, U_{2}\right\}, \mathcal{H}_{U}=\left\{\left(C_{U} \mapsto 1\right.\right.$ with $U \in C_{U}, C_{E} \mapsto 0 \forall E$ with $\left.U \notin E\right\}$. (That's because $U \in\left\{\left(Q_{1}, Q_{2}, \bar{a}\langle c\rangle . P^{\prime}, P, P^{\prime}\right\}\right.$. Indeed no such process $U$ can go out of its equivalence class with only $\tau$-actions, thus we can conclude. From there, we can immediately conclude that Condition 1 in Lemma 6 holds.
- We now check Condition 2 in Lemma 6. First, if $\alpha$ is an action for static equivalence, we see immediately that the condition holds: indeed all the relevant processes are statically equivalent, since their frames are empty. (In the semantics of GLPT07] channel names can be output without extending the frame.) Now, let us suppose that $\alpha$ is not an action for static equivalence. As a first step, we compute the $\mathcal{H}_{U}^{a}$ for $U \in\left\{\left(Q_{1}, Q_{2}, \bar{a}\langle c\rangle . P^{\prime}, P, P^{\prime}\right\}\right.$. Observe that $0_{\mathcal{H}}:=E \mapsto 0$ is always in $\mathcal{H}_{U}^{a}$, because the scheduler can always decide not to do the $a$ action. Moreover, we specify by $\left(E_{1} \mapsto r_{1}, \ldots E_{n} \mapsto r_{n}\right)$ the function $h$ and suppose it to be 0 on any class not in $E_{1}, \ldots E_{n}$.
$\mathcal{H}_{Q_{1}}^{\alpha}=\left\{\left(C_{1} \mapsto 1\right),\left(C_{1} \mapsto \frac{1}{2}\right), 0_{\mathcal{H}}\right\}$ when $\alpha=\bar{a}\langle c\rangle,\left\{0_{\mathcal{H}}\right\}$ otherwise.
$\mathcal{H}_{Q_{2}}^{\alpha}=\left\{\left(C_{1} \mapsto 1\right), 0_{\mathcal{H}}\right\}$ when $\alpha=\bar{a}\langle c\rangle,\left\{0_{\mathcal{H}}\right\}$ otherwise.
$\mathcal{H}_{\bar{a}\langle c\rangle . P^{\prime}}^{\alpha}=\left\{\left(C_{1} \mapsto 1\right), 0_{\mathcal{H}}\right\}$ when $\alpha=\bar{a}\langle c\rangle,\left\{0_{\mathcal{H}}\right\}$ otherwise.
$\mathcal{H}_{P}^{\alpha}=\left\{(\{S\} \mapsto 1), 0_{\mathcal{H}}\right\} \cup\left\{\left(\{S\} \mapsto 1,\left\{P_{d i}\right\} \mapsto 1\right) \mid i \in\{a, b\}\right\}$ when $\alpha=\bar{a}\langle c\rangle,\left\{0_{\mathcal{H}}\right\}$ otherwise.
$\mathcal{H}_{P^{\prime}}^{\alpha}=\left\{(\{S\} \mapsto 1), 0_{\mathcal{H}}\right\} \cup\left\{\left(\{S\} \mapsto 1,\left\{P_{d i}\right\} \mapsto 1\right) \mid i \in\{a, b\}\right\}$ when $\alpha=\bar{a}\langle c\rangle,\left\{0_{\mathcal{H}}\right\}$ otherwise.

We perform a case analysis depending on the first element in $\left(U_{1}, U_{2}\right)$ (seen as an ordered pair).
$-U_{1}=Q_{1}$ : Observe that there doesn't exist $\alpha \neq \tau$ such that $Q_{1} \xrightarrow{\alpha}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\varsigma}^{\ell}\right)} D$, thus we conclude.
$-U_{1}=Q_{2}$ : Suppose that $Q_{2} \xrightarrow[\rightarrow]{\alpha}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\circ}^{\ell}\right)} D$ with $\alpha \neq \tau$ : it means that $\alpha=$ $\bar{a}\langle c\rangle$, and $D=\delta_{P}$. So we need to show that $\left(C_{1} \mapsto 1\right) \in \mathcal{H}_{U_{2}}^{\alpha}$ for all $U_{2}$ such that $\left(U_{1}, U_{2}\right) \in R$. Then we conclude by seeing that indeed $h:\left(C_{1} \mapsto\right.$ 1) $\in \mathcal{H}_{Q_{1}}^{\alpha}, \mathcal{H}_{\bar{a}\langle c\rangle . P^{\prime}}^{\alpha}$ (for $Q_{1}$, for instance, it is simply the scheduling that does $\left.Q_{1} \xrightarrow{\tau}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\odot}^{\ell}\right)} \frac{1}{2} \delta_{\bar{a}\langle c\rangle . P}+\frac{1}{2} \delta_{\bar{a}\langle c\rangle . P^{\prime}} \xrightarrow{\alpha}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\circ}^{\ell}\right)} \frac{1}{2} \delta_{P}+\frac{1}{2} \delta_{P^{\prime}}\right)$.
$-U_{1}=\bar{a}\langle c\rangle \cdot P^{\prime}$ Whenever $\bar{a}\langle c\rangle . P^{\prime} \xrightarrow{\alpha}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\bullet}^{\ell}\right)} D$, it means that $\alpha=\bar{a}\langle c\rangle$, and $D=$ $\delta_{P^{\prime}}$. From there, we can see that the condition on $Q_{2}$ holds by observing that $\left(C_{1} \mapsto 1\right) \in \mathcal{H}_{Q_{2}}^{\alpha}, \mathcal{H}_{Q_{1}}^{\alpha}$.

- $U_{1}=P$ : whenever $P \xrightarrow{\alpha}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\ell}^{\ell}\right)} D$, it means that $\alpha=\bar{a}\langle c\rangle$, and $D=\delta_{S}$. So we can conclude by seeing that $(\{S\} \mapsto 1) \in \mathcal{H}_{P^{\prime}}^{\alpha}$.
$-U_{2}=P^{\prime}$ : there is no non silent actions that $P^{\prime}$ can do in one step, so we conclude.
Now, we are going to show that $Q_{1} \AA_{o b s}^{\diamond} Q_{2}$. First, observe that by definition $\approx_{o b s}^{\diamond}$ is closed by application of evaluation contexts, thus it is sufficient to show that $C\left[Q_{1}\right] \mathcal{\approx}_{o b s}^{\diamond} C\left[Q_{2}\right]$ for some evaluation context $C$. We take $C=[] \mid a(x) \cdot a(x) \cdot d(x)$. For any extended process $T \in \mathcal{P}_{\diamond}$, we write $\operatorname{cl}(T)$ for its equivalence class under $\approx_{o b s}^{\diamond}$. Since in particular elements connected by $\approx_{o b s}^{\diamond}$ must have the same (supremum) sucess probability for each barb, we see that the equivalence classes $\operatorname{cl}\left(\overline{b_{1}}\langle c\rangle\right), \operatorname{cl}\left(\overline{b_{2}}\langle c\rangle\right)$, and $\operatorname{cl}\left(C\left[Q_{1}\right]\right)$ are distinct. By considering the scheduler represented in Figure 10b, we see that there exists a $h \in \mathcal{H}_{C\left[Q_{1}\right]}$ such that $h\left(c l\left(\overline{b_{1}}\langle c\rangle\right)\right)=\frac{1}{2}$ and also $h\left(c l\left(\overline{b_{2}}\langle c\rangle\right)\right)=\frac{1}{2}$. Suppose now that $C\left[Q_{1}\right] \approx_{o b s}^{\diamond} C\left[Q_{2}\right]$ : it would mean that also $h \in \mathcal{H}_{C\left[Q_{2}\right]}$. But this is not possible, because of the following observation: since the schedulers are not randomized, and there is no probabilistic choice in the process $C\left[Q_{2}\right], h(E) \in\{0,1\}$ for every $h \in \mathcal{H}_{C\left[Q_{2}\right]}$, and $E$ an equivalence class (this statement can also be checked directly by looking at all cases in the operational semantics).

Another drawback of the definition of bisimulation given in GLPT07] is that it is not conservative for processes without probabilities, as explicited in Lemma 8 below. We write $\approx_{b i}^{\text {det, }}$ for the bisimulation defined from non-probabilistic one-step rules: it means the weak bisimulation-in the LTS sense-on the LTS obtained as the restriction of $\mathrm{N}_{\diamond}^{\ell}$ to thoses processes in $\mathcal{P}_{\diamond}$ that do not contain probabilistic primitives.

Lemma 8. There exist extended processes $Q_{1}, Q_{2} \in \mathcal{P}_{\diamond}$ such that no probabilistic primitives appear in $Q_{1}, Q_{2}$, and $Q_{1} \not \ddot{b}_{b i}^{\diamond} Q_{2}$ and $Q_{1} \approx_{b i}^{\text {det, } \diamond} Q_{2}$.

Proof. We consider the following pair of (non-probabilistic) programs:

$$
\begin{aligned}
& Q_{1}:=\text { if }(c=c) \text { then }(a(x) \mid(\bar{a}\langle 0\rangle+\bar{a}\langle 1\rangle) \text { else } 0 ; \\
& Q_{2}:=Q_{1}+0
\end{aligned}
$$

Observe that $Q_{1} \approx_{b i}^{\text {det, } \diamond} Q_{2}$. Now, we are going to show that $Q_{1} \not \mathcal{F}_{b i}^{\diamond} Q_{2}$. Let $R$ be a bisimulation on $\mathcal{P}_{\diamond}$. As previously, for any $P \in \mathcal{P}_{\diamond}$, we note $\operatorname{cl}(P)$ for the equivalence class of $P$ with respect to $R$. We do the proof by contradiction, so we suppose that $\operatorname{cl}\left(Q_{1}\right)=\operatorname{cl}\left(Q_{2}\right)$. Using the fact that $R$ is a bisimulation, we can show that the following $R$-equivalence classes are distinct:

- $C_{0}$ : the class containing the process 0 ;
- $C_{Q_{1}, Q_{2}}$ : the class containing the processes $Q_{1}$ and $Q_{2}$;
- $D_{0}$ : the class containing the process $a(x) \mid \bar{a}\langle 0\rangle$;
- $D_{1}$ : the class containing the process $a(x) \mid \bar{a}\langle 1\rangle$;

We can see that there exists a (non-randomized) scheduler $F$ such that $w_{F, Q_{2}}\left(C_{0}\right)=1$, $w_{F, Q_{2}}\left(C_{Q_{1}, Q_{2}}\right)=1$, and $w_{F, Q_{2}}\left(D_{i}\right)=0$ for $i \in\{0,1\}$. ( $F$ is the scheduler that, starting from $Q_{1}+0$, does the non-deterministic choice towards 0 ). But, by looking at all possible scheduling from $Q_{1}$, we can see that there doesn't exists $w_{F^{\prime}, Q_{1}}$ such that $w_{F^{\prime}, Q_{1}}=w_{F, Q_{2}}$ : as a consequence $\mathcal{H}_{Q_{1}} \neq \mathcal{H}_{Q_{2}}$, thus we have a contradiction.

### 5.3.2 The counter-example for a conservative variant of [GLPT07] bisimulation

We want to highlight here that the issue of non-conservativity is orthogonal to the issue of coincidence between bisimulation and observational equivalence: our claim is that the later is really based on the choice between randomized or non-randomized schedulers. In this section, we present a variant of the bisimulation defined in GLPT07] on $\mathcal{P}_{\diamond}$, which is conservative but where schedulers are non-randomized, and we show that we still do not have the coincidence between bisimulation and observational equivalence.

Definition 20. An observational congruence on $\mathcal{P}_{\diamond}$ is a symmetric relation $R$ on $\mathcal{P}_{\diamond}$ such that $\mathcal{P} R \mathcal{Q}$ implies:

- $\operatorname{RProb}_{\mathcal{R e r}_{\mathrm{nr}}\left(\mathrm{N}_{\circ}\right)}\left(\mathcal{P}, \downarrow^{\triangleright} a\right)=\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\stackrel{ }{ }}\right)}\left(\mathcal{Q}, \downarrow^{\triangleright} a\right)$;
- if $\mathcal{P} \xlongequal{\tau}{ }_{\mathcal{R}_{n r}\left(\mathrm{~N}_{\circ}^{\circ}\right)} D$ then there exists $E$ such that $\mathcal{Q} \xlongequal{\tau}{\mathcal{\mathcal { R } _ { n r } ( \mathrm { N } _ { \circ } ^ { \circ } )}} E$ and $D \widehat{R} E$;
- for all closing evaluation context $C, C[\mathcal{P}] R C[\mathcal{Q}]$.

We note $\approx_{o b s}^{\diamond}$ for the greatest observational congruence on $\mathcal{P}_{\diamond}$.
Definition 20 above can be seen as intermediate between our notion of observational congruence and the one in [GLPT07]: on the one hand, as in GLPT07] only non-randomized schedulers are considered, the one step reduction relation is the same, and all evaluations contexts (and not only contexts of the form [] | $A d v$ ) are taken into account. On the other hand, we diverge from [GLPT07] on the following point when we look to replicate one step $a$ by a succession $\tau^{\star} a \tau^{\star}$ of steps, we look only at the end point, and not at the path to go there. It is this divergence that allow us to get back conservativity.

Definition 21. A bisimulation on $\mathcal{P}_{\diamond}$ is a symmetric relation $R$ on $\mathcal{P}_{\diamond}$ such that $\mathcal{P} R \mathcal{Q}$ implies:

- if $\mathcal{P} \xlongequal{\tau}{ }_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\imath}^{\ell}\right)} D$ then there exists $E$ such that $\mathcal{Q} \xlongequal{\tau}{ }_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\odot}^{\ell}\right)} E$ and $D \widehat{R} E$;

We note $\approx_{b i}^{\diamond}$ for the greatest bisimulation on $\mathcal{P}_{\diamond}$.

Observe that bisimilarity in the sense of Definition 21 above does not coincide with bisimilarity-in the sense of Definition 17 on the labelled NPLTS $\mathrm{N}_{\diamond}^{\ell}$. The important difference is that, as for observational congruence, in GLPT07 only non-randomized schedulers are considered. Another technical difference is the use of $\stackrel{\tau}{\Rightarrow}$ instead of $\xrightarrow{\tau}$ on the left side in the first clause.

We are now going to show the counterpart of Lemma 3 for the observational congruence and weak bisimilarity in the sense of [GLPT07]. It actually disporoves [GLPT07, Theorem $2]$.

Lemma 9. There exist extended processes $Q_{1}, Q_{2} \in \mathcal{P}_{\diamond}$ such that $Q_{1} \approx_{b i}^{\diamond} Q_{2}$ and $Q_{1} \not \mathscr{z}_{o b s}^{\diamond}$ $Q_{2}$.

Proof. We need to change a little the processes used in the proof of Lemma 3, due to the change in the one-step reduction relation. We define $Q_{1}, Q_{2} \in \mathcal{P}_{\diamond}$ as:

$$
\begin{aligned}
P & =\bar{a}\langle c\rangle \cdot\left(\bar{d}\langle c\rangle \cdot \overline{b_{1}}\langle c\rangle+\bar{d}\langle c\rangle \cdot \overline{b_{2}}\langle c\rangle\right) \\
P^{\prime} & =\text { if } c=c \text { then } P \text { else } 0 \\
Q_{1} & =\bar{a}\langle c\rangle \cdot P \oplus_{1 / 2} \bar{a}\langle c\rangle \cdot P^{\prime} \\
Q_{2} & =\bar{a}\langle c\rangle \cdot P
\end{aligned}
$$

We first show that $Q_{1} \approx_{b i}^{\diamond} Q_{2}$, using the relevant fragment of $\mathbf{N}_{\diamond}^{\ell}$ represented in Figure 10a. We are going to show that the relation $R$ defined as the reflexive and symmetric closure of $\left\{\left(Q_{1}, Q_{2}\right),\left(Q_{2}, \bar{a}\langle c\rangle . P^{\prime}\right),\left(P, P^{\prime}\right)\right\}$ is a bisimulation on $\mathcal{P}_{\diamond}$ in the sense of Definition 21 . We do that by considering all (non-identical) pairs in $R$, and we show that the conditions of Definition 21 hold.

- $\left(Q_{1}, Q_{2}\right)$ : suppose that $Q_{1}{ }^{\tau}{ }_{\mathcal{R}_{\text {nr }}\left(\mathrm{N}_{\odot}^{\ell}\right)} D$, then $D$ is in $\left\{\delta_{Q_{1}},\left(\frac{1}{2} \delta_{Q_{2}}+\frac{1}{2} \delta_{\left.\bar{a}\langle c\rangle . P^{\prime}\right)}\right)\right\}$. From there, we can conclude by observing that $Q_{2} \xlongequal{\tau} \mathcal{R}_{\text {nr }\left(\mathrm{N}_{\circ}^{\ell}\right)} \delta_{Q_{2}}$, and both $\delta_{Q_{1}} \widehat{R} \delta_{Q_{2}}$ and $\left(\frac{1}{2} \delta_{Q_{2}}+\frac{1}{2} \delta_{\bar{a}\left\langle c c \cdot P^{\prime}\right.}\right) \widehat{R} \delta_{Q_{2}}$ Now, suppose that $Q_{1} \xrightarrow{\alpha} \mathcal{R}_{\text {nr }}\left(\mathrm{N}_{\mathrm{z}}\right) \mathrm{D}$ with $\alpha \neq \tau$. First, if $\alpha$ is an action for static equivalence, we see immediately that the condition holds: indeed all the relevant processes are statically equivalent, since their frames are empty. (For this reason, we will not consider explicitly again actions for static equivalence in the following). Looking at $\mathrm{N}_{\diamond}^{\ell}$, we see that there is no other non-silent action that $Q_{1}$ can do.
- $\left(Q_{2}, Q_{1}\right)$ : suppose that $Q_{2}{ }^{\tau}{ }_{\mathcal{R}_{n r}\left(N_{c}^{\ell}\right)} D$, then $D=\delta_{Q_{2}}$, and we can immediately conclude. Suppose now that $Q_{2}{ }_{\rightarrow}^{\alpha} \mathcal{R}_{\text {nr }}\left(\mathrm{N}_{\mathrm{o}}\right), D$ with $\alpha \neq \tau$ : it means that $\alpha=\bar{a}\langle c\rangle$, and $D=\delta_{P}$. Then we conclude by seeing that $Q_{1} \xlongequal{\alpha} \mathcal{R}_{\text {nr }}\left(\mathrm{N}_{\circ}^{\ell}\right) \delta_{P}$.
- $\left(Q_{2}, \bar{a}\langle c\rangle . P^{\prime}\right)$ : suppose that $Q_{2} \xlongequal{\tau} \mathcal{R}_{\text {nr }}\left(\mathrm{N}_{\star}^{\ell}\right), ~ D, ~ t h e n ~ a s ~ i n ~ t h e ~ p r e v i o u s ~ c a s e ~ D=\delta_{Q_{2}}$, and we can immediately conclude. Suppose now that $Q_{2} \xrightarrow{\alpha}_{\mathcal{R}_{\text {nr }}\left(N_{\circ}^{\ell}\right)} D$ with $\alpha \neq \tau$ : then $\alpha=\bar{a}\langle c\rangle$, and $D=\delta_{P}$. Then we can conclude by seeing that $\bar{a}\langle c\rangle \cdot P^{\prime} \xrightarrow{\alpha} \mathcal{R}_{\operatorname{nrr}}\left(\mathcal{N}_{\iota}^{\ell}\right) \delta_{P}$.
- $\left(\bar{a}\langle c\rangle \cdot P^{\prime}, Q_{2}\right)$. The only $\tau$ action that starts from $\bar{a}\langle c\rangle \cdot P^{\prime}$ is the loop $\tau$ action, thus we can immediately conclude for the $\tau$ clause. Whenever $\bar{a}\langle c\rangle . P^{\prime}{ }_{\rightarrow}^{\alpha} \mathcal{R}_{\text {nr }}\left(N_{o}^{\ell}\right)$, it means that $\alpha=\bar{a}\langle c\rangle$, and $D=\delta_{P^{\prime}}$. From there, we can see that the condition on $Q_{2}$ holds by observing that $Q_{2} \xrightarrow{\alpha}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\circ}^{\ell}\right)} \delta_{P}$, and $\delta_{P^{\prime}} \widehat{R} \delta_{P}$.
- $\left(P, P^{\prime}\right)$ : the only $\tau$ action that starts from $P$ is the loop action, thus we can pass immediately to the case of non-silent action. Whenever $P \xrightarrow{\alpha}_{\mathcal{R}_{\text {nr }}\left(N_{\circ}\right)} D$, it means that $\alpha=\bar{a}\langle c\rangle$, and $D=\delta_{S}$. Now, observe that $P^{\prime}{ }^{\alpha}{ }_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\circ}^{\ell}\right)} \delta_{S}$, and since $R$ is reflexive (by definition), $\delta_{S} \widehat{R} \delta_{S}$.
- $\left(P^{\prime}, P\right)$ : suppose that $P^{\prime} \stackrel{\tau}{\Longrightarrow}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\bullet}^{\ell}\right)} D$, then $D \in\left\{\delta_{P^{\prime}}, \delta_{P}\right\}$. Since by the loop action $P \xlongequal{\tau} \mathcal{R}_{\text {nr }}\left(\mathrm{N}_{夫}^{\ell}\right), \delta_{P}$, and moreover $P^{\prime} R P$, we can conclude. We look now at non-silent actions: there are actually none to consider, since there is no non silent actions that $P^{\prime}$ can do in one step.

Now, we show that $Q_{1} \overbrace{o b s}^{\diamond} Q_{2}$. First, observe that by definition $\approx_{o b s}^{\diamond}$ is closed by application of evaluation context, thus it is enough to show that $C\left[Q_{1}\right] \mathcal{\approx}_{o b s} C\left[Q_{2}\right]$ for some evaluation context $C$. We take $C=[] \mid a(x) \cdot a(x) \cdot d(x)$. Looking at the NPLTS $\mathrm{N}_{\diamond}^{o}$, we see that $C\left[Q_{1}\right] \xlongequal{\tau} \mathcal{R}_{\text {nr }}\left(\mathrm{N}_{8}^{\ell}\right) D:=\frac{1}{2} \delta_{\overline{b_{1}}\langle c\rangle}+\frac{1}{2} \delta_{\overline{b_{2}}\langle c\rangle}$. Now, we claim that it is not possible to find $E$ such that $C\left[Q_{2}\right] \xlongequal{\tau} \mathcal{R}_{\mathrm{nr}\left(\mathrm{N}_{\circ}^{\ell}\right)} E$, and $D \underset{\overbrace{o b s}^{\diamond}}{ } E$. The argument is as follows: first, observe that all $E$ such that $C\left[Q_{2}\right]{ }^{\tau}{ }_{\mathcal{R}_{n r}\left(\mathcal{N}_{\circ}^{\ell}\right)} E$ are dirac distributions: it is because the schedulers are not randomized, and there is no probilistic choice in the process $C\left[Q_{2}\right]$ (this statement can also be checked directly by looking at all cases in the operational semantics). It means that $D=\delta_{A}$, for some $A \in \mathcal{P}_{\diamond}$. But for having $\left(D, \delta_{\underline{P}}\right) \in \widehat{\widetilde{\sigma}_{o b s}^{\circ}}, A$ must be connected by $\approx_{o b s}^{\diamond}$ to all elements in the support of $D$, i.e. both to $\overline{b_{1}}\langle c\rangle$ and $\delta_{\overline{b_{2}}\langle c\rangle}$. Since in particular elements connected by $\approx_{o b s}^{\diamond}$ must have the same (supremum) sucess probability for each barb, we obtain a contradiction.

Remark 10. The processes $Q_{1}, Q_{2}$ used in the proof of Lemma 9 are not the simplest possible counter-example. However, they have the advantage to be robust to small changes in the defintion of bisimulation, in particular in the case where the double arrow $\Longrightarrow \Longrightarrow_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}_{\circ}^{\ell}\right)}$ is used both left and right in all clauses of the bisimulation definition.

For readability, we ommit the actions $(? \in E)$ for static equivalence. Observe that since none of these extended processes use active substitutions, in particular they are all in the same equivalence class for static equivalence. We used the following notations: $\mathcal{P}_{d a}=$ $\bar{d}\langle c\rangle . \overline{b_{1}}\langle c\rangle$ and $\mathcal{P}_{d b}=\bar{d}\langle c\rangle . \overline{b_{2}}\langle c\rangle$.
(a) The fragment of $\mathrm{N}_{\diamond}^{\ell}$ corresponding to $Q_{1}$ and $Q_{2}$.

(b) A non-randomized resolution on $\mathrm{N}_{\diamond}^{o}$ witnessing $C\left[Q_{1}\right]{ }_{\Longrightarrow}^{\tau} \mathcal{R}_{\text {nr }}\left(\mathrm{N}_{\diamond}^{\ell}\right) \frac{1}{2} \delta_{\overline{b_{1}}\langle c\rangle}+\frac{1}{2} \delta_{\overline{b_{2}}\langle c\rangle}$.

## Part II

## Well behaved subclasses of protocols

It is a well-known phenomenon that non-determinism and probabilistic choices do not interact well: a particular scheduler may for instance leak a secret probabilistic choice. Such schedulers are generally deemed unrealistic, and several papers aim at restricting schedulers CP10, AAPvR10. We illustrate this phenomenon on the following example.

Example 3. Consider the following two processes.

$$
\begin{aligned}
P:= & (\operatorname{in}(c, x) . \text { if } x=0 \text { then out }(o k, 1) \text { else out }(b a d, 1))++_{1 / 2} \\
& (\text { in }(c, x) . \text { if } x=0 \text { then out }(b a d, 1) \text { else out }(o k, 1)) \\
Q:= & \operatorname{in}(c, x) \cdot\left(\operatorname{out}(o k, 1)+{ }_{1 / 2} \operatorname{out}(b a d, 1)\right)
\end{aligned}
$$

One may, intuitively, consider that these two processes exhibit the same behaviour. $Q$ takes an input and then with probability $1 / 2$ decides to either output on $o k$ or on bad. $P$ on the other hand first choses a branch with probability $1 / 2$. Each branch performs an input and according to the input value outputs either on ok or on bad. However, as the two branches make opposite choices on the output depending on the input value, one might expect the probability to output on $o k$ to be $1 / 2$.

However, we now show that $P$ and $Q$ are not may testing equivalent and can be distinguished by the following adversary:

$$
A d v=\operatorname{out}(c, 0) \mid \operatorname{out}(c, 1)
$$

Indeed, we can show that:

$$
\begin{array}{ll} 
& \exists \text { resolution } R \text { s.t. } \operatorname{RProb}_{R}(P \mid A d v, \downarrow o k)=1 \\
\text { and } & \forall \text { resolution } R^{\prime}, \operatorname{RProb}_{R^{\prime}}(P \mid A d v, \downarrow o k) \leq \frac{1}{2}
\end{array}
$$

Intuitively, this results from the fact that the resolution may leak the probabilistic choice through the non-deterministic choice of the attacker to output 0 or 1 . The resolution chooses the attacker to output 0 in the first probabilistic branch of $P$ and 1 in the second.

In this part we identify two subclasses of processes that avoid this problem. The first such subclass is that of purely non-deterministic processes, i.e. without the $+_{p}$ operator. This is the class of the original applied pi calculus which also enjoys good tool support. Intuitively, the above problem is avoided as there are no secret probabilistic choices to leak. However, we show that even on purely non-deterministic processes probabilistic adversaries have a stronger distinguishing power for the may testing equivalence. We also show that when additionally restricting protocols to a bounded number of sessions, i.e.,
considering processes without replication, may-testing coincides with similarity. We therefore inherit from [CKR18] the fact that may-testing is coNEXP complete for a large class of cryptographic primitives.

The second subclass considers purely probabilistic processes with (nearly) no nondeterminism. We show that trace equivalence in this class (as considered for instance in CSV17]) corresponds to may-testing with a restricted adversary process which again avoids non-determinism. We also sketch how the algorithms of then DeepSec prover could be adapted to check trace equivalence in this probabilistic setting.

## 6 Non-Probabilistic Processes

In this section, we consider protocols that do not make probabilistic choices, but an adversary that can have a probabilistic behaviour. By Proposition 5, we already know that simulation preorder implies may-testing equivalence. We show in this section that for bounded non-probabilistic processes, may testing and simulation actually coincide. We also show that this is not the case in general for processes with an unbounded number of sessions, i.e., with replication.

### 6.1 May-testing with non-probabilistic adversary and trace equivalence coincide

We show in this section that our definitions of may testing and trace equivalence coincide with the classical definitions of the original, purely non-deterministic applied pi calculus when both regular and adversary processes are non probabilistic (up to the difference on static equivalence, discussed in Remark (4).

Indeed, when considering non-probabilistic processes, all distributions in the (labeled) operational semantics are Dirac distributions. Moreover, we already shown in Proposition 2 that trace equivalence with randomized or non-randomized resolutions are equivalent. Thus, when considering non-randomized resolutions, one can notice that the probability of executing a trace $w$ from $(\mathcal{P}, \phi)$ will always be 0 or 1 , and in fact is 1 if and only if $(\mathcal{P}, \phi) \rightarrow_{a_{1}} \ldots \rightarrow_{a_{n}}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ where $w=a_{1} \ldots a_{n}$ when having removed $\tau$ actions and writing $(\mathcal{P}, \phi) \rightarrow_{a}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ instead of $(\mathcal{P}, \phi) \rightarrow_{a} \delta_{\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)}$. Similarly, the probability of reaching a barb $c$ from $\mathcal{P}$ is always 0 or 1 , and in fact is 1 if and only if $\mathcal{P} \rightarrow^{*} \mathcal{P}^{\prime} \in \downarrow c$ when writing $\mathcal{P} \rightarrow \mathcal{Q}$ instead of $\mathcal{P} \rightarrow_{\tau} \mathcal{Q}$.

We show in the following lemma that may testing and trace equivalence coincide in nonprobabilistic settings. In particular, we recover the fact that for the classical definitions in non-probabilisitic settings, trace equivalence implies may-testing.
Proposition 6. Let $\mathcal{P}, \mathcal{Q} \in \mathcal{M} \mathcal{P}^{\mathrm{np}}$.

$$
(\mathcal{P}, \varnothing) \leq_{t r}(\mathcal{Q}, \varnothing) \quad \text { iff }
$$

$$
\begin{aligned}
& \forall A d v \in \mathcal{M} \mathcal{P}^{\mathrm{np}} \text { s.t. } f n(A d v) \subseteq \mathcal{N}_{p u b} . \forall c \in \mathcal{N}_{p u b} . \\
& \operatorname{RProb}_{\mathcal{R}}(\mathcal{P} \cup A d v, \downarrow c) \leq \operatorname{RProb}_{\mathcal{R}}(\mathcal{Q} \cup A d v, \downarrow c)
\end{aligned}
$$

The proof of this result can be found in Appendix G.2.

### 6.2 May-testing and simulation coincide for bounded processes

To show that may-testing (with probabilistic adversaries) and simulation coincide for bounded non-probabilistic processes, i.e. in $\mathcal{M} \mathcal{P}^{<\infty, n p}$, we rely on a modal characterization of strong simulation on image finite LTS by a Hennessy-Milner logic. We can rely on simple LTS since we consider non-probabilistic processes (which implies that all distributions on the fragment of $\mathrm{N}^{\ell}$ with states labeled by non-probabilistic processes are Dirac distributions).

Definition 22. A LTS $\mathrm{L}=(\mathcal{S}, \mathcal{A}, \rightarrow)$ is image-finite when for every $s \in \mathcal{S}, a \in \mathcal{A}$, the set $\{t \mid s \xrightarrow{a} t\}$ is finite.

Note that even the fragment of $\mathrm{N}^{\ell}$ restricted to states in $\mathcal{S P}_{\ell}^{<\infty, n \mathrm{n}}$ is technically not image finite. Indeed, the $\tau$-action executing a restriction, i.e. new $a ; P$, may lead to infinitely many states (one for each fresh private name $a^{\prime}$ replacing $a$ ). However, as all these states (and subsequent states) are equal up to renaming, we can consider a fragment of $\mathrm{N}^{\ell}$ where we only allow a single transition for the rule (NEW) per occurrence of name restriction in a state.

Definition 23. We say that a NPLTS N is a new-determinization of $\mathrm{N}^{\ell}$ when $\mathrm{N}=$ ( $\mathcal{S}_{\mathrm{N}^{\ell}}, \mathcal{A}_{\mathrm{N}^{\ell}}$, trans) with the following constraints on trans:

- either $\operatorname{trans}((\mathcal{P}, \phi))(a)=\varnothing$ for $a \in \mathcal{A}_{\mathbb{N}^{\ell}} \backslash\{\tau\}$, and $\operatorname{trans}((\mathcal{P}, \phi))(\tau)$ is the singleton $\left\{\delta_{(\mathcal{Q}, \phi)}\right\}$ where $\mathcal{P} \rightarrow_{\tau} \delta_{\mathcal{Q}}$ by the rule (NEW)
- or $\operatorname{trans}((\mathcal{P}, \phi))=\operatorname{trans}_{\mathcal{N}^{e}}((\mathcal{P}, \phi))$ and for all $D \in \operatorname{trans}((\mathcal{P}, \phi))(\tau),(\mathcal{P}, \phi) \rightarrow_{\tau} D$ by any other rule than (NEW).

Though we use new-determinization primarily in this section for bounded processes to obtain the image-finite property, we can show that new-determinization preserves trace equivalence, simulation and bisimulation in general. The proof of the following lemma can be found in Appendix E.
Lemma 10. Let N be a new-determinization of $\mathrm{N}^{\ell}$.

$$
\leq_{t r}^{\mathrm{N}}=\leq_{t r}^{\mathrm{N}^{\ell}} \quad \text { and } \quad \leq_{s i m}^{\mathrm{N}}=\leq_{s i m}^{\mathrm{N}^{\ell}} \quad \text { and } \quad \approx_{b i}^{\mathrm{N}}=\approx_{b i}^{\mathrm{N}^{\ell}}
$$

It is a well-known fact ( Ama16]) that simulation for a LTS can be expressed as strong simulation on the corresponding weak LTS. Thus, when we only consider non-probabilistic processes, if we write $(\mathcal{P}, \phi) \xrightarrow{a}\left(\mathcal{P}, \phi^{\prime}\right)$ instead of $(\mathcal{P}, \phi) \rightarrow_{a} \delta_{\left(\mathcal{P}, \phi^{\prime}\right)}$ then we can build from a new-determinization of $\mathrm{N}^{\ell}$ a LTS where the transitions $(\mathcal{P}, \phi) \xrightarrow{\tau} \xrightarrow{*} \xrightarrow{\tau}{ }^{*}(\mathcal{Q}, \psi)$ are merged into a single transition.

Definition 24. Given a new-determinization $N$ of $N^{\ell}$, we define the LTS $L_{N}$ as follows: its states and actions set are the same as those of N , and its transition function is defined as: for all $a \in \mathcal{A}_{N^{\ell}},(\mathcal{P}, \phi) \xrightarrow{a} \mathrm{~L}_{\mathrm{N}}(\mathcal{Q}, \psi)$ when $(\mathcal{P}, \phi) \xrightarrow{\tau^{* a}} \xrightarrow{\tau}{ }^{*}(\mathcal{Q}, \psi)$ in N and $\mathcal{P}$ is nonprobabilistic.

Notice that the fragment of $\mathrm{L}_{N}$ restricted to states in $\mathcal{S P}_{\ell}^{<\infty, n \mathrm{p}}$ is image finite.
If we denote the strong simulation on the LTS L by $\leq_{\text {ssim }}^{\mathrm{L}}$, we obtain the following result.

Lemma 11. Let N be a new-determinization of $\mathrm{N}^{\ell}$. For all $\mathcal{P}, \mathcal{Q} \in \mathcal{M} \mathcal{P}^{\mathrm{np}}$, we have:

$$
(\mathcal{P}, \varnothing) \leq_{\text {sim }}^{\mathrm{N}}(\mathcal{Q}, \varnothing) \quad \text { iff } \quad(\mathcal{P}, \varnothing) \leq_{s s i m}^{\mathrm{L}_{N}}(\mathcal{Q}, \varnothing)
$$

Proof. The proof directly follows from the following two observations: for all $a \in \mathcal{A}_{\mathbb{N} \ell}$,

- $(\mathcal{P}, \phi) \xrightarrow{a} \mathrm{r} D$ implies that for all $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \in \operatorname{supp}(D),(\mathcal{P}, \phi) \xrightarrow{\tau}{ }^{*} \xrightarrow{\tau}{ }^{*}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$, and
- $(\mathcal{P}, \phi) \xrightarrow{\tau^{*}} \xrightarrow{\tau}{ }^{*}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ implies $(\mathcal{P}, \phi) \xrightarrow{a} \mathrm{r} \delta_{\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)}$.

For the remaining of this section, we fix a new-determinization of $N^{\ell}$ and denote by $\mathrm{L}^{\ell}$ its corresponding LTS. Moreover, we denote by $\mathrm{L}_{<\infty}^{\ell}$ the fragment of $\mathrm{L}^{\ell}$ restricted to bounded processes.

### 6.2.1 Hennessy-Milner logical characterization of strong simulation

Our Hennessy-Milner logical characterization consists in expressing strong simulation preorder by the means of satisfaction of logical formulas by the LTS.

Definition 25. Let $\mathcal{A}$ be a countable set of actions. We define the set of logical formulas as:

$$
F \in \mathcal{F}:=\top|a . F| F_{1} \wedge F_{2}, \quad \text { where } a \in \mathcal{A}
$$

In our case, the set of a actions will correspond to $\mathcal{A}_{\text {ext }}^{\ell}$ that is indeed countable. The satisfaction of such formulas by a LTS is defined as follows.

Definition 26. Let $\mathrm{L}=(\mathcal{S}, \mathcal{A}, \rightarrow)$ be a LTS. We say that L satisfies a formula $F$, written $s \models F$, if for all $s \in \mathcal{S}$,

- $s \models \mathrm{~T}$;
- $s \models a . F$ when there exists $t$ such that $s \xrightarrow{a} t$ and $t \models F$;
- $s \models F_{1} \wedge F_{2}$ when $s \models F_{1}$ and $s \models F_{2}$.

The following proposition shows how to relate strong simulation with satisfiability of logical formulas.

Proposition 7 (HML caracterisation of simulation). For an image-finite LTS L,

$$
s \leq_{s s i m}^{\mathrm{L}} t \quad \text { iff } \quad \forall F \in \mathcal{F} . s \models F \text { implies } t \models F
$$

Proof. In Ama16, this caracterisation can be found with infinite disjunction. Using the fact that the bisimulation operator on relation is co-continuous for image-finite LTS, (as stated and shown in Ama16]), we can show that the restriction to finite disjunction is sufficient. A generic proof of the finite-disjunction restriction for any modal caracterisation can be found in GF12].

In order to prove that simulation coincides with may-testing for bounded non-probabilisitic processes, we show that we can emulate any logical formula by a probabilistic adversary: for all formulas $F$, we build a probabilistic adversary $A d v$ such that for all extended processes $(\mathcal{P}, \phi), \mathcal{P} \cup\{\{A d v \phi\}$ exhibits the adversarial barb ok with probability 1 , if and only if the state $(\mathcal{P}, \phi)$ satisfies the formula $F$ in $\mathrm{L}^{\ell}$.

Definition 27. Let $F$ be a formula in $\mathcal{F}$, ok $\in \mathcal{N}_{p u b}$ such that $o k \notin f n(F)$ and $n \in \mathbb{N}$. We define $A d v_{F, n}^{o k}$ by induction on the syntax of $F$ :

- if $F=\top$ then $A d v_{F, n}^{o k}=\operatorname{out}(o k, o k)$.
- if $F=\operatorname{in}(\xi, \zeta) \cdot F^{\prime}$ then $A d v_{F, n}^{o k}=\operatorname{out}(\xi, \zeta) ; A d v_{F^{\prime}, n}^{o k}$ when $\operatorname{vars}(\xi, \zeta) \subseteq \mathcal{A} \mathcal{X}_{n}$ and $A d v_{F, n}^{o k}=0$ otherwise.
- if $F=\operatorname{out}(\xi, \mathrm{ax}) . F^{\prime}$ then $A d v_{F, n}^{o k}=\mathrm{in}(\xi, \mathrm{ax}) ; A d v_{F^{\prime}, n+1}^{o k}$ when $\mathrm{ax}=\mathrm{ax}_{n+1}, \operatorname{vars}(\xi) \subseteq$ $\mathcal{A} \mathcal{X}_{n}$ and $A d v_{F, n}^{o k}=0$ otherwise.
- if $F=(\xi \stackrel{?}{=} \zeta) \cdot F^{\prime}$ then $A d v_{F, n}^{o k}=$ if $\xi=\zeta$ then $A d v_{F^{\prime}, n}^{o k}$ else 0 when $\operatorname{vars}(\xi, \zeta) \subseteq \mathcal{A} \mathcal{X}_{n}$ and $A d v_{F, n}^{o k}=0$ otherwise.
- if $F=(\xi \stackrel{?}{\neq} \zeta) \cdot F^{\prime}$ then $A d v_{F, n}^{o k}=$ if $\xi=\zeta$ then 0 else $A d v_{F^{\prime}, n}^{o k}$ when $\operatorname{vars}(\xi, \zeta) \subseteq \mathcal{A} \mathcal{X}_{n}$ and $A d v_{F, n}^{o k}=0$ otherwise.
- if $F=F_{1} \wedge F_{2}$, then $A d v_{F, n}^{o k}=A d v_{F_{1}, n}^{o k}+\frac{1}{2} A d v_{F_{2}, n}^{o k}$.

In Definition 27, the integer $n$ and the conditions on the variables of $\xi, \zeta$ ensure that the adversarial process $A d v_{F, n}^{o k}$ is closed (no free variables). This is not a restriction as ( $\mathcal{P}, \varnothing) \models F$ implies that $F$ satisfies these conditions.

Lemma 12. Let $\mathcal{P} \in \mathcal{M} \mathcal{P}^{\mathrm{np}}$ and $o k \in \mathcal{N}_{\text {pub }}$ such that $o k \notin f n(\mathcal{P})$. For all formula $F \in \mathcal{F}$, we have

$$
(\mathcal{P}, \varnothing) \models F \quad \text { iff } \quad \operatorname{RProb}_{\mathcal{R}_{r}}\left(\mathcal{P} \cup\left\{\left\{A d v_{F, 0}^{o k}\right\}, \downarrow o k\right)=1\right.
$$

The proof of Lemma 12 can be found in Appendix G.1. Notice that the lemma in fact also holds for processes with replication. The main result of this section follows almost directly.

Proposition 8. Let $\mathcal{P}, \mathcal{Q} \in \mathcal{M} \mathcal{P}^{<\infty, n p}$.

$$
(\mathcal{P}, \varnothing) \leq_{\text {sim }}^{\mathrm{N}^{\ell}}(\mathcal{Q}, \varnothing) \quad \text { iff } \quad \mathcal{P} \leq_{\text {may }} \mathcal{Q}
$$

Proof. Suppose $(\mathcal{P}, \varnothing) \leq_{\text {sim }}^{\mathcal{N}^{\ell}}(\mathcal{Q}, \varnothing)$. By Proposition 5. $\mathcal{P} \leq_{\text {obs }}^{\mathcal{R}_{r}} \mathcal{Q}$, which implies $\mathcal{P} \leq_{\text {may }} \mathcal{Q}$ by definition.

Let us now assume $\mathcal{P} \leq_{\text {may }} \mathcal{Q}$. From Lemmas 10 and 11 , we know that $(\mathcal{P}, \varnothing) \leq_{\text {sim }}^{\mathrm{N}^{\ell}}$ $(\mathcal{Q}, \varnothing)$ if and only if $(\mathcal{P}, \varnothing) \leq_{\text {ssim }}^{\mathrm{L}^{\ell}}(\mathcal{Q}, \varnothing)$. Moreover, since $\mathcal{P}$ and $\mathcal{Q}$ are bounded, we deduce that $(\mathcal{P}, \varnothing) \leq_{s s i m}^{\mathrm{N}^{\ell}}(\mathcal{Q}, \varnothing)$ if and only if $(\mathcal{P}, \varnothing) \leq_{s s i m}^{\mathrm{L}_{<\infty}^{\ell}}(\mathcal{Q}, \varnothing)$. As $\mathrm{L}_{<\infty}^{\ell}$ is image finite, we can rely on Proposition 7 to obtain that $(\mathcal{P}, \varnothing) \leq_{s s i m}^{\mathrm{L}^{\ell}<\infty}(\mathcal{Q}, \varnothing)$ if and only if for all $F \in \mathcal{F}$, $(\mathcal{P}, \varnothing) \models F$ implies $(\mathcal{Q}, \varnothing) \models F$. Therefore, let $F \in \mathcal{F}$ such that $(\mathcal{P}, \varnothing) \models F$. We take $o k \in \mathcal{N}_{\text {pub }}$ such that ok $\notin f n(F, \mathcal{P}, \mathcal{Q})$. By Lemma 12 , we have $\operatorname{RProb}_{\mathcal{R}_{r}}\left(\mathcal{P} \cup\left\{\left\{A d v_{F, 0}^{o k}\right\}, \downarrow\right.\right.$ $o k)=1$. Since $\mathcal{P} \leq$ may $^{\mathcal{Q}}$, we deduce that $\operatorname{RProb}_{\mathcal{R}_{r}}\left(\mathcal{Q} \cup\left\{\left\{A d v_{F, 0}^{o k}\right\}, \downarrow o k\right)=1\right.$ and so $(\mathcal{Q}, \varnothing) \models F$ once again by Lemma 12 .

### 6.2.2 Complexity

Cheval et al. have shown CKR18 that both deciding trace equivalence and bisimilarity is coNEXPTIME complete when cryptographic primitives are modelled by a subterm convergent destructor rewrite system and the number of sessions is bounded. (We refer the reader to [CKR18] for a precise definition of this class of rewrite systems.) The hardness proof reduces Succint 3Sat to both trace equivalence and bisimilarity using a same encoding which also proofs hardness of similarity. The coNEXPTIME decision procedure for bisimilarity can be directly adapted to the case of similarity, hence, by Proposition 8 we have the following result.

Corollary 1. Let $\mathcal{P}, \mathcal{Q} \in \mathcal{M} \mathcal{P}^{<\infty, n p}$. Deciding $\mathcal{P} \approx_{\text {may }} \mathcal{Q}$ is coNEXPTIME complete when $\doteq$ is defined by a subterm convergent destructor rewrite system.

### 6.3 May-testing and simulation do not coincide for unbounded processes

To prove that may-testing and simulation do not coincide for processes with replication, we consider the following two $\operatorname{LTS} \mathrm{L}_{1}$ and $\mathrm{L}_{2}$, that are an asymetric variant of the LTSs used in vG87 to show that the finitary Hennessy-Milner logic from Definition 26 do not caracterise bisimulation.

Though both $L_{1}$ and $L_{2}$ may produce an unbounded number of $a$ transitions, the initial transition in $L_{2}$ decides on an arbitrary, but fixed number of $a$ transitions in the rest of the execution. This in particular shows that $L_{2}$ does not simulate $L_{1}$, i.e. $L_{1} \not Z_{\text {sim }} L_{2}$.

In the applied pi calculus, $\mathrm{L}_{1}$ can be represented by the process !out $(c, a)$. Modeling $\mathrm{L}_{2}$ in the applied pi calculus is more complex as it requires to non-deterministically choose an integer $n \geq 0$, before outputting $n+1$ times $a$. To non deterministically choose $n$, we rely on the following process that outputs $n$ encoded in unary as $h^{n}(b)$ :

$$
Q_{\text {count }}(e)=\operatorname{new} d .(\operatorname{out}(d, b) \mid!\operatorname{in}(d, x) .(\operatorname{out}(e, x)+\operatorname{out}(d, h(x))))
$$

Intuitively, the channel $d$ represents a memory cell initiated with a public name $b$ (encoding 0 ). When reading on channel $d$ the current value $x$, the process non deterministically chooses to increment $x$ (updating the cell with $h(x)$ ) or to select the value $x$ by outputting it on channel $e$.

It remains to model the process that given an integer $x$, produces $x+1$ outputs of $a$ :

$$
Q_{\text {out }}(e)=\operatorname{new} d^{\prime} \cdot \operatorname{in}(e, x) \cdot\left(\operatorname{out}\left(d^{\prime}, b\right) \mid!\operatorname{in}\left(d^{\prime}, y\right) . \text { out }(c, a) . \text { if } x=y \text { then } 0 \text { else out }\left(d^{\prime}, h(y)\right)\right)
$$

Similarly to $Q_{\text {count }}(e), Q_{\text {out }}(e)$ relies on a private $d^{\prime}$ to increament $b$ until reaching the value $x$ read on $e$. It is easy to see that the process outputs $x+1$ times $a$.

Lemma 13. Let $Q=$ new $e .\left(Q_{\text {count }}(e) \mid Q_{\text {out }}(e)\right)$. We have:

$$
(!\text { out }(c, a), \varnothing) \not \not 又 \text { sim }_{\mathrm{N}^{\ell}}(Q, \varnothing) \quad \text { but } \quad \text { out }(c, a) \leq_{\text {may }} Q
$$

Proof. To show that $(!\operatorname{out}(c, a), \varnothing) \mathbb{Z}_{\text {sim }}^{\mathrm{N}^{\ell}}(Q, \varnothing)$, we rely on the same idea used to show that $\mathrm{L}_{1} \not \leq_{\text {sim }} \mathrm{L}_{2}$. Before the first output on $c$, the process $Q$ must produce a communication on $e$, hence fixing the value of $x$ used in $Q_{\text {out }}(e)$ which bounds the number of following outputs on $c$ by $x+1$. As !out $(c, a)$ may output on $c$ an unbounded number of times, we conclude.

To prove that $\operatorname{lout}(c, a) \leq_{\text {may }} Q$, we need to show that for all $A d v \in \mathcal{M P}$, for all $c h \in \mathcal{N}_{p u b}$, if $f n(A d v) \subseteq \mathcal{N}_{p u b}$ then $\operatorname{RProb}_{\mathcal{R}}(\{\{!$ out $(c, a)\}\} \cup A d v, \downarrow c h) \leq \operatorname{RProb}_{\mathcal{R}}(\{\{Q\} \cup$
$A d v, \downarrow c h)$. Let $\mathcal{P}=\{!$ !out $(c, a)\}$. By unfolding the definition of $\operatorname{RProb}_{\mathcal{R}}(\mathcal{P} \cup A d v, \downarrow c h)$, we know that:

$$
\begin{aligned}
& \operatorname{RProb}_{\mathcal{R}}(\mathcal{P} \cup A d v, \downarrow c h)=\sup _{\substack{\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}, \operatorname{corrr}_{\mathrm{R}}, \text { trans }_{\mathrm{R}}\right) \in \mathcal{R} \\
\text { corrren } \\
(s)=\mathcal{P} \cup A d v}} \operatorname{RProb}_{\mathrm{R}}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\downarrow c h)\right) \\
& =\sup _{\substack{\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}, \text { corrp }_{\mathrm{R}}, \text { trans } \\
\text { corr }\right) \in \mathcal{R}}} \sup _{n \in \mathbb{N}} \operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\downarrow c h)\right)
\end{aligned}
$$

Let $\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $\left._{\mathrm{R}}, \operatorname{trans}_{\mathrm{R}}\right) \in \mathcal{R}, s \in \mathcal{S}_{\mathrm{R}}$ such that $\operatorname{corr}_{\mathrm{R}}(s)=\mathcal{P} \cup A d v$ and let $n \in \mathbb{N}$. By definition, the number of transitions from $s$ in the computation of $\operatorname{RProb}_{\bar{R}}^{\leq n}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\downarrow\right.$ $c h)$ ) is bounded by $n$. Thus, the resolution R may at most unfold $n$ times the process !out $(c, a)$. By denoting $P^{n}=\underbrace{\operatorname{out}(c, a) ; \ldots ; \operatorname{out}(c, a)}_{n \text { times }}$, we can therefore easily build a reso-
lution $\mathrm{R}^{\prime}=\left(\mathcal{S}_{\mathrm{R}^{\prime}}\right.$, corr $_{\mathrm{R}^{\prime}}$, trans $\left._{\mathrm{R}^{\prime}}\right) \in \mathcal{R}$ and $s^{\prime} \in \mathcal{S}_{\mathrm{R}^{\prime}}$ such that $\operatorname{corr}_{\mathrm{R}}\left(s^{\prime}\right)=\left\{\left\{P^{n}\right\} \cup A d v\right.$ and $\operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\downarrow c h)\right)=\operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(s^{\prime}, \operatorname{corr}_{\mathrm{R}^{\prime}}^{-1}(\downarrow c h)\right)$.

However, one can easily show that $\left(P^{n}, \varnothing\right) \leq_{\text {sim }}^{N^{\ell}}(Q, \varnothing)$ ( $Q$ only needs to choose integer $n-1$ to output exactly $n$ times $a$ ). Since, by Proposition 5 , simulation implies may-testing, we have:

$$
\sup _{\mathbb{R}^{\prime}=\left(\mathcal{S}_{R^{\prime}}, \operatorname{corr}_{\mathbb{R}^{\prime}}, \operatorname{trans}_{\mathcal{R}^{\prime}}\right) \in \mathcal{R}} \sup _{n^{\prime} \in \mathbb{N}} \operatorname{RProb}_{\mathrm{R}^{\prime}}^{\leq n^{\prime}}\left(s^{\prime}, \operatorname{corr}_{\mathrm{R}^{\prime}}^{-1}(\downarrow c h)\right) \leq \operatorname{RProb}_{\mathcal{R}}(\{Q\} \cup A d v, \downarrow c h)
$$

By selecting $n^{\prime}=n$, we deduce that $\operatorname{RProb}_{\mathrm{R}^{\prime}}^{\leq n}\left(s^{\prime}, \operatorname{corr}_{\mathrm{R}^{\prime}}^{-1}(\downarrow c h)\right) \leq \operatorname{RProb}_{\mathcal{R}}(\{\{Q\} \cup A d v, \downarrow c h)$ and so $\operatorname{RProb}_{\bar{R}}^{\leq n}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\downarrow c h)\right) \leq \operatorname{RProb}_{\mathcal{R}}(\{Q\} \cup \mathcal{R})(\downarrow v, \downarrow c h)$. It allows us to conclude that $\operatorname{RProb}_{\mathcal{R}}(\mathcal{P} \cup A d v, \downarrow c h) \leq \operatorname{RProb}_{\mathcal{R}}(\{\{Q\} \cup A d v, \downarrow c h)$.

## 7 Fully Probabilistic Agents Communicating on Public Channels

We now do a formal comparaison with the probabilistic concurrent systems considered in CSV17, BCSV18. They consider systems that are build as the parallel compositions of independant agents, called roles, that are not able to communicate directly with each others: all communications are mediated by the adversary. Moreover, there is no nondeterminism in the internal behavior of a role; the only non-determinism is controlled by the adversary-thus external-and consists in the adversary's choice for managing the communications.

Definition 28. We say that a process $\mathcal{P}=\left\{\mathcal{P}_{1}, \ldots, \mathcal{P}_{n}\right\} \in \mathcal{M P}$ is fully probabilistic (FP) when:

- there is no non-deterministic choice $+\operatorname{in} \mathcal{P}_{i}$, and no parallel composition $\mid$ and no !;
- there exists a list $u_{1}, \ldots, u_{n}$ of public channels such that all input and output actions in $\mathcal{P}_{i}$ are only done on $u_{i}$.

Notation 11. For a FP process $Q=Q_{1}|\ldots| \ldots Q_{m}$, and $j \in\{1, \ldots, m\}$, we write out $\left(c_{j}, t\right) \cdot Q$ and $\operatorname{in}\left(c_{j}, x\right) \cdot Q$ for $\left(Q_{1}|\ldots| \operatorname{out}\left(c_{j}, t\right) \cdot Q_{j} \mid \ldots Q_{m}\right)$ and $\left(Q_{1}|\ldots| \operatorname{in}\left(c_{j}, x\right) \cdot Q_{j} \mid\right.$ $\left.\ldots Q_{m}\right)$ respectively.

Remark 11. Observe that when looking at the un-labelled semantics for a component $\mathcal{P}_{i}$ without the syntaxic constructs + and $\mid$, the only source of non-determinism in $\xrightarrow{\tau}$ comes from new -redexes. To overcome this residual non-determinism, we replace as in Section 6 the NPLTS $\mathrm{N}^{\ell}$ by a strict new -determinization of $\mathrm{N}^{\ell}$. In the present section, by abuse of notation, we will write $\mathrm{N}^{\ell}$ for an (arbitrary) new -determinization of $\mathrm{N}^{\ell}$.

In CSV17, BCSV18, the authors consider the trace equivalence for a restricted fragments of FP processes. More precisely, their processes have a constrained shape, used to suppress the necessity of scheduling decisions for inteleaving of honest $\tau$-actions, and thus ensure that weak trace equivalence and strong trace equivalence coincide.

Remark 12. Observe that at this point, fully probabilistic processes have no replication. As a consequence, whenever $s \stackrel{\tau}{\Rightarrow} E$, it is actually a finite scheme, and the sub-distribution $E$ is actually a proper distribution.

### 7.1 Removing residual non-determinism

In this section, we are interested in the fragment of $\mathrm{N}^{\ell}$ whose states are of the form $(\mathcal{P}, \phi)$, with $\mathcal{P}$ a FP processes. Observe that this fragment has still internal non-determinism, since starting from a state $\left(P_{1}|\ldots| P_{n}, \phi\right)$, it can be possible to do a $\tau$ action either in a component $P_{i}$, or in a component $P_{j}$. However, this internal non-determinism is much more limited that for general processes: indeed, intuitively, that we chose to reduce first $P_{i}$ or first $P_{j}$ will not have an effect on the resulting trace equivalence. In this section, we formalize this intuition by transfering known confluence results from (non-probabilistic) abstract rewriting systems to NPLTSs.

The first step consists in building, from any NPLTS N with only one action $\{\tau\}$, an abstract rewriting system $\overline{\mathrm{N}}$ by moving all information about probabilities from transition to states.

Definition 29. Let $\mathrm{N}=\left(\mathcal{S},\{\tau\}, h_{\tau}\right)$ be a NPLTS. We define (non-probabilistic) abstract rewriting system $\overline{\mathrm{N}}$-i.e. a LTS with only one action $\tau$-as follows:

- its set of states is $\left\{\mu=\left[\left(\alpha_{1}, s_{1}\right), \ldots\left(\alpha_{n}, s_{n}\right)\right] \in \mathcal{M}_{\text {fin }}([0,1] \times \mathcal{S}) \mid \sum \alpha_{i}=1\right\}$.
- its only action is $\tau$;
- the transition function $\xrightarrow{\tau}$ is defined as follows:

$$
\frac{s \rightarrow_{\mathrm{N}} E \quad(\alpha, s) \in \operatorname{Support}(\mu)}{\mu \xrightarrow[\tau]{\tau}_{\overline{\mathrm{N}}} \cup_{t \in \operatorname{Support}(D)}\{\{(\alpha \cdot D(t), t)\} \cup \mu \backslash\{(\alpha, s)\}\}} .
$$

We formalize in Lemma 14 below how we can recover informations about probabilistic executions in a NPLTS N by looking at (non-probabilistic) execution in the abstract rewriting system $\bar{N}$. Here, it should be observed that this correspondance holds only when N has no infinite sequence.

Lemma 14. Let N be a NPLTS with only one $\tau$ action and no infinite sequence, $s$ be a state in $\mathrm{N}, A \subseteq \mathcal{S}_{\text {ext }}(\mathrm{N})$ a set of external states, and $\alpha \in[0,1]$. Then there exists a non-randomized (maximal) resolution $\mathrm{R} \in \mathcal{R}_{\mathrm{nr}}(\mathrm{N})$ such that $\operatorname{RProb}_{\mathrm{R}}\left(s, \operatorname{corr}^{-1}(A)\right)=\alpha$ if and only if there is a finite (maximal) sequence $\sigma:=\left\{\{(1, s)\} \xrightarrow{\tau}_{\bar{N}} \mu_{1} \xrightarrow{\tau}_{\bar{N}} \ldots \mu_{n}\right.$, and $\alpha=\sum_{i, t_{i} \in A} \alpha_{i}$ with $\mu_{n}=\left\{\left(\alpha_{1}, t_{1}\right), \ldots,\left(\alpha_{m}, t_{m}\right)\right\}$.

Proof. $\Rightarrow$ : Let $\mathrm{R} \in \mathcal{R}_{\mathrm{nr}}(\mathrm{N}), s_{\mathrm{R}} \in \mathcal{S}_{\mathrm{R}}$ with $\operatorname{corr}_{\mathrm{R}}\left(s_{\mathrm{R}}\right)=s$, and such that $\operatorname{RProb}_{\mathrm{R}}\left(s_{\mathrm{R}}, \operatorname{corr}^{-1}(A)\right)=$ $\alpha$. Since $\mathbf{N}$ has no infinite sequence, there exists $n \in \mathbb{N}$ such that $\operatorname{RProb}_{\bar{R}}^{\leq n}\left(s_{\mathrm{R}}, \operatorname{corr}^{-1}(A)\right)=$ $\alpha$, and when R is maximal, we can moreover require that $\left\{t \mid \operatorname{RProb}_{\mathrm{R}}^{\leq_{\mathrm{R}}}{ }^{-n}\left(s_{\mathrm{R}}, t\right)>0\right\} \subseteq$ $\left\{u \mid \operatorname{corr}_{\mathrm{R}}(u) \in \mathcal{S}_{\text {ext }}(\mathrm{N})\right\}$. We build a reduction sequence $\mu_{0}=\left\{\{(1, s)\} \xrightarrow{\tau}_{\overline{\mathrm{N}}} \mu_{1} \stackrel{\tau}{\tau}_{\bar{N}}\right.$ $\ldots \mu_{n}$ in $\overline{\mathrm{N}}$ by first defining a family $\left(\rho_{j}\right)_{j \in \mathbb{N}}$ as $\rho_{j}:=\left\{\left\{\left(D_{j}(u), \operatorname{corr}_{\mathrm{R}}(u)\right) \mid u \in \mathcal{S}_{\mathrm{R}}\right\}\right.$, with $D_{j}$ the distribution obtained after $j$ steps from $s^{\prime}$ in R . Then we can observe that for every $j \in \mathbb{N}$, it holds that there exists a $N$ such that $\rho_{j} \rightarrow \frac{N}{N} \rho_{j+1}$, and from there we have the result. Moreover, if R is maximal, $\operatorname{Support}\left(D_{n}\right) \subseteq\left\{u \mid \operatorname{corr}_{\mathrm{R}}(u) \in \mathcal{S}_{\text {ext }}(\mathrm{N})\right\}$, thus $\rho_{n}$ is a normal form in $\overline{\mathrm{N}}$.
$\Leftarrow$ : Let $\sigma$ be a reduction sequence $\mu_{0}=\left\{\{(1, s)\} \xrightarrow{\tau}_{\bar{N}} \mu_{1} \xrightarrow{\tau}_{\bar{N}} \ldots \mu_{n}\right.$ in $\overline{\mathrm{N}}$. We build a resolution $\mathrm{R} \in \mathcal{R}_{\mathrm{nr}}(\mathrm{N})$ by induction on $n$ :

- if $n=0$, the resolution has only one state $s^{\prime}$ with $\operatorname{corr}_{\mathrm{R}}\left(s^{\prime}\right)=s$. Moreover, if $\mu_{n}=\mu_{0}$ is a normal form in $\overline{\mathrm{N}}$, it means that $s$ is an external state in N , thus R is a maximal resolution.
- Suppose that the result holds for $n \in \mathbb{N}$. Let $\sigma:=\mu_{0}=\{(1, s)\} \xrightarrow{\tau}_{\bar{N}} \mu_{1} \xrightarrow{\tau}_{\bar{N}}$ $\ldots \mu_{n+1}$. We write $\mu_{1}=\left\{\left(\alpha_{1}, s_{1}\right), \ldots\left(\alpha_{m}, s_{m}\right)\right\}$. Looking at the definition of the ARS $\overline{\mathrm{N}}$, we see that we can split $\sigma$ into $m$ sequences $\left\{\left(1, s_{i}\right)\right\} \xrightarrow{{ }^{\tau}} \overline{\mathrm{N}} \rho_{1}^{i} \xrightarrow{\tau} \overline{\mathrm{~N}}$ $\ldots \rho_{N_{i}}^{i}$, with $N_{i} \leq n$, and $\left.\mu_{n}=\left\{\left(\alpha_{i} \cdot \beta, s\right) \mid i \in\{1, \ldots, m\},(\beta, s) \in \rho_{N_{i}}^{i}\right\}\right\}$. From there, we can apply the induction hypothesis, and we obtain a resolution $\mathrm{R}_{i}$ for $i \in\{1, \ldots, m\}$, and a $s_{i}^{\prime} \in \mathcal{S}_{\mathrm{R}_{i}}$ with $\operatorname{corr}_{\mathrm{R}_{i}}\left(s_{i}^{\prime}\right)=s_{i}$. We can suppose that the $\mathcal{S}_{\mathrm{R}_{i}}$ are all disjoints. From there, we build a resolution R as the disjoint union of all $\mathrm{R}_{i}$, plus a fresh state $s_{0}^{\prime}$ with $\operatorname{corr}\left(s_{0}^{\prime}\right)=s$, and $\operatorname{trans}_{\mathrm{R}}\left(s_{0}^{\prime}\right)=\sum \alpha_{i} \cdot \delta_{s_{i}^{\prime}}$. Moreover, if $\mu_{n}=$ is a normal form in $\overline{\mathrm{N}}$, then also the $\rho_{N_{i}}^{i}$ are normal from: it means that the induction hypothesis tolds us that each of the $\mathrm{R}_{i}$ is maximal, and from there we can conclude that R also is maximal.

In the next step, we show that confluence and termination properties are passed down from N to $\overline{\mathrm{N}}$. We are interested in these properties, because it is a well-known result of the literature on abstract rewriting system (Newmann's Lemma) that a ARS with no infinite
sequence and locally confluent is normalizing, i.e. each state has exactly one normal form.

Lemma 15. Let N a NPLTS with no infinite sequence (that is there is no $s_{1}, s_{2}, \ldots$ such that for all $i \in \mathbb{N}, s_{i} \rightarrow_{\mathrm{N}} D_{i}$, and $s_{i+1} \in \operatorname{Support}\left(D_{i}\right)$, and which is locally confluent (i.e. for any $s \in \mathcal{S}_{\mathrm{N}}, D_{1}, D_{2}$ such that $s \xrightarrow{\tau}_{\mathrm{N}} D_{1}$, and $s \xrightarrow{\tau} D_{2}$, then there exists $E$ such that $D_{1} \rightarrow{ }_{n r}^{\leq 1} E$ and $D_{2} \Rightarrow{ }_{n r}^{\leq 1} E$ ). Then the abstract rewriting system $\overline{\mathrm{N}}$ also has also infinite sequence and is locally confluent.

Proof. - Let N be a NPLTS with no infinite sequence. We prove by contradiction that also $\overline{\mathrm{N}}$ has no infinite sequence: suppose that $\overline{\mathrm{N}}$ has an infinite sequence $\sigma:=$ $\mu_{0} \xrightarrow{\tau} \mu_{1} \xrightarrow{\tau} \mu_{2} \ldots$. We write $\mu_{0}=\left\{\left(\alpha_{1}, s_{1}\right), \ldots,\left(\alpha_{n}, s_{n}\right)\right\}$. Looking at the definition of $\overline{\mathrm{N}}$, we see that we can extract from $\sigma$ a $s_{i}$, and an infinite reduction sequence
 sequence on N , and it ends the proof.

- Let N be a locally confluent NPLTS. We prove that also $\overline{\mathrm{N}}$ is locally confluent. We suppose $D, E_{1}, E_{2}$ such that $D \xrightarrow{\tau} E_{1}$, and $D \xrightarrow{\tau} E_{2}$. Looking at Definition 29, it means that there exists $\left(s_{1}, w_{1}\right),\left(s_{2}, w_{2}\right) \in \operatorname{Support}(D)$ such that $\left(s_{i}, w_{i}\right) \xrightarrow{\tau}{ }_{\mathrm{N}^{t r}} F_{i}$, and $E_{i}=D\left(s_{i}, w_{i}\right) \cdot F_{i}+D_{\mid \mathcal{S} \backslash\left(s_{i}, w_{i}\right)}$ for $i \in\{1,2\}$. There are two possible cases:
- either $\left(s_{1}, w_{1}\right) \neq\left(s_{2}, w_{2}\right)$, and in this case $F_{i} \xrightarrow{\tau}_{\overline{N^{\ell}}} \sum_{i \in\{1,2\}} D\left(s_{i}, w_{i}\right) \cdot F_{i}+$ $D_{\mid \mathcal{S} \backslash\left\{\left(s_{i}, w_{i}\right) \mid i \in\{1,2\}\right\}}$ for every $i \in\{1,2\}$, thus we can conclude.
- or $\left(s_{1}, w_{1}\right)=\left(s_{2}, w_{2}\right)$. In this case, we can use the fact that by hypothesis N is confluent, thus there exists $E_{3}$ such that $D_{1} \xrightarrow{\tau} D_{3}$ and $D_{2} \xrightarrow{\tau} D_{3}$, and we can conclude from there.

Proposition 9. Let N be a NPLTS with only one $\tau$ action, that has no infinite sequence, and which is locally confluent. Let $A \subseteq \mathcal{S}_{\text {ext }}(\mathrm{N})$. Then for any maximal resolution R in $\mathcal{R}_{\mathrm{nr}}(\mathrm{N})$ it holds that:

$$
\operatorname{RProb}_{\mathrm{R}}\left(s_{\mathrm{R}}, \operatorname{corr}_{\mathrm{R}}^{-1}(A)\right)=\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}(\mathrm{~N})}\left(\operatorname{corr}_{\mathrm{R}}\left(s_{\mathrm{R}}\right), A\right) .
$$

Proof. Let $A \subseteq \mathcal{S}_{e x t}(\mathbb{N})$. If $\rho=\left\{\left(\alpha_{1}, t_{1}\right), \ldots,\left(\alpha_{m}, t_{m}\right)\right\} \in \mathcal{S}_{\overline{\mathrm{N}}}$, we write $\rho(A):=\sum_{j \text { s.t. } t_{j} \in A} \alpha_{j}$. Let $\mathrm{R}_{1}$ in $\mathcal{R}_{\mathrm{nr}}(\mathrm{N})$ be a maximal resolution, and $\mathrm{R}_{2} \in \mathcal{R}_{\mathrm{nr}}(\mathrm{N})$ any resolution. Then we obtain by Lemma 14 two finite sequences $\sigma^{i}:=\left\{\left\{\left(1, s^{i}\right)\right\} \xrightarrow{\tau}_{\bar{N}} \mu_{1}^{i} \xrightarrow[\rightarrow]{\tau}_{\bar{N}} \ldots \mu_{n^{i}}^{i}\right.$, and $\operatorname{RProb}_{\mathrm{R}_{i}}\left(s^{i}, \operatorname{corr}_{\mathrm{R}_{i}}^{-1}(A)\right)=\sum_{j \text { s.t. } t_{j}^{i} \in A} \alpha_{j}^{i}$ with $\mu_{n^{i}}^{i}=\left\{\left(\alpha_{1}^{i}, t_{1}^{i}\right), \ldots,\left(\alpha_{m^{i}}^{i}, t_{m^{i}}^{i}\right)\right\}$ for $i \in\{1,2\}$. Moreover, since $R_{1}$ is maximal, $\mu_{n^{1}}^{1}$ is a normal form for $\bar{N}$. Using Lemma 15 and Newmann's Lemma, we can see that $\overline{\mathrm{N}}$ is strongly normalizing, thus $\mu_{n^{2}}^{2} \xrightarrow{\tau}{ }_{\bar{N}} \mu_{n^{1}}^{1}$. In order to conclude, it is enough to see that ince $A \subseteq \mathcal{S}_{\text {ext }}(\mathrm{N}), \rho \stackrel{\tau}{\Rightarrow}{ }_{\overline{\mathrm{N}}} \rho^{\prime}$ implies that $\rho(A) \leq \rho^{\prime}(A)$.

### 7.1.1 Determinizing may-testing for FP processes

Proposition 10. Let $P$ be an FP process, $\phi$ a frame and $A d v$ a fully determinate adversary. Let $A$ be a target subset of states of the form $P^{\prime} \cup A d v^{\prime}$, with $P^{\prime}$ a FP process, and $A d v^{\prime}$ a fully deterministic adversary. Then for any maximal non-randomized resolution R on $\mathrm{N}^{o}$ :

$$
\operatorname{RProb}_{\mathrm{R}}(P \cup A d v, A)=\operatorname{RProb}_{\mathcal{R}_{\mathrm{r}}\left(\mathbb{N}^{o}\right)}(P \cup A d v, A)
$$

Proof. We first define a NPLTS $\left(\mathrm{N}^{o}\right)_{A}$ we obtain from $\mathrm{N}^{o}$ as follows:

- We remove all transitions starting from states $a \in A$;
- we add a state success, and from each state $a \in A$, we add the transition $a \rightarrow \delta_{\text {success }}$

We can see that to each resolution $R$, we can associate a resolution $R_{A}$ on such that:

$$
\operatorname{RProb}_{\mathrm{R}}(P \cup A d v, A)=\operatorname{RProb}_{\mathrm{R}_{A}}(P \cup A d v, \text { success })
$$

Since neither FP processes nor fully deterministic adversaries have !, the (smallest) fragment of $\mathrm{N}^{\circ}$ containing them has no infinite reduction sequence, and moreover using the fact that we have no meaningful non-determinism, we can show that $\mathrm{N}^{o}$ is locally confluent. As a consequence, it is also the case for $\left(\mathrm{N}^{o}\right)_{A}$. From there-and using the fact that $A$ is a set of external states for $\left(\mathrm{N}^{o}\right)_{A}$, we can conclude as a direct consequence of Proposition 9 .

### 7.1.2 On trace equivalence for FP processes

It is possible to caracterise trace equivalence as the probility of reaching a particular external state success on a NPLTS $\left(\mathrm{N}^{\ell}\right)^{t r}$ with only one $\tau$ action, built from $\mathrm{N}^{\ell}$. The construction is done in Definition 33 in Section B.1, and the caracterisation is shown in Lemma 22. Since FP processes have no!, the FP fragment of $\mathrm{N}^{\ell}$ has no infinite reduction sequences labelled by $\tau$, and moreover is locally confluent. Looking at the way we defined $\left(\mathrm{N}^{\ell}\right)^{t r}$, we say that our construction preserves these properties.

As a corollary, and using Lemma 21, we obtain that we can caracterise the trace preorder using the ARS $\overline{\left(\mathrm{N}^{\ell}\right)^{t r}}$.

Proposition 11. For any non-randomized maximal resolution R on $\mathrm{N}^{\ell}$ :

$$
\forall s \in \mathcal{S}_{\mathrm{R}}, \forall w \in \mathcal{A}_{e x t}^{\star}, \operatorname{Prob}_{\mathrm{R}}(s, w)=\operatorname{Prob}_{\mathcal{R}_{\mathrm{r}}^{\ell}}\left(\operatorname{corr}_{\mathrm{R}}(s), w\right)
$$

Proof. First, observe that the FP fragment of $\mathrm{N}^{\ell}$ has no infinite $\tau$-reduction sequence, and is locally confluent. Then, we can see that those properties can be passed down to $\left(\mathrm{N}^{\ell}\right)^{t r}$. From there, we can conclude as a direct consequence of the caracterisation of the success probability of reaching a trace from Lemma 22, and Proposition 9 ,

Remark 13. The proofs in the present section uses heavily the fact that there is no replication into FP-processes. Indeed, suppose that we consider instead processes of the form $\mathcal{P}_{1}|\ldots| \mathcal{P}_{n}$, where the processes $\mathcal{P}_{i}$ have no non-determinism, but can implement
recursion, then Proposition 11 would fail. It is because maximal resolutions can then lead to non-optimal strategies, where non-essential part of the system can execute a loop infinitely often. Nonetheless, we believe that is possible-for a given trace $w$-to build one optimal resolution $\mathrm{R}_{w}$ that would maximise $\operatorname{Prob}_{\mathrm{R}}(s, w)$ for each process $s$, thus allowing us to remove non-determinism in computing the success probability for traces.

### 7.2 May testing equivalence of FP processes with unrestricted adversary.

As shown by the following example, even on [CSV17, BCSV18]'s fragment, trace equivalence do not coincide with may testing equivalence.

Example 4. Consider again the two processes of Example 3.

$$
\begin{aligned}
P:= & (\operatorname{in}(c, x) . \text { if } x=0 \text { then out }(c, o k) \text { else out }(c, b a d))+{ }^{1 / 2} \\
& (\text { in }(c, x) . \text { if } x=0 \text { then out }(c, b a d) \text { else out }(c, o k)) \\
Q:= & \operatorname{in}(c, x) \cdot\left(\operatorname{out}(c, o k)+{ }^{1 / 2} \operatorname{out}(c, b a d)\right)
\end{aligned}
$$

We have already shown in Example 3 that they are not testing equivalent (using a nondeterminate adversary). We can however show easily that $(P, \varnothing)$ and $(Q, \varnothing)$ are trace equivalent. Indeed, the relevant traces are of the form $t_{k}:=\operatorname{in}(c, k) \cdot \operatorname{out}\left(c, x_{1}\right) \cdot\left(x_{1}\right.$ ? $=$ $o k)$, for all the integers $k \in \mathbb{N}$. We can see that for every $k, \operatorname{Prob}_{\mathcal{R}_{r}^{k}}\left((P, \varnothing), t_{k}\right)=$ $\operatorname{Prob}_{\mathcal{R}_{\mathrm{r}}^{2}}\left((Q, \varnothing), t_{k}\right)=\frac{1}{2}$.

### 7.3 A fully probabilistic operational semantics for FP processes and determinate adversaries

However, if we restrict the set of possible adversary and that we consider only adversaries without non-determinism-i.e. written whitout using + or $\mid$-we obtain a (weaker) notion of may testing equivalence for FP processes. The main result of this section is that this weaker may testing coincide with trace equivalence.

Definition 30. We say that a process $A d v$ is fully determinate if it is generated by the following grammar:

$$
P, Q:=0|\operatorname{in}(u, x) \cdot P| \operatorname{out}(u, v) \cdot P \mid \text { new } a \cdot P \mid \text { if } u=v \text { then } P \text { else } Q \mid P+_{p} Q
$$

Moreover, we ask for a sucess token-formally a channel $o k$-that only the adversary can use. We say that two process $P, Q$ are determinate may testing equivalent whenever they are indistinguishable by fully determinate adversaries.

Our goal is to show that two FP-processes are in the trace pre-ordered if and only if they are in the determinate may-testing preorder. Observe that one direction is immediate: it is
enough to show that any trace can be encoded by a determinate adversary $A d v$, thus two process that are in the determinate may-testing pre-order are also in the trace pre-order. In the remaining of this section, we show that the reverse implication also holds.

Definition 31. Given a fully determinate process $A d v$ and an integer $n$, we define the set $T r^{o k}(A d v, n)$ inductively on $A d v$ as:

- $\operatorname{Tr}^{o k}(0, n)=\varnothing$;
- $\operatorname{Tr}^{o k}(\operatorname{in}(u, x) ; A d v, n)=\left\{\left\{\left(p_{i},(u \neq \text { ok }) . o u t\left(u, \mathrm{ax}_{n+1}\right) \cdot w_{i}\right)\right\}_{i=1}^{m}\right.$ when $\operatorname{Tr}^{o k}\left(\operatorname{Adv}\left\{\mathrm{ax}_{n+1} / x\right\}, n+\right.$ 1) $=\left\{\left\{\left(p_{i}, w_{i}\right)\right\}\right\}_{i=1}^{m}$
- $\operatorname{Tr}^{o k}\left(\operatorname{out}(u, v) ; A d v^{\prime}, n\right)=\left\{\left\{\left(p_{i},(u \neq o k) \cdot i n(u, v) \cdot w_{i}\right)\right\}_{i=1}^{m} \cup\{(1, u \stackrel{?}{=} o k)\}\right.$ when $\operatorname{Tr}^{o k}(A d v, n)=$ $\left\{\left(p_{i}, w_{i}\right)\right\}_{i=1}^{m}$
- $\operatorname{Tr}^{o k}\left(A d v_{1}+{ }_{p} A d v_{2}, n\right)=\left\{\left\{\left(p \cdot p_{k}^{1}, w_{k}^{1}\right)\right\}_{k=1}^{n_{1}} \cup\left\{\left\{\left((1-p) \cdot p_{k}^{2}, w_{k}^{2}\right)\right\}_{k=1}^{n_{2}}\right.\right.$ when $\operatorname{Tr}^{o k}\left(A d v_{i}, n\right)=$ $\left\{\left(p_{k}^{i}, w_{k}^{i}\right)\right\}_{k=1}^{n_{i}}$ for $i=1,2$
- $T r^{o k}\left(\right.$ if $u=v$ then $A d v_{1}$ else $\left.A d v_{2}, n\right)=\left\{\left\{\left(p_{k}^{1},(u \stackrel{?}{=} v) \cdot w_{k}^{1}\right)\right\}_{k=1}^{n_{1}} \cup\left\{\left\{\left(p_{k}^{2},(u \stackrel{?}{=} v) \cdot w_{k}^{2}\right)\right\}_{k=1}^{n_{2}}\right.\right.$
- $\operatorname{Tr}^{o k}($ new $a ; A d v, n)=\operatorname{Tr}^{o k}\left(\operatorname{Adv}\left\{{ }^{b} / a\right\}, n\right)$ with $b \in \mathcal{N}_{p u b}$ fresh.

The proof of the following lemma can be found in Appendix $H$.
Lemma 16. Let $o k \in \mathcal{N}_{p u b}$. Let $(\mathcal{P}, \phi)$ be a purely probabilistic process. Let $A d v$ be a fully determinate adversarial process such that $f v(A d v) \subseteq \operatorname{dom}(\phi)$.

$$
\begin{aligned}
\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}(\mathcal{P} \cup A d v \phi, \downarrow o k)= & \operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}(\mathcal{P}, \downarrow o k)+\left(1-\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathbb{N}^{o}\right)}(\mathcal{P}, \downarrow o k)\right) \times \\
& \left.\sum_{(\alpha, w) \in T r^{o k}(\operatorname{Adv},|\operatorname{dom}(\phi)|)} \alpha \cdot \operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{\ell}\right)}(\mathcal{P}, \phi), w\right)
\end{aligned}
$$

We can now show the main proposition of this section.
Proposition 12. Let $\mathcal{P}, \mathcal{Q}$ be two FP processes. Then $(\mathcal{P}, \mathcal{Q})$ is in the may testing preorder for determinate adversaries if and only if $(\mathcal{P}, \varnothing)$ and $(\mathcal{Q}, \varnothing)$ are in the trace pre-order.

Proof. We focus on the non-straightforward implication: the trace preorder implies the may testing preorder for determinate adversaries. Let $A d v$ be a fully determinate adversary process and let $o k$ be a public name.

First, notice that as $\mathcal{P}$ and $\mathcal{Q}$ are both fully probabilisitic processes, we have

$$
\begin{aligned}
& \operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathbb{N}^{o}\right)}(\mathcal{P}, \downarrow o k)=\operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathbb{N}^{\ell}\right)}\left((\mathcal{P}, \varnothing), \text { out }\left(o k, \operatorname{ax}_{1}\right)\right) \\
& \operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}(\mathcal{Q}, \downarrow o k)=\operatorname{Prob}_{\mathcal{R}_{\mathrm{Rr}}\left(\mathrm{~N}^{\ell}\right)}\left((\mathcal{Q}, \varnothing), \text { out }\left(o k, \mathrm{ax}_{1}\right)\right)
\end{aligned}
$$

Let $a_{1}=\operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}^{\ell}\right)}\left((\mathcal{P}, \varnothing)\right.$, out $\left.\left(o k, \mathrm{ax}_{1}\right)\right)$ and $a_{2}=\operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}^{\ell}\right)}\left((\mathcal{Q}, \varnothing)\right.$,out $\left.\left(o k, \mathrm{ax}_{1}\right)\right)$. Since $(\mathcal{P}, \varnothing)$ and $(\mathcal{Q}, \varnothing)$ are in the trace pre-order, $a_{1} \leq a_{2}$.

Similarly, for all $(\alpha, w) \in \operatorname{Tr}^{o k}(A d v,|\operatorname{dom}(\phi)|)$, as $(\mathcal{P}, \varnothing)$ and $(\mathcal{Q}, \varnothing)$ are in the trace pre-order we have that $\operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathbb{N}^{\ell}\right)}((\mathcal{P}, \varnothing), w) \leq \operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathbb{N}^{\ell}\right)}((\mathcal{Q}, \varnothing), w)$. Defining

$$
\begin{aligned}
b_{1} & =\sum_{(\alpha, w) \in T r^{o k}(A d v,|\operatorname{dom}(\phi)|)} \alpha \cdot \operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{\ell}\right)}((\mathcal{P}, \phi), w) \\
b_{2} & =\sum_{(\alpha, w) \in T r^{o k}(\operatorname{Adv},|\operatorname{dom}(\phi)|)} \alpha \cdot \operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathbf{N}^{\ell}\right)}((\mathcal{Q}, \varnothing), w)
\end{aligned}
$$

we obtain that $b_{1} \leq b_{2}$.
Thus, by Lemma 16, $\operatorname{RProb}_{\mathcal{R}_{n r}\left(\mathbb{N}^{\circ}\right)}(\mathcal{P}, \downarrow o k)=a_{1}+\left(1-a_{1}\right) \times b_{1}$ and $\operatorname{RProb}_{\mathcal{R}_{n r}\left(N^{\circ}\right)}(\mathcal{Q}, \downarrow$ $o k)=a_{2}+\left(1-a_{2}\right) \times b_{2}$ with $0 \leq a_{1} \leq a_{2} \leq 1$ and $0 \leq b_{1} \leq b_{2} \leq 1$.

By considering the function $f(x, y)=x+y-x y$, we notice that showing $a_{1}+(1-$ $\left.a_{1}\right) \times b_{1} \leq a_{2}+\left(1-a_{2}\right) \times b_{2}$ is equivalent to showing that $f\left(a_{2}, b_{2}\right)-f\left(a_{1}, b_{1}\right) \geq 0$. By computing the partial derivations, we can see that $f\left(a_{2}, b_{2}\right) \geq f\left(a_{1}, b_{2}\right) \geq f\left(a_{1}, b_{1}\right)$ which allows us to conclude.

### 7.4 Deciding trace equivalence

As previous mentioned, Cheval et al. present in CKR18 a decision procedure for trace equivalence when cryptographic primitives are modelled by a subterm convergent destructor rewrite system and when the number of sessions are bounded. This procedure is based on constraint solving techniques that represent in a finite symbolic tree all possible concrete executions of the processes with the attacker. Intuitively, each node of this symbolic tree represents the state of the two processes after executing a trace $t r$. Due to non-determinism, a node may contain several constraint systems corresponding to every possible interleaving allowing the execution of such trace tr. Deciding trace equivalence between two processes $A$ and $B$, in the non-probabilisitic setting, comes back to checking that in every node of the symbolic tree, there is always one constraint system derived from the process $A$ and one constraint system derived from the process $B$; or the node is empty.

In our setting with fully probabilistic agents communicating on public channels, as the non-determinism disappear, we can associate to each constraint system the probability of executing this trace, depending on the probabilisitic choice taken during the execution of the processes. Thus, using the same constraint solving techniques, we could obtain a symbolic tree representing once again the state of the processes after executing a trace $t r$ but where the constraint systems of a node correspond to every possible probabilistic choices taken. Deciding trace equivalence between two processes $A$ and $B$ would thus comes back to checking that in every node, the sum of the probabilities of the constraint systems derived from the process $A$ is equal to the sum of the probabilities of the constraint systems derived from $B$.

## 8 Conclusion and future work

In this paper we introduced a framework to reason about indistinguishability properties, modelled as process equivalences, in symbolic models enhanced with probabilities. Defining such a framework turns out to rely on subtle technicalities such as the need for randomized schedulers, overseen in previous attempts. We define different, classical behavioral and labelled equivalences and show their precise relations. As usual in models mixing nondeterminism and probabilities, the resulting equivalences may be considered as too strong: indeed arbitrary schedulers may leak the (private) probabilistic choices of the processes and give the attacker an unrealistically strong distinguishing power. We therefore study two classes of protocols where this problem is avoided. First, we study protocols that do not make probabilistic choices, but allow the adversary to do so. We show that for a bounded number of sessions may testing with such probabilistic adversaries coincides with purely possibilistic similarity. Second, we study a class of fully probabilistic protocols, also considered in CSV17, and show that trace equivalence on such protocols coincides with may testing in the presence of a (syntactic) class of determinate adversaries.

Our work paves the road towards several future work. We sketched a decision procedure in the DeepSec tool for the class of fully probabilistic adversaries. A thorough treatment of this idea and an implementation are a natural next step. Also, the insight that (purely possibilistic) similarity takes into account probabilistic adversaries (as it coincides with may testing) when the number of sessions is bounded and protocols are non-deterministic motivates adding support for (bi)similarity in a tool such as DeepSec (which currently only verifies trace equivalence). A different direction going beyond the subclasses considered in this paper is to investigate restrictions of the scheduler (building, e.g., on ideas from CP10, AAPvR10]) in our framework to limit the adversary's power without restricting the class of protocols. Finally, a more prospective direction is the use of more quantitative equivalences, i.e., distances between processes, that might be interesting to compare different protocols that try to achieve a same property.

## A Randomized and non-randomized resolutions coincide for may-testing

Lemma 17 (One-step derandomization). Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}, \operatorname{trans}_{\mathrm{N}}\right)$ be a NPLTS, such that $\operatorname{trans}_{\mathrm{N}}(s, \tau)=D$ implies that $D$ has finite support. Let $\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $\left._{\mathrm{R}}, \operatorname{trans}_{\mathrm{R}}\right) \in \mathcal{R}_{\mathrm{r}}(\mathrm{N})$, and $s \in \mathcal{S}_{\mathrm{R}}$ an internal state. Let $(\tau, D) \in \mathcal{A}_{\text {int }} \times \mathcal{D}\left(\mathcal{S}_{\mathrm{R}}\right)$ the R-transition step from $s$, i.e. $\operatorname{trans}_{\mathbb{R}}(s)=(\tau, D)$. We define the set of possible de-randomizations of $\beta=(s, \tau, D)$ as.

$$
\begin{aligned}
\Delta(\beta)=\left\{F \in \mathcal{D}\left(\mathcal{S}_{\mathrm{R}}\right) \mid\right. & \left(\tau, \operatorname{corr}_{\mathrm{R}}(F)\right) \in \operatorname{trans}_{\mathrm{N}}\left(\operatorname{corr}_{\mathrm{R}}(s)\right), \\
& \text { corr} \\
& \operatorname{supp}(F) \subseteq \operatorname{supp}(D)\}
\end{aligned}
$$

Then the randomized transition step $\beta$ can be expressed as the convex sum of de-randomized step, or more formally:

$$
\exists \eta \in \mathcal{D}(\Delta(\beta)) \text { s.t. } \sum_{F \in \Delta(\beta)} \eta(F) \cdot F=D .
$$

Proof. By hypothesis, $\mathrm{R} \in \mathcal{R}_{\mathrm{r}}(\mathrm{N})$, thus there exists a distribution $\gamma$ over $\operatorname{trans}_{\mathrm{N}}\left(\operatorname{corr}_{\mathrm{R}}(s)\right)(\tau)$ such that $\operatorname{corr}_{\mathrm{R}}(D)=\sum_{E \in \operatorname{trans}_{\mathrm{N}}\left(\operatorname{corr}_{\mathrm{R}}(s)\right)(\tau)} \gamma(E) \cdot E$. Recall that, for any $F \in \Delta(\beta)$, since corr $_{\mathbf{R}}$ is injective on the support of $F$, we can define $\left(\operatorname{corr}_{\mathrm{R}}\right)_{\mid \operatorname{supp}(F)}^{-1}(t) \in \mathcal{S}_{\mathbf{R}}$, for any $t \in \mathcal{S}_{\mathrm{N}}$. We define, for $F \in \Delta(\beta) \subseteq \mathcal{D}\left(\mathcal{S}_{\mathrm{R}}\right)$ :

$$
\eta(F)=\gamma\left(\operatorname{corr}_{\mathrm{R}}(F)\right) \cdot \prod_{s \in \operatorname{supp}\left(\operatorname{corr}_{\mathrm{R}}(F)\right)} \frac{D\left(\left(\operatorname{corr}_{\mathrm{R}}\right)_{\mid \operatorname{supp}(F)}^{-1}(s)\right)}{\operatorname{corr}_{\mathrm{R}}(D)(s)}
$$

Notice that $\operatorname{supp}(F) \subseteq \operatorname{supp}(D)$ implies $\operatorname{supp}\left(\operatorname{corr}_{\mathrm{R}}(F)\right) \subseteq \operatorname{supp}\left(\operatorname{corr}_{\mathrm{R}}(D)\right)$, and so for all $s \in \operatorname{supp}\left(\operatorname{corr}_{\mathrm{R}}(F)\right), \operatorname{corr}_{\mathrm{R}}(D)(s) \neq 0$ which ensures that $\eta(D)$ is correctly defined.

- First, we check that $\eta$ is indeed a distribution.

$$
\begin{aligned}
\sum_{F \in \Delta(\beta)} \eta(F) & =\sum_{F \in \Delta(\beta)} \gamma\left(\operatorname{corr}_{\mathrm{R}}(F)\right) \cdot \prod_{s \in \operatorname{supp}\left(\operatorname{corr}_{\mathrm{R}}(F)\right)} \frac{D\left(\left(\operatorname{corr}_{\mathrm{R}}\right)_{\mid \operatorname{supp}(F)}^{-1}(s)\right)}{\operatorname{corr}_{\mathrm{R}}(D)(s)} \\
& =\sum_{E \in \operatorname{trans}_{\mathrm{N}}(s)(\tau)} \gamma(E) \cdot \sum_{F \in \Delta(\beta) \mid \operatorname{corr}_{\mathrm{R}}(F)=E} \prod_{s \in \operatorname{supp}\left(\operatorname{corr}_{\mathrm{R}}(F)\right)} \frac{D\left(\left(\operatorname{corr}_{\mathrm{R}}\right)_{\mid \operatorname{supp}(F)}^{-1}(s)\right)}{\operatorname{corr}_{\mathrm{R}}(D)(s)} .
\end{aligned}
$$

Recall that $\gamma$ is a distribution over $\operatorname{trans}_{\mathcal{N}}\left(\operatorname{corr}_{\mathrm{R}}(s)\right)(\tau)$. Hence, for all $E \in \operatorname{trans}_{\mathrm{N}}\left(\operatorname{corr}_{\mathrm{R}}(s)\right)(\tau)$, $\gamma(E) \neq 0$ if and only if $E \in \operatorname{supp}(\gamma)$. Hence:

$$
\sum_{F \in \Delta(\beta)} \eta(F)=\sum_{\substack{E \in \operatorname{transs}_{\mathrm{N}}(s)(\tau) \\ \cap \operatorname{supp}(\gamma)}} \gamma(E) \cdot \sum_{F \in \Delta(\beta) \mid \operatorname{corr}_{\mathrm{R}}(F)=E} \prod_{s \in \operatorname{supp}\left(\operatorname{corrr}_{\mathrm{R}}(F)\right)} \frac{D\left(\left(\operatorname{corr}_{\mathrm{R}}\right)_{\mid \operatorname{supp}(F)}^{-1}(s)\right)}{\operatorname{corr}_{\mathrm{R}}(D)(s)} .
$$

Observe that, given some $E \in \operatorname{trans}_{\mathcal{N}}(s)(\tau) \cap \operatorname{supp}(\gamma)$, choosing some $F \in \Delta(\beta)$ such that $\operatorname{corr}_{\mathrm{R}}(F)=E$ is equivalent to choosing, for every $s \in \operatorname{supp}(E)$, a unique $\widetilde{s} \in \mathcal{S}_{\mathrm{R}}$ such that $\operatorname{corr}_{\mathrm{R}}(\widetilde{s})=s$, and then to define $F=\sum_{s \in \operatorname{supp}(E)} E(s) \cdot \delta_{\widetilde{s}}$. Notice that by construction, we have $\operatorname{corr}_{\mathrm{R}}$ injective on $\operatorname{supp}(F)$. Moreover, for all $v \in \operatorname{supp}(F)$, $\operatorname{corr}_{\mathrm{R}}(v) \in \operatorname{supp}(E)$. Since $E \in \operatorname{supp}(\gamma)$ and $\operatorname{corr}_{\mathrm{R}}(D)=\sum_{E \in \operatorname{trans}_{\mathrm{N}}\left(\operatorname{corrr}_{\mathrm{R}}(s)\right)(\tau)} \gamma(E) \cdot E$, we deduce that $\operatorname{corr}_{\mathrm{R}}(v) \in \operatorname{supp}\left(\operatorname{corr}_{\mathrm{R}}(D)\right)$ and so $v \in \operatorname{supp}(D)$. This ensure that $F \in \Delta(\beta)$.
As a consequence, for $E \in \operatorname{trans}_{\mathcal{N}}(s)(\tau) \cap \operatorname{supp}(\gamma)$ :

$$
\begin{equation*}
\sum_{\substack{F \in \Delta(\beta) \\ \mid \operatorname{corr}_{\mathrm{R}}(F)=E}} \prod_{s \in \operatorname{supp}\left(\operatorname{corr}_{\mathrm{R}}(F)\right)} \frac{D\left(\left(\operatorname{corr}_{\mathrm{R}}\right)_{\mid \operatorname{supp}(F)}^{-1}(s)\right)}{\operatorname{corr}_{\mathrm{R}}(D)(s)}=\sum_{\substack{\phi: \operatorname{supp}(E) \mapsto \mathcal{S}_{\mathrm{R}} \\ \mid \forall u, \operatorname{corr}(\phi(u))=u}} \prod_{s \in \operatorname{supp}(E)} \frac{D(\phi(s))}{\operatorname{corr}_{\mathrm{R}}(D)(s)} \tag{3}
\end{equation*}
$$

Recall that for all $E \in \operatorname{supp}(\gamma)$, for all $s \in \operatorname{supp}(E), \operatorname{corr}_{\mathrm{R}}(D)(s) \neq 0$ and $\operatorname{corr}_{\mathrm{R}}(D)(s)=$ $\sum_{u \in \operatorname{corr}_{\mathrm{R}}^{-1}(\{s\})} D(u)$, and thus $u \in \operatorname{corr}_{\mathrm{R}}^{-1}(\{s\}) \mapsto \frac{D(u)}{\operatorname{corr}_{\mathrm{R}}(D)(s)} \in[0,1]$ is a distribution. From there, we can consider the product distribution for any (finite) set $\mathcal{S}_{I}=\left\{s_{i} \mid i \in\right.$ $\left.I \wedge \operatorname{corr}_{\mathrm{R}}(D)\left(s_{i}\right) \neq 0\right\} \subseteq \mathcal{S}_{\mathrm{N}}$ given as: $\left(u_{i}\right)_{i \in I} \in \prod_{i \in I} \operatorname{corr}_{\mathrm{R}}^{-1}\left(\left\{s_{i}\right\}\right) \mapsto \prod_{i \in I} \frac{D\left(u_{i}\right)}{\operatorname{corr}_{\mathrm{R}}(D)\left(s_{i}\right)}$. In particular, since this product distribution is indeed a distribution, it holds that:

$$
\begin{equation*}
\sum_{\substack{\phi: \mathcal{S}_{I} \mapsto \mathcal{S}_{\mathrm{R}} \\ \mid \forall u, \operatorname{corr}(\phi(u))=u}} \prod_{s \in \mathcal{S}_{I}} \frac{D(\phi(s))}{\operatorname{corr}_{\mathrm{R}}(D)(s)}=1 \tag{4}
\end{equation*}
$$

By taking $\mathcal{S}_{I}=\operatorname{supp}(E),(4)$ tells us that: $\sum_{\substack{\phi: \operatorname{supp}(E) \mapsto \mathcal{S}_{\mathbb{R}} \\ \mid \forall u, \operatorname{corr}(\phi(u))=u}} \prod_{s \in \operatorname{supp}(E)} \frac{D(\phi(s))}{\operatorname{corr}_{\mathbb{R}}(D)(s)}=1$, and we can conclude from there.

- we want now to show that $\sum_{F \in \Delta(\beta)} \eta(F) \cdot F=D$. Let $t \in \mathcal{S}_{\mathrm{R}}$. By unfolding the definition of $\eta(F)$ and using the same reasoning as in the previous bullet point, we obtain:

$$
\begin{aligned}
& \sum_{F \in \Delta(\beta)} \eta(F) \cdot F(t) \\
= & \sum_{F \in \Delta(\beta)} \gamma\left(\operatorname{corr}_{\mathrm{R}}(F)\right) \cdot \prod_{s \in \operatorname{supp}(\operatorname{corr}(F))} \frac{D\left(\left(\operatorname{corr}_{\mathrm{R}}\right)_{\mid \operatorname{supp}(F)}^{-1}(s)\right)}{\operatorname{corr}_{\mathrm{R}}(D)(s)} \cdot F(t) \\
= & \sum_{E \in \operatorname{trans}_{\mathrm{N}}(s)(\tau)} \gamma(E) \cdot \sum_{\substack{\phi: \operatorname{supp}(E) \rightarrow \mathcal{S}_{\mathrm{R}} \\
\mid \forall u, \operatorname{corr}(\phi(u))=u, t \in \operatorname{Im}(\phi)}} \prod_{s \in \operatorname{supp}(E)} \frac{D(\phi(s))}{\operatorname{corr}_{\mathrm{R}}(D)(s)} \cdot E\left(\phi^{-1}(t)\right)
\end{aligned}
$$

The last equality is obtain using the same reasoning as in the previous bullet point. Additionally, we restrict the function $\phi$ we consider by only taking the one where $t \in \operatorname{Im}(\phi)$ (as $t \notin \operatorname{Im}(\phi)$ would imply $F(t)=0)$. Also notice that $F(t)=E\left(\phi^{-1}(t)\right)$.

Finally, since $\phi^{-1}(t)=\operatorname{corr}_{\mathrm{R}}(t)$, we obtain the following:

$$
\begin{aligned}
& \sum_{F \in \Delta(\beta)} \eta(F) \cdot F(t) \\
& =\sum_{E \in \operatorname{trans}_{\mathrm{N}}(s)(\tau)} \gamma(E) \cdot \sum_{\substack{\phi: \operatorname{supp}^{(E) \rightarrow \mathcal{S}_{\mathbb{R}}} \\
\mid \forall u \operatorname{corrr}_{\mathrm{R}}(\phi(u))=u, \phi\left(\operatorname{corrr}_{\mathrm{R}}(t)\right)=t}} \prod_{\substack{s \in \operatorname{supp}^{2}(E)}} \frac{D(\phi(s))}{\operatorname{corr}_{\mathrm{R}}(D)(s)} \cdot E\left(\operatorname{corr}_{\mathrm{R}}(t)\right) \\
& =\sum_{E \in \operatorname{trans}_{\mathrm{N}}(s)(\tau)} \gamma(E) \cdot\left(\sum_{\substack{\phi: \operatorname{supp}^{\mid \forall u) \backslash\left\{\operatorname{corr}_{\mathrm{R}}(t)\right\} \rightarrow \mathcal{S}_{\mathrm{R}}} \\
\mid \forall \operatorname{corr}(\phi(u))=u}} \prod_{s \in \operatorname{supp}(E) \backslash\left\{\operatorname{corrR}_{\mathrm{R}}(t)\right\}} \frac{D(\phi(s))}{\operatorname{corr}_{\mathrm{R}}(D)(s)}\right) \\
& \cdot \frac{D(t)}{\operatorname{corr}_{\mathrm{R}}(D)\left(\operatorname{corr}_{\mathrm{R}}(t)\right)} \cdot E\left(\operatorname{corr}_{\mathrm{R}}(t)\right) \\
& =\sum_{E \in \operatorname{trans}_{N}(s)(\tau)} \gamma(E) \cdot \frac{D(t)}{\operatorname{corr}_{\mathrm{R}}(D)\left(\operatorname{corr}_{\mathrm{R}}(t)\right)} \cdot E\left(\operatorname{corr}_{\mathrm{R}}(t)\right) \text { by (4) } \\
& =\frac{D(t)}{\operatorname{corr}_{\mathrm{R}}(D)\left(\operatorname{corr}_{\mathrm{R}}(t)\right)} \cdot \operatorname{corr}_{\mathrm{R}}(D)\left(\operatorname{corr}_{\mathrm{R}}(t)\right) \text { by hypothesis on } \gamma \\
& =D(t) \text {. }
\end{aligned}
$$

Lemma 18 (finite steps derandomization). Let N be a NPLTS defined by its transition function $\operatorname{trans}_{\mathrm{N}}: \mathcal{S}_{\mathrm{N}} \rightarrow \mathcal{A}_{\text {int }} \sqcup \mathcal{A}_{\text {ext }} \rightarrow \mathcal{P}\left(\mathcal{D}\left(\mathcal{S}_{\mathrm{N}}\right)\right)$. Moreover, we ask N to be such that $\operatorname{trans}_{\mathrm{N}}(s, \tau)=D$ implies that $D$ has finite support. For every set $\mathcal{T} \subseteq \mathcal{S}_{\mathrm{N}}$, for every randomized resolution $\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $\left._{\mathrm{R}}, \operatorname{trans}_{\mathrm{R}}\right) \in \mathcal{R}_{\mathrm{r}}(\mathrm{N})$, for every state $s \in \mathcal{S}_{\mathrm{R}}$, it holds that for every $n \in \mathbb{N}$ :

$$
\begin{aligned}
\operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\mathcal{T})\right) \in \operatorname{conv} & \left(\left\{\operatorname{RProb}_{\mathrm{R}^{\prime}}\left(s^{\prime}, \operatorname{corr}_{\mathrm{R}^{\prime}}^{-1}(\mathcal{T})\right)\right.\right. \\
& \left.\left.\mid \mathrm{R}^{\prime}=\left(\mathcal{S}_{\mathrm{R}^{\prime}}, \operatorname{corr}_{\mathrm{R}^{\prime}}, \operatorname{trans}_{\mathrm{R}^{\prime}}\right) \in \mathcal{R}_{\mathrm{nr}}(\mathrm{~N}), \operatorname{corr}_{\mathrm{R}}(s)=\operatorname{corr}_{\mathrm{R}^{\prime}}\left(s^{\prime}\right)\right\}\right)
\end{aligned}
$$

Proof of Lemma 18. Let $\mathcal{T} \subseteq \mathcal{S}_{\mathrm{N}}$, and $\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $\left._{\mathrm{R}}, \operatorname{trans}_{\mathrm{R}}\right) \in \mathcal{R}_{\mathrm{r}}(\mathrm{N})$. We do the proof by induction on $n$ :

- Base case $n=0$ : We define $\mathrm{R}_{0}:=\left(\mathcal{S}_{\mathrm{N}}, i d\right.$, trans $\left._{\mathrm{R}_{0}}\right)$, where $i d$ stands for the identity function, and all states in $\mathcal{S}_{\mathrm{N}}$ are external states such that $\operatorname{trans}_{\mathrm{R}_{0}}(u)(a)=\star$ for every $u \in \mathcal{S}_{\mathrm{N}}, a \in A_{\text {ext }}$. We can see immediately that $\mathrm{R}_{0} \in \mathcal{R}_{\mathrm{nr}}(\mathrm{N})$. Observe that $\operatorname{RProb}_{\mathrm{R}_{0}}(u, \mathcal{T})=1$ when $u \in \mathcal{T}$, and 0 otherwise. As a consequence, for $s \in \mathcal{S}_{\mathrm{R}}$, $\operatorname{RProb}_{\mathrm{R}}^{\leq 0}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\mathcal{T})\right)=\operatorname{RProb}_{\mathrm{R}_{0}}(s, \mathcal{T})$.
- Inductive step: We suppose that the result holds for $n \geq 0$. Let $s \in \mathcal{S}_{\mathrm{R}}$. We do a case disjunction on the first R-transition from $s$ :
- if $s$ is an external state or $s \in \operatorname{corr}_{\mathrm{R}}^{-1}(\mathcal{T})$ then $\operatorname{RProb}_{\mathrm{R}}^{\leq n+1}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\mathcal{T})\right)=$ $\operatorname{RProb}_{\mathrm{R}}^{\leq 0}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\mathcal{T})\right)$ by definition. By applying the same reasoning as in the base case, the result holds;
- otherwise there exists a distribution $E \in \mathcal{D}\left(\mathcal{S}_{\mathrm{R}}\right)$ such that $\operatorname{trans}_{\mathrm{R}}(s)=(\tau, E)$, with $\tau$ an internal action, and $\operatorname{corr}_{\mathrm{R}}(E) \in \operatorname{conv}\left(\operatorname{trans}_{\mathrm{N}}\left(\operatorname{corr}_{\mathrm{R}}(s)\right)(\tau)\right)$. For each $v \in \mathcal{S}_{\mathrm{N}}$, we define the set of resolutions starting from $v$ as: $\mathcal{R}_{\mathrm{nr}}(\mathrm{N}, v)=\left\{\left(\mathrm{R}^{\prime}, w\right) \mid\right.$ $\left.\mathrm{R}^{\prime}=\left(\mathcal{S}_{\mathrm{R}^{\prime}}, \operatorname{corr}_{\mathrm{R}^{\prime}}, \operatorname{trans}_{\mathrm{R}^{\prime}}\right) \in \mathcal{R}_{\mathrm{nr}}(\mathrm{N}), w \in \mathcal{S}_{\mathrm{R}^{\prime}}, \operatorname{corr}_{\mathrm{R}^{\prime}}(w)=v\right\}$. By applying the induction hypothesis to the states in the support of $E$, we obtain that for all $t \in \operatorname{supp}(E)$ there exists a distribution $\Theta_{t} \in \mathcal{D}\left(\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}, \operatorname{corr}_{\mathrm{R}}(t)\right)\right)$ such that:

$$
\begin{equation*}
\operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(t, \operatorname{corr}_{\mathrm{R}}^{-1}(\mathcal{T})\right)=\sum_{\left(\mathrm{R}^{\prime}, u\right) \in \mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}, \operatorname{corr}_{\mathrm{R}}(t)\right)} \Theta_{t}\left(\mathrm{R}^{\prime}, u\right) \cdot \operatorname{RProb}_{\mathrm{R}^{\prime}}\left(u, \operatorname{corr}_{\mathrm{R}^{\prime}}^{-1}(\mathcal{T})\right) \tag{5}
\end{equation*}
$$

Observe that choosing, for every $t \in \operatorname{supp}(E)$, one non-randomized resolution starting from $\operatorname{corr}(t)$, i.e a $\left(\mathrm{R}_{t}, u_{t}\right) \in \mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}, \operatorname{corr}_{\mathrm{R}}(t)\right)$, means choosing a function $f: t \in \operatorname{supp}(E) \mapsto\left(\mathrm{R}_{t}, u_{t}\right) \in \mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}, \operatorname{corr}_{\mathrm{R}}(t)\right)$. We write $\mathcal{F}$ for the set of all those functions. Using the distributions $\Theta_{t}$, we can built the product distribution, that compute the probability of choosing some $f \in \mathcal{F}$, when choosing each $f(t)$ with the probabilities specified by the distribution $\Theta_{t}$. This way, we obtain $\Theta \in \mathcal{D}(\mathcal{F})$ defined as $\Theta(f)=\prod_{t \in \operatorname{supp}(E)} \Theta_{t}(f(t))$. Observe that, for any $t \in \operatorname{supp}(E)$, and ( $\left.\mathrm{R}^{\prime}, u\right) \in \mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}, \operatorname{corr}_{\mathrm{R}}(t)\right)$, it holds that:

$$
\begin{equation*}
\Theta_{t}\left(\mathrm{R}^{\prime}, u\right)=\sum_{f \mid f(t)=\left(\mathrm{R}^{\prime}, u\right)} \Theta(f) \tag{6}
\end{equation*}
$$

Moreover, by defining $\beta=(s, \tau, E)$ and using Lemma 17, we obtain the existence of a distribution $\eta \in \mathcal{D}(\Delta(\beta))$, with $\Delta$ defined in Lemma 17 , such that:

$$
\begin{equation*}
\sum_{D \in \Delta(\beta)} \eta(D) \cdot D=E \tag{7}
\end{equation*}
$$

For every element $D \in \Delta(\beta)$, and any function $f: t \in \operatorname{supp}(E) \mapsto\left(\mathrm{R}_{t}, u_{t}\right) \in$ $\left.\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}, \operatorname{corr}_{\mathrm{R}}(t)\right)\right\}$, we build a non-randomized resolution $\mathrm{R}_{D, f}$ as:
$* \mathcal{S}_{\mathrm{R}_{D, f}}=\{s\} \sqcup\left\{\mathcal{S}_{\mathrm{R}_{t}} \mid t \in \operatorname{supp}(E), f(t)=\left(\mathrm{R}_{t}, u_{t}\right)\right\} ;$

* the correspondance function $\operatorname{corr}_{\mathrm{R}_{D, f}}$ is defined as: $\operatorname{corr}_{\mathrm{R}_{D, f}}(u)=\operatorname{corr}_{\mathrm{R}_{t}}$ if $z \in \mathcal{S}_{\mathbb{R}_{t}}$, and $\operatorname{corr}_{\mathrm{R}_{D, f}}(s)=\operatorname{corr}(s) ;$
* the transition function $\operatorname{trans}_{\mathrm{R}_{D, f}}$ is defined as: if $u \in \mathcal{S}_{\mathrm{R}_{t}}$, then $\operatorname{trans}_{\mathrm{R}_{D, f}}(u)=$ $\operatorname{trans}_{\mathrm{R}_{t}}(u)$, and for all $u \in \mathcal{S}_{\mathrm{R}_{D, f}}$, $\operatorname{trans}_{\mathrm{R}_{D, f}}(s)(u)=D(t)$ when $\exists t \in \operatorname{supp}(E)$ such that $f(t)=\left(\mathrm{R}_{t}, u\right)$ for some $\mathrm{R}_{t}$; and 0 otherwise.
We can easily check that $\mathrm{R}_{D, f} \in \mathcal{R}_{n r}(\mathrm{~N})$ : to do so, we need to use the fact that, by induction hypothesis, all the $\mathrm{R}_{t}$ given by $f$ are in $\mathcal{R}_{\mathrm{nr}}(\mathrm{N})$, and the definition
of $\Delta(\beta)$ given in Lemma 17. In order to conclude, we are going to show:

$$
\operatorname{RProb}_{\mathrm{R}}^{\leq n+1}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\mathcal{T})\right)=\sum_{\substack{D \in \Delta(\beta) \\ f \in \mathcal{F}}} \eta(D) \cdot \Theta(f) \cdot \operatorname{RProb}_{\mathrm{R}_{D, f}}\left(s, \operatorname{corr}_{\mathrm{R}_{D, f}}^{-1}(\mathcal{T})\right)
$$

$$
\begin{aligned}
& \operatorname{RProb}_{\mathrm{R}}{ }^{\leq n+1}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\mathcal{T})\right) \\
& =\sum_{t \in \operatorname{supp}(E)} E(t) \cdot \operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(t, \operatorname{corr}_{\mathrm{R}}^{-1}(\mathcal{T})\right) \text { by Definition } 7 \\
& =\sum_{t \in \operatorname{supp}(E)} E(t) \cdot \sum_{\left(\mathrm{R}^{\prime}, u\right) \in \mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}, \operatorname{corr}_{\mathrm{R}}(t)\right)} \Theta_{t}\left(\mathrm{R}^{\prime}, u\right) \cdot \operatorname{RProb}_{\mathrm{R}^{\prime}}\left(u, \operatorname{corr}_{\mathrm{R}^{\prime}}^{-1}(\mathcal{T})\right) \text { by (5) } \\
& =\sum_{t \in \operatorname{supp}(E)}\left(\sum_{D \in \Delta(\beta)} \eta(D) \cdot D(t)\right) \\
& \text { • } \sum_{\left(\mathrm{R}^{\prime}, u\right) \in \mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}, \operatorname{corr}_{\mathrm{R}}(t)\right)}\left(\sum_{f \mid f(t)=\left(\mathrm{R}^{\prime}, u\right)} \Theta(f)\right) \cdot \operatorname{RProb}_{\mathrm{R}^{\prime}}\left(u, \operatorname{corr}_{\mathrm{R}^{\prime}}^{-1}(\mathcal{T})\right) \text { by (7) and (6) } \\
& =\sum_{\substack{D \in \Delta(\beta) \\
f \in \mathcal{F}}} \eta(D) \cdot \Theta(f) \cdot \sum_{t \in \operatorname{supp}(E)} D(t) \cdot \sum_{\substack{\left(\mathrm{R}^{\prime}, u\right) \in \mathcal{R}_{\mathrm{n}}\left(\mathbb{N}, \mathrm{~N}_{2}, \operatorname{cor}_{\mathrm{R}}(t)\right) \\
\mid f(t)=\left(\mathrm{R}^{\prime}, u\right)}} \operatorname{RProb}_{\mathrm{R}^{\prime}}\left(u, \operatorname{corr}_{\mathrm{R}^{\prime}}^{-1}(\mathcal{T})\right) \\
& =\sum_{\substack{D \in \Delta(\beta) \\
f \in \mathcal{F}}} \eta(D) \cdot \Theta(f) \cdot \sum_{\substack{t \in \operatorname{supp}(E) \\
\left(\mathrm{R}^{\prime}, u \in \mathcal{R}_{\text {nr }}\left(\mathbb{N}, \operatorname{corrr}_{\mathrm{R}}(t)\right) \\
\mid f(t)=\left(\mathrm{R}^{\prime}, u\right)\right.}} D(t) \cdot \operatorname{RProb}_{\mathrm{R}^{\prime}}\left(u, \operatorname{corr}_{\mathrm{R}^{\prime}}^{-1}(\mathcal{T})\right)
\end{aligned}
$$

By definition of $\mathrm{R}_{D, f}$, for all $t \in \operatorname{supp}(E)$ with $f(t)=\left(\mathrm{R}^{\prime}, u\right)$, we know that $\operatorname{trans}_{\mathrm{R}_{D, f}}(s)(u)=D(t)$, and for all other states $u \in \mathcal{S}_{\mathrm{R}_{f, D}}, \operatorname{trans}_{\mathrm{R}_{D, f}}(s)(u)=0$. Hence:

$$
\begin{aligned}
& \operatorname{RProb}_{\mathrm{R}}^{\leq n+1}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\mathcal{T})\right) \\
& =\sum_{\substack{D \in \Delta(s, \tau, E) \\
f \in \mathcal{F}}} \eta(D) \cdot \Theta(f) \cdot \sum_{u \in \mathcal{S}_{\mathbb{R}_{D, f}}} \operatorname{trans}_{\mathrm{R}_{D, f}}(s)(u) \cdot \operatorname{RProb}_{\mathrm{R}_{D, f}}\left(u, \operatorname{corr}_{\mathrm{R}_{D, f}}^{-1}(\mathcal{T})\right)
\end{aligned}
$$

Finally, $\operatorname{RProb}_{\mathrm{R}_{f, D}}\left(u, \operatorname{corr}_{\mathrm{R}_{f, D}}^{-1}(\mathcal{T})\right)=\lim _{n \rightarrow+\infty} \operatorname{RProb}_{\mathrm{R}_{f, D}}^{\leq n}\left(u, \operatorname{corr}_{\mathrm{R}_{f, D}}^{-1}(\mathcal{T})\right)$. With $\operatorname{supp}\left(\operatorname{trans}_{\mathrm{R}_{f, D}}(s)\right)$ being finite, we deduce that:

$$
\begin{aligned}
& \sum_{u \in \mathcal{S}_{\mathbb{R}_{D, f}}} \operatorname{trans}_{\mathrm{R}_{D, f}}(s)(u) \cdot \operatorname{RProb}_{\mathrm{R}_{D, f}}\left(u, \operatorname{corr}_{\mathrm{R}_{D, f}}^{-1}(\mathcal{T})\right) \\
= & \sum_{u \in \mathcal{S}_{\mathbb{R}_{D, f}}} \operatorname{trans}_{\mathrm{R}_{D, f}}(s)(u) \cdot \lim _{n \rightarrow+\infty} \operatorname{RProb}_{\mathrm{R}_{D, f}}^{\leq n}\left(u, \operatorname{corr}_{\mathrm{R}_{D, f}}^{-1}(\mathcal{T})\right) \\
= & \lim _{n \rightarrow+\infty} \sum_{u \in \mathcal{S}_{\mathrm{R}_{D, f}}} \operatorname{trans}_{\mathrm{R}_{D, f}}(s)(u) \cdot \operatorname{RProb}_{\mathrm{R}_{D, f}}^{\leq n}\left(u, \operatorname{corr}_{\mathrm{R}_{D, f}}^{-1}(\mathcal{T})\right) \\
= & \operatorname{RProb}_{\mathrm{R}_{D, f}}\left(s, \operatorname{corr}_{\mathrm{R}_{D, f}}^{-1}(\mathcal{T})\right)
\end{aligned}
$$

We conclude that:

$$
\operatorname{RProb}_{\mathrm{R}}^{\leq n+1}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\mathcal{T})\right)=\sum_{\substack{D \in \Delta(\beta) \\ f \in \mathcal{F}}} \eta(D) \cdot \Theta(f) \cdot \operatorname{RProb}_{\mathrm{R}_{D, f}}\left(s, \operatorname{corr}_{\mathrm{R}_{D, f}}^{-1}(\mathcal{T})\right)
$$

Lemma 19. For all $\mathcal{P} \in \mathcal{M} \mathcal{P}$, for all $c \in \mathcal{N}_{p u b}, \operatorname{RProb}_{\mathcal{R}_{n r}^{o}}(\mathcal{P}, \downarrow c)=\operatorname{RProb}_{\mathcal{R}_{r}^{o}}(\mathcal{P}, \downarrow c)$.
Proof. Since $\mathcal{R}_{\mathrm{nr}}^{o} \subset \mathcal{R}_{\mathrm{r}}^{o}$, we immediately have that $\operatorname{RProb}_{\mathcal{R}_{\mathrm{rr}}^{o}}(\mathcal{P}, \downarrow c) \leq \operatorname{RProb}_{\mathcal{R}_{\mathrm{r}}^{o}}(\mathcal{P}, \downarrow c)$.
The reverse inequality follows by Lemma 18 (observe that the NPLTS $\mathrm{N}^{o}$ is indeed such that $\operatorname{trans}_{\mathrm{N}^{o}}(s, \tau)=D$ implies that $D$ has finite support): for any resolution $\mathrm{R} \in \mathcal{R}_{\mathrm{r}}^{o}$, it holds that for every $n \in \mathbb{N}$

$$
\operatorname{RProb}_{\mathrm{R}}^{\leq n}(\mathcal{P}, \downarrow c) \leq \operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}^{o}}(\mathcal{P}, \downarrow c)
$$

As a consequence:

$$
\operatorname{RProb}_{\mathcal{R}_{r}^{o}}(\mathcal{P}, \downarrow c)=\sup _{\mathrm{R} \in \mathcal{R}_{r}^{o}}\left(\sup _{n \in \mathbb{N}}\left(\operatorname{RProb}_{\mathrm{R}}^{\leq n}(\mathcal{P}, \downarrow c)\right) \leq \operatorname{RProb}_{\mathcal{R}_{n r}^{o}}(\mathcal{P}, \downarrow c)\right.
$$

Proposition 1. The may testing preorder coincides for randomized and non-randomized resolutions:

$$
\leq_{m a y}^{\mathcal{R}_{r}^{o}}=\leq_{m a y}^{\mathcal{R}_{n}^{o}}
$$

Proof. Direct from Lemma 19.

## B Appendix on trace equivalence

## B. 1 Randomized and non-randomized resolutions coincide for trace equivalence

Lemma 20. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}}\right)$ be a NPLTS, and $\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $_{\mathrm{R}}$, trans $\left._{\mathrm{R}}\right) \in$ $\mathcal{R}_{\mathrm{r}}(\mathbb{N})$. For $n \in \mathbb{N}, w \in \mathcal{A}_{\text {ext }}{ }^{*}$ and $s \in \mathcal{S}_{\mathrm{R}}$, we define $\operatorname{Prob}_{\mathrm{R}}^{n}(s, w)$ as:

$$
\begin{aligned}
& \operatorname{Prob}_{\mathrm{R}}^{n}(s, \epsilon)=1 \\
& \operatorname{Prob}_{\mathrm{R}}^{n}(s, a . w)=\sum_{\substack{t \in \mathcal{S}_{\mathrm{R}} \\
\text { s.t. } \exists D \in \mathcal{D}\left(\mathcal{S}_{\mathrm{R}}\right), \operatorname{trans}_{\mathrm{R}}(t)(a)=D}} \operatorname{RProb}_{\mathrm{R}}^{\leq n}(s,\{t\}) \cdot \sum_{s^{\prime} \in \operatorname{supp}(D)} D\left(s^{\prime}\right) \cdot \operatorname{Prob}_{\mathrm{R}}^{n}\left(s^{\prime}, w\right)
\end{aligned}
$$

Then, for any $u \in \mathcal{S}_{\mathrm{N}}$, it holds that:

$$
\operatorname{Prob}_{\mathcal{R}}(u, w)=\sup _{n \in \mathbb{N}} \sup _{\substack{\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}, \operatorname{corr}, \text {,trans } \\ s \in \mathcal{S}_{\mathrm{R}} \text { s.t. } \operatorname{cor}(s)=u\right.}} \operatorname{Prob}_{\mathrm{R}}(s, w)
$$

Proof. The proof is by induction on the length of $w$.
Here, we develop the tools to compute the trace success probability as reachability pribabilities on a new auxilliary NPLTS: the traces NPLTS $\mathrm{N}^{\text {tr }}$, that we build from any NPLTS N. We first define a particular kind of NPLTS: aprobabilistic abstract rewriting system(PARS) is a NPLTS with no external actions, and a unique internal action $\tau$.

Definition 32. We say that a NPLTS N is a probabilistic abstract rewriting system when N has exactly one internal action $\tau$, and no external action. When it is the case, we say that a N state $s$ is a normal form when $\operatorname{trans}(s, \tau)=\varnothing$, i.e. no transition starts from $s$.

Definition 33. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}}\right)$ be a NPLTS. We define the PARS $\mathrm{N}^{t r}$ as follows: its states are $\left\{(s, w) \mid s \in \mathcal{S}_{\mathrm{N}}, w \in \mathcal{A}_{\text {ext }}^{\star}\right\} \sqcup\{$ success $\}$. The transition function $\rightarrow$ is defined as:

- $(s, w) \rightarrow_{\mathbf{N}^{t r}}(D, w)$ when $s \stackrel{\tau}{\rightarrow}_{\mathrm{N}} D ;$
- $(s, a w) \rightarrow_{\mathrm{N}^{t r}}(D, w)$ when $s{ }^{a}{ }_{\mathrm{N}} D$;
- $(s, \epsilon) \rightarrow \delta_{\text {success }}$.

Observe that the normal forms of this PARS are: either the state success, or states of the form ( $s, a . w$ ), with $s \xrightarrow{a}$ and $s \stackrel{H}{\leftrightarrows}$.

Our goal is to prove that the trace equivalence can be computed directly in the PARS $\mathrm{P}^{t r}$, instead of the labelled NPLTS $\mathrm{N}^{\ell}$. As a first step, we build a correspondence between N resolutions and $\mathrm{N}^{t r}$ resolutions. This correspondance consists actually of two operators: $\mathbf{C}: \mathcal{R}_{\mathrm{r}}(\mathrm{N}) \rightarrow \mathcal{R}_{\mathrm{r}}\left(\mathrm{N}^{t r}\right)$ and $\mathbf{D}: \mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}^{t r}\right) \rightarrow \mathcal{R}_{\mathrm{nr}}(\mathrm{N})$. Observe that, for technical reasons, the operator $\mathbf{D}$ can only be applied to non-randomized resolutions.

Definition 34. We define an operator $\mathbf{C}: \mathcal{R}_{r}(\mathrm{~N}) \rightarrow \mathcal{R}_{\mathrm{r}}\left(\mathrm{N}^{t r}\right)$ as follows: let $\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $\left._{\mathrm{R}}, \operatorname{trans}_{\mathrm{R}}\right) \in$ $\mathcal{R}_{r}(\mathrm{~N})$. We take $\mathbf{C R}=\left(\mathcal{S}_{\mathrm{CR}}\right.$, corr $\left._{\mathrm{CR}}, \operatorname{trans}_{\mathrm{CR}}\right)$ where:

- $\mathcal{S}_{\mathrm{CR}}=\left\{(s, w) \mid s \in \mathcal{S}_{\mathrm{R}}, w \in \mathcal{A}_{\text {ext }}^{\star}\right\} \sqcup\{$ success $\} ;$
- $\operatorname{corr}_{\mathrm{CR}}(s, w)=\left(\operatorname{corr}_{\mathrm{R}}(s), w\right)$, and $\operatorname{corr}_{\mathrm{CR}}($ success $)=$ success ;
- $\operatorname{trans}_{\mathbf{C R}}(s, w)(\tau)=\left\{\begin{array}{l}\left(\operatorname{trans}_{\mathrm{R}}(s), w\right) \text { if } s \text { is an internal state in } \mathrm{R} \\ \delta_{\text {success }} \text { if } s \text { external state and } w=\epsilon \\ \left(\operatorname{trans}_{\mathrm{R}}(s)(a), w^{\prime}\right) \text { when } w=a \cdot w^{\prime} \text { and } \operatorname{trans}_{\mathrm{R}}(s)(a) \text { is defined } \\ \text { undefined otherwise. }\end{array}\right.$

Observe moreover that whenever R is a non-randomized resolution over $\mathrm{N}, \mathrm{CR}$ is a nonrandomized resolution over $\mathrm{N}^{t r}$.

Definition 35. We define an operator $\mathbf{D}: \mathcal{R}_{n r}\left(N^{t r}\right) \rightarrow \mathcal{R}_{n r}(N)$ as follows: let $\mathrm{R}=$ $\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $_{\mathrm{R}}$, trans $\left._{\mathrm{R}}\right) \in \mathcal{R}_{\mathrm{r}}\left(\mathrm{N}^{t r}\right)$. We take $\mathrm{DR}=\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $\left._{\mathrm{R}}, \operatorname{trans}_{\mathrm{DR}}\right)$ where: $\operatorname{trans}_{\mathrm{DR}}: \mathcal{S}_{\mathrm{R}} \times$ $\mathcal{A}_{\mathrm{N}} \rightarrow \mathcal{D}\left(\mathcal{S}_{\mathrm{R}}\right)$ is defined as:

- if $u \in \mathcal{S}_{\mathrm{R}}$ is such that $\operatorname{trans}_{\mathrm{R}}(u)(\tau)$ is undefined, then $\operatorname{trans}_{\mathrm{R}}(u)(a)$ is undefined for every $a \in \mathcal{A}_{e x t} \cup\{\tau\}$;
- suppose now that $\operatorname{trans}_{\mathrm{R}}(u)(\tau)=D$. Since R is a non-randomized resolution, we can do the following cases disjunction:
- either $u \in \mathcal{S}_{\mathrm{R}}$ is such that $\operatorname{corr}_{\mathrm{R}}(u)=(s, \epsilon)$, and $\operatorname{corr}_{\mathrm{R}}(D)=\delta_{\text {success }}$. Then we take $\operatorname{trans}_{\mathrm{DR}}(u)(a)$ as undefined for every $a \in \mathcal{A}_{\text {ext }} \cup\{\tau\}$;
- or $u \in \mathcal{S}_{\mathrm{R}}$ is such that $\operatorname{corr}_{\mathrm{R}}(u)=(s, w)$, and $\operatorname{corr}_{\mathrm{R}}(D)=(E, w)$. Then we take $\operatorname{trans}_{\mathbf{D R}}(u)(\tau)=D$, and $\operatorname{trans}_{\mathrm{DR}}(u)(a)$ as undefined for every $a \in \mathcal{A}_{\text {ext }}$;
- or $u \in \mathcal{S}_{\mathrm{R}}$ is such that $\operatorname{corr}_{\mathrm{R}}(u)=\left(s, a_{0} \cdot w\right)$, and $\operatorname{corr}_{\mathrm{R}}(D)=(E, w)$. Then we take $\operatorname{trans}_{\mathrm{DR}}(u)\left(a_{0}\right)=D$, and $\operatorname{trans}_{\mathbf{D R}}(u)(a)$ as undefined for every $a \in$ $\{\tau\} \cup\left(\mathcal{A}_{\text {ext }} \backslash\left\{a_{0}\right\}\right)$.

Lemma 21. Let N a NPLTS, and $w \in \mathcal{A}_{\text {ext }}^{\star}$. . Then:

1. For every $\mathrm{R} \in \mathcal{R}_{\mathbf{r}}(\mathbb{N})$, and $s \in \mathcal{S}_{\mathbf{R}}, \operatorname{Prob}_{\mathbf{R}}(s, w) \leq \operatorname{RProb}_{\mathbf{C R}}\left((s, w)\right.$, $\operatorname{corr}_{\mathbf{C R}}^{-1}($ success $\left.)\right)$.
2. For every $\mathrm{R} \in \mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}^{t r}\right)$, and $s \in \mathcal{S}_{\mathrm{R}}$ such that there exists $u$, $\operatorname{corr}(s)=(u, w)$, it holds that $\operatorname{Prob}_{\mathbf{D R}}(s, w) \geq \operatorname{RProb}_{\mathrm{R}}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\right.$ success $\left.)\right)$.

Proof of item 1 in Lemma 21. Let us suppose $\mathrm{R} \in \mathcal{R}_{\mathrm{r}}(\mathrm{N})$, and $s \in \mathcal{S}_{\mathrm{R}}$. First, we can show easily by induction on $n$, that for all non-empty trace $\omega$, for all states $t \in \mathcal{S}_{\mathrm{R}}, z \in \mathcal{S}_{\mathrm{CR}}$, it holds that:

$$
\operatorname{RProb}_{\mathrm{CR}}^{\leq n}((t, w),\{z\})=\left\{\begin{array}{l}
\operatorname{RProb}_{\mathrm{R}}^{\leq n}(t, u) \text { if } z=(u, w)  \tag{8}\\
0 \text { if } \nexists u \text { with } z=(u, w)
\end{array}\right.
$$

Now, observe that corr ${ }_{\mathrm{CR}}^{-1}($ success $)=\{$ success $\}$. We use the limit-based caracterisation of trace success probability (see Lemma 20), and we obtain a rewriting of our goal-i.e. item 1 in Lemma 21 as the Equation (9) below:

$$
\begin{equation*}
\forall n \in \mathbb{N}, \operatorname{Prob}_{\mathrm{R}}^{n}(s, w) \leq \operatorname{RProb}_{\mathbf{C R}}((s, w),\{\text { success }\}) \tag{9}
\end{equation*}
$$

Th proof of Equation 9 is by induction on length $(w)$. If $w=\epsilon$, then $\operatorname{Prob}_{\mathrm{R}}^{n}(s, w)=1$. Moreover, $\operatorname{RProb}_{\mathbf{C R}}((s, \epsilon),\{$ success $\})=1$ since $\operatorname{trans}_{\mathbf{C R}}(s, \epsilon)(\tau)=\delta_{\text {success }}$, thus the result
holds. Suppose now that $w=a . w^{\prime}$, and that Equation 9 holds for $w^{\prime}$. Then:

$$
\begin{aligned}
& \operatorname{Prob}_{\mathrm{R}}^{n}\left(s, a \cdot w^{\prime}\right) \\
& =\sum_{\substack{t \in \mathcal{S}_{\mathrm{R}} \\
\text { s.t. } \exists D \in \mathcal{D}\left(\mathcal{S}_{\mathrm{R}}\right),}} \operatorname{RProb}_{\mathrm{R}}^{\leq n}(s,\{t\}) \cdot \sum_{s^{\prime} \in \operatorname{supp}(D)} D\left(s^{\prime}\right) \cdot \operatorname{Prob}_{\mathrm{R}}^{n}\left(s^{\prime}, w^{\prime}\right) \text { by Lemma } 20 \\
& \begin{array}{l}
\text { s.t. } \exists D \in \mathcal{D}\left(\mathcal{S}_{\mathrm{R}}\right), \\
\text { transp } \\
\text { ( })(a)=D
\end{array} \\
& =\sum_{\substack{t \in \mathcal{S}_{\mathrm{R}} \\
\text { s.t. } \exists D \in \mathcal{D}\left(\mathcal{S}_{\mathrm{R}}\right),}} \operatorname{RProb}_{\mathrm{CR}}^{\leq n}\left(\left(s, a \cdot w^{\prime}\right),\left\{\left(t, a \cdot w^{\prime}\right)\right\}\right) \cdot \sum_{s^{\prime} \in \operatorname{supp}(D)} D\left(s^{\prime}\right) \cdot \operatorname{Prob}_{\mathrm{R}}^{n}\left(s^{\prime}, w^{\prime}\right) \\
& \operatorname{trans}_{\mathrm{R}}(t)(a)=D \\
& \leq \sum_{\substack{t \in \mathcal{S}_{\mathbb{R}} \\
\text { s.t. } \exists D \in \mathcal{D}\left(\mathcal{S}_{\mathrm{R}}\right), \\
\text { trans }(t)(a)=D}} \operatorname{RProb}_{\mathrm{CR}}^{\leq n}\left(\left(s, a . w^{\prime}\right),\left\{\left(t, a . w^{\prime}\right)\right\}\right) \cdot \sum_{s^{\prime} \in \operatorname{supp}(D)} D\left(s^{\prime}\right) \cdot \operatorname{RProb}_{\mathbf{C R}}\left(\left(s^{\prime}, w^{\prime}\right),\left\{\text { success }^{\leq}\right\}\right) \text {by HI; } \\
& =\sum_{\substack{u=\left(t, a . w^{\prime}\right) \in \mathcal{S}_{\mathbf{C R}} \\
s,(\mathcal{D}}} \operatorname{RProb}_{\mathbf{C R}}^{\leq n}\left(\left(s, a . w^{\prime}\right),\{u\}\right) \cdot \sum_{v=\left(s^{\prime}, w^{\prime}\right) \in \operatorname{supp}(D)} D(v) \cdot \operatorname{RProb}_{\mathbf{C R}}(v,\{\text { success }\}) \\
& \text { s.t. } \exists D \in \mathcal{D}\left(\mathcal{S}_{\mathrm{CR}}\right) \text {, } \\
& \operatorname{trans}_{\text {CR }}(u)(\tau)=D \\
& \leq \sum_{\substack{u=\left(t, a . w^{\prime}\right) \in \mathcal{S}_{\mathbf{C R}} \\
\text { s. } \\
\exists \in \mathcal{D}\left(\mathcal{S}_{\mathbf{C}}\right)}} \operatorname{RProb}_{\mathbf{C R}}\left(\left(s, a . w^{\prime}\right),\{u\}\right) \cdot \sum_{v=\left(s^{\prime}, w^{\prime}\right) \in \operatorname{supp}(D)} D(v) \cdot \operatorname{RProb}_{\mathbf{C R}}(v,\{s u c c e s s\}) \\
& \text { s.t. } \exists D \in \mathcal{D}\left(\mathcal{S}_{\mathrm{CR}}\right) \text {, } \\
& \operatorname{trans}_{\text {CR }}(u)(\tau)=D \\
& =\operatorname{RProb}_{\mathbf{C R}}\left(\left(s, a . w^{\prime}\right),\{\text { success }\}\right)
\end{aligned}
$$

Proof of item 2 in Lemma 21. Let be $\mathrm{R} \in \mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}^{t r}\right)$, and $s \in \mathcal{S}_{\mathrm{R}}$ such that there exists $u$, $\operatorname{corr}_{\mathrm{R}}(s)=(u, w)$. First, observe that we can restate our goal as:

$$
\operatorname{Prob}_{\mathrm{DR}}(s, w) \geq \operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\text { success })\right) .
$$

We do the proof by induction on $n$ :

- $n=0$ : since by hypothesis $\operatorname{corr}_{\mathrm{R}}(s)=(u, w) \neq$ success, it holds that $\operatorname{RProb}_{\mathrm{R}}^{\leq 0}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\right.$ success $\left.)\right)=$ 0 , thus the result holds;
- $n=1$ : looking at the way we define $\mathrm{N}^{t r}$, we see that $\operatorname{RProb}_{\mathrm{R}}^{\leq 1}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\right.$ success $\left.)\right)>0$ implies that $w=\epsilon$. When it is the case, $\operatorname{Prob}_{\mathbf{D R}}(s, w)=1$, thus we can conclude;
- $n \rightarrow n+1$ with $n>0$ : if $\operatorname{RProb}_{\mathrm{R}}^{\leq n+1}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\right.$ success $\left.)\right)=0$, we have immediately
the result. Otherwise, it means that there exists $D$ such that $s \rightarrow_{\mathrm{R}} D$, and:

$$
\begin{align*}
& \operatorname{RProb}_{\mathrm{R}}^{\leq n+1}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\text { success })\right)=\sum_{s^{\prime}} D(t) \cdot \operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(s^{\prime}, \operatorname{corr}_{\mathrm{R}}^{-1}(s u c c e s s)\right)  \tag{10}\\
& =\sum_{s^{\prime} \mid \operatorname{corr}_{\mathrm{R}}\left(s^{\prime}\right)=\text { success }} D\left(s^{\prime}\right)+\sum_{t \mid \exists u^{\prime}, w^{\prime} \text { s.t. } \operatorname{corr}_{\mathrm{R}}\left(s^{\prime}\right)=\left(u^{\prime}, w^{\prime}\right)} D\left(s^{\prime}\right) \cdot \operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(s^{\prime}, \operatorname{corr}_{\mathrm{R}}^{-1}(\text { success })\right)  \tag{11}\\
& \leq \sum_{s^{\prime} \mid \operatorname{corr}_{\mathrm{R}}(t)=\text { success }} D\left(s^{\prime}\right)+\sum_{s^{\prime} \mid \exists u^{\prime}, w^{\prime} \text { s.t. corr }\left(s^{\prime}\right)=\left(u^{\prime}, w^{\prime}\right)} D\left(s^{\prime}\right) \cdot \operatorname{Prob}_{\mathrm{DR}}\left(s^{\prime}, w^{\prime}\right) \quad \text { by induction hyp. } \tag{12}
\end{align*}
$$

Looking at the way $\mathrm{N}^{t r}$ is defined, we do the following case disjunction on $s \rightarrow_{\mathrm{R}} D$ :

1. either $w=\epsilon$. In that case, we see that $\operatorname{Prob}_{\mathbf{D R}}(s, w)=\operatorname{Prob}_{\mathbf{D R}}(s, w)=1$, and we can conclude.
2. or $w=a . w_{1}$. In that case, $\sum_{s^{\prime} \mid \operatorname{corrr}_{\mathrm{R}}(t)=s u c c e s s} D\left(s^{\prime}\right)=0$, and using the fact that R is a non-randomized distrubution, it holds that:

- either $D=(E, w)$ with $E \in \mathcal{D}\left(\mathcal{S}_{\mathrm{N}}\right)$, and $u \stackrel{\tau}{\rightarrow}_{\mathrm{N}} E$; In that case, looking at the definition of the operator $\mathbf{D}$, we see that $s{ }^{\tau}{ }_{\mathbf{D R}} D$. From there, we can rewrite Equation (12) as: $\operatorname{RProb}_{\mathrm{R}}^{\leq n+1}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\right.$ success $\left.)\right) \leq \sum_{s^{\prime}} D\left(s^{\prime}\right)$. $\operatorname{Prob}_{\mathbf{D R}}\left(s^{\prime}, w\right)=\sum_{s^{\prime}}\left(\operatorname{trans}_{\text {DR }}(s)(\tau)\right)\left(s^{\prime}\right) \cdot \operatorname{Prob}_{\mathbf{D R}}\left(s^{\prime}, w\right)$, and we can conclude by looking at how we defined the probability of doing a trace.
- or $D=\left(E, w_{1}\right)$ whith $u \xrightarrow{a}_{\mathrm{N}} E$; in that case, looking at the definition of the operator $\mathbf{D}$, we see that $s{ }^{a}{ }_{\mathbf{D R}} D$. From there, we can conclude as in the previous case.

Lemma 22. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}}\right)$ be a NPLTS. Let be $s \in \mathcal{S}_{\mathrm{N}}$, and $w \in \mathcal{A}_{\text {ext }}^{\star}$.

1. Randomized case:

$$
\operatorname{Prob}_{\mathcal{R}_{r}(\mathbb{N})}(s, w) \leq \sup \left\{\operatorname{RProb}_{\mathbf{R}}\left(s^{\prime}, \operatorname{corr}_{\mathbf{R}}^{-1}(\text { success })\right) \text { s.t. } \mathrm{R} \in \mathcal{R}_{\mathbf{r}}\left(\mathbf{N}^{t r}\right), s^{\prime} \in \mathcal{S}_{\mathbf{R}} \operatorname{corr}_{\mathrm{R}}\left(s^{\prime}\right)=(s, w)\right\} .
$$

2. Non-randomized case:

$$
\operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}(\mathbb{N})}(s, w)=\sup \left\{\operatorname{RProb} \mathrm{R}_{\mathrm{R}}\left(s^{\prime}, \operatorname{corr}_{\mathrm{R}}^{-1}(\text { success })\right) \text { s.t. } \mathrm{R} \in \mathcal{R}_{\mathrm{nr}}\left(\mathbf{N}^{t r}\right), s^{\prime} \in \mathcal{S}_{\mathrm{R}} \operatorname{corr}_{\mathrm{R}}\left(s^{\prime}\right)=(s, w)\right\}
$$

Proof. We do the proof using Lemma 21; let us fix $s \in \mathcal{S}_{\mathrm{N}}$.

- Using (the first part of) Lemma 21, we see that for every $\mathrm{R} \in \mathcal{R}_{\mathrm{r}}(\mathrm{N})$, and $s^{\prime} \in \mathcal{S}_{\mathrm{R}}$ with $\operatorname{corr}_{\mathrm{R}}\left(s^{\prime}\right)=s$, it holds that $\operatorname{Prob}_{\mathrm{R}}\left(s^{\prime}, w\right) \leq \operatorname{RProb}_{\mathbf{C R}}\left(\left(s^{\prime}, w\right), \operatorname{corr}_{\mathbf{C R}}^{-1}(s u c c e s s)\right)$. From there, we can see that $\operatorname{Prob}_{\mathrm{R}}\left(s^{\prime}, w\right) \leq \sup _{\mathrm{R}^{\prime} \in \mathcal{R}_{r}\left(N^{t r}\right), u \in \mathcal{S}_{\mathcal{R}^{\prime}}, \operatorname{corr}_{\mathrm{R}^{\prime}}(u)=(s, w)} \operatorname{RProb}_{\mathrm{R}^{\prime}}\left(u, \operatorname{corr}_{\mathrm{R}^{\prime}}^{-1}(\right.$ success $\left.)\right)$. As a consequence, we obtain the item 1 in Lemma 22 . Since moreover $\mathbf{C}\left(\mathcal{R}_{n r}(N)\right) \subseteq$ $\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}^{t r}\right)$, we obtain also the $\leq$ inequality for the item 2 in Lemma (22).
- Using (the second part of) Lemma 21, we see that for every $\mathrm{R} \in \mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}^{t r}\right)$, and $s^{\prime} \in \mathcal{S}_{\mathrm{R}}$, such that $\operatorname{corr}_{\mathrm{R}}\left(s^{\prime}\right)=(s, w)$, it holds that $\operatorname{RProb}_{\mathrm{R}}\left(s^{\prime}, \operatorname{corr}_{\mathrm{R}}^{-1}(\right.$ success $\left.)\right) \leq$ $\operatorname{Prob}_{\mathbf{D R}}\left(s^{\prime}, w\right)$. From there, we obtain that $\operatorname{RProb} \boldsymbol{P}_{\mathbf{R}}\left(s^{\prime}, \operatorname{corr}_{\mathrm{R}}^{-1}(s u c c e s s)\right) \leq \operatorname{Prob}_{\mathcal{R}_{\text {nr }}(\mathbb{N})}(s, w)$, thus we can conclude.

Proposition 2. Let $(\mathcal{P}, \phi)$ and $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ be two extended processes.

$$
(\mathcal{P}, \phi) \leq_{t r}^{\mathcal{R}_{r}^{\ell}}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \quad \text { iff } \quad(\mathcal{P}, \phi) \leq_{t r}^{\mathcal{R}_{n r}^{\ell}}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)
$$

Proof. First, observe that it is enough to show that for every trace $w$, for every $\mathrm{N}^{\ell}$-state $u: \operatorname{Prob}_{\mathcal{R}_{\mathrm{r}}\left(\mathrm{N}^{\ell}\right)}(u, w)=\operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathbf{N}^{\ell}\right)}(u, w)$.

- Since $\mathcal{R}_{\mathrm{nr}}\left(\mathbf{N}^{\ell}\right) \subseteq \mathcal{R}_{\mathbf{r}}\left(\mathbf{N}^{\ell}\right)$, we see immediately that $\operatorname{Prob}_{\mathcal{R}_{r}\left(\mathbf{N}^{\ell}\right)}(u, w) \geq \operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}^{\ell}\right)}(u, w)$.
- We now show the reverse inequality.

$$
\begin{aligned}
& \operatorname{Prob}_{\mathcal{R}_{\mathrm{r}}\left(N^{\ell}\right)}(u, w) \\
& =\sup \left\{\operatorname{RProb}_{\mathrm{R}}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\text { success })\right) \mid \mathrm{R} \in \mathcal{R}_{\mathrm{r}}\left(\mathrm{~N}^{t^{t r}}\right), s^{\prime} \in \mathcal{S}_{\mathrm{R}}, \operatorname{corr}_{\mathrm{R}}\left(s^{\prime}\right)=s\right\} \text { by Lemma 22; } \\
& =\sup \left\{\operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\text { success })\right) \mid \mathrm{R} \in \mathcal{R}_{\mathrm{r}}\left(\mathrm{~N}^{\ell t r}\right), s^{\prime} \in \mathcal{S}_{\mathrm{R}}, \operatorname{corr}_{\mathrm{R}}\left(s^{\prime}\right)=s, n \in \mathbb{N}\right\} \\
& \leq \sup \left\{\operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\text { success })\right) \mid \mathrm{R} \in \mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{\ell^{t r}}\right), s^{\prime} \in \mathcal{S}_{\mathrm{R}}, \operatorname{corr}_{\mathrm{R}}\left(s^{\prime}\right)=s, n \in \mathbb{N}\right\} \text { by Lemma } 18 \\
& =\operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{\ell}\right)}(u, w) \text { by Lemma } 22
\end{aligned}
$$

## C Relations $\xlongequal{\tau}{ }_{r}$ and $\Longrightarrow_{\mathcal{R}_{r}}$ coincide

Lemma 23. Let $\mathrm{N}=\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}}\right)$ be an NPLTS and a resolution $\mathrm{R}=$ $\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $_{\mathrm{R}}$, trans $\left._{\mathrm{R}}\right)$ of N . For all subset $\mathcal{T} \subseteq \mathcal{S}_{\mathrm{R}}$, for all $s \in \mathcal{S}_{\mathrm{R}}$,

$$
\begin{aligned}
& \operatorname{RProb}_{\mathrm{R}}(s, \mathcal{T})= \begin{cases}1 & \text { if } s \in \mathcal{T} \\
0 & \text { otherwise }\end{cases} \\
& \operatorname{RProb}_{\mathrm{R}}(s, \mathcal{T})= \begin{cases}1 & \text { if } s \in \mathcal{T} \\
0 & \text { if } s \notin \mathcal{T} \wedge \operatorname{trans}_{\mathrm{R}}(s)=\star \\
\sum_{u \in \operatorname{supp}(D)} D(u) \cdot \operatorname{RProb}_{\mathrm{R}}(u, \mathcal{T}) \quad \text { if } s \notin \mathcal{T} \wedge \operatorname{trans}_{\mathrm{R}}(s)=(a, D)\end{cases}
\end{aligned}
$$

Proof. Direct from Definition 7 and the fact that $\operatorname{RProb}_{R}^{\leq n}(s, \mathcal{T})$ is increasing on $n$.
We now state three technical lemmas-Lemmas 24, 25, 26, about basic properties of the reduction relation $\rightarrow$ on distributions. These lemmas are used later in the proof of Lemma 1 .

Lemma 24. Let $X$ be a discrete set, $\rightarrow \subset X \times \mathcal{D}(X)$ a binary relation, and $s \in X$.

$$
\delta_{s} \rightarrow_{\mathrm{r}} D \quad \text { iff } \quad D \in \operatorname{conv}(\{E \mid s \rightarrow E\})
$$

Proof. Direct from Definition 14 and Notation 4.
Lemma 25. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}}\right)$ be a NPLTS, $\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $_{\mathrm{R}}$, trans $\left.{ }_{\mathrm{R}}\right) \in \mathcal{R}_{\mathrm{r}}(\mathrm{N})$

Proof. By Definition 5, for all $s \in \operatorname{supp}(D), \operatorname{corr}_{R}\left(\operatorname{trans}_{R}(s)\right) \in \operatorname{conv}\left(\operatorname{trans}_{\mathcal{N}}\left(\operatorname{corr}_{\mathrm{R}}(s)\right)\right)$. Hence $\operatorname{corr}_{\mathrm{R}}\left(\operatorname{trans}_{\mathrm{R}}(s)\right) \in \operatorname{conv}\left(\left\{E_{s} \mid \operatorname{corr}_{\mathrm{R}}(s) \rightarrow E_{s}\right\}\right)$. Furthermore, $\operatorname{corr}_{\mathrm{R}}\left(\operatorname{trans}_{\mathrm{R}}(D)\right)=$ $\sum_{s \in \operatorname{supp}(D)} D(s) \cdot \operatorname{corr}_{\mathrm{R}}\left(\operatorname{trans}_{\mathrm{R}}(s)\right)=\sum_{s \in \operatorname{supp}(D)} D(s) \cdot \sum_{i=1}^{n_{s}} \alpha_{i}^{s} \cdot E_{i}^{s}=\sum_{s \in \operatorname{supp}(D)} \sum_{i=1}^{n_{s}}(D(s)$. $\left.\alpha_{i}^{s}\right) \cdot E_{i}^{s}$ with $\operatorname{corr}_{\mathrm{R}}(s) \rightarrow E_{i}^{s}$ for all $i \in\left\{1, \ldots, n_{s}\right\}$ and $\sum_{i=1}^{n_{s}} \alpha_{i}^{s}=1$. Since $D=$ $\sum_{s \in \operatorname{supp}(D)} D(s) \cdot \sum_{i=1}^{n_{s}} \alpha_{i}^{s} \cdot \delta_{s}$, we conclude that $\operatorname{corr}_{\mathrm{R}}(D)=\sum_{s \in \operatorname{supp}(D)} D(s) \cdot \sum_{i=1}^{n_{s}} \alpha_{i}^{s} \cdot \delta_{\text {corrr }(s)}$ and so $\operatorname{corr}_{\mathrm{R}}(D) \xrightarrow{\tau}_{\mathrm{r}} \operatorname{corr}_{\mathrm{R}}\left(\operatorname{trans}_{\mathrm{R}}(D)\right)$.

Lemma 26. Let $X$ be any discrete set, and let $\rightarrow$ be a binary relation in $X \times \mathcal{D}(X)$.
Suppose that $D \rightarrow_{\mathrm{r}} E$. There there exists a family of sub-distribution over $X:\left(E_{s}\right)_{s \in \operatorname{supp}(D)}$ such that for all $s \in \operatorname{supp}(D), \delta_{s} \rightarrow_{\mathrm{r}} E_{s}$ and $E=\sum_{s \in \operatorname{supp}(D)} D(s) \cdot E_{s}$.

Proof. Assume that $D \rightarrow_{\mathrm{r}} E$. By definition, there exists a countable set $I$ and a multiset $\left\{x_{i}\right\}_{i \in I}$ with for all $i \in I, x_{i} \in X$ such that:

- $D=\sum_{i \in I} \alpha_{i} \cdot \delta_{x_{i}}$
- for all $i \in I, x_{i} \rightarrow D_{i}$
- $E=\sum_{i \in I} \alpha_{i} \cdot D_{i}$

Note that $E=\sum_{s \in \operatorname{supp}(D)} \cdot \sum_{\substack{i \in x_{i} \\ s=x_{i}}} \alpha_{i} \cdot D_{i}$ and for all $s \in X, D(s)=\sum_{\substack{i \in I \\ s=x_{i}}} \alpha_{i}$. Hence, $E=\sum_{s \in \operatorname{supp}(D)} D(s) \cdot \sum_{i \in I} \frac{\alpha_{i}}{s=x_{i}} \overline{D(s)} \cdot D_{i}$. If we define for all $s \in \operatorname{supp}(D), E_{s}=\sum_{\substack{i=x_{i} \\ s=x_{i}}} \frac{\alpha_{i}}{D(s)} \cdot D_{i}$, we obtain that $E=\sum_{s \in \operatorname{supp}(D)} D(s) \cdot E_{s}$ and for all $s \in \operatorname{supp}(D), E_{s} \in \operatorname{conv}(\{F \mid s \rightarrow F\})$ which implies $\delta_{s} \rightarrow_{r} E_{s}$ by Lemma 24 .

Corollary 2. Let $X$ be any discrete set, and let $\rightarrow$ be a binary relation in $X \times \mathcal{D}(X)$.
Suppose that $D \rightarrow_{r} E+F$. Then there exists two families of sub-distribution over $X$ : $\left(E_{s}\right)_{s \in \operatorname{supp}(D)},\left(F_{s}\right)_{s \in \operatorname{supp}(D)}$ such that for all $s \in \operatorname{supp}(D), \delta_{s} \rightarrow_{\mathrm{r}} E_{s}+F_{s}, E=\sum_{s \in \operatorname{supp}(D)} D(s)$. $E_{s}$ and $F=\sum_{s \in \operatorname{supp}(D)} D(s) \cdot F_{s}$.

Proof. By Lemma 26, we know that there exists $\left(D_{s}\right)_{s \in \operatorname{supp}(D)}$ such that for all $s \in \operatorname{supp}(D)$, $\delta_{s} \rightarrow_{\mathrm{r}} D_{s}$ and $E+F=\sum_{s \in \operatorname{supp}(D)} D(s) \cdot D_{s}$.

We define the two families $\left(E_{s}\right)_{s \in \operatorname{supp}(D)}$ and $\left(F_{s}\right)_{s \in \operatorname{supp}(D)}$ as follows: for all $s \in \operatorname{supp}(D)$, for all $x \in X$,

- $E_{s}(x)=\frac{D_{s}(x) \cdot E(x)}{E(x)+F(x)}$
- $F_{s}(x)=\frac{D_{s}(x) \cdot F(x)}{E(x)+F(x)}$

We trivially have $D_{s}=E_{s}+F_{s}$.
Lemma 1. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}}\right)$ be a NPLTS and $D, E \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$.

$$
D \Longrightarrow_{\mathrm{r}}^{\tau} E \text { if and only if } D \Longrightarrow_{\mathcal{R}_{\mathrm{r}}} E
$$

Proof. We prove the two directions of the equivalences separately.
Left-to-right direction. Let us suppose that $D{ }_{\tau}^{\tau} E$. It means that there exists an infinite scheme of the form:

$$
\begin{aligned}
& D=D_{0}^{\rightarrow}+D_{0}^{\top} \\
& D_{0}^{\rightarrow} \xrightarrow{\tau}_{\mathrm{r}} D_{1}^{\rightarrow}+D_{1}^{\top} \\
& \ldots \\
& D_{k}^{\rightarrow} \xrightarrow{\tau}_{\mathrm{r}} D_{k+1}+D_{k+1}^{\top}
\end{aligned}
$$

with $E=\sum_{k \in \mathbb{N}} D_{k}^{\top}$. The proof consists of two steps: we first define a resolution $\mathrm{R} \in \mathcal{R}_{\mathrm{r}}(\mathrm{N})$, and in a second step we use R to show that $D \Longrightarrow{\mathcal{\mathcal { R } _ { \mathrm { r } }}} E$.

1. We define $\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $_{\mathrm{R}}$, trans $\left._{\mathrm{R}}\right)$, where $\mathcal{S}_{\mathrm{R}}=\{(s, n, \alpha) \mid n \in \mathbb{N}, \alpha \in\{\rightarrow, \top\}, s \in$ $\left.\operatorname{supp}\left(D_{n}^{\alpha}\right)\right\}$ and $\operatorname{corr}(s, n, \alpha)=s$ for every $n \in \mathbb{N}$ and every $\alpha \in\{\rightarrow, \top\}$, and

$$
\operatorname{trans}_{\mathrm{R}}(s, n, \alpha)=\left\{\begin{array}{l}
\star_{\mathcal{A}} \quad \text { if } \alpha=\top ; \\
\left(\tau, \sum_{s^{\prime} \in \mathcal{S}} \Delta(s, n, \top)\left(s^{\prime}\right) \cdot \delta_{\left(s^{\prime}, n+1, \mathrm{~T}\right)}+\Delta(s, n, \rightarrow)\left(s^{\prime}\right) \cdot \delta_{\left(s^{\prime}, n+1, \rightarrow\right)}\right) \\
\text { if } \alpha=\rightarrow
\end{array}\right.
$$

where $\star_{\mathcal{A}}$ stands for the function $\left(a \in \mathcal{A}_{\text {ext }} \mapsto \star\right), \mathcal{S}=\left\{s \mid(s, n, \alpha) \in \mathcal{S}_{\mathrm{R}}\right\}$ and for all $s \in \operatorname{supp}\left(D_{n}^{\vec{n}}\right), n \in \mathbb{N}, \alpha \in\{\rightarrow, \top\}$, the sub-distributions $\Delta(s, n, \alpha)$ are obtained from Corollary 2 such that:

$$
\begin{align*}
& \delta_{s} \stackrel{\tau}{\rightarrow}_{\mathrm{r}} \Delta(s, n, \rightarrow)+\Delta(s, n, \top), \quad \forall s \in \operatorname{supp}\left(D_{n}^{\rightarrow}\right) ;  \tag{13}\\
& D_{n+1}^{\rightarrow}=\sum_{s \in \operatorname{supp}\left(D_{n}\right)} D_{n}^{\rightarrow}(s) \cdot \Delta(s, n, \rightarrow)  \tag{14}\\
& D_{n+1}^{\top}=\sum_{s \in \operatorname{supp}\left(D_{n}\right)} D_{n}^{\rightarrow}(s) \cdot \Delta(s, n, \top) \tag{15}
\end{align*}
$$

We first check that R is indeed a N -resolution: first observe that for all external states $s^{\prime} \in \mathcal{S}_{\text {ext }}(\mathrm{R})$, for all $a \in \mathcal{A}_{\text {ext }}$, $\operatorname{trans}_{\mathrm{R}}\left(s^{\prime}\right)=\star$. Secondly, for all internal states $s^{\prime} \in \mathcal{S}_{\text {int }}(\mathrm{R})$ with $\operatorname{trans}_{\mathrm{R}}\left(s^{\prime}\right)=(\tau, F)$, it means that $s^{\prime}=(s, n, \rightarrow), s \in \operatorname{supp}\left(D_{n}^{\rightarrow}\right)$ and

$$
F=\sum_{s^{\prime} \in \mathcal{S}} \Delta(s, n, \top)\left(s^{\prime}\right) \cdot \delta_{\left(s^{\prime}, n+1, \top\right)}+\sum_{s^{\prime} \in \mathcal{S}} \Delta(s, n, \rightarrow)\left(s^{\prime}\right) \cdot \delta_{\left(s^{\prime}, n+1, \rightarrow\right)}
$$

Note that for all $s \in \mathcal{S}, n \in \mathbb{N}, \operatorname{supp}(\Delta(s, n, \top)) \subseteq \mathcal{S}$ and $\operatorname{supp}(\Delta(s, n, \rightarrow)) \subseteq \mathcal{S}$. Hence $\operatorname{corr}_{\mathrm{R}}(F)=\Delta(s, n, \rightarrow)+\Delta(s, n, \top)$. From (13) and Lemma 24, we obtain that $\operatorname{corr}_{\mathrm{R}}(F) \in \operatorname{conv}\left(\operatorname{trans}_{\mathrm{N}}(s)(\tau)\right)$, thus we can conclude that $\mathrm{R} \in \mathcal{R}_{r}(\mathrm{~N})$.
2. We define a distribution over R-states: $D^{\prime}=\sum_{s \in \mathcal{S}} D_{0}(s) \cdot \delta_{s, 0, \rightarrow}+\sum_{s \in \mathcal{S}} D_{0}^{\top}(s) \cdot \delta_{s, 0, T}$. We see immediately that $\operatorname{corr}_{\mathrm{R}}\left(D^{\prime}\right)=D$.
Looking at Definition 13, we see that we need now to compute the sub-distribution $\operatorname{corr}\left(E^{\prime}\right)$, with $E^{\prime}$ defined as $\operatorname{supp}\left(E^{\prime}\right) \subseteq \mathcal{S}_{\text {ext }}(\mathrm{R})$ and for all $u^{\prime} \in \mathcal{S}_{\text {ext }}(\mathrm{R}), E^{\prime}\left(u^{\prime}\right)=$ $\sum_{s^{\prime} \in \mathcal{S}_{\mathbb{R}}} D^{\prime}\left(s^{\prime}\right) \cdot \operatorname{RProb} \mathrm{R}_{\mathrm{R}}\left(s^{\prime},\left\{u^{\prime}\right\}\right)$. First, recall that for all $u^{\prime} \in \mathcal{S}_{\text {ext }}(\mathrm{R}), u^{\prime}$ is of the form $(u, p, \top)$ with $p \in \mathbb{N}$ and $u \in \mathcal{S}$. Additionally, note that both $\operatorname{supp}\left(D_{0}\right)$ and $\operatorname{supp}\left(D_{0}^{\top}\right)$ are included in $\mathcal{S} \subseteq \mathcal{S}_{\mathrm{N}}$.

$$
\begin{aligned}
E^{\prime}(u, p, \top)= & \sum_{s \in \mathcal{S}_{\mathrm{N}}} D_{0}(s) \cdot \operatorname{RProb}_{\mathrm{R}}((s, 0, \rightarrow),\{(u, p, \top)\}) \\
& +\sum_{s \in \mathcal{S}_{\mathrm{N}}} D_{0}^{\top}(s) \cdot \operatorname{RProb}_{\mathrm{R}}((s, 0, \top),\{(u, p, \top)\})
\end{aligned}
$$

Observe that for every $(s, 0, \top) \in \mathcal{S}_{\text {ext }}(\mathrm{R}), \operatorname{RProb}_{\mathrm{R}}((s, 0, \top),\{(u, p, \top)\})=1$ if $u=s$, $p=0$ and 0 otherwise.
Furthermore, by definition of $\operatorname{trans}_{\mathrm{R}}$, if $\operatorname{trans}_{\mathrm{R}}(s, n, \rightarrow)=(\tau, F)$ then $\left(s^{\prime}, n^{\prime}, \alpha^{\prime}\right) \in$ $\operatorname{supp}(F)$ implies $n^{\prime}=n+1$. Thus, we can easily prove by induction that for all $(s, n, \rightarrow),(t, m, \top) \in \mathcal{S}_{\mathrm{R}}, \operatorname{RProb}_{\mathrm{R}}((s, n, \rightarrow),\{(t, m, \top)\})>0$ implies that $m>n$. Using these two facts, we obtain that:

$$
\begin{align*}
& E^{\prime}(u, 0, \top)=D_{0}^{\top}(u)  \tag{16}\\
& E^{\prime}(u, p, \top)=\sum_{s \in \mathcal{S}_{\mathrm{N}}} D_{0}^{\rightarrow}(s) \cdot \operatorname{RProb}_{\mathrm{R}}((s, 0, \rightarrow),\{(u, p, \top)\}) \quad \text { for } p \geq 1 \tag{17}
\end{align*}
$$

To go forward from here, we are going to show the following auxiliary statement: for all $p \in \mathbb{N}$, for all $m<p \in \mathbb{N}$, for all $u \in \mathcal{S}$,

$$
\begin{equation*}
\sum_{s \in \mathcal{S}_{N}} D_{m}^{\rightarrow}(s) \cdot \operatorname{RProb}_{\mathrm{R}}((s, m, \rightarrow),\{(u, p, \top)\})=D_{p}^{\top}(u) \tag{18}
\end{equation*}
$$

We do the proof by induction on $p-m$. For all $(s, n, \rightarrow) \in \mathcal{S}_{\text {int }}(\mathrm{R})$, let us denote $F_{s, n}$ the distribution such that $\operatorname{trans}_{\mathrm{R}}(s, n, \rightarrow)=\left(\tau, F_{s, n}\right)$.

$$
\begin{aligned}
& \sum_{s \in \mathcal{S}_{\mathrm{N}}} D_{m}^{\rightarrow}(s) \cdot \operatorname{RProb}_{\mathrm{R}}((s, m, \rightarrow),\{(u, p, \top)\}) \\
& =\sum_{s \in \mathcal{S}_{\mathrm{N}}} D_{m}^{\rightarrow}(s) \cdot \sum_{t \in \operatorname{supp}\left(F_{s, m}\right)} F_{s, m}(t) \cdot \operatorname{RProb}_{\mathrm{R}}(t,\{(u, p, \top)\}) \text { by Lemma } 23
\end{aligned}
$$

By definition of $F_{s, n}, t \in \operatorname{supp}\left(F_{s, n}\right)$ implies that $t=\left(t^{\prime}, m+1, \alpha\right)$ with $t^{\prime} \in \mathcal{S}$ and $\alpha \in\{\top, \rightarrow\}$ and $F_{s, n}(t)=\Delta(s, m, \top)\left(t^{\prime}\right)+\Delta(s, m, \rightarrow)\left(t^{\prime}\right)$. Hence:

$$
\begin{aligned}
& \sum_{s \in \mathcal{S}_{\mathrm{N}}} D_{m}^{\rightarrow}(s) \cdot \operatorname{RProb}_{\mathrm{R}}((s, m, \rightarrow),\{(u, p, \top)\}) \\
& =\sum_{s \in \mathcal{S}_{\mathrm{N}}} D_{m}^{\vec{m}}(s) \cdot \\
& \quad\left(\sum _ { t \in \mathcal { S } _ { \mathrm { N } } } \left(\Delta(s, m, \top)(t) \cdot \operatorname{RProb}_{\mathrm{R}}((t, m+1, \top),\{(u, p, \top)\})\right.\right. \\
& \\
& \left.+\sum_{t \in \mathcal{S}_{\mathrm{N}}} \Delta(s, m, \rightarrow)(t) \cdot \operatorname{RProb}_{\mathrm{R}}((t, m+1, \rightarrow),\{(u, p, \top)\})\right)
\end{aligned}
$$

- if $p=m+1$ then for all $t \in \mathcal{S}_{\mathrm{N}}, \operatorname{RProb}_{\mathrm{R}}((t, m+1, \top),\{(u, m+1, \top)\})=1$ if $t=u$ and 0 otherwise. Moreover, as we previously shown, $\operatorname{RProb}_{\mathrm{R}}((t, m+1, \rightarrow$ ), $\{(u, m+1, \top)\})=0$. Therefore:

$$
\begin{aligned}
\sum_{s \in \mathcal{S}_{\mathcal{N}}} D_{m}^{\rightarrow}(s) \cdot \operatorname{RProb}_{\mathrm{R}}((s, m, \rightarrow),\{(u, p, \top)\}) & =\sum_{s \in \mathcal{S}_{\mathrm{N}}} D_{m}^{\rightarrow}(s) \cdot \Delta(s, m, \top)(u) \\
& \left.=D_{p}^{\top}(u) \quad \text { by } 15\right) .
\end{aligned}
$$

- if $p>m+1$ then for all $t \in \mathcal{S}_{\mathrm{N}}, \operatorname{RProb}_{\mathrm{R}}((t, m+1, \top),\{(u, p, \top)\})=0$. Hence:

$$
\begin{aligned}
& \sum_{s \in \mathcal{S}_{\mathrm{N}}} D_{m}^{\rightarrow}(s) \cdot \operatorname{RProb}_{\mathrm{R}}((s, m, \rightarrow),\{(u, p, \top)\}) \\
& =\sum_{s \in \mathcal{S}_{\mathrm{N}}} D_{m}^{\rightarrow}(s) \cdot \sum_{t \in \mathcal{S}_{\mathrm{N}}} \Delta(s, m, \rightarrow)(t) \cdot \operatorname{RProb}_{\mathrm{R}}((t, m+1, \rightarrow),\{(u, p, \top)\}) \\
& =\sum_{t \in \mathcal{S}_{N}}\left(\sum_{s \in \mathcal{S}_{\mathrm{N}}} D_{m}^{\rightarrow}(s) \cdot \Delta(s, m, \rightarrow)(t)\right) \cdot \operatorname{RProb}_{\mathrm{R}}((t, m+1, \rightarrow),\{(u, p, \top)\}) \\
& \left.=\sum_{t \in \mathcal{S}_{\mathrm{N}}} D_{m+1}^{\rightarrow}(t) \cdot \operatorname{RProb}_{\mathrm{R}}((t, m+1, \rightarrow),\{(u, p, \top)\})\right) \quad \text { by } \\
& =D_{p}^{\top}(u) \quad \text { by induction hypothesis }
\end{aligned}
$$

This concludes the proof of Equation 18. Combining (16), (17) and (18), we have shown:

$$
E^{\prime}(u, p, \top)=D_{p}^{\top}(u) \quad \forall p \in \mathbb{N}
$$

We conclude the proof by noticing that $\operatorname{corr}\left(E^{\prime}\right)(u)=\sum_{p \in \mathbb{N}} D_{p}^{\top}(u)=E(u)$.
Right-to-left direction. We suppose that $D \Longrightarrow_{\mathcal{R}_{\mathrm{r}}} E$. It means that there exists a resolution $\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $\left._{\mathrm{R}}, \operatorname{trans}_{\mathrm{R}}\right) \in \mathcal{R}_{\mathrm{r}}(\mathrm{N})$ and $D^{\prime}, E^{\prime} \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{R}}\right)$ such that $\operatorname{corr}_{\mathrm{R}}\left(D^{\prime}\right)=D, \operatorname{corr}_{\mathrm{R}}\left(E^{\prime}\right)=$ $E, \operatorname{supp}\left(E^{\prime}\right) \subseteq \mathcal{S}_{\text {ext }}(\mathrm{R})$ and for every $u \in \mathcal{S}_{\text {ext }}(\mathrm{R}), E^{\prime}(u)=\sum_{s^{\prime} \in \mathcal{S}_{\mathrm{R}}} D^{\prime}\left(s^{\prime}\right) \cdot \operatorname{RProb} \mathrm{R}_{\mathrm{R}}\left(s^{\prime},\{u\}\right)$. From there, we are going to build an infinite scheme, in the spirit of Definition 15 . We
define by induction on $n$ two families of sub-distributions on $\mathcal{S}_{\mathbb{R}},\left(D_{n}^{\prime \rightarrow}\right)_{n \in \mathbb{N}}$ and $\left(D_{n}^{\prime \top}\right)_{n \in \mathbb{N}}$, as follows:

$$
\begin{array}{ll}
D_{0}^{\prime \rightarrow}=D_{\mid \mathcal{S}_{\text {int }}(\mathrm{R})}^{\prime} & D_{0}^{\prime \top}=D_{\mid \mathcal{S}_{\text {ext }}(\mathrm{R})}^{\prime} \\
D_{n+1}^{\prime \prime}=\operatorname{trans}_{\mathrm{R}}\left(D_{n}^{\prime \rightarrow}\right)_{\mid \mathcal{S}_{\text {int }}(\mathrm{R})} & D_{n+1}^{\prime \top}=\operatorname{trans}_{\mathrm{R}}\left(D_{n}^{\prime \rightarrow}\right)_{\mid \mathcal{S}_{\text {ext }}(\mathrm{R})}
\end{array}
$$

We denote for all $n \in \mathbb{N}, D_{n}^{\prime}=D_{n}^{\prime \rightarrow}+D_{n}^{\prime \top}$. Hence, $D^{\prime}=D_{0}^{\prime}$. Using Lemma 25, we can check that for all $n \in \mathbb{N}, \operatorname{corr}_{\mathrm{R}}\left(D_{n}^{\prime \rightarrow}\right) \xrightarrow{\tau}_{\mathrm{r}} \operatorname{corr}_{\mathrm{R}}\left(D^{\prime}{ }_{n+1}\right)$. Then we define, for every $n \in \mathbb{N}$, $\alpha \in\{\rightarrow, \top\}, D_{n}^{\alpha}=\operatorname{corr}_{\mathrm{R}}\left(D_{n}^{\prime \alpha}\right) \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$.

We now show that for all $n \in \mathbb{N}$, for all $j \leq n$, for all $u \in \mathcal{S}_{\text {ext }}(\mathrm{R})$,

$$
\begin{equation*}
\sum_{s^{\prime} \in \mathcal{S}_{\mathbb{R}}} D_{j}^{\prime}\left(s^{\prime}\right) \cdot \operatorname{RProb}_{R}^{\leq n-j}\left(s^{\prime},\{u\}\right)=\sum_{j \leq k \leq n} D_{k}^{\prime \top}(u) . \tag{19}
\end{equation*}
$$

We prove this property by induction on $n-j$ :

- if $n=j$, then we can first see that $\sum_{s^{\prime} \in \mathcal{S}_{R}} D^{\prime}{ }_{j}\left(s^{\prime}\right) \cdot \operatorname{RProb}_{R}^{\leq 0}\left(s^{\prime},\{u\}\right)=D^{\prime}{ }_{j}(u)$. Since $u$ is an external state, and by definition of $D_{j}^{\prime}$, it holds that $D^{\prime}{ }_{j}(u)=D^{\prime}{ }_{j}{ }^{\prime}(u)$, so the result holds.
- case $n-j>0$ :

$$
\begin{aligned}
& \sum_{s^{\prime} \in \mathcal{S}_{\mathbb{R}}} D_{j}{ }^{\prime}\left(s^{\prime}\right) \cdot \operatorname{RProb}_{R}^{\leq n-j}\left(s^{\prime},\{u\}\right) \\
& =\sum_{s^{\prime} \in \mathcal{S}_{\mathrm{R}}} D_{j}^{\prime \rightarrow}\left(s^{\prime}\right) \cdot \operatorname{RProb}_{R}^{\leq n-j}\left(s^{\prime},\{u\}\right)+\sum_{s^{\prime} \in \mathcal{S}_{\mathrm{R}}} D_{j}^{\prime^{\top}}\left(s^{\prime}\right) \cdot \operatorname{RProb}_{R}^{\leq n-j}\left(s^{\prime},\{u\}\right) \\
& =\sum_{s^{\prime} \in \mathcal{S}_{\mathrm{R}}} D_{j}^{\prime \rightarrow}\left(s^{\prime}\right) \cdot \operatorname{RProb}_{R}^{\leq n-j}\left(s^{\prime},\{u\}\right)+{D^{\prime}}_{j}^{\top}(u) \quad \text { since } s^{\prime} \in \operatorname{supp}\left(D_{j}^{\prime \top}\right) \Rightarrow s^{\prime} \in \mathcal{S}_{\text {ext }}(\mathrm{R}) \\
& =\sum_{s^{\prime} \in \mathcal{S}_{\mathbb{R}}, \operatorname{trans}_{\mathrm{R}}\left(s^{\prime}\right)=\left(\tau, F_{s^{\prime}}\right)} D_{j}^{\prime \rightarrow}\left(s^{\prime}\right) \cdot \sum_{v^{\prime} \in \mathcal{S}_{\mathbb{R}}} F_{s^{\prime}}\left(v^{\prime}\right) \cdot \operatorname{RProb}_{R}^{\leq n-j-1}\left(v^{\prime},\{u\}\right)+D_{j}^{\prime \top}(u) \\
& =\sum_{v^{\prime} \in \mathcal{S}_{\mathrm{R}}} D_{j+1}^{\prime}\left(v^{\prime}\right) \cdot \operatorname{RProb}_{R}^{\leq n-(j+1)}\left(v^{\prime},\{u\}\right)+D_{j}^{\prime \top}(u) \quad \text { since } \operatorname{trans}_{\mathrm{R}}\left(D_{j}^{\prime \rightarrow}\right)=D_{j+1}^{\prime} \\
& =\sum_{j+1 \leq k \leq n}{D^{\prime}}_{k}^{\top}(u)+{D^{\prime}}_{j}^{\top}(u) \quad \text { by induction hypothesis, }
\end{aligned}
$$

and that concludes the proof of (19).

We are now able to end the proof, by seeing that for all $w \in \mathcal{S}_{\mathrm{N}}$,

$$
\begin{aligned}
E(w) & =\sum_{u \in \operatorname{corr}^{-1}(w)} E^{\prime}(u) \quad \text { since by hypothesis } \operatorname{corr}_{\mathrm{R}}\left(E^{\prime}\right)=E \\
& =\sum_{u \in \operatorname{corr}^{-1}(w)} \sum_{s^{\prime} \in \mathcal{S}_{\mathbb{R}}} D_{0}^{\prime}\left(s^{\prime}\right) \cdot \operatorname{RProb}_{R}\left(s^{\prime},\{u\}\right) \quad \text { by hypothesis, and since } D^{\prime}=D_{0}^{\prime} \\
& =\sup _{n \in \mathbb{N}} \sum_{u \in \operatorname{corr}^{-1}(w)} \sum_{s^{\prime} \in \mathcal{S}_{R}} D_{0}^{\prime}\left(s^{\prime}\right) \cdot \operatorname{RProb}_{R}^{\leq n}\left(s^{\prime},\{u\}\right) \\
& =\sup _{n \in \mathbb{N}} \sum_{u \in \operatorname{corr}^{-1}(w)} \sum_{0 \leq k \leq n} D_{k}^{\prime \top}(u) \quad \text { by (19) instantiated with } j=0 \\
& =\sup _{n \in \mathbb{N}} \sum_{0 \leq k \leq n} D_{k}^{\top}(w) \quad \text { since } \operatorname{corr}_{\mathrm{R}}\left(D_{k}^{\prime \top}\right)=D_{k}^{\top} \\
& =\sum_{k \in \mathbb{N}} D_{k}^{\top}(w),
\end{aligned}
$$

which ends the proof.

## D Observational equivalence with name restriction in context

In the original applied pi calculus, observational equivalence is closed by application of an adversarial context, i.e., if $P \approx Q$ then $C[P] \approx C[Q]$ where $C[-]$ is a context of the form new $a_{1} ; \ldots ;$ new $a_{n} ;(-\mid A d v)$ where $A d v$ is a process. Intuitively, previously public names $a_{1}, \ldots, a_{n}$ in $P$ and $Q$ may becomes restricted, i.e. private, by the application of the adversarial context.

In our definition of observational equivalence (Definition 18), we only require that the adversarial process $A d v$ is put in parellel of $P$ and $Q$ without allowing for additional name restrictions. In our formalism, this corresponds to the third bullet point of Definition 18 , i.e.:
for all closed $A d v \in \mathcal{M P}$ such that $f n(A d v) \subseteq \mathcal{N}_{p u b},\{A d v\} \cup \mathcal{P} R\{A d v\} \cup \mathcal{Q}$.
We show in this section that in fact adding these restrictions in the definition of observational equivalence does not add any power to the attacker by showing that the classical definition and our definition coincide. Note that the original formalism of the applied pi calculus is slightly different from ours as they do not separate names in public and private names as we do. Furthermore, they do not have a rule that executes the name restriction as our rule (NEW). Instead, they consider a structural equivalence $\equiv$ that manages name restrictions. For instance,

$$
\begin{gathered}
\text { new } a ; 0 \equiv 0 \quad \text { new } a ; \text { new } b ; P \equiv \text { new } b ; \text { new } a ; P \\
P \mid \text { new } a ; Q \equiv \text { new } a ;(P \mid Q) \text { when } a \notin f v(P) \cup f n(P)
\end{gathered}
$$

Similarly, by the fact that our calculus relies on multisets of processes, the rules (NULL), (PAR) and (REPL) capture the following equations in the structural equivalence:

$$
P \equiv P\left|0 \quad P_{1}\right|\left(P_{2} \mid P_{3}\right) \equiv\left(P_{1} \mid P_{2}\right)\left|P_{3} \quad P\right| Q \equiv Q|P \quad!P \equiv P|!P
$$

Thus, as mentioned in ABF17, Section 2.3], any process $P$ in the original applied pi calculus is structurally equivalent as a process of the form new $a_{1} ; \ldots ;$ new $a_{n} ;\left(P_{1}|\ldots|\right.$ $P_{n}$ ) where name restrictions have been pushed to the top, which can be expressed by a configuration $\left(\left\{a_{1}, \ldots, a_{n}\right\},\left\{\left\{P_{1}, \ldots, P_{n}\right\}\right\}\right)$. In our calculus, the distinction between private and public names enforces that all names $a_{1}, \ldots, a_{n}$ are in $\mathcal{N}_{\text {priv }}$ which allows us to only keep the multiset $\left\{\left\{P_{1}, \ldots, P_{n}\right\}\right.$ (see Figure 2).

Therefore, applying an adversarial context with restriction is equivalent in our formalism to applying a renaming from public names of our process to fresh privates names. This leads to the following definition of the original observational equivalence:
Definition 36. The original observational preorder $\leq_{\text {ori }}^{\mathcal{R}}$ is the largest relation $R$ on $\mathcal{M P}$ such that $\mathcal{P} R \mathcal{Q}$ implies :

- for all $c \in \mathcal{N}_{p u b}, \operatorname{RProb}_{\mathcal{R}}(\mathcal{P}, \downarrow c) \leq \operatorname{RProb}_{\mathcal{R}}(\mathcal{Q}, \downarrow c)$;
- if $\mathcal{P} \xlongequal{\tau}{ }_{\mathrm{r}} D$ then $\mathcal{Q} \xlongequal{\tau} \mathrm{r} E$ and $D \widehat{R} E$;
- for all closed $A d v \in \mathcal{M P}$, for all renaming $\rho$, if $f n(A d v) \subseteq \mathcal{N}_{p u b}, \operatorname{dom}(\rho) \subseteq \mathcal{N}_{p u b}$, $i m g(\rho) \subseteq \mathcal{N}_{\text {priv }}$ and $\operatorname{img}(\rho) \cap \operatorname{names}(\mathcal{P}, \mathcal{Q}, A d v)=\varnothing$ then $\{A d v \rho\} \cup \mathcal{P} \rho R\{A d v \rho\} \cup$ $\mathcal{Q} \rho$.
The original observational equivalence $\approx_{o r i}^{\mathcal{R}}$ is defined by additionally requesting $R$ to be symmetric and in the second bullet point, by requesting both $D \widehat{R} E$ and $E \widehat{R} D$ to hold.

Let us now show that the two notions coincide.
Lemma 27. $\leq_{o r i}^{\mathcal{R}}=\leq_{o b s}^{\mathcal{R}}$ and $\approx_{o r i}^{\mathcal{R}}=\approx_{o b s}^{\mathcal{R}}$.
Proof. Trivially, we have that $\leq_{o r i}^{\mathcal{R}} \subseteq \leq_{o b s}^{\mathcal{R}}$ and $\approx_{o r i}^{\mathcal{R}} \subseteq \approx_{o b s}^{\mathcal{R}}$ since we can always take $\rho$ being the empty renaming.

Consider the relation $\mathcal{R}$ defined as $\mathcal{P} \mathcal{R} \mathcal{Q}$ iff there exists $\mathcal{P}^{\prime}, \mathcal{Q}^{\prime}$ and a renaming such that $\rho$ such that $\mathcal{P}=\mathcal{P}^{\prime} \rho, \mathcal{Q}=\mathcal{Q}^{\prime} \rho, \mathcal{P}^{\prime} \leq_{o b s}^{\mathcal{R}} \mathcal{Q}^{\prime}, \operatorname{dom}(\rho) \subseteq \mathcal{N}_{\text {pub }}, \operatorname{img}(\rho) \subseteq \mathcal{N}_{\text {priv }}$ and $i m g(\rho) \cap \operatorname{names}\left(\mathcal{P}^{\prime}, \mathcal{Q}^{\prime}, A d v\right)=\varnothing$.

Recall that $\doteq$ is closed under substitution of names by terms. Therefore, for all $u, v$ such that $\operatorname{img}(\rho) \cap \operatorname{names}(u, v)=\varnothing, u \doteq v$ if and only if $u \rho \doteq v \rho$. Thus, $\mathcal{P} \rho \rightarrow_{\tau} D^{\prime}$ implies $\mathcal{P} \rightarrow_{\tau} D$ where $\operatorname{dom}\left(D^{\prime}\right)=\operatorname{dom}(D) \rho$ and $D^{\prime}(x \rho)=D(x \rho)$. Furthermore, if $\mathcal{P} \rightarrow_{\tau} D$ then $\mathcal{P} \rho \rightarrow_{\tau} D \rho$ where $D \rho$ is the distribution such that $\operatorname{dom}(D \rho)=\operatorname{dom}(D)$ and $D \rho(x \rho)=D(x \rho)$. Notice that for the rule (New), we consider w.l.o.g. that $a^{\prime}$ is fresh also with respect to the private names in $\rho$. In other words, we have that $\mathcal{P} \rho \rightarrow_{\tau} D \rho$ iff $\mathcal{P} \rightarrow{ }_{\tau} D$.

This can be propagate to schedulers, i.e. $(\operatorname{corr}, R) \in \mathcal{R}_{\mathrm{r}}^{o}$ if and only if $(\operatorname{corr} \rho, R) \in \mathcal{R}_{\mathrm{r}}^{o}$. Hence, we derive that

- $\operatorname{RProb}_{\mathcal{R}_{r}^{o}}(\mathcal{P}, \mathcal{T})=\operatorname{RProb}_{\mathcal{R}_{r}^{o}}(\mathcal{P} \rho, \mathcal{T} \rho)$
- $D \xlongequal{\tau} \mathcal{R}_{r}^{o} E$ if and only if $D \rho \xlongequal{\tau} \mathcal{R}_{r}^{o} E \rho$

We now show that $\mathcal{R}$ satisfies the three items in Definition 36;

- Let $c \in \mathcal{N}_{\text {pub }}$. If $c \in \operatorname{dom}(\rho)$ then $c$ does neither occur in $\mathcal{P}^{\prime} \rho$ nor in $\mathcal{Q}^{\prime} \rho$. Hence, $\operatorname{RProb}_{\mathcal{R}_{r}^{o}}\left(\mathcal{P}^{\prime}, \downarrow c\right)=0=\operatorname{RProb}_{\mathcal{R}_{r}^{o}}\left(\mathcal{Q}^{\prime}, \downarrow c\right)$. Otherwise, $\downarrow c=\downarrow c \rho \cup \mathcal{T}$ where for all $\mathcal{P}^{\prime} \in \mathcal{T}, f n\left(\mathcal{P}^{\prime}\right) \cap \operatorname{dom}(\rho) \neq \varnothing$. Since, $\mathcal{P}^{\prime} \rho$ and $\mathcal{Q}^{\prime} \rho$ do not contain public names from $\operatorname{dom}(\rho)$, they can never reach states from $\mathcal{T}$. Hence, $\operatorname{RProb}_{\mathcal{R}_{r}^{o}}\left(\mathcal{P}^{\prime} \rho, \downarrow\right.$ $c)=\operatorname{RProb}_{\mathcal{R}_{r}^{o}}\left(\mathcal{P}^{\prime} \rho, \downarrow c \rho\right)=\operatorname{RProb}_{\mathcal{R}_{r}^{o}}\left(\mathcal{P}^{\prime}, \downarrow c\right)$. Since $\mathcal{P}^{\prime} \leq_{o b s}^{\mathcal{R}} \mathcal{Q}^{\prime}$, we deduce that $\operatorname{RProb}_{\mathcal{R}_{r}^{o}}\left(\mathcal{P}^{\prime}, \downarrow c\right) \leq \operatorname{RProb}_{\mathcal{R}_{r}^{o}}\left(\mathcal{Q}^{\prime}, \downarrow c\right) \leq \operatorname{RProb}_{\mathcal{R}_{r}^{o}}\left(\mathcal{Q}^{\prime} \rho, \downarrow c \rho\right) \leq \operatorname{RProb}_{\mathcal{R}_{r}^{o}}\left(\mathcal{Q}^{\prime}, \downarrow c\right)$.
- If $\mathcal{P} \rho \xlongequal{\tau}{ }_{\mathcal{R}_{\mathrm{r}}} D \rho$ then $\mathcal{P}^{\prime} \xlongequal{\tau}{ }_{\mathcal{R}_{r}^{o}} D$. By $\mathcal{P}^{\prime} \leq_{o b s}^{\mathcal{R}} \mathcal{Q}^{\prime}$, we have $\mathcal{Q}^{\prime} \xlongequal{\tau}{ }_{\mathcal{R}_{r}} E$ and $D \widehat{{ }_{o b s}^{\mathcal{R}}} E$. This implies that $D \rho \widehat{\mathcal{R}} E \rho$ with $\mathcal{Q}^{\prime} \rho \xlongequal{\tau} \mathcal{R}_{\mathrm{r}} E \rho$.
- Let $A d v \in \mathcal{M P}$ and $\rho^{\prime}$ be a renaming such that $f n(A d v) \subseteq \mathcal{N}_{p u b}, \operatorname{dom}\left(\rho^{\prime}\right) \subseteq \mathcal{N}_{\text {pub }}$, $\operatorname{img}\left(\rho^{\prime}\right) \subseteq \mathcal{N}_{\text {priv }}$ and $\operatorname{img}\left(\rho^{\prime}\right) \cap \operatorname{names}\left(\mathcal{P}^{\prime} \rho, \mathcal{Q}^{\prime} \rho\right)=\varnothing$. Note that the domains of $\rho$ and $\rho^{\prime}$ may not be disjoint. Similarly, the process $A d v$ may contain public names from $\operatorname{dom}(\rho)$.
Hence, let $\rho_{p u b}$ be a renaming such that $\operatorname{dom}\left(\rho_{\text {pub }}\right)=\operatorname{dom}(\rho) \cap\left(\operatorname{dom}\left(\rho^{\prime}\right) \cup f n(A d v)\right)$, $\operatorname{img}\left(\rho_{p u b}\right) \subseteq \mathcal{N}_{p u b} \backslash f n\left(\mathcal{P}^{\prime}, \mathcal{Q}^{\prime}, A d v\right)$. Hence, we define $\rho_{1}=\rho \rho_{p u b}^{-1} \rho^{\prime}$.
We have $\mathcal{P}^{\prime} \rho_{1}=\left(\mathcal{P}^{\prime} \rho\right) \rho^{\prime}$ since $\operatorname{img}\left(\rho_{p u b}\right) \subseteq \mathcal{N}_{\text {pub }} \backslash f n\left(\mathcal{P}^{\prime}, \mathcal{Q}^{\prime}, A d v\right)$. Moreover, as $\operatorname{dom}\left(\rho_{\text {pub }}\right)=\operatorname{dom}(\rho) \cap\left(\operatorname{dom}\left(\rho^{\prime}\right) \cup f n(A d v)\right)$, we have that

$$
\left(A d v \rho_{p u b}\right) \rho=\left.A d v \rho_{p u b} \rho\right|_{\operatorname{dom}(\rho) \backslash \operatorname{dom}\left(\rho_{p u b}\right)}=\left.A d v \rho\right|_{\operatorname{dom}(\rho) \backslash \operatorname{dom}\left(\rho_{p u b}\right)} \rho_{p u b}=A d v \rho_{p u b}
$$

Therefore, $A d v \rho_{p u b} \rho_{1}=A d v \rho_{p u b} \rho_{p u b}^{-1} \rho^{\prime}=A d v \rho^{\prime}$. This allows us to deduce that $\left\{A d v \rho^{\prime}\right\} \cup \mathcal{P}^{\prime} \rho^{\prime}=\left(\left\{A d v \rho_{p u b}\right\} \cup \mathcal{P}^{\prime}\right) \rho_{1}$. Similarly, we have $\left\{A d v \rho^{\prime}\right\} \cup \mathcal{Q}^{\prime} \rho^{\prime}=\left(\left\{A d v \rho_{p u b}\right\} \cup\right.$ $\left.\mathcal{Q}^{\prime}\right) \rho_{1}$.
We know that $\mathcal{P}^{\prime} \leq \leq_{o b s}^{\mathcal{R}} \mathcal{Q}^{\prime}$. Hence $\left\{A d v \rho_{p u b}\right\} \cup \mathcal{P}^{\prime} \leq_{o b s}^{\mathcal{R}}\left\{A d v \rho_{p u b}\right\} \cup \mathcal{Q}^{\prime}$ which allows us to conclude that $\left\{A d v \rho_{p u b} \rho_{1}\right\} \cup \mathcal{P}^{\prime} \rho_{1} \mathcal{R}\left\{A d v \rho_{p u b} \rho_{1}\right\} \cup \mathcal{Q}^{\prime} \rho_{1}$ and so $\left\{A d v \rho^{\prime}\right\} \cup$ $\mathcal{P} \rho^{\prime} \mathcal{R}\left\{A d v \rho^{\prime}\right\} \cup \mathcal{Q} \rho^{\prime}$.

## E $\tau$-determinisation

Notation 12. We says that a NPLTS N is a new -determinization of $\mathrm{N}^{\ell}$ when $\mathrm{N}=$ ( $\mathcal{S}_{\mathrm{N}^{\ell}}, \mathcal{A}_{\mathrm{N}^{\ell}}$, trans) with the following constraints on its transition function trans:

- for $a \in \mathcal{A}_{\mathbb{N}^{e}} \backslash\{\tau\}, \operatorname{trans}(s)(a)=\operatorname{trans}_{\mathrm{N}^{e}}(s)(a)$, and $\operatorname{trans}(s)(\tau) \subseteq \operatorname{trans}_{\mathrm{N}^{e}}(s)(\tau)$;
- for every $D \in \operatorname{trans}_{N^{\ell}}(s)(\tau)$ not obtained by a new reduction, $D \in \operatorname{trans}(s)(a)$;
- for $s=(\{$ new $a \cdot \mathcal{Q}\} \cup \mathcal{P}, \phi)$, there exists at least one $E \in \operatorname{trans}(s)(\tau)$ with $E$ of the form $\delta_{(\{\mathcal{Q}\{b / a\}\} \cup \mathcal{P}, \phi)}$ with $b \in \mathcal{N}_{\text {priv }}$ fresh in $s$. We say that the new -determinisation is strict when there is exactly one such $E \in \operatorname{trans}(s)(\tau)$.

Observe that we can easily build a particular strict new -determinization by ordering the private names, and choosing for each new -reduction the first available fresh private name.

Notation 13. We define an equivalence relation on $\mathcal{S} \mathcal{P}_{\ell}$, that we call equivalence with respect to private names substitution, and that we note $\equiv_{\mathcal{N}_{\text {priv }}}:(\mathcal{P}, \phi) \equiv_{\mathcal{N}_{\text {priv }}}(\mathcal{Q}, \psi)$ when there exists private names $a_{1}, \ldots, a_{n}, b_{1}, \ldots, b_{n}$ with $b_{1}, \ldots, b_{n}$ fresh in $(\mathcal{P}, \phi)$ such that

$$
(\mathcal{Q}, \psi)=\left(\mathcal{P}\left\{a_{1} / b_{1}\right\} \ldots\left\{a_{n} / b_{n}\right\}, \phi\left\{a_{1} / b_{1}\right\} \ldots\left\{a_{n} / b_{n}\right\}\right)
$$

Lemma 28. Let N be a new -determinization of $\mathrm{N}^{\ell}$, and $s, t \in \mathcal{S} \mathcal{P}_{\ell}$ such that $s \equiv{ }_{\mathcal{N}_{\text {priv }}} t$. Then $s \leq_{s i m}^{\mathrm{N}} t$.

Observe that in particular $\mathrm{N}^{\ell}$ is a (non strict) new -determinization of itself, thus Lemma 28 also holds for $\mathrm{N}=\mathrm{N}^{\ell}$.

Lemma 29. Let N be a new -determinization of $\mathrm{N}^{\ell}$. Let $s \in \mathcal{S} \mathcal{P}_{\ell}$, and $a \in \mathcal{A}_{\mathrm{N}^{\ell}}$ such that $s{\xrightarrow{a}{ }_{\mathrm{N}}{ }^{\ell}} D$. Then there exists $E$ such that $s \xrightarrow{a}_{\mathrm{N}} E$, and $D\left(\widehat{\left.{\overline{\mathcal{N}_{\text {priv }}}}\right) E}\right.$

Lemma 30. Let N be a new -determinization of $\mathrm{N}^{\ell}$. Let $s \in \mathcal{S P}{ }_{\ell}$, and $a \in \mathcal{A}_{\mathrm{N}^{\ell}}$ such that $s \stackrel{a}{\mid}_{\mathrm{N}^{\ell}} D$. Then there exists $E$, such that $s \stackrel{a}{\Rightarrow} E$, and $D\left(\overline{\equiv_{\mathcal{N}_{\text {priv }}}}\right) E$.

Notation 14. Let $\mathrm{N}_{1}=\left(\mathcal{S}_{\mathrm{N}_{1}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}_{1}}\right)$ and $\mathrm{N}_{2}=\left(\mathcal{S}_{\mathrm{N}_{2}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left.\mathrm{N}_{\mathrm{N}_{2}}\right)$ be two NPLTSs, with the same set of actions. We define the disjoint union of $\mathrm{N}_{1}$ and $\mathrm{N}_{2}$ as the NPLTS $\mathrm{N}_{1}+\mathrm{N}_{2}:=\left(\mathcal{S}_{\mathrm{N}_{1}} \sqcup \mathcal{S}_{\mathrm{N}_{2}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}_{1}+\mathrm{N}_{2}}\right)$ where the transition function $\operatorname{trans}_{N_{1}+\mathrm{N}_{2}}$ defined as:

$$
\operatorname{trans}_{\mathrm{N}_{1}+\mathrm{N}_{2}}(s)=\left\{\begin{array}{l}
\operatorname{trans}_{\mathrm{N}_{1}}(s) \text { when } s \in \mathcal{S}_{\mathrm{N}_{1}} \\
\operatorname{trans}_{\mathrm{N}_{2}}(s) \text { when } s \in \mathcal{S}_{\mathrm{N}_{2}}
\end{array}\right.
$$

In the following, when considering $\mathrm{N}_{1}+\mathrm{N}_{2}$, where $\mathrm{N}_{1}$ and $\mathrm{N}_{2}$ have non disjoint states spaces, we will write $s^{\mathrm{N}_{1}}, s^{\mathrm{N}_{2}}$ to design the copies of $s$ in $\mathcal{S}_{\mathrm{N}_{1}}$ and $\mathcal{S}_{\mathrm{N}_{2}}$ respectively. Similarly, if $D$ is a distribution over $\mathcal{S}_{\mathrm{N}_{1}} \cup \mathcal{S}_{\mathrm{N}_{2}}$, we will write $D^{\mathrm{N}_{1}}$ and $D^{\mathrm{N}_{2}}$ to mean the distributions over $\mathcal{S}_{\mathrm{N}_{1}} \sqcup \mathcal{S}_{\mathrm{N}_{2}}$ where all states $s$ in the support of the distribution are taken in $\mathcal{S}_{\mathrm{N}_{1}}$ and $\mathcal{S}_{\mathrm{N}_{2}}$ respectively.

Lemma 31. Let N be a new -determinization of $\mathrm{N}^{\ell}$. Then the binary relation $R \subseteq$ $\mathcal{S}_{\mathbb{N}^{\ell}+\mathrm{N}} \times \mathcal{S}_{\mathrm{N}^{\ell}+\mathrm{N}}$ defined as $R=\left\{\left(s^{\mathrm{N}^{\ell}}, t^{\mathrm{N}}\right) \mid s \equiv_{\mathcal{N}_{\text {priv }}} t\right\} \cup\left\{\left(s^{\mathrm{N}}, t^{\mathrm{N}^{\ell}}\right) \mid s \equiv_{\mathcal{N}_{\text {priv }}} t\right\}$, is a (strong) bisimulation on the NPLTS $\mathrm{N}_{1}+\mathrm{N}_{2}$.

Proof. First, we can easily check that it is an equivalence relation (reflexive, transitive and symmetric).

- Let $\left(s^{\mathbb{N}^{\ell}}, t^{\mathrm{N}}\right)$ such that $s \equiv_{\mathcal{N}_{\text {priv }}} t$, and let be $a$ such that $s^{\mathbb{N}^{\ell}} \xrightarrow{a}{ }_{\mathrm{N}^{\ell}+\mathrm{N}} D^{\mathbb{N}^{\ell}}$. Then by definition of the transition function $\operatorname{trans}_{\mathrm{N}^{\ell}+\mathrm{N}}$, it means that $s{\xrightarrow{a} \mathrm{~N}^{\ell}} D$. Using Lemma 29, we see that there exists $E$ such that $s \xrightarrow{a}_{\mathcal{N}} E$, and $D\left(\widehat{\overline{\mathcal{N}}_{\text {priv }}}\right) E$. Since we know from Lemma 28 that $\equiv_{\mathcal{N}_{\text {priv }}}$ is a bisimulation on N , and since by hypothesis $s \equiv_{\mathcal{N}_{\text {priv }}} t$, we obtain the existence of a third distribution $F$ such that $t{ }^{a}{ }_{\mathrm{N}} F$, and $E \equiv \widehat{\mathcal{N}_{\text {priv }}} F$. Recall that by definition of $\mathrm{N}^{\ell}+\mathrm{N}, t{ }_{\rightarrow}^{a} \mathrm{~N} F$ implies that $t^{\mathrm{N}}{ }_{\rightarrow}^{a}{ }_{\mathrm{N}^{\ell}+\mathrm{N}} F^{\mathrm{N}}$. Moreover, since $\equiv_{\mathcal{N}_{\text {priv }}}$ is transitive, and since $\widehat{\text { • preserves transitivity-from ??-, we }}$ can conclude that $D \widehat{\equiv \mathcal{N}_{\text {priv }}} F$.
- Let $\left(s^{\mathrm{N}}, t^{\mathrm{N}^{\ell}}\right)$ such that $s \equiv_{\mathcal{N}_{\text {priv }}} t$, and let be $a$ such that $s^{\mathrm{N}}{\xrightarrow{a}{ }_{\mathrm{N}^{\ell}+\mathrm{N}}} D^{\mathrm{N}}$. Then it is also true that $s^{\mathrm{N}^{\ell}}{ }_{\rightarrow}^{a}{ }_{\mathrm{N}^{\ell}+\mathrm{N}} D^{\mathrm{N}^{\ell}}$. Since by Lemma $28 \equiv_{\mathcal{N}_{\text {priv }}}$ is a bisimulation on $\mathrm{N}^{\ell}$, we
 from there.

Corollary 3. Let N be a new -determinization of $\mathrm{N}^{\ell}$. Then $\leq_{t r}^{\mathrm{N}}$ coincides with $\leq_{t r}^{\mathrm{N}^{\ell}}$.
Proof. It is known-and easy to prove-that any pair $(s, t)$ of bisimular states in a NPLTS N have also the same supremum probability of doing a trace. Using that fact, and Lemma 31, we see that for any state in $\mathrm{N}^{\ell}$, and for any $w \in\left(\left(\mathcal{A}_{\text {ext }}\right)_{\mathrm{N}^{\ell}}\right)^{\star}$ :

$$
\begin{aligned}
\operatorname{Prob}_{\mathcal{R}_{n r}\left(\mathcal{N}^{\ell}\right)}(s, w) & =\operatorname{Prob}_{\mathcal{R}_{n r}\left(\mathcal{N}^{\ell}+\mathrm{N}\right)}\left(s^{\mathrm{N}^{\ell}}, w\right) \text { by definition of NPLTSs dijoint union } \\
& =\operatorname{Prob}_{\mathcal{R}_{n r}\left(\mathrm{~N}^{\ell}+\mathrm{N}\right)}\left(s^{\mathrm{N}}, w\right) \text { since } s^{\mathrm{N}^{\ell}}, s^{\mathrm{N}} \text { are bisimilar by Lemma } 31 \\
& =\operatorname{Prob}_{\mathcal{R}_{n r}(\mathrm{~N})}(s, w),
\end{aligned}
$$

and we can conclude from there.
Corollary 4. Let N be a new -determinization of $\mathrm{N}^{\ell}$. Then $\leq_{s i m}^{\mathrm{N}}$ coincides with $\leq_{s i m}^{\mathrm{N}^{\ell}}$.
Proof. - Let us first show that $\leq_{s i m}^{\mathrm{N}}$ is a simulation on $\mathrm{N}^{\ell}$ : let $s, t \in \mathcal{S P}_{\ell}$ such that $s \leq_{\operatorname{sim}}^{\mathrm{N}} t$. We suppose that for some $a \in \mathcal{A}_{\mathbb{N}^{\ell}}, s \xrightarrow{a}_{\mathrm{N}^{\ell}} D$. From there, we can write that $s^{\overline{N^{\ell}}} \xrightarrow{s i m}{ }_{N^{\ell}+\mathrm{N}} D^{\mathrm{N}^{\ell}}$. By Lemma 31, there exists $E$ such that $D \widehat{{\overline{\underline{\mathcal{N}_{\text {priv }}}}} E \text {, and } s^{\mathrm{N}} \xrightarrow{a}{ }_{\mathrm{N}^{\ell}+\mathrm{N}}}$ $E^{\mathrm{N}}$. From there, we are able to use the fact that $s \leq_{s i m}^{\mathrm{N}} t$, to obtain a third distribution
 bisimulation for any NPLTS-and Proposition 4 -we can again use Lemma 31 to get
 we have $t \stackrel{a}{\Rightarrow} H$, and $D\left(\widehat{\equiv_{\mathcal{N}^{\ell} \text { priv }}} ; \widehat{\leq_{s i m}^{\mathcal{N}}} ; \widehat{\equiv_{\mathcal{N}_{\text {priv }}}}\right) H$. By Lemma 28 , $\equiv_{\mathcal{N}_{\text {priv }}} \subseteq \leq_{\text {sim }}^{\mathcal{N}}$, and we can conclude by transitivity of $\leq_{\text {sim }}^{\mathrm{N}}$ and Lemma??.

- We show similarly that $\leq_{\text {sim }}^{N^{\ell}}$ is a simulation on N .

As a consequence from Corollary 3 and ??, it is enough to consider N , a strict new determinization of $\mathrm{N}^{\ell}$.

## F Simulation and observational preorders coincide

This section is dedicated to the proof of Proposition 5.

## F. 1 Some preliminary results

Lemma 32. For all $a \in \mathcal{N}$, for all ground terms $t$, if $a \notin s t(t)$ then $a \neq t$.
Proof. Recall that $\doteq$ is closed under substitution of names by other terms. Let $b \in \mathcal{N} \backslash$ $\{a, s t(t)\}$ and $\sigma=\left\{{ }^{b} / a\right\}$. Thus, if $a \doteq t$ then $a \sigma \doteq t \sigma$ and $b \doteq t$ which would imply $a \doteq b$ which contradicts our hypothesis.

Lemma 33. Let $(\mathcal{P}, \phi) \in \mathcal{S} \mathcal{P}_{\ell}$. For all $\mathcal{P} \xrightarrow{\tau} \delta_{\mathcal{P}^{\prime}}$ by application of the rules (PAR) or $(\mathrm{NIL}), \mathcal{P} \approx_{o b s}^{\mathcal{R}_{r}} \mathcal{P}^{\prime}$ and $(\mathcal{P}, \phi) \approx_{b i}^{\mathrm{N}^{\ell}}\left(\mathcal{P}^{\prime}, \phi\right)$.

Proof. Trivial.
Lemma 34. Let $\mathcal{P}, \mathcal{P}^{\prime} \in \mathcal{S} \mathcal{P}, \phi, \phi^{\prime}$ be two frames and $\rho$ be a renaming of names.
If one of the two following properties holds

- $\operatorname{img}(\rho) \cap \operatorname{names}\left(\mathcal{P}, \mathcal{P}^{\prime}, \phi, \phi^{\prime}\right)=\varnothing$ and $\operatorname{dom}(\rho) \cap \operatorname{img}(\rho)=\varnothing$
- $\left(f n\left(\mathcal{P}, \mathcal{P}^{\prime}, \phi, \phi^{\prime}\right) \cap \mathcal{N}_{\text {priv }}\right)=\operatorname{dom}(\rho)$ and $\operatorname{img}(\rho) \subseteq \mathcal{N}_{\text {priv }}$
then
- For all $R \in\left\{\leq_{o b s}^{\mathcal{R}_{r}}, \approx_{o b s}^{\mathcal{R}_{r}}\right\}, \mathcal{P} R \mathcal{P}^{\prime}$ if and only if $\mathcal{P} \rho R \mathcal{P}^{\prime} \rho$
- For all $R \in\left\{\leq_{s i m}^{\mathrm{N}^{\ell}}, \approx_{b i}^{\mathrm{N}^{\ell}}\right\},(\mathcal{P}, \phi) R\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ if and only if $(\mathcal{P}, \phi) \rho R\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \rho$.

Proof. Direct by noticing that $\doteq$ is closed by under substitution of names by other terms, i.e. for all $u, v$ such that $\operatorname{img}(\rho) \cap \operatorname{names}(u, v), u \doteq v$ if and only if $u \rho \doteq v \rho$.

Lemma 35. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}}\right)$ be a NPLTS, $D, E \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$ and $R$ be a relation over $\mathcal{S}_{\mathrm{N}}$. If $D$ has a finite support and $D \widehat{R} E$ then there exists a family of sub-distributions $\left\{E_{x}\right\}_{x \in \operatorname{supp}(D)}$ such that:

- for all $y \in \mathcal{S}_{\mathrm{N}}, \sum_{x \in \operatorname{supp}(D)} E_{x}(y) \leq E(y)$
- for all $x \in \operatorname{supp}(D), D(x) \cdot \delta_{x} \widehat{R} E_{x}$ and $\operatorname{supp}\left(E_{x}\right)=R(\{x\})$

Proof. For this proof, we rely on [LSA14, Lemma 3.9] that states the following: Assume $p_{1}, \ldots, p_{n} \leq 1$ and a family $\left\{r_{I} \leq 1\right\}_{I \subseteq\{1, \ldots, n\}}$. If for all $I \subseteq\{1, \ldots, n\}, \sum_{i \in I} p_{i} \leq$ $\sum_{\substack{J \subseteq\{1, \ldots, n\} \\ J \cap \cap \neq \varnothing}} r_{J} \leq 1$ then for all nonempty $I \subseteq\{1, \ldots, n\}$, for all $k \in I$, there exists $s_{k, I} \leq 1$ such that:

- for all $I \subseteq\{1, \ldots, n\}, \sum_{k \in I} s_{k, I} \leq 1$
- for all $k \in\{1, \ldots, n\}, p_{k} \leq \sum_{\substack{I \subseteq\{1, \ldots, n\} \\ k \in I}} s_{k, I} \cdot r_{I}$.

We know that $D$ has finite support. Hence, we can consider $\operatorname{supp}(D)=\left\{x_{1}, \ldots, x_{n}\right\}$ and so we define for all $i \in\{1, \ldots, n\}, p_{i}=D\left(x_{i}\right)$. For all $I \subseteq\{1, \ldots, n\}$, let us define the sets $X_{I}=\left\{x_{i}\right\}_{i \in I}$ and $S_{I}$ such that:

$$
S_{I}=\left\{y \in \mathcal{S}_{\mathrm{N}} \mid \forall i \in\{1, \ldots, n\}, x_{i} R y \Leftrightarrow i \in I\right\}
$$

First, notice that $S_{I} \cap S_{J} \neq \varnothing$ implies $I=J$. Second, let us show that $R\left(X_{I}\right)=$ $\bigcup_{\substack{\begin{subarray}{c}{\begin{subarray}{c}{J 1, \ldots, n\} \\ J \cap \neq \varnothing} }} \end{subarray}}\end{subarray}} S_{J}$. Let $y \in R\left(X_{I}\right)$. There exists $i \in I$ such that $x_{i} R y$. By taking the largest set $J \subseteq\{1, \ldots, n\}$ such that for all $j \in J, x_{j} R y$, we deduce that $y \in S_{J}$. Notice that $i \in J$ and so $J \cap I \neq \varnothing$. On the other hand, for all $J \subseteq\{1, \ldots, n\}$, for all $y \in J$, if $J \cap I \neq \varnothing$ then there exists $i \in I$ such that $x_{i} R y$ an so $y \in R\left(X_{I}\right)$.

Thus, for all $I \subseteq\{1, \ldots, n\}$, we define $r_{I}=E\left(S_{I}\right)$. Recall that $D \widehat{R} E$ and $S_{I} \cap S_{J} \neq \varnothing$ implies $I=J$. Therefore we obtain that for all $I \subseteq\{1, \ldots, n\}, \sum_{i \in I} p_{i}=D\left(X_{I}\right) \leq$ $E\left(R\left(X_{I}\right)\right)=\sum_{\substack{J \subseteq\{1, \ldots, n\} \\ J \cap I \neq \varnothing}} E\left(S_{J}\right)$. Hence, for all nonempty $I \subseteq\{1, \ldots, n\}$, for all $k \in I$, there exists $s_{k, I} \leq 1$ such that:

- for all $I \subseteq\{1, \ldots, n\}, \sum_{k \in I} s_{k, I} \leq 1$
- for all $k \in\{1, \ldots, n\}, D\left(x_{k}\right) \leq \sum_{\substack{I \subseteq\{1, \ldots, n\} \\ k \in I}} s_{k, I} \cdot E\left(S_{I}\right)$.

For all $k \in\{1, \ldots, k\}$, we define the sub-distribution $E_{x_{k}}=\sum_{\substack{I \subseteq\{1, \ldots, n\} \\ k \in I}} s_{k, I} \cdot \sum_{y \in S_{I}} E(y) \cdot \delta_{y}$. Let us show the two desired properties:

- Let $y \in \mathcal{S}_{\mathrm{N}}$. Since $S_{I} \cap S_{J} \neq \varnothing$ implies $I=J$, there is a most one $I \subseteq\{1, \ldots, n\}$ such that $y \in S_{I}$. Hence $\sum_{k=1}^{n} E_{x_{k}}(y)=\sum_{k=1, k \in I}^{n} s_{k, I} \cdot E(y)=E(y) \cdot \sum_{k=1, k \in I}^{n} s_{k, I} \leq E(y)$.
- for all $k \in\{1, \ldots, n\}, D\left(x_{k}\right) \leq \sum_{\substack{I \subseteq\{1, \ldots, n\} \\ k \in I}} s_{k, I} \cdot E\left(S_{I}\right)$. By taking $X_{\{k\}}$, we already showed that $R\left(\left\{x_{k}\right\}\right)=\bigcup_{\substack{I \subseteq\{1, \ldots, n\} \\ I \cap\{k\} \neq \varnothing}} S_{I}$. Hence $E_{x_{k}}\left(R\left(\left\{x_{k}\right\}\right)=\sum_{\substack{I \subseteq\{1, \ldots, n\} \\ k \in I}} E_{x_{k}}\left(S_{I}\right)\right.$. Since $E_{x_{k}}\left(S_{I}\right)=s_{k, I} \cdot E\left(S_{I}\right)$, we conclude that $D\left(x_{k}\right) \cdot \delta_{x_{k}} \widehat{R} E_{x_{k}}$.

The following lemma is similar to the previous one but for equivalence relation.
Lemma 36. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}}\right)$ be a NPLTS, $D, E \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$ and $R$ be an equivalence relation over $\mathcal{S}_{\mathrm{N}}$. If $D \widehat{R} E$ and $E \widehat{R} D$ then there exists a family of sub-distributions $\left\{E_{x}\right\}_{x \in \operatorname{supp}(D)}$ such that:

- $\sum_{x \in \operatorname{supp}(D)} E_{x}=E$
- for all $x \in \operatorname{supp}(D), D(x) \cdot \delta_{x} \widehat{R} E_{x}, E_{x} \widehat{R} D(x) \cdot \delta_{x}$ and $\operatorname{supp}\left(E_{x}\right)=R(\{x\})$

Proof. Since $R$ is an equivalence relation, $D \widehat{R} E$ and $E \widehat{R} D$ imply that for all $x \in$ $\operatorname{supp}(D), D(R(\{x\}))=E(R(\{x\}))$. Hence, we define $E_{x}=\sum_{y \in R(x)} \frac{E(y) \cdot D(x)}{E(R\{x\})} \delta_{y}$. For all $y \in \mathcal{S}_{\mathrm{N}}$,

$$
\sum_{x \in \operatorname{supp}(D)} E_{x}(y)=\sum_{x \in \operatorname{supp}(D) \cap R(\{y\})} \frac{E(y) \cdot D(x)}{E(R(\{x\}))}=E(y)
$$

Moreover, for all $x \in \operatorname{supp}(D), E_{x}(R(\{x\}))=\sum_{y \in R(\{x\})} \frac{E(y) \cdot D(x)}{E(R\{x\})}=D(x)$ which allows us to conclude.

In the following, we say that $D \xrightarrow{\tau}_{\mathrm{r}} E$ has finite support if both $D$ and $E$ have finite support. Similarly, $D \xrightarrow{\tau}{ }_{\mathrm{r}} E$ has finite support if all $D_{k} \xrightarrow{\tau}_{\mathrm{r}} D_{k+1}+D_{k+1}^{\top}$ composing the infinite scheme of $D \xlongequal{\tau} E$ have also finite support. Note that it implies that $D$ has finite support but $E$ may still have infinite support.

Lemma 37. Let $\mathrm{N} \in\left\{\mathrm{N}^{\ell}, \mathrm{N}^{o}\right\}$. Let $D_{1}, D_{2}, E_{1}, E_{2} \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$. Let $R$ be a relation on $\mathcal{S}_{\mathrm{N}}$. We have the following properties:

1. $D_{1} \widehat{R} D_{2}, E_{1} \widehat{R} E_{2}$ and $\left(D_{2}+E_{2}\right) \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$ imply $D_{1}+E_{1} \widehat{R} D_{2}+E_{2}$.
2. $\forall \alpha, D_{1} \widehat{R} D_{2}$ and $\alpha \cdot D_{2} \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$ imply $\alpha \cdot D_{1} \widehat{R} \alpha \cdot D_{2}$
3. if $D_{1}+D_{2} \widehat{R} E$ and $D_{1}, D_{2}$ have finite support (resp. $D_{1}+D_{2} \widehat{R} E, E \widehat{R} D_{1}+D_{2}$ and $R$ is an equivalence relation) then there exist $E_{1}, E_{2}$ such that $E_{1}+E_{2}=E$ and $D_{i} \widehat{R} E_{i}\left(\right.$ resp. $D_{i} \widehat{R} E_{i}$ and $\left.E_{i} \widehat{R} D_{i}\right)$ for $i=1,2$
4. if $D_{1} \widehat{R} E_{1}$ and $\forall x \in \operatorname{supp}\left(D_{1}\right), \forall y \in R(x), x \rightarrow F_{1}$ implies $\delta_{y} \xlongequal{\tau} F_{2}$ and $F_{1} \widehat{R} F_{2}$ then
(a) $D_{1} \xrightarrow{\tau}_{\mathrm{r}} D_{2}$ with finite support implies $E_{1}{ }_{\Longrightarrow}^{\tau} E_{2}$ and $D_{2} \widehat{R} E_{2}$
(b) $D_{1}{ }^{\tau} D_{2}$ with finite support implies $E_{1}{ }^{\tau}{ }_{\mathrm{r}} E_{2}$ and $D_{2} \widehat{R} E_{2}$
5. if $R$ is an equivalence relation, $D_{1} \widehat{R} E_{1}, E_{1} \widehat{R} D_{1}$ and $\forall x \in \operatorname{supp}\left(D_{1}\right), \forall y \in R(x)$, $x \rightarrow F_{1}$ implies $\delta_{y} \xrightarrow{\tau} F_{2}, F_{1} \widehat{R} F_{2}$ and $F_{2} \widehat{R} F_{1}$ then
(a) $D_{1} \xrightarrow{\tau}_{\mathrm{r}} D_{2}$ implies $E_{1} \xrightarrow{\tau} E_{2}, D_{2} \widehat{R} E_{2}$ and $E_{2} \widehat{R} D_{2}$
(b) $D_{1} \xlongequal{\tau} \mathrm{r} D_{2}$ and $D_{2} \in \mathcal{D}\left(\mathcal{S}_{\mathrm{N}}\right)$ imply $E_{1} \xlongequal{\tau}{ }_{\mathrm{r}} E_{2}, D_{2} \widehat{R} E_{2}$ and $E_{2} \widehat{R} D_{2}$

Proof. Properties 1 and 2 are immediate, by definition of $\widehat{R}$.
For Property 3, let $D=D_{1}+D_{2}$. If $D$ has finite support, we can apply Lemma 35 to obtain the family sub-distributions $\left\{E_{x}\right\}_{x \in \operatorname{supp}(D)}$ such that

- for all $y \in \mathcal{S}_{\mathrm{N}}, \sum_{x \in \operatorname{supp}(D)} E_{x}(y) \leq E(y)$
- for all $x \in \operatorname{supp}(D), D(x) \cdot \delta_{x} \widehat{R} E_{x}$ and $\operatorname{supp}\left(E_{x}\right)=R(\{x\})$

Let us define

$$
E_{1}^{\prime}=\sum_{x \in \operatorname{supp}(D)} \frac{D_{1}(x)}{D(x)} \cdot E_{x} \quad \text { and } \quad E_{2}^{\prime}=\sum_{x \in \operatorname{supp}(D)} \frac{D_{2}(x)}{D(x)} \cdot E_{x}
$$

We first prove that $D_{i} \widehat{R} E_{i}^{\prime}$ for $i \in\{1,2\}$. We know that for all $x \in \operatorname{supp}(D), D(x)$. $\delta_{x} \widehat{R} E_{x}$. Hence, $D_{i}(x) \cdot \delta_{x} \widehat{R} \frac{D_{i}(x) \cdot E_{x}}{D(x)}$ and so $D_{i} \widehat{R} E_{i}^{\prime}$. Finally, since for all $y \in \mathcal{S}_{\mathrm{N}}$, $\sum_{x \in \operatorname{supp}(D)} E_{x}(y) \leq E(y)$ and $\sum_{x \in \operatorname{supp}(D)} E_{x}=E_{1}^{\prime}+E_{2}^{\prime}$, there exists $H$ such that $E_{1}^{\prime}+E_{2}^{\prime}+$ $H=E$, meaning that we can arbitrarily define $E_{1}=E_{1}^{\prime}+H_{1}$ and $E_{2}=E_{2}^{\prime}+H_{2}$ with $H_{1}+H_{2}=H$ in order to conclude.

If $R$ is an equivalence relation, $D_{1}+D_{2} \widehat{R} E$ and $E \widehat{R} D_{1}+D_{2}$, then we can instead apply Lemma 36. Hence, for $i \in\{1,2\}$, for all $x \in \operatorname{supp}(D), D_{i}(x) \cdot \delta_{x} \widehat{R} \frac{D_{i}(x) \cdot E_{x}}{D(x)}$ and $\frac{D_{i}(x) \cdot E_{x}}{D(x)} \widehat{R} D_{i}(x) \cdot \delta_{x}$. Defining $E_{1}^{\prime}$ and $E_{2}^{\prime}$ as above we obtain that $D_{i} \widehat{R} E_{i}^{\prime}$ and $E_{i}^{\prime} \widehat{R} D_{i}$. Moreover, by Lemma 36, for all $y \in \mathcal{S}_{\mathrm{N}}, \sum_{x \in \operatorname{supp}(D)} E_{x}(y)=E(y)$ and so $E_{1}^{\prime}+E_{2}^{\prime}=E$ which allows us to conclude.

We now prove Property 4a. Assume that $D_{1}$ has finite support, $D_{1} \widehat{R} E_{1}$ and $\forall x \in$ $\operatorname{supp}\left(D_{1}\right), \forall y \in R(x), x \rightarrow F_{1}$ implies $\delta_{y}{ }_{\mathrm{\tau}}^{\tau} F_{2}$ and $F_{1} \widehat{R} F_{2}$.

Let us assume that $D_{1} \xrightarrow{\tau}_{\mathrm{r}} D_{2}$ and $D_{2}$ has finite support. Thus there exists a countable set $I$ and a multiset $\left\{x_{i}\right\}_{i \in I}$ with for all $i \in I, x_{i} \in \mathcal{S}_{\mathrm{N}}$ such that $D_{1}=\sum_{i \in I} \alpha_{i} \cdot \delta_{x_{i}}$, $D_{2}=\sum_{i \in I} \alpha_{i} \cdot F_{i}$ and for all $i \in I, x_{i} \rightarrow F_{i}$. Note that by hypothesis, $x_{i} \rightarrow F_{i}$ implies that $F_{i}$ has finite support. Thus, $D_{2}$ having finite support allows us to consider w.l.o.g that $I$ is finite.

By applying Lemma 35, $D_{1} \widehat{R} E_{1}$ implies that there exists $\left\{E_{x}\right\}_{x \in D_{1}}$ such that

- for all $y \in \mathcal{S}_{\mathrm{N}}, \sum_{x \in \operatorname{supp}\left(D_{1}\right)} E_{x}(y) \leq E_{1}(y)$
- for all $x \in \operatorname{supp}\left(D_{1}\right), D_{1}(x) \cdot \delta_{x} \widehat{R} E_{x}$ and $\operatorname{supp}\left(E_{x}\right)=R(\{x\})$

Let $i \in I$. Let $y \in \operatorname{supp}\left(E_{x_{i}}\right)$. As $y \in R\left(\left\{x_{i}\right\}\right)$, by hypothesis, $\delta_{y} \Longrightarrow_{r}^{\tau} F_{i, y}^{\prime}$ and $F_{i} \widehat{R}$ $F_{i, y}^{\prime}$. Thus by properties 1 and $2, \sum_{y \in \operatorname{supp}\left(E_{x_{i}}\right)} E_{x_{i}}(y) \cdot F_{i} \widehat{R} \sum_{y \in \operatorname{supp}\left(E_{x_{i}}\right)} E_{x_{i}}(y) \cdot F_{i, y}^{\prime}$ and hence $F_{i} \widehat{R} \sum_{y \in \operatorname{supp}\left(E_{x_{i}}\right)} \frac{E_{x_{i}}(y)}{E_{x_{i}}\left(R\left(\left\{x_{i}\right\}\right)\right.} \cdot F_{i, y}^{\prime}$. Since $E_{2}=\sum_{i \in I} \alpha_{i} \cdot F_{i}$, if we denote $H_{2}=$ $\sum_{i \in I} \sum_{y \in \operatorname{supp}\left(E_{x_{i}}\right)} \frac{\alpha_{i} \cdot E_{x_{i}}(y)}{E_{x_{i}}\left(R\left(\left\{x_{i}\right\}\right)\right)} \cdot F_{i, y}^{\prime}$ then $D_{2} \widehat{R} H_{2}$. Notice that:

$$
\begin{aligned}
H_{2} & =\sum_{x \in \operatorname{supp}\left(D_{1}\right)} \sum_{i \in I} \sum_{\substack{x=x_{i}}} \frac{\alpha_{i} \cdot E_{x_{i}}(y)}{E_{x_{i}}\left(R\left(\left\{x_{i}\right\}\right)\right)} \cdot F_{i, y}^{\prime} \\
& =\sum_{x \in \operatorname{supp}\left(D_{1}\right)} \sum_{i \in I} \sum_{\substack{ \\
x=x_{i}}} \frac{\alpha_{i} \cdot E_{x_{i}}(y)}{E_{x}(R(\{x\}))} \cdot F_{i, y}^{\prime} \\
& =\sum_{x \in \operatorname{supp}\left(D_{1}\right)} \sum_{\substack{i \in I \\
x=x_{i}}} \frac{\alpha_{i}}{E_{x}(R(\{x\}))} \cdot \sum_{y \in \operatorname{supp}\left(E_{x_{i}}\right)} E_{x_{i}}(y) \cdot F_{i, y}^{\prime}
\end{aligned}
$$

Furthermore, we know that for all $i \in I$, for all $y \in R\left(\left\{x_{i}\right\}\right), \delta_{y} \xlongequal{\tau}_{\mathrm{r}} F_{i, y}^{\prime}$. Therefore, $E_{x_{i}} \xrightarrow{\tau} \sum_{y \in \operatorname{supp}\left(E_{x_{i}}\right)} E_{x_{i}}(y) \cdot F_{i, y}^{\prime}$, which implies that:

$$
\sum_{x \in \operatorname{supp}\left(D_{1}\right)} \sum_{\substack{i \in I \\ x=x_{i}}} \frac{\alpha_{i}}{E_{x}(R(\{x\}))} \cdot E_{x}{\underset{\mathrm{r}}{ }}_{\tau}^{\Longrightarrow} H_{2}
$$

Note that the following holds:

$$
\begin{aligned}
\sum_{x \in \operatorname{supp}\left(D_{1}\right)} \sum_{\substack{i \in I \\
x=x_{i}}} \frac{\alpha_{i}}{E_{x}(R(\{x\})} \cdot E_{x} & =\sum_{x \in \operatorname{supp}\left(D_{1}\right)} \frac{\sum_{\substack{i \in I \\
x=x_{i}}} \alpha_{i}}{E_{x}(R(\{x\}))} \cdot E_{x} \\
& =\sum_{x \in \operatorname{supp}\left(D_{1}\right)} \frac{D_{1}(x)}{E_{x}(R(\{x\}))} \cdot E_{x}
\end{aligned}
$$

Hence, if we denote $H_{1}=\sum_{x \in \operatorname{supp}\left(D_{1}\right)} \frac{D_{1}(x)}{E_{x}(R(\{x\}))} \cdot E_{x}$, we obtain $H_{1} \xlongequal{\tau_{\mathrm{r}}} H_{2}$. Finally, we know that for all $x \in \operatorname{supp}\left(D_{1}\right), D_{1}(x) \leq E_{x}(R(\{x\}))$ and for all $y \in \mathcal{S}_{\mathrm{N}}, \sum_{x \in \operatorname{supp}\left(D_{1}\right)} E_{x}(y) \leq$ $E_{1}(y)$. Thus, there exists $H_{1}^{\prime}$ such that $E_{1}=H_{1}+H_{1}^{\prime}$. This allows us to deduce that $E_{1} \xrightarrow{\tau} H_{2}+H_{1}^{\prime}$ and $D_{2} \widehat{R}\left(H_{2}+H_{1}^{\prime}\right)$. This completes the proof of property 4 a .

The proof for property 5a follows very closely. Instead of using Lemma 355, we rely on Lemma 36. Note in this case, $D_{1}(x)=E_{x}(R(\{x\}))$ implying that $H_{1}=\sum_{x \in \operatorname{supp}\left(D_{1}\right)} E_{x}=$ $E_{1}$. This allows us to conclude the proof of property 5a.

Let us now prove property 4b. Assume $D_{1}{ }^{\tau}{ }_{r} D_{2}$ with internal finite support. By definition, there exists the following infinite scheme:

$$
\begin{aligned}
& D_{1}=D_{0}^{\overrightarrow{ }}+D_{0}^{\top} \\
& D_{0}^{\rightarrow} \xrightarrow{\tau}_{\mathrm{r}} D_{1}^{\rightarrow}+D_{1}^{\top} \\
& \ldots \\
& D_{k}^{\vec{\tau}} \xrightarrow{\mathrm{T}}_{\mathrm{r}} D_{k+1}^{\overrightarrow{ }}+D_{k+1}^{\top}
\end{aligned}
$$

such that $D_{2}=\sum_{k \in \mathbb{N}} D_{k}^{\top}$ and for all $k \in \mathbb{N}, D_{k}$ and $D_{k}^{\top}$ have finite support. We can easily show by induction that for all $k \in \mathbb{N}$,

- $E_{1} \xlongequal{\tau} E_{k}+\sum_{i=0}^{k} E_{i}^{\top}$
- $D_{k} \widehat{R} E_{k}$
- $\sum_{i=0}^{k} D_{i}^{\top} \widehat{R} \sum_{i=0}^{k} E_{i}^{\top}$

In the base case $k=0$, we can apply Property 3 to deduce that there exists $E_{0}^{\rightarrow}$ and $E_{0}^{\top}$ such that $E=E_{0}+E_{0}^{\top}$ and for all $\alpha \in\{\rightarrow, \top\}, D_{0}^{\alpha} \widehat{R} E_{0}^{\alpha}$.

In the inductive step $k>0$, we know that $D_{k-1} \xrightarrow{\tau}_{\mathrm{r}} D_{k}+D_{k}^{\top}$. By induction hypothesis, we know that there exist $E_{1} \xrightarrow{\tau}{ }_{\mathrm{r}} E_{k-1}+\sum_{i=0}^{k-1} E_{i}^{\top}$ such that $E_{k-1} \widehat{R} E_{k-1}^{\rightarrow}$ and $\sum_{i=0}^{k-1} D_{i}^{\top} \widehat{R}$ $\sum_{i=0}^{k-1} E_{i}^{\top}$. By applying Property 4a, we obtain that $E_{k-1} \xlongequal{\tau}{ }_{\mathrm{r}} E^{\prime}$ such that $D_{k}+D_{k}^{\top} \widehat{R} E^{\prime}$. By applying Property 3, we deduce that there exists $E_{k}^{\rightarrow}, E^{\prime \prime}$ such that $E^{\prime}=E_{k}+E_{k}^{\top}$, $D_{k}^{\overrightarrow{ }} \widehat{R} E_{k}^{\rightarrow}$ and $D_{k}^{\top} \widehat{R} E_{k}^{\top}$. Therefore, $\sum_{i=0}^{k} D_{i}^{\top} \widehat{R} \sum_{i=0}^{k} E_{i}^{\top}$. Note that $E_{k-1}^{\vec{~}} \xlongequal{\tau} E_{k}^{\vec{k}}+E_{k}^{\top}$ implies $E_{k-1}^{\overrightarrow{2}}+\sum_{i=0}^{k-1} E_{i}^{\top} \xrightarrow{\tau} E_{k}+\sum_{i=0}^{k} E_{i}^{\top}$. This concludes the inductive proof.

In the case where $\lim _{k \rightarrow \infty} E_{k}^{\overrightarrow{ }}$ exists, we obtain that $E_{1} \xlongequal{\tau} \lim _{k \rightarrow \infty} E_{k}+\sum_{k \in \mathbb{N}} E_{k}^{\top}$ with $\sum_{k \in \mathbb{N}} D_{i}^{\top} \widehat{R} \sum_{k \in \mathbb{N}} E_{k}^{\top}$. Hence, we conclude by defining $E_{2}=\lim _{k \rightarrow \infty} E_{k}+\sum_{k \in \mathbb{N}} E_{k}^{\top}$ and so $D_{2} \widehat{R} E_{2}$. In the case $\lim _{k \rightarrow \infty} E_{k}$ does not exist, the semantics in Figures 2 and 10 imply that there exists $k_{!} \in \mathbb{N}$ and a set $S$ such that for all $k>k_{!}, \operatorname{supp}\left(E_{k}\right) \cap\{\{!P\} \cup$ $\mathcal{P} \in \mathcal{S P}\}=S$ (resp. $\{(\{!P\}, \phi) \cup \mathcal{P} \in \mathcal{S P}\}$ when $\left.\mathrm{N}=\mathrm{N}^{\ell}\right)$. Note that if we define $E_{k}^{S}=\sum_{x \in S} E_{k}(x) \cdot \delta_{x}$ then $\lim _{k \rightarrow \infty} E_{k}^{S}$ exists. Moreover, thanks to Remark 7, we have that $E_{k}^{\rightarrow} \xlongequal{\tau} E_{k}^{S}$. Thus, $E_{1} \xrightarrow{\tau} \mathrm{r} E_{k}^{S}+\sum_{i=0}^{k} E_{i}^{\top}$. We can therefore conclude by defining $E_{2}=\lim _{k \rightarrow \infty} E_{k}^{S}+\sum_{k \in \mathbb{N}} E_{k}^{\top}$.

Finally, the proof of property 5b follows the same reasoning as property 4b; We prove by induction that for all $k \in \mathbb{N}$,

- $E_{1} \xlongequal{\tau} \mathrm{r} E_{k}^{\rightarrow}+\sum_{i=0}^{k} E_{i}^{\top}$
- $D_{k}^{\vec{k}} \widehat{R} E_{k}^{\rightarrow}$ and $E_{k} \widehat{R} D_{k}^{\vec{~}}$
- $\sum_{i=0}^{k} E_{i}^{\top} \widehat{R} \sum_{i=0}^{k} D_{i}^{\top}$

The base case once again uses property 3 but the inductive step relies on property 5 a rather than property 4a. To conclude the final proof, we know that $E_{2} \in \mathcal{D}\left(\mathcal{S}_{\mathrm{N}}\right)$. Thus, $\lim _{k \rightarrow \infty} E_{k}=\varnothing$. This allows us to conclude by defining $E=\sum_{k \in \mathbb{N}} E_{k}^{\top}$.

## F.1.1 Properties on $\operatorname{RProb}_{\mathcal{R}_{\dot{r}}}(\mathcal{P}, \downarrow c)$

We define $\mathcal{R}_{r}^{o f}=\left\{(\mathcal{S}\right.$, corr, trans $) \in \mathcal{R}_{r}^{o} \mid \forall s \in \mathcal{S}, \operatorname{trans}(s)=D$ implies $D$ has finite support $\}$.
Let us define $\mathcal{P} \equiv \mathcal{P}^{\prime}$ when there exists a renaming of names $\rho$ such that $f n(\mathcal{P}) \cap \mathcal{N}_{\text {priv }}=$ $\operatorname{dom}(\rho), \operatorname{img}(\rho) \subseteq \mathcal{N}_{\text {priv }}$ and $\mathcal{P} \rho=\mathcal{P}^{\prime}$. Note that $\mathcal{P} \equiv \mathcal{P}^{\prime}$ implies $\mathcal{P} \approx_{o b s} \mathcal{P}^{\prime}$ thanks to Lemma 34. Given a distribution $F$, we denote $F / \equiv=\sum_{x \in \operatorname{supp}(F) / \equiv} \sum_{y \equiv x} F(y) \cdot \delta_{x}$. Given two distributions $F$ and $F^{\prime}$, we say that $F \equiv F^{\prime}$ when $F / \equiv=F^{\prime} / \equiv$.

Lemma 38. For all $F, H \in \mathcal{D}^{\leq 1}\left(\mathrm{~N}^{o}\right), F \xrightarrow{\tau}_{\mathrm{r}} H$ with $F$ having finite support implies that $F \xrightarrow{\tau}_{\mathrm{r}} H^{\prime}$ with $H \equiv H^{\prime}$ and $H^{\prime}$ having finite support.

$$
x_{i} \rightarrow D_{i} .
$$

$$
\begin{aligned}
F & =\sum_{i \in I} \alpha_{i} \cdot \delta_{x_{i}} \\
& =\sum_{x \in \operatorname{supp}(F)} \sum_{\substack{i \in I \\
x=x_{i}}} \alpha_{i} \cdot \delta_{x} \\
& =\sum_{x \in \operatorname{supp}(F)} \sum_{\substack{D \in \mathcal{D}\left(N^{o}\right) /=\\
\mid x \rightarrow D}}\left(\sum_{\substack{i \in I \\
\mid x=x_{i} \\
\wedge D \equiv D_{i}}} \alpha_{i}\right) \cdot \delta_{x}
\end{aligned}
$$

Notice that by Figure 2, given $x$ the set $\left\{D \in \mathcal{D}\left(\mathrm{~N}^{o}\right) / \equiv\right\}$ is finite. Indeed we only consider finite multisets of processes and the only rule that can generate an infinite number of successor is the rule (NEW) but they are all equivalent under $\equiv$. Thus, by defining $H^{\prime}=$ $\sum_{x \in \operatorname{supp}(F) / \equiv} \sum_{\substack{D \in \mathcal{D} \leq 1\left(\mathcal{N}^{\circ}\right) / \equiv \\ \mid x \rightarrow D}}\left(\sum_{\substack{i \in I \\ \mid x=x_{i} \\ \wedge D \equiv D_{i}}} \alpha_{i}\right) \cdot D$, the result holds.

Lemma 39. Let $\mathrm{R}=(\mathcal{S}$, corr, trans $) \in \mathcal{R}_{r}^{o}$ (resp. $\left.\mathcal{R}_{r}^{o f}\right)$. For all $n \in \mathcal{N}_{\text {pub }}$, for all $c \in \mathcal{N}_{\text {pub }}$, for all $\mathcal{P} \in \mathcal{M} \mathcal{P}$, for all $s \in \mathcal{S}$, if $\operatorname{corr}(s)=\mathcal{P}$ then there exists $D \in \mathcal{D}\left(\mathcal{S}_{\mathrm{N}}^{o}\right)$ such that:

- $\mathcal{P} \xlongequal{\tau}{ }_{\mathrm{r}} D$ (resp. with finite support)
- $\operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(s, \operatorname{corr}^{-1}(\downarrow c)\right) \leq D(\downarrow c)$

Proof. We prove this property by induction on $n$.
Base case $n=0$ : In such a case, $\operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(s, \operatorname{corr}^{-1}(\downarrow c)\right)=1$ if $\mathcal{P} \in \downarrow c$ and 0 otherwise. Thus, we can define $D=\delta_{\mathcal{P}}$ to directly obtain that $\mathcal{P} \xlongequal{\tau} D$ and $\operatorname{RProb}_{\overline{\mathrm{R}}}^{\leq n}(\mathcal{P}, \downarrow c) \leq D(\downarrow$ c).

Inductive step $n>0$ : If $s \in \operatorname{corr}^{-1}(\downarrow c)$ or if $\operatorname{trans}(s)=\star$ then we can again define $D=\delta_{\mathcal{P}}$ to conclude. Let us now assume that $s \notin \operatorname{corr}^{-1}(\downarrow c)$ and $\operatorname{trans}(s)=E$. In such a case,

$$
\operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(s, \operatorname{corr}^{-1}(\downarrow c)\right)=\sum_{u \in \operatorname{supp}(E)} E(u) \cdot \operatorname{RProb}_{\mathrm{R}}^{\leq n-1}\left(u, \operatorname{corr}^{-1}(\downarrow c)\right)
$$

By definition of a resolution, $\operatorname{corr}(E) \in \operatorname{conv}\left(\operatorname{trans}_{N^{o}}(\operatorname{corr}(s))\right)$ and so $\delta_{\mathcal{P}}{ }^{\tau}{ }_{\mathrm{r}} \operatorname{corr}(E)$. Note that when $\mathrm{R} \in \mathcal{R}_{r}^{o f}$, we know that $\operatorname{corr}(E)$ has finite support.

By inductive hypothesis, we know that for all $u \in \operatorname{supp}(E)$, there exists $D_{u} \in \mathcal{D}\left(\mathcal{S}_{\mathrm{N}}^{o}\right)$ such that:

- $\operatorname{corr}(u) \xrightarrow{\tau} D_{u}$ (with finite support when $\mathrm{R} \in \mathcal{R}_{\mathrm{r}}^{\text {of }}$ )
- $\operatorname{RProb}_{\mathrm{R}}^{\leq n-1}\left(\operatorname{corr}(u), \operatorname{corr}^{-1}(\downarrow c)\right) \leq D_{u}(\downarrow c)$

Let us define $D=\sum_{u \in \operatorname{supp}(E)} E(u) \cdot D_{u}$. Furthermore,

$$
\sum_{\mathcal{Q} \not \downarrow_{c}} D(Q)=\sum_{\mathcal{Q} \in \downarrow_{c}} \sum_{u \in \operatorname{supp}(E)} E(u) \cdot D_{u}(\mathcal{Q})=\sum_{u \in \operatorname{supp}(E)} E(u) \cdot \sum_{\mathcal{Q} \in \downarrow_{c}} D_{u}(\mathcal{Q})
$$

Thus, $\operatorname{RProb}_{\mathrm{R}}^{\leq n}\left(s, \operatorname{corr}^{-1}(\downarrow c)\right) \leq D(\downarrow c)$. Note that since for all $u \in \operatorname{supp}(E), \operatorname{corr}(u) \xlongequal{\tau}{ }_{r}$ $D_{u}$, we conclude that $\delta(\mathcal{P}) \underset{\tau}{\tau} D$. Furthermore when $\mathrm{R} \in \mathcal{R}_{\mathrm{r}}^{o f}$, we know that $\operatorname{corr}(E)$ has finite support and $\operatorname{corr}(u) \xlongequal{\tau}_{\mathrm{r}} D_{u}$ has finite support. Hence so does $\delta(\mathcal{P}) \xlongequal{\tau}_{\mathrm{r}} D$.

Lemma 40. For all $\mathcal{P} \in \mathcal{M P}$, for all $c \in \mathcal{N}_{p u b}$,

- $\delta_{\mathcal{P}} \Longrightarrow_{\mathrm{r}}^{\tau} E$ implies $E(\downarrow c) \leq \operatorname{RProb}_{\mathcal{R}_{r}^{o}}(\mathcal{P}, \downarrow c)$
- $\delta_{\mathcal{P}} \Longrightarrow_{\mathrm{r}} E$ with finite support implies $E(\downarrow c) \leq \operatorname{RProb}_{\mathcal{R}_{\mathrm{r}}^{\text {of }}}(\mathcal{P}, \downarrow c)$

Proof. Thanks to Lemma 1, we know that $\delta_{\mathcal{P}}{ }^{\tau}{ }_{\mathrm{r}} E$ implies that there exists $R=$ $(\mathcal{S}$, corr, trans $) \in \mathcal{R}_{r}^{o}$, and $D^{\prime}, E^{\prime} \in \mathcal{D}^{\leq 1}(\mathcal{S})$ such that $\operatorname{corr}\left(D^{\prime}\right)=\delta_{\mathcal{P}}, \operatorname{corr}\left(E^{\prime}\right)=E$, $\operatorname{supp}\left(E^{\prime}\right) \subseteq \mathcal{S}_{\text {ext }}(R)$ and for all $u \in \mathcal{S}_{\text {ext }}(R), E^{\prime}(u)=\sum_{s^{\prime} \in \mathcal{S}} D^{\prime}\left(s^{\prime}\right) \cdot \operatorname{RProb}_{R}\left(s^{\prime},\{u\}\right)$. Therefore,

$$
\begin{aligned}
E(\downarrow c) & =\sum_{\substack{u \in \mathcal{S}_{\text {ext }}(R) \\
\mid \operatorname{corr}(u) \in \downarrow c}} E^{\prime}(u) \\
& =\sum_{\substack{u \in \mathcal{S}_{\text {ext }}(R) \\
\mid \operatorname{corr}(u) \in \downarrow c}} \sum_{s^{\prime} \in \mathcal{S}} D^{\prime}\left(s^{\prime}\right) \cdot \operatorname{RProb}_{R}\left(s^{\prime},\{u\}\right) \\
& =\sum_{s^{\prime} \in \mathcal{S}} D^{\prime}\left(s^{\prime}\right) \cdot \sum_{\substack{u \in \mathcal{S}_{\text {ext }}(R) \\
\mid \operatorname{corr}(u) \in \downarrow_{c}}} \operatorname{RProb}_{R}\left(s^{\prime},\{u\}\right) \\
& \leq \sum_{s^{\prime} \in \mathcal{S}} D^{\prime}\left(s^{\prime}\right) \cdot \operatorname{RProb}_{R}\left(s^{\prime}, \operatorname{corr}^{-1}(\downarrow c)\right) \\
& \leq \sup _{\substack{s^{\prime} \in \mathcal{S} \\
\operatorname{corr}\left(\mathcal{S}^{\prime}\right)=\mathcal{P}}} \operatorname{RProb}_{R}\left(s^{\prime}, \operatorname{corr}^{-1}(\downarrow c)\right) \\
& \leq \operatorname{RProb}_{\mathcal{R}_{r}^{o}}(\mathcal{P}, \downarrow c)
\end{aligned}
$$

Note that one can easily check from the proof of Lemma 1 that the results carries over to $\delta_{\mathcal{P}} \xlongequal{\tau} D$ with finite support, i.e. in that case, the resolution $R$ is in $\mathcal{R}_{\mathrm{r}}^{o f}$, and so the rest of the proof follows.

Lemma 41. For all $\mathcal{P} \in \mathcal{M P}$, for all $c \in \mathcal{N}_{p u b}$,

$$
\begin{aligned}
\operatorname{RProb}_{\mathcal{R}_{r}^{o}}(\mathcal{P}, \downarrow c) & =\sup \left\{D(\downarrow c) \mid \delta_{\mathcal{P}} \xlongequal{\tau}_{\mathrm{r}} D\right\} \\
& =\sup \left\{D(\downarrow c) \mid \delta_{\mathcal{P}} \xlongequal{\tau}_{\mathrm{r}} D \text { with finite support }\right\} \\
& =\operatorname{RProb}_{\mathcal{R}_{r}^{o f}}(\mathcal{P}, \downarrow c)
\end{aligned}
$$

Proof. Consider the set $S=\left\{D(\downarrow c) \mid \delta_{\mathcal{P}} \xlongequal{\tau}_{\mathrm{r}} D\right\}$. By Lemma 39, we know that $\operatorname{RProb}_{\mathcal{R}_{r}^{o}}(\mathcal{P}, \downarrow c) \leq \sup S$ and by Lemma 40 , we have that $\sup S \leq \operatorname{RProb}_{\mathcal{R}_{r}^{o}}(\mathcal{P}, \downarrow c)$. Similarly, if we denote $S_{f}=\left\{D(\downarrow c) \mid \delta_{\mathcal{P}} \Longrightarrow_{\mathrm{T}} D\right.$ with finite support $\}$, we have $\sup S_{f}=$ $\operatorname{RProb}_{\mathcal{R}_{r}^{\text {of }}}(\mathcal{P}, \downarrow c)$.

However, by Lemma 38, a simple induction on the infinite scheme building $\delta_{\mathcal{P}} \xlongequal{\tau}{ }_{\mathrm{r}} D$ allows us to deduce that there exists $D^{\prime}$ such that $\delta_{\mathcal{P}}{ }^{\tau}{ }_{\mathrm{r}} D^{\prime}$ having finite support and such that $D \equiv D^{\prime}$. Since the equivalence $\equiv$ only affects private names, we conclude that $D(\downarrow c)=D^{\prime}(\downarrow c)$ and so $S=S_{f}$.

## F. 2 Restricted characterization of observational relations

Let us define the following equivalences:
Definition 37. The restricted observational preorders $\leq_{o b s}^{r_{0}}, \leq_{o b s}^{r_{1}}, \leq_{o b s}^{r_{2}}$ are the largest relation $R$ on $\mathcal{M P}$ such that $\mathcal{P} R \mathcal{Q}$ implies :

- for all $c \in \mathcal{N}_{p u b}, \operatorname{RProb}_{\mathcal{R}_{r}}(\mathcal{P}, \downarrow c) \leq \operatorname{RProb}_{\mathcal{R}_{r}}(\mathcal{Q}, \downarrow c)$;
- Case $\leq_{o b s}^{r_{0}}:$ if $\mathcal{P} \xlongequal{\tau} D$ then $\mathcal{Q} \xlongequal{\tau}^{{ }_{\mathrm{r}}} E$ and $D \widehat{R} E$;

Case $\leq_{o b s}^{r_{1}}:$ if $\mathcal{P} \xrightarrow{\tau} D$ then $\mathcal{Q} \xrightarrow{\tau} E$ and $D \widehat{R} E$;
Case $\leq_{o b s}^{r_{2}}:$ if $\mathcal{P} \xlongequal{\tau} D$ with finite support then $\mathcal{Q} \xlongequal{\tau}^{\boldsymbol{\tau}} \mathrm{r} E$ and $D \widehat{R} E$;

- for all closed $A d v \in \mathcal{M P}$ such that $f n(A d v) \subseteq \mathcal{N}_{p u b},\{A d v\} \cup \mathcal{P} R\{A d v\} \cup \mathcal{Q}$.

The restricted observational equivalences $\approx_{o b s}^{r_{0}}, \approx_{o b s}^{r_{1}}$ and $\approx_{o b s}^{r_{2}}$ are defined by additionally requesting $R$ to be symmetric respectively in the cases of $\leq_{o b s}^{r_{0}}, \leq_{o b s}^{r_{1}}$ and $\leq_{o b s}^{r_{2}}$. The restricted observational equivalence $\approx_{o b s}^{\prime r_{0}}, \approx_{o b s}^{r_{1}}$ and $\approx_{o b s}^{\prime r_{2}}$ are defined respectively in the cases $\leq_{o b s}^{r_{0}}, \leq_{o b s}^{r_{1}}$, $\leq_{o b s}^{r_{2}}$ by additionally requesting that $R$ to be symmetric and in the second bullet point, by requesting $D$ to be a distribution and both $D \widehat{R} E$ and $E \widehat{R} D$ to hold.

Lemma 42. $\leq_{o b s}, \leq_{o b s}^{r_{0}}, \leq_{o b s}^{r_{1}}$ and $\leq_{o b s}^{r_{2}}$ coincide. $\approx_{o b s}^{r_{0}}, \approx_{o b s}^{r_{1}}, \approx_{o b s}^{r_{2}}, \approx_{o b s}^{r_{0}}, \approx_{o b s}^{r_{1}}$ and $\approx_{o b s}^{r_{2}}$ coincide.

Proof. Let us start with the simple results: Notice that $\leq_{o b s}^{r_{0}}$ is in fact the same definition as $\leq_{o b s}$. In the definition of $\approx_{o b s}^{r_{1}}$, if $\mathcal{P} \xrightarrow{\tau} D$ then $\mathcal{Q} \xlongequal{\tau} E$ and $D \widehat{\widetilde{च}_{o b s}^{r_{1}}} E$. However, $D$ is a distribution by Figure 2. Hence, $D \widehat{\approx_{o b s}^{r_{1}}} E$ also implies that $E$ is a distribution. Since $\approx_{o b s}^{r_{1}}$ is symmetric, we deduce that $E \widehat{\widetilde{\sigma}_{o b s}^{r_{1}}} D$ and so $\approx_{o b s}^{r_{1}}$ and $\approx_{o b s}^{\prime r_{1}}$ coincide.

We show that $\leq_{o b s}^{r_{0}}$ coincide with $\leq_{o b s}^{r_{2}}$. We trivially have $\leq_{o b s}^{r_{0}}$ implies $\leq_{o b s}^{r_{2}}$. Let us thus focus on the other implication. Assume that $\mathcal{P} \leq_{o b s}^{r_{2}} \mathcal{Q}$. Take $\mathcal{P} \xlongequal{\tau} \mathrm{r} D$. By definition,
there exists the following infinite scheme:

$$
\begin{aligned}
& \delta_{\mathcal{P}}=D_{0}^{\rightarrow}+D_{0}^{\top} \\
& D_{0}^{\rightarrow} \xrightarrow{\tau}_{\mathrm{r}} D_{1}^{\rightarrow}+D_{1}^{\top} \\
& \ldots \\
& D_{k}^{\rightarrow} \xrightarrow{\tau}_{\mathrm{r}} D_{k+1}+D_{k+1}^{\top}
\end{aligned}
$$

such that $D=\sum_{k \in \mathbb{N}} D_{k}^{\top}$.
Thanks to Lemma 38, a simple induction allows us to deduce that there exists $\mathcal{P} \xlongequal{\tau} D^{\prime}$ with finite support ( $D^{\prime}$ may have infinite support) such that $D \equiv D^{\prime}$. By $\mathcal{P} \leq_{o b s}^{r_{2}} \mathcal{Q}$, we deduce that there exists $\mathcal{Q} \xlongequal{\tau} E$ such that $D^{\prime} \widehat{{ }_{o b s}^{r_{2}}} E$. But $D \equiv D^{\prime}$ implies $D \widehat{{ }_{o b s}^{r_{2}}} E$ which allows us to conclude.

The same proof allows us to show that $\approx_{o b s}^{r_{0}}$ and $\approx_{o b s}^{r_{2}}$ coincide. A minor modification of the proof also allows us to show that $\approx_{o b s}^{\prime r_{0}}$ and $\approx_{o b s}^{\prime r_{2}}$. Indeed, only the last sentence would change as we would obtain that there exists $\mathcal{Q} \xlongequal{\tau} E$ such that $D^{\prime} \widehat{\approx_{o b s}^{r_{2}}} E$ and $E \widehat{\widetilde{\sigma}_{o b s}^{r_{2}}} D^{\prime}$. But once again $D \equiv D^{\prime}$ and $E \widehat{\approx_{o b s}^{\prime r_{2}}} D^{\prime}$ also imply $E \widehat{\widetilde{\approx}_{o b s}^{r_{2}}} D$.

Let us now show that $\leq_{o b s}^{r_{1}}$ and $\leq_{o b s}^{r_{2}}$ coincide. We trivially have $\leq_{o b s}^{r_{2}}$ implies $\leq_{o b s}^{r_{1}}$ thus let us focus on the other implication. Assume that $\mathcal{P} \leq_{o b s}^{r_{1}} \mathcal{Q}$. Hence $\delta_{\mathcal{P}} \widehat{\leq_{o b s}^{r_{1}}} \delta_{\mathcal{Q}}$. Let $\mathcal{P} \xlongequal{\tau}{ }_{\mathrm{r}} D$ with finite support. By Property 4 b of Lemma 37, we have that there exists $E$ such that $\mathcal{Q} \xlongequal{\tau}{ }_{\mathrm{r}} E$ such that $D \widehat{\underline{S}_{\text {obs }}} E$. Hence we conclude the proof. Note that the same proof allows us to prove that $\approx_{o b s}^{r_{1}}$ and $\approx_{o b s}^{r_{2}}$ coincide.

The same proof where we apply Property 5 b of Lemma 37 allows us to prove that $\approx_{o b s}^{r_{1}}$ and $\approx_{o b s}^{\prime r_{2}}$ coincide.

## F. 3 Observational preorder implies simulation

For this direction of the equivalence, we need to represent as a process the frame of an extended process $(\mathcal{P}, \phi)$. Intuitively, for all $\mathrm{ax}_{i} \in \operatorname{dom}(\phi)$, we will output on a public name $c_{\mathrm{ax}_{i}}$ the term $\mathrm{ax}_{i} \phi$. Formally, consider a frame $\phi=\left\{\mathrm{ax}_{1} \rightarrow t_{1}, \ldots \mathrm{ax}_{n} \rightarrow t_{n}\right\}$ and a sequence of public names $\mathcal{N}_{c h}=\left[c_{\mathrm{ax}}{ }_{i} \in \mathcal{N}_{p u b}\right]_{i=1}^{n}$, we define $\mathcal{F}\left(\phi, \mathcal{N}_{c h}\right)=\left\{\left\{\operatorname{out}\left(c_{\mathrm{ax}_{i}}, t_{i}\right) .0\right\}\right\}_{i=1}^{n}$.

Given a frame $\phi$ and a sequence $\mathcal{N}_{c h}$, we define the following sets and functions:

- $\mathcal{S P} \mathcal{P}_{\ell}\left(\phi, \mathcal{N}_{c h}\right)=\left\{(\mathcal{P}, \phi) \in \mathcal{S} \mathcal{P}_{\ell}\left|f n(\phi, \mathcal{P}) \cap \mathcal{N}_{c h}=\varnothing \wedge\right| \phi\left|=\left|\mathcal{N}_{c h}\right|\right\}\right.$.
- $\mathcal{S P}\left(\phi, \mathcal{N}_{c h}\right)=\left\{\mathcal{P} \cup \mathcal{F}\left(\phi, \mathcal{N}_{c h}\right) \in \mathcal{S P}\left|f n(\phi, \mathcal{P}) \cap \mathcal{N}_{c h}=\varnothing \wedge\right| \phi\left|=\left|\mathcal{N}_{c h}\right|\right\}\right.$
- $\pi_{\phi, \mathcal{N}_{c h}}^{e \rightarrow p}: \mathcal{S P} \mathcal{P}_{\ell}\left(\phi, \mathcal{N}_{c h}\right) \rightarrow \mathcal{S P}\left(\phi, \mathcal{N}_{c h}\right)$ such that $\pi_{\phi, \mathcal{N}_{c h}}^{e \rightarrow p}((\mathcal{P}, \phi))=\mathcal{P} \cup \mathcal{F}\left(\phi, \mathcal{N}_{c h}\right)$
- $\pi_{\phi, \mathcal{N}_{c h}}^{p \rightarrow e}: \mathcal{S P}\left(\phi, \mathcal{N}_{c h}\right) \rightarrow \mathcal{S} \mathcal{P}_{\ell}\left(\phi, \mathcal{N}_{c h}\right)$ such that $\pi_{\phi, \mathcal{N}_{c h}}^{p \rightarrow e}\left(\mathcal{P} \cup \mathcal{F}\left(\phi, \mathcal{N}_{c h}\right)\right)=(\mathcal{P}, \phi)$

To prove that observational preorder and equivalence imply simulation and bisimulation respectively, we define the relation $R_{o p}$ with $o p \in\{\leq, \approx\}$ on extended processes as follows: For all $(\mathcal{P}, \phi),\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \in \mathcal{S} \mathcal{P}_{\ell},(\mathcal{P}, \phi) R_{o p}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ if and only if $(\mathcal{P}, \phi) \in \mathcal{S} \mathcal{P}_{\ell}\left(\phi, \mathcal{N}_{c h}\right)$, $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \in \mathcal{S P}_{\ell}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)$ and $\pi_{\phi, \mathcal{N}_{c h}}^{e \rightarrow p}((\mathcal{P}, \phi))$ op $\mathcal{P}_{o b s}^{\mathcal{R}_{r}} \pi_{\phi^{\prime}, \mathcal{N}_{c h}}^{e \rightarrow p}\left(\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)\right)$ for some $\mathcal{N}_{c h}$.

Our definition of $R_{o p}$ parametrized by op will allow us to prove intermediate results that will holds both for the proof of observational preorder implying simulation and the proof of observational equivalence implying bisimulation.

Lemma 43. Let $\mathcal{N}_{c h}$ be a sequence of public names and $\phi, \phi^{\prime}$ two frames. Let $D, E \in$ $\mathcal{D}^{\leq 1}\left(\bigcup_{\phi} \mathcal{S P}\left(\phi, \mathcal{N}_{c h}\right)\right)$. For all op $\in\{\leq, \approx\}, D \widehat{o p_{o b s}^{\mathcal{R}_{r}}} E$ implies $\sum_{\phi} \sum_{Q \in \mathcal{S P}\left(\phi, \mathcal{N}_{c h}\right)} D(Q)$. $\delta_{\pi_{\phi, \mathcal{N}_{c h}}^{p \rightarrow e}(Q)} \widehat{R_{o p}} \sum_{\phi} \sum_{Q \in \mathcal{S P}\left(\phi, \mathcal{N}_{c h}\right)} E(Q) \cdot \delta_{\pi_{\phi, \mathcal{N}_{c h}}^{p \rightarrow e}(Q)}$.

Proof. Let $\mathcal{S} \subseteq \mathcal{S} \mathcal{P}_{\ell}$. Let $[\mathcal{S}]=\left\{\left(\mathcal{P}^{\prime \prime}, \phi^{\prime \prime}\right) \in \mathcal{S} \mathcal{P}_{\ell} \mid(\mathcal{P}, \phi) \in \mathcal{S} \wedge(\mathcal{P}, \phi) R_{o p}\left(\mathcal{P}^{\prime \prime}, \phi^{\prime \prime}\right)\right\}$. Let $\mathcal{S}_{1}=\bigcup_{\phi} \pi_{\phi, \mathcal{N}_{c h}}^{e \rightarrow p}\left(\mathcal{S P} \mathcal{P}_{\ell}\left(\phi, \mathcal{N}_{c h}\right) \cap \mathcal{S}\right)$ and $\left[\mathcal{S}_{1}\right]=\left\{\mathcal{Q}^{\prime} \in \mathcal{S P} \mid \mathcal{Q} \in \mathcal{S}_{1} \wedge \mathcal{Q}\right.$ op $\left.{ }_{o b s}^{\mathcal{R}_{r}} \mathcal{Q}^{\prime}\right\}$.

Since $D \widehat{o p_{o b s}^{\mathcal{R}_{r}}} E$, we know that $D\left(\mathcal{S}_{1}\right) \leq E\left(\left[\mathcal{S}_{1}\right]\right)$. By definition of $\mathcal{S}_{1}$ and since $D$ is a sub-distribution of $\cup_{\phi} \mathcal{S} \mathcal{P}\left(\phi, \mathcal{N}_{c h}\right)$, we have $D\left(\mathcal{S}_{1}\right)=\sum_{\phi} \sum_{(Q, \phi) \in \mathcal{S P}_{\ell}\left(\phi, \mathcal{N}_{c h}\right) \cap \mathcal{S}} D\left(\pi_{\phi, \mathcal{N}_{c h}}^{e \rightarrow p}(Q)\right)$.

Moreover, we know by hypothesis that $E \in \bigcup_{\phi} \mathcal{D}^{\leq 1}\left(\mathcal{S P}\left(\phi, \mathcal{N}_{c h}\right)\right)$. Hence, if we define $\left[\mathcal{S}_{2}\right]=\left\{\mathcal{Q}^{\prime} \in \mathcal{S P}\left(\phi, \mathcal{N}_{c h}\right) \mid \mathcal{Q} \in \mathcal{S}_{1} \wedge \mathcal{Q} o p_{o b s}^{\mathcal{R}_{r}} \mathcal{Q}^{\prime} \wedge\right.$ frame $\left.\phi\right\}$ then $E\left(\left[\mathcal{S}_{1}\right]\right)=E\left(\left[\mathcal{S}_{2}\right]\right)$. Therefore, by definition of $R_{o p}$ and $\left[\mathcal{S}_{2}\right]$, we deduce that $\mathcal{S}_{3}=\left\{\pi_{\phi, \mathcal{N}_{c h}}^{p \rightarrow e}(Q) \mid Q \in\left[\mathcal{S}_{2}\right]\right\} \subseteq$ $[\mathcal{S}]$. This allows us to deduce that $\sum_{\phi} \sum_{Q \in \mathcal{S P}\left(\phi, \mathcal{N}_{c h}\right)} D(Q) \cdot \delta_{\pi_{\phi, \mathcal{N}_{c h}}^{p \rightarrow e}(Q)}\left(\mathcal{S}_{1}\right)=D\left(\mathcal{S}_{1}\right) \leq$ $E\left(\left[\mathcal{S}_{1}\right]\right) \leq E\left(\left[\mathcal{S}_{2}\right]\right)=\sum_{\phi} \sum_{Q \in \mathcal{S P}\left(\phi, \mathcal{N}_{c h}\right)} E(Q) \cdot \delta_{\pi_{\phi, \mathcal{N}_{c h}}^{p \rightarrow e}(Q)}\left(\mathcal{S}_{3}\right) \leq \sum_{\phi}^{c h} \sum_{Q \in \mathcal{S P}\left(\phi, \mathcal{N}_{c h}\right)} E(Q)$. $\delta_{\pi_{\phi, \mathcal{N}_{c h}}^{p \rightarrow e}(Q)}([\mathcal{S}])$.

Corollary 5. Let $\mathcal{N}_{c h}$ be a sequence of public names and $\phi, \phi^{\prime}$ two frames. Let $D \in$ $\mathcal{D}^{\leq 1}\left(\mathcal{S P}\left(\phi, \mathcal{N}_{c h}\right)\right), E \in \mathcal{D}^{\leq 1}\left(\mathcal{S P}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)\right)$. For all op $\in\{\leq, \approx\}, D \widehat{o p_{o b s}^{\mathcal{R}_{r}}} E$ implies $\pi_{\phi, \mathcal{N}_{c h}}^{p \rightarrow e}(D) \widehat{R_{o p}} \pi_{\phi^{\prime}, \mathcal{N}_{c h}}^{p \rightarrow e}(E)$.

## F.3.1 $\tau$ transitions

Lemma 44. For all $o p \in\{\leq, \approx\}$, for all $(\mathcal{P}, \phi),\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \in \mathcal{S P} \ell$, if $(\mathcal{P}, \phi) R_{o p}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ and

 that $(\mathcal{P}, \phi) \in \mathcal{S} \mathcal{P}_{\ell}\left(\phi, \mathcal{\mathcal { N }}_{c h}\right),\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \in \mathcal{S} \mathcal{P}_{\ell}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)$ and $\mathcal{P} \cup \mathcal{F}\left(\phi, \mathcal{N}_{c h}\right)$ op $p_{o b s}^{\mathcal{R}_{r}} \mathcal{P}^{\prime} \cup \mathcal{F}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)$ for some $\mathcal{N}_{c h}$.

By Figure 2, we deduce that $\mathcal{P} \cup \mathcal{F}\left(\phi, \mathcal{N}_{c h}\right) \xrightarrow{\tau}_{\mathrm{N}^{*}} D_{1}=\sum_{\mathcal{Q} \in \operatorname{supp}\left(D^{\prime}\right)} D^{\prime}(\mathcal{Q}) \cdot \delta_{\mathcal{Q} \cup \mathcal{F}\left(\phi, \mathcal{N}_{c h}\right)}$ and so $\mathcal{P} \cup \mathcal{F}\left(\phi, \mathcal{N}_{c h}\right) \xlongequal{\tau}_{r, \mathcal{N}^{\circ}} D_{1}$. By Definition 18, $\mathcal{P}^{\prime} \cup \mathcal{F}\left(\phi^{\prime}, \mathcal{N}_{c h}\right) \xlongequal{\tau}_{r, \mathcal{N}^{\circ}} E_{1}$ for some $E_{1}$ such that $D_{1} \widehat{o p_{o b s}^{\mathcal{R}_{r}}} E_{1}$ (and $E_{1} \widehat{R_{\approx}} D_{1}$ when $o p=\approx$ ).

Let us analyse the support of $E_{1}$. For all $\mathcal{Q} \cup \mathcal{F}\left(\phi^{\prime}, \mathcal{N}_{c h}\right) \xrightarrow{\tau}_{\mathrm{N}^{\prime}} F$ with $\mathcal{N}_{c h} \cap f n(\mathcal{Q})=\varnothing$, the only transition from Figure 2 that may reduce an output from $\mathcal{F}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)$ is the rule $(\mathrm{Comm})$. However that would imply that $\mathcal{Q}=\left\{\{\operatorname{in}(u, x) . Q\} \cup \mathcal{Q}^{\prime}\right.$ with $c_{\mathrm{ax}_{i}} \doteq u$ for some $i \in$
$\left\{1, \ldots,\left|\phi^{\prime}\right|\right\}$. But, we know that $c_{\mathrm{ax}_{i}} \notin s t(u)$ and so by Lemma $32, c_{\mathrm{ax}_{i}} \neq u$, hence a contradiction. This allows us to deduce that $\operatorname{supp}(F) \subseteq \mathcal{S P}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)$ and $\left(\mathcal{Q}, \phi^{\prime}\right) \xrightarrow{\tau}_{\mathcal{N}^{e}} \pi_{\phi_{\tau}^{\prime}, \mathcal{N}_{c h}}^{p \rightarrow e}(F)$. Lemma 24 and a simple induction on the infinite scheme defining $\mathcal{P}^{\prime} \cup \mathcal{F}\left(\phi^{\prime}, \mathcal{N}_{c h}\right){ }_{\Longrightarrow}^{\tau}{ }_{r, N^{\circ}} E_{1}$ allow us to conclude that $\operatorname{supp}\left(E_{1}\right) \subseteq \mathcal{S P}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)$ and $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \xlongequal{\tau}_{\mathrm{r}, \mathcal{N}^{\ell}} \pi_{\phi^{\prime}, \mathcal{N}_{c h}}^{p \rightarrow e}\left(E_{1}\right)$. Since $\pi_{\phi, \mathcal{N}_{c h}}^{p \rightarrow e}\left(D_{1}\right)=D$, we conclude by Lemma 43 .

## F.3.2 Static equivalence transitions

Lemma 45. For all $o p \in\{\leq, \approx\}$, for all $(\mathcal{P}, \phi),\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \in \mathcal{S P}$, if $(\mathcal{P}, \phi) R_{o p}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ and
 $E \widehat{R_{\approx}} D$ when $o p=\approx$ ).

Proof. By definition of $R_{o p}$, we know that $(\mathcal{P}, \phi) R_{o p}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ implies $(\mathcal{P}, \phi) \in \mathcal{S} \mathcal{P}_{\ell}\left(\phi, \mathcal{N}_{c h}\right)$, $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \in \mathcal{S} \mathcal{P}_{\ell}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)$ and $\pi_{\phi, \mathcal{N}_{c h}}^{e \rightarrow p}((\mathcal{P}, \phi))$ op obs $\pi_{\phi^{\prime}, \mathcal{N}_{c h}}^{e \rightarrow p}\left(\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)\right)$ for some $\mathcal{N}_{c h}$. Hence,
 which implies $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \stackrel{a}{\Longrightarrow}{ }_{\mathrm{r}, \mathrm{N}^{\ell}} \delta_{\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)}$. Since $(\mathcal{P}, \phi) R_{o p}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$, we directly have that $\delta_{(\mathcal{P}, \phi)} \widehat{R_{o p}} \delta_{\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)}$. When $o p=\approx, R_{\approx}$ is symmetric hence $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) R_{\approx}(\mathcal{P}, \phi)$ also implying $\delta_{\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)} \widehat{R_{\approx}} \delta_{(\mathcal{P}, \phi)}$. Thus the result holds.

Let us now focus on the case where $a=\xi o \zeta$ with $o \in\{\doteq, \neq\}$. Let $n=|\phi|$ and assume that $\mathcal{N}_{c h}=\left[c_{\mathrm{ax}_{i}}\right]_{i=1}^{n}$. We consider a public name ok such that ok $\notin f n\left(\mathcal{P}, \mathcal{P}^{\prime}, \phi, \phi^{\prime}\right)$, some variables $x_{1}, \ldots, x_{n}$ and the renaming $\rho=\left\{{ }^{x_{i}} / \mathrm{ax}_{i}\right\}_{i=1}^{n}$. We build the following processes Test ${ }^{\doteq}$ and Test ${ }^{\neq}$.

$$
\begin{aligned}
& \text { Test } \doteq:=\operatorname{in}\left(c_{\mathrm{ax}_{1}}, x_{1}\right) \ldots \operatorname{in}\left(c_{\mathrm{ax}_{n}}, x_{n}\right) \cdot \text { Test }_{\overline{\overline{i f}}}^{\dot{\text { if }}} \\
& \text { Test } \dot{\overline{\overline{i f}}:=\operatorname{if} \xi \rho=\zeta \rho \text { then out }(o k, o k) \cdot 0 \text { else } 0} \\
& \text { Test }^{\neq}:=\operatorname{in}\left(c_{\mathrm{ax}_{1}}, x_{1}\right) \ldots \operatorname{in}\left(c_{\mathrm{ax}_{n}}, x_{n}\right) \cdot \text { Test }_{i f}^{\neq} \\
& \text {Test }_{i f}^{\neq}:=\text {if } \xi \rho=\zeta \rho \text { then } 0 \text { else out }(o k, o k) \cdot 0
\end{aligned}
$$

Since $\xi, \zeta$ are recipes we know that $f n(\xi, \zeta) \subseteq \mathcal{N}_{\text {pub }}$ and so $f n\left(\right.$ Test $t^{\dot{\epsilon}}$, Test $\left.t^{\neq}\right) \subseteq \mathcal{N}_{\text {pub }}$. Hence, by Definition 18, for all $o \in\{\dot{=}, \neq\},\left\{\left\{\right.\right.$ Test $\left.^{o}\right\} \cup \cup \pi_{\phi, \mathcal{N}_{c h}}^{e \rightarrow p}((\mathcal{P}, \phi))$ op obs $\mathcal{R}_{r}\left\{\right.$ Test $\left.{ }^{o}\right\} \cup$ $\pi_{\phi^{\prime}, \mathcal{N}_{c h}}^{e \rightarrow p}\left(\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)\right)$.

Let us denote $\mathcal{P}_{T}=\left\{\right.$ Test $\left.{ }^{o}\right\} \cup \pi_{\phi, \mathcal{N}_{c h}}^{e \rightarrow p}((\mathcal{P}, \phi))$ and $\mathcal{P}_{T}^{\prime}=\{$ Test $\} \cup \cup \pi_{\phi^{\prime}, \mathcal{N}_{c h}}^{e \rightarrow p}\left(\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)\right)$.
 $\left\{\text { out }\left(c_{\mathrm{ax}_{i}}, \mathrm{ax}_{i} \phi\right) .0\right\}_{i=1}^{n}$. Hence, by successively applying the rule (Comm) on $c_{\mathrm{ax}_{1}}, \ldots, c_{\mathrm{ax}_{n}}$, we deduce that $\mathcal{P}_{T} \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}^{\circ}} \delta_{\mathcal{P} \cup\left\{\text { Test }_{i f}^{o} \sigma\right\}}$ with $\sigma=\rho^{-1} \phi$. Since $\xi \phi o \zeta \phi$ implies $(\xi \rho) \rho^{-1} \phi o$ $(\zeta \rho) \rho^{-1} \phi$, we can apply the rule (THEN) when $o$ is $\doteq$ and (ELSE) otherwise to obtain that $\mathcal{P}_{T} \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}^{\circ}} \delta_{\mathcal{P} \cup\{0 \text { out }(o k, o k) .0\}}$. Thus, $\operatorname{RProb}_{\mathcal{R}_{\mathrm{r}}}\left(\mathcal{P}_{T}, \downarrow o k\right)=1$.

Since $\mathcal{P}_{T}$ op ${ }_{o b s}^{\mathcal{R}_{r}} \mathcal{P}_{T}^{\prime}$, we deduce that $\operatorname{RProb}_{\mathcal{R}_{r}}\left(\mathcal{P}_{T}^{\prime}, \downarrow o k\right)=1$. Hence, there exists a resolution $\mathrm{R}=\left(\mathcal{S}_{\mathrm{R}}\right.$, corr $_{\mathrm{R}}$, trans $\left._{\mathrm{R}}\right) \in \mathcal{R}_{\mathrm{r}}$ and $s \in \mathcal{S}_{\mathrm{R}}$ such that $\operatorname{corr}_{\mathrm{R}}(s)=\mathcal{P}_{T}^{\prime}$ and $\operatorname{RProb}_{\mathrm{R}}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\downarrow o k)\right)>0$, meaning that there exists $p \in \mathbb{N}$ such that $\operatorname{RProb}_{\mathrm{R}}^{\leq p}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\downarrow\right.$ $o k))>0$.

Let us define $A=\left\{\mathcal{Q} \cup\left\{\operatorname{out}\left(c_{\mathrm{ax}_{i}}, \mathrm{ax}_{i} \phi^{\prime}\right) \cdot 0\right\}_{i=j}^{n} \cup\left\{\left\{\operatorname{in}\left(c_{\mathrm{ax}_{j}}, x_{j}\right) \ldots \operatorname{in}\left(c_{\mathrm{ax}_{n}}, x_{n}\right) \cdot T e s t_{i f}^{o} \sigma_{j}\right\}\right\} \mid\right.$ $\left.j=1 \ldots n+1,\left(\mathcal{Q}, \phi^{\prime}\right) \in \mathcal{S} \mathcal{P}_{\ell}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)\right\}$ where $\sigma_{j}=\left\{\operatorname{ax}_{i} \phi^{\prime} / x_{i}\right\}_{i=1}^{j-1}$. We first notice that $\mathcal{P}_{T}^{\prime} \in A$. Moreover, thanks to the fact that $\left.\left(\mathcal{Q}, \phi^{\prime}\right) \in \mathcal{S} \mathcal{P}_{\ell}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)\right\}$ implies $c_{\mathrm{ax}}$ $\notin f n(\mathcal{Q})$ and thanks to Lemma 32, we can show that for all $\mathcal{Q}^{\prime} \in A, \mathcal{Q}^{\prime}{ }^{\tau}{ }_{\mathrm{N}}{ }^{\circ} F \operatorname{implies} \operatorname{supp}(F) \subseteq$ $A \cup \downarrow o k$.

This allows us to prove by induction on $p \in \mathbb{N}$ that for all $s \in \mathcal{S}_{\mathrm{R}}, \operatorname{RProb}_{\mathrm{R}}^{\leq p}\left(s, \operatorname{corr}_{\mathrm{R}}^{-1}(\downarrow\right.$ $o k))>0$ and $\operatorname{corr}_{\mathrm{R}}(s) \in A$ imply there exist $s_{1}, s_{2} \in \mathcal{S}_{\mathrm{R}}$ such that $\operatorname{corr}_{\mathrm{R}}\left(s_{1}\right)=\mathcal{Q}^{\prime} \cup$ $\left.\left\{T e s t_{i f}^{o} \sigma_{n}\right\}\right\} \in A, \operatorname{corr}_{\mathrm{R}}\left(s_{2}\right)=\mathcal{Q}^{\prime} \cup\{$ out $(o k, o k) .0\}$ and $s_{2} \in \operatorname{supp}\left(\operatorname{trans}_{\mathrm{R}}\left(s_{1}\right)\right)$. For $s_{2}$ to be in $\operatorname{supp}\left(\operatorname{trans}_{\mathbb{R}}\left(s_{1}\right)\right)$, it implies that $\mathcal{Q}^{\prime} \cup\left\{\{\operatorname{out}(o k, o k) .0\} \xrightarrow{\tau}_{\mathbb{N}^{o}} \delta_{\mathcal{Q}^{\prime} \cup\{o u t(o k, o k) .0\}}\right.$ by application of the rule (THEN) when $o$ is $\doteq$ and the rule (ELSE) otherwise. Thus, $\xi \rho \sigma_{n} o \zeta \rho \sigma_{n}$ holds and so $\xi \phi^{\prime} o \zeta \phi^{\prime}$ holds.

We can therefore conclude that $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \xrightarrow{a}{ }^{e}{ }^{e} \delta_{\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)}$ and once again noticing that $(\mathcal{P}, \phi) R_{o p}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ implies $\delta_{(\mathcal{P}, \phi)} \widehat{R_{o p}} \delta_{\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)}$; and that when $o p=\approx, R_{\approx}$ is symmetric hence $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) R_{\approx}(\mathcal{P}, \phi)$ also implying $\delta_{\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)} \widehat{R_{\approx}} \delta_{(\mathcal{P}, \phi)}$.

## F.3.3 Input and output transitions

For input and output transitions, we will need to consider predicates on the relation $\rightarrow$ of a NPLTS. Given a predicate $\pi$, we will write $\pi(x \rightarrow D)$ when $\pi$ holds on $x \rightarrow D$. Given a logic formula $\phi$ with predicates as atoms, we denote by $(x \rightarrow D) \vDash \phi$ the natural satisfiability of $\phi$ by $x \rightarrow D$. Given $D \xrightarrow{\tau}_{\mathrm{r}} E$ with $D=\sum_{i \in I} \alpha_{i} \cdot \delta_{x_{i}}, E=\sum_{i \in I} \alpha_{i} \cdot D_{i}$ and $x_{i} \rightarrow D_{i}$, we will write $\left(D \rightarrow_{r}^{\tau} E\right) \models \phi$ when for all $i \in I, \pi\left(x_{i} \rightarrow D_{i}\right) \models \phi$. Finally, given $D \xlongequal{\tau}{ }_{\mathrm{r}} E$ with the infinite scheme $D=D_{0} \rightarrow+D_{0}^{\top}$ and $D_{k} \xrightarrow{\tau}_{\mathrm{r}} D_{k+1}+D_{k+1}^{\top}$ for $k \in \mathbb{N}$, we write $(D \xlongequal{\tau} E) \models \phi$ when for all $k \in \mathbb{N},\left(D_{k} \xrightarrow[\rightarrow]{\tau}_{\mathrm{r}} D_{k+1}+D_{k+1}^{\top}\right) \models \phi$.

For some of our proof, we will consider a measure function on states of our NPLTS associated with a total order. Formally, a measure for a NPLTS $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}, \operatorname{trans}_{\mathrm{N}}\right)$ is a function $\mathrm{m}: \mathcal{S}_{\mathrm{N}} \mapsto I$ for some set $I$ associated with a total order $<_{\mathrm{m}}$ on $I$ that includes a minimal element for $<_{\mathrm{m}}$. Given a sub-distribution $D \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$, we denote $\mathrm{m}(D)=\max \{\mathrm{m}(x) \mid x \in \operatorname{supp}(D)\}$.

Lemma 46. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans N$)$ be a NPLTS with $\mathcal{A}_{\text {int }}=\{\tau\}$. Let $\pi_{1}, \ldots, \pi_{n}$ be predicates on $\rightarrow$. For all $\left(\sum_{i=1}^{m_{A}} A_{i} \rightarrow_{r} \sum_{i=1}^{m_{B}} B_{i}\right) \models \pi_{1} \vee \ldots \vee \pi_{n}$, there exist $\left\{A_{k}^{p} \mid p=\right.$ $\left.1 \ldots n, k=1 \ldots m_{A}\right\}$ and $\left\{B_{k, i}^{p} \mid p=1 \ldots n, k=1 \ldots m_{A}, i=1 \ldots m_{B}\right\}$ such that:

- for all $p \in\{1, \ldots, n\}$, for all $k \in\left\{1, \ldots, m_{A}\right\},\left(A_{k}^{p} \xrightarrow{\tau}_{{ }_{\mathrm{r}}} \sum_{i=1}^{m_{B}} B_{k, i}^{p}\right) \models \pi_{p}$
- for all $k \in\left\{1, \ldots, m_{A}\right\}, A_{k}=\sum_{p=1}^{n} A_{k}^{p}$
- for all $i \in\left\{1, \ldots, m_{B}\right\}, B_{i}=\sum_{p=1}^{n} \sum_{k=1}^{m_{A}} B_{k, i}^{p}$

Proof. By definition of $\left(\sum_{i=1}^{m_{A}} A_{i} \xrightarrow{\tau}_{\mathrm{r}} \sum_{i=1}^{m_{B}} B_{i}\right) \models \pi_{1} \vee \ldots \vee \pi_{n}$, we know there exists a countable set $I$ and a multiset $\left\{x_{i}\right\}_{i \in I}$ with for all $i \in I, x_{i} \in \mathcal{S}_{\mathrm{N}}$ such that $\sum_{i=1}^{m_{A}} A_{i}=$ $\sum_{i \in I} \alpha_{i} \cdot \delta_{x_{i}}, \sum_{i=1}^{m_{B}} B_{i}=\sum_{i \in I} \alpha_{i} \cdot D_{i}$ and for all $i \in I, x_{i} \rightarrow D_{i}$ with $\pi_{p}\left(x_{i} \rightarrow D_{i}\right)$ for some $p \in\{1, \ldots, n\}$.

With partition $I$ into $I_{1} \cup \ldots \cup I_{n}$ such that for all $p \in\{1, \ldots, n\}$, for all $i \in I_{p}$, $\pi_{p}\left(x_{i} \rightarrow D_{i}\right)$. We define for all $k \in\left\{1 \ldots m_{A}\right\}, p \in\{1 \ldots n\}$, the sub-distribution $A_{k}^{p}=$ $\sum_{i \in I_{p}} \frac{\alpha_{i} \cdot A_{k}\left(x_{i}\right)}{\sum_{j=1}^{n} A_{k}\left(x_{i}\right)} \cdot \delta_{x_{i}}$. Hence, $\left(A_{k}^{p} \xrightarrow{\tau}_{\mathrm{r}}^{\mathrm{r}} \sum_{i \in I_{p}} \frac{\alpha_{p} \cdot A_{k}\left(x_{i}\right)}{\sum_{j=1}^{i n} A_{j}\left(x_{i}\right)} \cdot D_{i}\right) \models \pi_{p}$. Therefore, for all $\ell \in\left\{1, \ldots, m_{B}\right\}$, we define $B_{k, \ell}^{p}$ such that for all $x \in \operatorname{supp}\left(B_{\ell}\right), B_{k, \ell}^{p}(x)=\frac{B_{\ell}(x)}{\sum_{j=1}^{m_{B}} B_{j}(x)}$. $\sum_{i \in I_{p}} \frac{\alpha_{p} \cdot A_{k}\left(x_{i}\right)}{\sum_{j=1}^{m_{A} A} A_{j}\left(x_{i}\right)} \cdot D_{i}(x)$. We directly have $\sum_{\ell=1}^{m_{B}} B_{k, \ell}^{p}=\sum_{i \in I_{p}} \frac{\alpha_{i} \cdot A_{k}\left(x_{i}\right)}{\sum_{j=1}^{m_{A} A_{j}} A_{j}\left(x_{i}\right)} \cdot D_{i}$ and so $\left(A_{k}^{p} \stackrel{\tau}{\tau}_{\mathrm{r}}\right.$ $\left.\sum_{\ell=1}^{m_{B}} B_{k, \ell}^{p}\right) \models \pi_{p}$.

Let us show that for all $k \in\left\{1, \ldots, m_{A}\right\}, A_{k}=\sum_{p=1}^{n} A_{k}^{p}$. Let $k \in\left\{1, \ldots, m_{A}\right\}$ and $x \in \mathcal{S}_{\mathrm{N}}$. We have $\sum_{p=1}^{n} A_{k}^{p}(x)=\sum_{p=1}^{n} A_{k}^{p}(x)=\sum_{p=1}^{n} \sum_{i \in I_{p}} \frac{\alpha_{i} \cdot A_{k}\left(x_{i}\right)}{\sum_{j=1}^{m} A_{j}\left(x_{i}\right)} \cdot \delta_{x_{i}}(x)=$ $\sum_{p=1}^{n} \sum_{i \in I_{p}} \frac{\alpha_{i} \cdot A_{k}(x)}{\sum_{j=1}^{m m_{A}} A_{j}(x)} \cdot \delta_{x_{i}}(x)=\frac{A_{k}(x)}{\sum_{j=1}^{m_{A} A} A_{j}(x)} \sum_{p=1}^{n} \sum_{i \in I_{p}} \alpha_{i} \cdot \delta_{x_{i}}(x)=\frac{\cdot A_{k}(x)}{\sum_{j=1}^{m_{A}} A_{j}(x)} \cdot \sum_{i=1}^{m_{A}} A_{i}(x)=$ $A_{k}(x)$.

Finally, let us show that for all $\ell \in\left\{1, \ldots, m_{B}\right\}, B_{\ell}=\sum_{p=1}^{n} \sum_{k=1}^{m_{A}} B_{k, \ell}^{p}$. By definition, for all $x \in \mathcal{S}_{\mathrm{N}}$,

$$
\begin{aligned}
\sum_{p=1}^{n} \sum_{k=1}^{m_{A}} B_{k, i}^{p}(x) & =\sum_{p=1}^{n} \sum_{k=1}^{m_{A}} \sum_{i \in I_{p}} \frac{\alpha_{i} \cdot A_{k}\left(x_{i}\right)}{\sum_{j=1}^{m_{A}} A_{j}\left(x_{i}\right)} \cdot D_{i}(x) \\
& =\frac{B_{\ell}(x)}{\sum_{j=1}^{m_{B}} B_{j}(x)} \cdot \sum_{p=1}^{n} \sum_{k=1}^{m_{A}} \sum_{i \in I_{p}} \frac{\alpha_{i} \cdot A_{k}\left(x_{i}\right)}{\sum_{j=1}^{m_{A}} A_{j}\left(x_{i}\right)} \cdot D_{i}(x) \\
& =\frac{B_{\ell}(x)}{\sum_{j=1}^{m_{B}} B_{j}(x)} \cdot \sum_{p=1}^{n} \sum_{i \in I_{p}} \frac{\alpha_{i} \cdot \sum_{k=1}^{m_{A}} A_{k}\left(x_{i}\right)}{\sum_{j=1}^{m_{A}} A_{j}\left(x_{i}\right)} \cdot D_{i}(x) \\
& =\frac{B_{\ell}(x)}{\sum_{j=1}^{m_{B}} B_{j}(x)} \cdot \sum_{p=1}^{n} \sum_{i \in I} \alpha_{i} \cdot D_{i}(x) \\
& =\frac{B_{\ell}(x)}{\sum_{j=1}^{m_{B}} B_{j}(x)} \cdot \sum_{i=1}^{m_{B}} B_{i}(x) \\
& =B_{\ell}(x)
\end{aligned}
$$

Lemma 47. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans N$)$ be a NPLTS with $\mathcal{A}_{\text {int }}=\{\tau\}$. Let $\pi_{c}^{\rightarrow}, \pi_{s}^{\rightarrow}$, $\pi_{\text {all }}$ be three predicates on $\rightarrow$. Let $\pi^{\mathcal{S}}$ be a predicate on $\mathcal{S}_{\mathrm{N}}$ such that for all $x \in \mathcal{S}_{\mathrm{N}}$, for all $D \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$,

- if $\pi^{\mathcal{S}}(x)$ then $\pi_{c}(x \rightarrow D)$ or $\pi_{s}(x \rightarrow D)$
- if $\pi_{c}^{\rightarrow}(x \rightarrow D)$ then $\pi^{\mathcal{S}}(D)$

For all $D, E \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$, if $D \xlongequal{\tau}{ }_{\mathrm{r}} E$ with the following infinite scheme

$$
D=D_{0}^{\rightarrow}+D_{0}^{\top} \quad \forall k \in \mathbb{N} . D_{k} \rightarrow_{r} D_{k+1}+D_{k+1}^{\top}
$$

and $\pi^{\mathcal{S}}\left(D_{0}\right)$ then there exists $A, A^{\top}, B, B^{\top}, C \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$ such that

$$
\left(D \stackrel{\tau}{\Longrightarrow} \mathrm{r} A+A^{\top}\right) \models \pi_{c}^{\rightarrow} \quad\left(A{\underset{\mathrm{r}}{\mathrm{r}}} B+B^{\top}\right) \models \pi_{s}^{\rightarrow} \quad B \xlongequal{\tau}_{\mathrm{r}} C \quad E=C+B^{\top}+A^{\top}
$$

Moreover, if we assume the existence of measure function m on N such that for all $x \in$ $\mathcal{S}_{\mathrm{N}}$, for all $D^{\prime} \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right), \pi_{s}^{\rightarrow}\left(x \rightarrow D^{\prime}\right)$ implies $\mathrm{m}(x)>_{\mathrm{m}} \mathrm{m}\left(D^{\prime}\right)$ and if $\mathrm{m}(A) \leq_{\mathrm{m}} \mathrm{m}\left(B+B^{\top}\right)$ then $\left(D \xlongequal{\tau}{ }_{\mathrm{r}} E\right) \models \pi_{c}$.

Finally, if $\left(D \Longrightarrow_{\mathrm{r}}^{\tau} E\right) \models \pi_{\text {all }}$ then $\left(D \xlongequal{\tau}{ }_{\mathrm{r}} A+A^{\top}\right) \models \pi_{\text {all }},\left(A \xlongequal{\tau}{ }_{\mathrm{r}} B+B^{\top}\right) \models \pi_{\text {all }}$ and $\left(B{ }_{\mathrm{\tau}}{ }_{\mathrm{r}} C\right)=\pi_{\text {all }}$.

Proof. Consider the following property $P(n)$ defined as: there exist $\left(\left(S a v e_{i, k}\right)_{k=0}^{n-i}\right)_{i=0}^{n-1}$, $\left(\left(\operatorname{Save}_{i, k}^{\top}\right)_{k=0}^{n-i}\right)_{i=0}^{n-1}, k \in\{0, \ldots, n-i\},\left(\bar{F}_{k}\right)_{k=0}^{n},\left(F_{k}^{\top}\right)_{k=0}^{n}$, and $\left(F_{k}\right)_{k=0}^{n-1}$ such that

1. for all $k \in\{0, \ldots, n\}, \pi^{\mathcal{S}}\left(\vec{F}_{k}\right)$
2. for all $k \in\{0, \ldots, n\}, D_{k}=\vec{F}_{k}+\sum_{i=0}^{k-1} \operatorname{Save}_{\vec{i}, k-i}$
3. for all $k \in\{0, \ldots, n\}, D_{k}^{\top}=F_{k}^{\top}+\sum_{i=0}^{k-1} \operatorname{Save}_{i, k-i}^{\top}$
4. for all $i \in\{0, \ldots, n-1\}$, for all $k \in\{0, \ldots, n-i-1\}, S a v e_{i, k} \rightarrow_{r} \operatorname{Save}_{i, k+1}+$ Save $_{i, k+1}^{\top}$
5. for all $i \in\{0, \ldots, n-1\},\left(\right.$ Save $_{i, 0} \rightarrow_{\mathrm{r}}$ Save $\left._{i, 1}+\operatorname{Save}_{i, 1}^{\top}\right) \models \pi_{s}^{\rightarrow}$
6. for all $k \in\{0, \ldots, n-1\},\left(F_{k} \xrightarrow{\tau}_{r} \vec{F}_{k+1}+F_{k+1}^{\top}\right) \models \pi_{c}$
7. for all $k \in\{0, \ldots, n-1\}, \overrightarrow{F_{k}}=F_{k}+$ Save $_{\vec{k}, 0}$

We show that for all $n \in \mathbb{N}, P(n)$ holds by induction on $n$.
Base case $n=0$ : By choosing $\overrightarrow{F_{0}}=D_{0}$ and $F_{0}^{\top}=D_{0}^{\top}$, the result directly holds since by hypothesis $\pi^{\mathcal{S}}\left(D_{0}^{\rightarrow}\right)$ holds.
Inductive step $n>0$ : We have that by hypothesis that $D_{n} \rightarrow_{\mathrm{r}} D_{n+1}+D_{n+1}^{\top}$. Furthermore by inductive hypothesis, $D_{n}^{\vec{~}}=\overrightarrow{F_{n}}+\sum_{i=0}^{n-1} S a v e_{i, n-i}$.

By Lemma 46, we know that there exist some sub-distributions $S a v e_{i, n-i+1}$ and $S a v e_{i, n-i+1}^{\top}$ for all $i \in\{0, \ldots, n-1\}$ and $H^{\rightarrow}$ and $H^{\top}$ such that:

- $\bar{F}_{n} \rightarrow_{r} H^{\rightarrow}+H^{\top}$
- for all $i \in\{0, \ldots, n-1\}, \operatorname{Save}_{i, n-i} \rightarrow_{\mathrm{r}} \operatorname{Save}_{\overrightarrow{i, n-i+1}}+\operatorname{Save}_{i, n-i+1}^{\top}$
- for all $\alpha \in\{\rightarrow, \top\}, D_{n+1}^{\alpha}=H^{\alpha}+\sum_{i=0}^{n-1} \operatorname{Save}_{i, n-i+1}^{\alpha}$

By hypothesis, $\pi^{\mathcal{S}}\left(\vec{F}_{n}\right)$ hence $\left(\vec{F}_{n} \rightarrow_{\mathrm{r}} H^{\rightarrow}+H^{\top}\right) \models \pi_{c} \vee \pi_{s}$. By Lemma 46, we deduce that there exists $\bar{F}_{n}^{c}, \bar{F}_{n}^{s}, H^{c, \rightarrow}, H^{s, \rightarrow}, H^{c, \top}, H^{s, \top}$ such that:

- $\vec{F}_{n}=\bar{F}_{n}^{c}+\bar{F}_{n}^{s}$
- for all $a \in\{s, c\},\left(\bar{F}_{n}^{a} \rightarrow_{\mathrm{r}} H^{a, \rightarrow}+H^{a, \top}\right) \models \pi_{a}$
- for all $\alpha \in\{\rightarrow, \top\}, H^{\alpha}=H^{c, \alpha}+H^{s, \alpha}$

We define the sub-distributions $F_{n}^{\rightarrow}=\bar{F}_{n}^{c}, \vec{F}_{n+1}=H^{c, \rightarrow}, F_{n+1}^{\top}=H^{c, \top}$, Save $\overrightarrow{n, 0}=\bar{F}_{n}^{s}$, $\operatorname{Save}_{n, 0}^{\top}=\varnothing$, Save $_{n, 1}=H^{s, \rightarrow}$ and $\operatorname{Save}_{n, 1}^{\top}=H^{s, \top}$.

We prove the different properties of $P(n+1)$ by applying the inductive hypothesis on $P(n)$ and the following reasoning: Since $\left(\bar{F}_{n}^{c} \rightarrow_{\mathrm{r}} H^{c, \rightarrow}+H^{c, \top}\right) \models \pi_{c}^{\vec{~}}$, we know from our hypotheses on $\pi_{c}^{\rightarrow}$ and $\pi^{\mathcal{S}}$ that $\pi^{\mathcal{S}}\left(\vec{F}_{n+1}\right)$ holds, hence property 1 holds. Moreover,
 $\sum_{i=0}^{n} S a v e_{i,(n+1)-i}$, hence hence property 2 holds. Similarly, $D_{n+1}^{\top}=H^{\top}+\sum_{i=0}^{n-1} S a v e_{i, n-i+1}^{\top}$ and so $D_{n+1}^{\top}=F_{n+1}^{\top}+\operatorname{Save}_{n, 1}^{\top}+\sum_{i=0}^{n-1} S a v e_{i, n-i+1}^{\top}=F_{n+1}^{\top}+\sum_{i=0}^{n} S a v e_{i,(n+1)-i}^{\top}$, hence hence property 3 holds. Notice that we showed $\left(\bar{F}_{n}^{s} \rightarrow_{\mathrm{r}} H^{s, \rightarrow}+H^{s, \top}\right) \models \pi_{s}^{\rightarrow}$. Thus, $\left(\right.$ Save $_{n, 0}^{\rightarrow} \rightarrow_{\mathrm{r}}$ Save $_{n, 1}^{\vec{~}}+$ Save $\left._{n, 1}^{\top}\right) \models \pi_{s}^{\rightarrow}$ and so property 5 holds. We already proved that for all $i \in\{0, \ldots, n-1\}$, Save $\overrightarrow{i, n-i} \rightarrow_{r} \operatorname{Save}_{i, n-i+1}+$ Save $_{i, n-i+1}^{\top}$. Since $\left(\right.$ Save $_{n, 0} \rightarrow_{\mathrm{r}}$ Save $\left._{n, 1}+\operatorname{Save}_{n, 1}^{\top}\right) \models \pi_{s}^{\rightarrow}$, we directly deduce that for all $i \in\{0, \ldots, n\}$, Save $\overrightarrow{i, n-i} \rightarrow_{r}$ $\operatorname{Save}_{i,(n+1)-i}+\operatorname{Save}_{i,(n+1)-i}^{\top}$ and so property 4 holds. Similarly, we proved that $\left(\bar{F}_{n}^{c} \rightarrow_{\mathrm{r}}\right.$ $\left.H^{c, \rightarrow}+H^{c, \top}\right) \models \pi_{c}$ meaning that $\left(F_{n} \rightarrow_{r} \vec{F}_{n+1}+F_{n+1}^{\top}\right) \models \pi_{c}$, thus property 6 holds. Finally, we know that $\overrightarrow{F_{n}}=\bar{F}_{n}^{c}+\bar{F}_{n}^{s}$ implying $\overrightarrow{F_{n}}=F_{n}+$ Save $\overrightarrow{n, 0}$. Therefore, property 7 holds. This conclude the proof of $P(n)$ for all $n \in \mathbb{N}$.

To complete the main proof, notice that $F_{0}+$ Save $\overrightarrow{e_{0,0}}=D_{0}^{\rightarrow}, F_{0}^{\top}=D_{0}^{\top}$ and for all $k \in \mathbb{N}, F_{k}^{\rightarrow} \xrightarrow{\tau}_{\mathrm{r}} F_{k+1}+\left(\right.$ Save $\left._{k+1,0}+F_{k+1}^{\top}\right)$ imply that $D \Longrightarrow_{\mathrm{r}} \sum_{k \in \mathbb{N}} S a v e_{k, 0}+F_{k}^{\top}$. Notice that for all $k \in \mathbb{N}$, we already proved that $\left(F_{k} \xrightarrow{\tau}_{\mathrm{r}} F_{k+1}^{\vec{~}}+\left(\operatorname{Save}_{\overrightarrow{k+1,0}}+F_{k+1}^{\top}\right)\right) \models \pi_{c} \vec{c}^{\text {. By }}$ denoting $A=\sum_{k \in \mathbb{N}} S a v e_{k, 0}$ and $A^{\top}=\sum_{k \in \mathbb{N}} F_{k}^{\top}$, we deduce that $\left(D \Longrightarrow_{\mathrm{r}} A+A^{\top}\right) \models \pi_{c}$.

Now notice that for all $i \in \mathbb{N}$, we know from the property 5 of $\forall n \in \mathbb{N} . P(n)$ that $\left(\right.$ Save $_{i, 0} \rightarrow_{\mathrm{r}}$ Save $_{i, 1}+$ Save $\left._{i, 1}^{\top}\right) \models \pi_{s}$. Thus $\left(\sum_{i \in \mathbb{N}}\right.$ Save $_{i, 0} \rightarrow_{\mathrm{r}} \sum_{i \in \mathbb{N}} S$ Save $\overrightarrow{i, 1}+$ Save $\left._{i, 1}^{\top}\right) \models \pi_{s} \rightarrow$. By denoting $B=\sum_{i \in \mathbb{N}} S a v e_{i, 1}$ and $B^{\top}=\sum_{i \in \mathbb{N}} S a v e_{i, 1}^{\top}$, we deduce that $\left(A \rightarrow_{r} B+B^{\top}\right) \models$ $\pi_{s}$.

Finally let us build $B_{0}^{\rightarrow}=\sum_{i \in \mathbb{N}} S a v e_{i, 1}$ and $B_{0}^{\top}=\varnothing$. We know from the property $\forall n \in \mathbb{N} . P(n)$ that for all $i \in \mathbb{N}$, for all $k>0, S a v e_{i, k} \rightarrow_{r} S a v e_{i, k+1}+S a v e_{i, k+1}^{\top}$. Hence for all $k>0, \sum_{i \in \mathbb{N}} S a v e_{i, k} \rightarrow_{\mathrm{r}} \sum_{i \in \mathbb{N}} S a v e_{i, k+1}+\sum_{i \in \mathbb{N}} S a v e_{i, k+1}^{\top}$. Hence, if we define for all $k>0$, for all $\alpha \in\{\rightarrow, \top\}, B_{k}^{\alpha}=\sum_{i \in \mathbb{N}}$ Save $_{i, k+1}^{\alpha}$, we deduce that for all $k \in \mathbb{N}, B_{k} \rightarrow_{r}$ $B_{k+1}^{\rightarrow}+B_{k+1}^{\top}$. Therefore, by denoting $C=\sum_{k>0} \sum_{i \in \mathbb{N}} S a v e_{i, k+1}^{\top}$, we obtain $B \Longrightarrow_{r} C$. It remains to prove that $E=A^{\top}+B^{\top}+C: A^{\top}+B^{\top}+C=\sum_{k \in \mathbb{N}^{\top}} F_{k}^{\top}+\sum_{i \in \mathbb{N}}$ Save $_{i, 1}^{\top}+$ $\sum_{k>0} \sum_{i \in \mathbb{N}} S a v e_{i, k+1}^{\top}=\sum_{i \in \mathbb{N}} F_{i}^{\top}+\sum_{k \in \mathbb{N}} \sum_{i \in \mathbb{N}} S_{\text {Sve }}^{\top}{ }_{i, k+1}^{\top}=\sum_{k \in \mathbb{N}} D_{k}^{\top}=E$ (see property 3 of the property $P$ ). This allows us to conclude that $E=A^{\top}+B^{\top}+C$.

Let us now assume that $\mathrm{m}(A) \leq_{\mathrm{m}} \mathrm{m}\left(B+B^{\top}\right)$. We proved that $\left(A \xrightarrow[\rightarrow]{\tau}_{\mathrm{r}} B+B^{\top}\right) \models \pi_{s}^{\rightarrow}$. Thus, $\mathrm{m}(A)>_{\mathrm{m}} \mathrm{m}\left(B+B^{\top}\right)$ and so $A=B=B^{\top}=\varnothing$. Since $B{ }_{\tau}^{\tau_{\mathrm{r}}} C$, we deduce that $C=\varnothing$. With $E=C+B^{\top}+A^{\top}$ and $\left(D \xlongequal{\tau}{ }_{\mathrm{r}} A+A^{\top}\right) \models \pi_{c}^{\rightarrow}$, we conclude that $\left(D{ }_{\mathrm{\tau}}^{\Longrightarrow} E\right) \models \pi_{c}$.

Lemma 48. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, trans $\left._{\mathrm{N}}\right)$ be a NPLTS with $\mathcal{A}_{\text {int }}=\{\tau\}$. Let $\pi_{1}, \pi_{2}$ be two predicates on $\rightarrow$ and $\pi_{1}^{\mathcal{S}}, \pi_{2}^{\mathcal{S}}$ be two predicates on $\mathcal{S}_{\mathrm{N}}$ such that for all $x \in \mathcal{S}_{\mathrm{N}}$, for all $D \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$

- $\pi_{1}^{\mathcal{S}}(x) \wedge \pi_{2}^{\mathcal{S}}(x)$ does not hold;
- for all $i \in\{1,2\}, \pi_{i}^{\mathcal{S}}(x)$ iff $\pi_{i}(x \rightarrow D)$
- for all $i \in\{1,2\}, \pi_{i}(x \rightarrow D)$ implies $\pi_{i}^{\mathcal{S}}(D)$.

For all $A_{1}, A_{2}, B \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$, if

$$
A_{1}+A_{2}{ }_{\mathrm{\tau}}^{\tau_{\mathrm{r}}} B \quad \pi_{1}^{\mathcal{S}}\left(A_{1}\right) \quad \pi_{2}^{\mathcal{S}}\left(A_{2}\right)
$$

then there exist $B_{1}, B_{2} \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$ such that $B=B_{1}+B_{2}$ and for all $i \in\{1,2\}, \pi^{\mathcal{S}}\left(B_{i}\right)$ and $\left(A_{i}{ }_{\mathrm{\tau}}{ }_{\mathrm{r}} B_{i}\right) \models \pi_{i}$

Proof. By definition of $A_{1}+A_{2}{ }_{\mathrm{\tau}}^{\tau} B$, we know there exists an infinite scheme $A_{1}+A_{2}=$ $C_{0}+C_{0}^{\top}$ and for all $k \in \mathbb{N}, C_{k}^{\rightarrow} \xrightarrow[\rightarrow]{\tau}_{r} C_{k+1}+C_{k+1}^{\top}$ and $B=\sum_{k \in \mathbb{N}} C_{k}^{\top}$.

Let us consider the property $P(n)$ defined as: there exist $\left\{C_{k, i}^{\alpha} \mid \alpha \in\{\rightarrow, \top\}, i \in\right.$ $\{1,2\}, k \in\{0, \ldots, n\}\}$ such that

1. for all $\alpha \in\{\rightarrow, \top\}$, for all $k \in\{0, \ldots, n\}, C_{k, 1}^{\alpha}+C_{k, 2}^{\alpha}=C_{k}^{\alpha}$
2. for all $\alpha \in\{\rightarrow, \top\}$, for all $k \in\{0, \ldots, n\}$, for all $i \in\{1,2\}, \pi_{i}^{\mathcal{S}}\left(C_{k, i}^{\alpha}\right)$ holds.
3. for all $k \in\{0, \ldots, n-1\}$, for all $i \in\{1,2\},\left(C_{k, i}^{\rightarrow} \xrightarrow{\tau}_{r} C_{k+1, i}+C_{k+1, i}^{\top}\right) \models \pi_{i}$.

We prove $P(n)$ for all $n \in \mathbb{N}$ by induction on $n$.
Base case $n=0$ : Since for all $x \in \mathcal{S}_{\mathrm{N}}, \pi_{1}^{\mathcal{S}}(x) \wedge \pi_{2}^{\mathcal{S}}(x)$ and $\pi_{i}\left(A_{i}\right)$ for $i=1,2$, we deduce that there exists $C_{0,1}^{\rightarrow}, C_{0,2}, C_{0,1}^{\top}, C_{0,2}^{\top}$ such that for all $\alpha \in\{\rightarrow, \top\}, C_{0,1}^{\alpha}+C_{0,2}^{\alpha}=C_{0}^{\alpha}$, and $\pi_{i}^{\mathcal{S}}\left(C_{0, i}^{\alpha}\right)$ for $i=1,2$.
Inductive step $n>0$ : By our inductive hypothesis, we know that $C_{n}^{\rightarrow}=C_{n, 1}^{\rightarrow}+C_{n, 2}$ with $\pi_{1}^{\mathcal{S}}\left(C_{n, 1}\right)$ and $\pi_{2}^{\mathcal{S}}\left(C_{n, 2}\right)$. Furthermore, $C_{k} \xrightarrow{\tau}_{\mathrm{r}} C_{k+1}+C_{k+1}^{\top}$.

By hypothesis on $\pi_{1}$ and $\pi_{2}$ and the fact that both $\pi_{1}^{\mathcal{S}}\left(C_{n, 1}\right)$ and $\pi_{2}^{\mathcal{S}}\left(C_{n, 2}\right)$ hold, we deduce that $\left(C_{n}^{\rightarrow} \xrightarrow{\tau}_{r} C_{n+1}^{\rightarrow}+C_{n+1}^{\top}\right) \models \pi_{1} \vee \pi_{2}$. By Lemma 46, we deduce that there exists $\left\{C_{n, k}^{\rightarrow, p} \mid p=1,2 \wedge k=1,2\right\}$ and $\left\{C_{n+1, k}^{\alpha, p} \mid \alpha \in\{\rightarrow, \top\}, k \in\{1,2\}, p \in\{1,2\}\right\}$ such that:

- for all $p=1,2$, for all $k=1,2,\left(C_{n, k}^{\rightarrow, p} \xrightarrow{\tau}^{r} C_{n+1, k}^{\rightarrow \rightarrow, p}+C_{n+1, k}^{\top, p}\right) \models \pi_{p}$
- for all $k=1,2, C_{n, k}^{\rightarrow}=C_{n, k}^{\rightarrow, 1}+C_{n, k}^{\rightarrow, 2}$
- for all $\alpha \in\{\rightarrow, \top\}, C_{n+1}^{\alpha}=\sum_{p=1}^{2} \sum_{k=1}^{2} C_{n+1, k}^{\alpha, p}$

By hypothesis on $\pi_{1}$ and $\pi_{2}$, for all $p=1,2$, for all $k=1,2,\left(C_{n, k}^{\rightarrow, p} \xrightarrow[\rightarrow]{r}_{r} C_{n+1, k}^{\rightarrow, p}+C_{n+1, k}^{\top, p}\right) \models \pi_{p}$ implies $\pi_{p}^{\mathcal{S}}\left(C_{n, k}^{\rightarrow, p}\right)$ holds. However, $\pi_{1}^{\mathcal{S}}\left(C_{n, 1}^{\rightarrow}\right)$ implies that for all $x \in \operatorname{supp}\left(C_{n, 1}\right), \neg \pi_{2}^{\mathcal{S}}(x)$. Hence $\neg \pi_{2}^{\mathcal{S}}\left(C_{n, 1}^{\rightarrow, 2}\right)$ and so $C_{n, 1}^{\rightarrow, 2}=\varnothing$. Similarly, we deduce that $C_{n, 2}^{\rightarrow \rightarrow 1}=\varnothing$. Both of them imply that $C_{n+1,2}^{\rightarrow, 1}=C_{n+1,2}^{\top, 1}=C_{n+1,1}^{\rightarrow \rightarrow 2}=C_{n+1,1}^{\top, 2}=\varnothing$. To summarize, we have that for all $p \in\{1,2\}$,

- $\left(C_{n, p}^{\rightarrow, p} \xrightarrow{\tau}_{r} C_{n+1, p}^{\rightarrow, p}+C_{n+1, p}^{\top, p}\right) \models \pi_{p}$
- $C_{n, p}^{\rightarrow}=C_{n, p}^{\rightarrow, p}$
- for all $\alpha \in\{\perp, \rightarrow\}, C_{n+1}^{\alpha}=C_{n+1,1}^{\alpha, 1}+C_{n+1,2}^{\alpha, 2}$.

We conclude by defining $C_{n+1, i}^{\alpha}=C_{n+1, i}^{\alpha, i}$ for $i \in\{1,2\}$ and $\alpha \in\{\rightarrow, \top\}$.
Since $P(n)$ holds for all $n \in \mathbb{N}$, we directly obtain that for all $i \in\{1,2\},\left(C_{0, i}^{\rightarrow}+C_{0, i}^{\top} \xrightarrow{\tau}{ }_{r}\right.$ $\left.\sum_{k \in \mathbb{N}} C \top_{k, i}\right) \models \pi_{i}$ with $\pi_{i}^{\mathcal{S}}\left(\sum_{k \in \mathbb{N}} C \top_{k, i}\right)$. With $B=\sum_{k \in \mathbb{N}} C_{k}^{\top}=\sum_{k \in \mathbb{N}} C_{k, 1}^{\top}+\sum_{k \in \mathbb{N}} C_{k, 2}^{\top}$, we conclude by taking $B_{i}=\sum_{k \in \mathbb{N}} C_{k, i}^{\top}$ for $i=1,2$.

Lemma 49. Let $\mathrm{N}=\left(\mathcal{S}_{\mathrm{N}}, \mathcal{A}_{\text {ext }} \sqcup \mathcal{A}_{\text {int }}\right.$, rrans $\left._{\mathrm{N}}\right)$ and $\mathrm{N}^{\prime}=\left(\mathcal{S}_{\mathrm{N}^{\prime}}, \mathcal{A}_{\text {ext }}^{\prime} \sqcup \mathcal{A}_{\text {int }}^{\prime}\right.$, trans $\left._{\mathrm{N}^{\prime}}\right)$ be two NPLTS with $\mathcal{A}_{\text {int }}=\mathcal{A}_{\text {int }}^{\prime}=\{\tau\}$. Let $f: \mathcal{S}_{\mathrm{N}} \rightarrow \mathcal{S}_{\mathrm{N}^{\prime}}$. Let $\pi_{\text {all }}$ and $\pi_{c}$ two predicates on $\rightarrow_{\mathrm{N}}$. Let $\pi^{\mathcal{S}}$ be a predicate.

If for all $A, B \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$, for all $D \in \mathcal{D}\left(\mathcal{S}_{\mathrm{N}}\right)$, for all $x \in \mathcal{S}_{\mathrm{N}}$,

- if $\pi_{c}^{\rightarrow}\left(x \rightarrow_{\mathrm{N}} D\right)$ then $\pi^{\mathcal{S}}(D)$
- $\left(A \xrightarrow[\tau]{\tau}_{\mathrm{r}, \mathrm{N}} B\right) \models \neg \pi_{c} \wedge \pi_{\text {all }}$ implies $f(A)=f(B)$ and either $A=\varnothing$ or $\mathrm{m}(A)>\mathrm{m}(B)$

then for all $\left(D \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}} E\right) \models \pi_{\text {all }}$, we have $f(D) \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}^{\prime}} f(E)$
Proof. Consider three sub-distributions $A, A_{1}^{\top}, A_{2}^{\top}$ such that $\left(D \Longrightarrow_{\mathrm{r}, \mathrm{N}} A+A_{1}^{\top}\right) \models \pi_{\text {all }}$, $E=A_{1}^{\top}+A_{2}^{\top},\left(A \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}} A_{2}^{\top}\right) \models \pi_{\text {all }}$ and $f(D) \xlongequal{\tau}_{\mathrm{r}, \mathrm{N}^{\prime}} f\left(A+A_{1}^{\top}\right)$. Such sub-distributions exist since we can take $A=D, A_{1}^{\top}=\varnothing$ and $A_{2}^{\top}=E$. Let us take $A, A_{1}^{\top}, A_{2}^{\top}$ a maximal for the following order $\left(A, A_{1}^{\top}, A_{2}^{\top}\right)<\left(B, B_{1}^{\top}, B_{2}^{\top}\right)$ when $A_{1}^{\top}<_{\mathcal{D}} B_{1}^{\top}$ or $A_{1}^{\top}=B_{1}^{\top}$ and $\mathrm{m}(A)>_{\mathrm{m}} \mathrm{m}(B)$ (where $<_{\mathcal{D}}$ stands for the inclusion of distribution, i.e. $D<_{\mathcal{D}} D^{\prime}$ if for all $\left.x, D(x)<D^{\prime}(x)\right)$.

By applying Lemma 47 on $\left(A \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}} A_{2}^{\top}\right) \models \pi_{\text {all }}$ (with $\pi_{c}^{\overrightarrow{ }}=\pi_{c}$ and $\pi_{s}^{\vec{s}}=\neg \pi_{c}$ ), we deduce that there exist $\vec{A} \vec{~}, \bar{A}^{\top}, \bar{B} \rightarrow \bar{B}^{\top}, \bar{C}$ such that:
$\left(A \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}} \bar{A} \rightarrow \bar{A}^{\top}\right) \models \pi_{c} \wedge \pi_{\text {all }} \quad\left(\bar{A} \xrightarrow{\tau}_{\mathrm{r}, \mathrm{N}} \bar{B}+\bar{B}^{\top}\right) \models \neg \pi_{c} \wedge \pi_{\text {all }} \quad\left(\bar{B} \xrightarrow{\tau}{ }_{\mathrm{r}, \mathrm{N}} \bar{C}\right) \models \pi_{\text {all }}$
with $A_{2}^{\top}=\bar{C}+\bar{B}^{\top}+\bar{A}^{\top}$. Let us define $\bar{A}=\bar{B}{ }^{\prime}, \bar{A}_{1}^{\top}=\bar{A}^{\top}+\bar{B}^{\top}+A_{1}^{\top}$ and $\bar{A}_{2}^{\top}=\bar{C}$. We show the following properties:

- $f(D) \xlongequal{\tau}_{\mathrm{r}, \mathrm{N}^{\prime}} f(\bar{A})+f\left(\bar{A}_{1}^{\top}\right)$ : We know that $\left(A \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}} \bar{A}^{\rightarrow}+\bar{A}^{\top}\right) \models \pi_{c} \wedge \pi_{\text {all }}$. By hypothesis on $\pi_{c} \wedge \pi_{\text {all }}$, we deduce that $f(A) \xlongequal{\tau}{\mathrm{r}, \mathrm{N}^{\prime}} f\left(\vec{A}^{\vec{\prime}}\right)+f\left(\bar{A}^{\top}\right)$. Hence $f(A)+$ $f\left(A_{1}^{\top}\right) \stackrel{\tau}{\mathrm{r}, \mathrm{N}^{\prime}} \mathrm{f}\left(\vec{A}^{\vec{\prime}}\right)+f\left(\bar{A}^{\top}\right)+f\left(A_{1}^{\top}\right)$. By hypothesis on $\neg \pi_{c} \wedge \pi_{\text {all }}$, we deduce from $\left(\vec{A} \xrightarrow{\tau}_{\mathrm{r}, \mathrm{N}} \vec{B}+\bar{B}^{\top}\right) \models \neg \pi_{c} \wedge \pi_{\text {all }}$ that $f(\vec{A})=f(\vec{B})+f\left(\bar{B}^{\top}\right)$. Hence $f(A)+f\left(A_{1}^{\top}\right) \Longrightarrow_{\mathrm{r}, \mathrm{N}^{\prime}}^{\tau} f(\bar{A})+f\left(\bar{A}_{1}^{\top}\right)$ and so $f(D) \xlongequal{\tau} \mathrm{r}_{\mathrm{N}} \mathrm{N}^{\prime} f(\bar{A})+f\left(\bar{A}_{1}^{\top}\right)$.
- $\left(D \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}} \bar{A}+\bar{A}_{1}^{\top}\right) \models \pi_{\text {all }}:\left(A \xlongequal{\tau} \mathrm{r}_{\mathrm{N}} \mathrm{N} \bar{A}^{\rightarrow}+\bar{A}^{\top}\right) \models \pi_{c} \wedge \pi_{\text {all }}$ implies that $\left(A+A_{1}^{\top} \xlongequal{\tau}_{\mathrm{r}, \mathrm{N}}\right.$ $\left.\bar{A}+\bar{A}^{\top}+A_{1}^{\top}\right) \models \wedge \pi_{\text {all }}$. Furthermore $\left(\bar{A} \xrightarrow{\tau}_{\mathrm{r}, \mathrm{N}} \bar{B} \rightarrow \bar{B}^{\top}\right) \models \neg \pi_{c} \wedge \pi_{\text {all }}$ implies that $\left(\bar{A} \rightarrow \bar{A}^{\top}+A_{1}^{\top} \xrightarrow{\tau}{ }_{\mathrm{r}, \mathrm{N}} \bar{B}^{\rightarrow}+\bar{B}^{\top}+\bar{A}^{\top}+A_{1}^{\top}\right) \models \pi_{\text {all }}$. With $\vec{B}+\bar{B}^{\top}+\bar{A}^{\top}+A_{1}^{\top}=\bar{A}+\bar{A}_{1}^{\top}$ and the fact that $\left(D \Longrightarrow_{\mathrm{r}, \mathrm{N}} A+A_{1}^{\top}\right) \models \pi_{\text {all }}$, we conclude that $\left(D \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}} \bar{A}+\bar{A}_{1}^{\top}\right) \models$ $\pi_{\text {all }}$.
- $\left(\bar{A} \xrightarrow[\mathrm{r}, \mathrm{N}]{\tau} \bar{A}_{2}^{\top}\right) \vDash \pi_{c} \vee \pi_{s}$ : Notice that $\bar{A}_{2}^{\top}=\bar{C}$ and $\bar{A}=\bar{B}$ hence the result holds.
- $\bar{A}_{1}^{\top}+\bar{A}_{2}^{\top}=\bar{A}^{\top}+\bar{B}^{\top}+A_{1}^{\top}+\bar{C}=A_{2}^{\top}+A_{1}^{\top}=E$.

Since we selected $A, A_{1}^{\top}, A_{2}^{\top}$ as a maximal, then $\left(A, A_{1}^{\top}, A_{2}^{\top}\right) \nless\left(\bar{A}, \bar{A}_{1}^{\top}, \bar{A}_{2}^{\top}\right)$. Since $\bar{A}_{1}^{\top}=$ $\bar{A}^{\top}+\bar{B}^{\top}+A_{1}^{\top} \geq A_{1}^{\top}$, we deduce that $\bar{A}^{\top}=\bar{B}^{\top}=\varnothing$. Therefore, $\left(A, A_{1}^{\top}, A_{2}^{\top}\right) \nless\left(\bar{A}, \bar{A}_{1}^{\top}, \bar{A}_{2}^{\top}\right)$ implies $\mathrm{m}(A) \leq_{\mathrm{m}} \mathrm{m}(\bar{A})$.

Note that by hypothesis on $\pi_{c} \wedge \pi_{\text {all }},\left(A \xlongequal{\tau}, \mathrm{~N} \vec{A}+\bar{A}^{\top}\right) \models \pi_{c} \wedge \pi_{\text {all }}$ implies that $\mathrm{m}(A)=\mathrm{m}(\vec{A})$ and so $\mathrm{m}(\vec{A}) \leq_{\mathrm{m}} \mathrm{m}(\bar{A})=\mathrm{m}(\vec{B})$. By Lemma 47, we obtain that $\left(A \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}} A_{2}^{\top}\right) \models \pi_{c} \wedge \pi_{\text {all }}$ and so $\left(A+A_{1}^{\top} \Longrightarrow_{\mathrm{r}}^{\tau} E\right) \models \pi_{c} \wedge \pi_{\text {all }}$. By hypothesis on $\pi_{c} \wedge \pi_{\text {all }}$, we conclude that $f(A)+f\left(A_{1}^{\top}\right){ }^{\tau}{ }_{\mathrm{r}, \mathrm{N}^{\prime}} f(E)$ and so $f(D){ }^{\tau}{ }_{\mathrm{r}} f(E)$.

Lemma 50. For all $o p \in\{\leq, \approx\}$, for all $a \in\{\operatorname{in}(\xi, \zeta)$, out $(\xi$, ax $) \mid \xi, \zeta$ recipes, ax $\in \mathcal{A X}\}$, for all $(\mathcal{P}, \phi),\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \in \mathcal{S} \mathcal{P}_{\ell}$, if $(\mathcal{P}, \phi) R_{o p}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ and $(\mathcal{P}, \phi){\xrightarrow{a} \mathrm{~N}^{\ell}} D$ then $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right){\xlongequal{a}{ }_{\mathrm{r}, \mathrm{N}^{\ell}} E}$ and $D \widehat{R_{o p}} E$ (and $E \widehat{R_{\approx}} D$ when $o p=\approx$ ).

Proof. The proof for both input actions and output actions follows the same structure. We will start by considering the case when $a=i n(\xi, \zeta)$ and only illustrate the part that change for the case $a=\operatorname{out}(\xi, \mathrm{ax})$.

By definition, $(\mathcal{P}, \phi) \xrightarrow{i n(\xi, \zeta)} \mathbf{N}^{e} D$ implies that $\mathcal{P}=\mathcal{P}_{1} \cup\{\operatorname{in}(u, x) . P\}, u \doteq \xi \phi, M s g(\zeta \phi)$, $\operatorname{vars}(\xi, \zeta) \subseteq \operatorname{dom}(\phi)$ and $D=\delta_{\left(\{P\{\zeta \phi / x\}\} \cup \mathcal{P}_{1}, \phi\right)}$. By definition of $R_{o p}$, we know that $(\mathcal{P}, \phi) R_{o p}\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$ implies $(\mathcal{P}, \phi) \in \mathcal{S} \mathcal{P}_{\ell}\left(\phi, \mathcal{N}_{c h}\right),\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \in \mathcal{S} \mathcal{P}_{\ell}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)$ and $\pi_{\phi, \mathcal{N}_{c h}}^{e \rightarrow p}((\mathcal{P}, \phi))$ op $p_{o b s}^{\mathcal{R}_{r}}$ $\pi_{\phi^{\prime}, \mathcal{N}_{c h}}^{e \rightarrow p}\left(\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)\right)$ for some $\mathcal{N}_{c h}$. Hence, $|\phi|=\left|\phi^{\prime}\right|$ and let us denote $n=|\phi|$. Thanks to Lemma 34, we can assume that $\mathcal{N}_{\text {ch }} \cap f n(\xi, \zeta)=\varnothing$.

Let us consider a fresh sequence $\mathcal{N}_{c h}^{\prime}=\left[c_{\mathrm{ax}_{i}}^{\prime}\right]_{i=1}^{n}$ of public name, i.e. $f n\left(\mathcal{N}_{c h}^{\prime}\right) \cap f n\left(\mathcal{P}, \phi, \mathcal{P}^{\prime}\right.$, $\left.\phi^{\prime}, \mathcal{N}_{c h}\right)=\varnothing$. Let us define $\rho=\left\{x_{i} / \mathrm{ax}_{i}\right\}_{i=1}^{n}$. Finally, consider a fresh public name ok $\in \mathcal{N}_{\text {pub }}$. We build the following process Out:

$$
\begin{aligned}
\text { Out } & :=\operatorname{in}\left(c_{\mathrm{ax}_{1}}, x_{1}\right) \ldots \operatorname{in}\left(c_{\mathrm{ax}_{n}}, x_{n}\right) \cdot \operatorname{out}(\xi \rho, \zeta \rho) .\left(\text { Frame }+_{0.5} \operatorname{out}(o k, o k) .0\right) \\
\text { Frame } & :=\operatorname{out}\left(c_{\mathrm{ax}_{1}}^{\prime}, x_{1}\right) \cdot 0|\ldots| \operatorname{out}\left(c_{\mathrm{ax}_{n}}^{\prime}, x_{n}\right) \cdot 0
\end{aligned}
$$

First notice that $O u t$ is closed and $f n(O u t) \subseteq \mathcal{N}_{\text {pub }}$ since $\xi$ and $\zeta$ are recipes such that $\operatorname{vars}(\xi, \zeta) \subseteq \operatorname{dom}(\phi)$. If we denote $\mathcal{P}_{O}=\left\{\{O u t\} \cup \pi_{\phi, \mathcal{N}_{c h}}^{e \rightarrow p}((\mathcal{P}, \phi))\right.$ and $\mathcal{P}_{O}^{\prime}=\{O u t\} \cup$ $\pi_{\phi^{\prime}, \mathcal{N}_{c h}}^{e \rightarrow p}\left(\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)\right)$, we have $\mathcal{P}_{O}$ op ${ }_{o b s}^{\mathcal{R}_{r}} \mathcal{P}_{O}^{\prime}$.

Since $\pi_{\phi, \mathcal{N}_{c h}}^{e \rightarrow p}((\mathcal{P}, \phi))=\mathcal{P} \cup\left\{\left\{\operatorname{out}\left(c_{\text {ax }}, \text { ax }_{i} \phi\right) .0\right\}_{i=1}^{n}\right.$, we can successively apply the rule (Comm) on $c_{\mathrm{ax}_{1}}, \ldots, c_{\mathrm{ax}_{n}}$ to obtain that $\mathcal{P}_{O} \xlongequal{\tau}{ }_{\mathrm{r}} \delta_{\mathcal{P} \cup\left\{\text { out }(\xi \rho \sigma, \zeta \rho \sigma) .\left(\text { Frame }{ }_{0.50}\right)\right\}}$ with $\sigma=\rho^{-1} \phi$. By hypothesis, $\xi \phi \doteq u$ and $\operatorname{Msg}(\zeta \phi)$. Hence we can apply the rule (Comm) on $u$ to obtain
 we have the following:

$$
\mathcal{P}_{O} \xlongequal{\tau} 0.5 \cdot \delta_{\mathcal{P}_{1} \cup\{P\{\{\zeta / x\}, \text { out }(o k, o k) .0\}}+0.5 \cdot \delta_{\mathcal{P}_{1} \cup\left\{\{P\{\zeta \phi / x\}\} \cup \mathcal{F}\left(\phi, \mathcal{N}_{c h}^{\prime}\right)\right.}
$$

By denoting $D_{1}=0.5 \cdot \delta_{\mathcal{P}_{1} \cup\{\{\{\{\zeta \phi / x\} ; \text { out }(o k, o k) .0\}}+0.5 \cdot \delta_{\mathcal{P}_{1} \cup\left\{\{P\{\zeta \phi / x\}\} \cup \mathcal{F}\left(\phi, \mathcal{N}_{c h}^{\prime}\right)\right.}$, we deduce from $\mathcal{P}_{O}$ op ${ }_{o b s}^{\mathcal{R}_{r}} \mathcal{P}_{O}^{\prime}$ that there exists $E_{1}$ such that $\mathcal{P}_{O}^{\prime} \xlongequal{\tau} E_{1}$ and $D_{1} \underset{o p_{o b s}^{\mathcal{R}_{r}}}{ } E_{1}$. Thanks to Lemma 33, we can assume w.l.o.g. that no rule (PAR) or (NiL) is applicable on $E_{1}$.

Let us analyse $E_{1}$. We consider the following processes:

- $A_{f}^{j, k}\left(\mathcal{Q}^{\prime}\right)=\left\{\operatorname{in}\left(c_{\mathrm{ax}_{j}}, x_{j}\right) \ldots . \operatorname{in}\left(c_{\mathrm{ax}_{n}}, x_{n}\right) \cdot \operatorname{out}\left(\xi \rho \sigma_{j}, \zeta \rho \sigma_{j}\right) \cdot\left(\right.\right.$ Frame $\left.\left._{j-1}+{ }_{0.5} \operatorname{out}(o k, o k)\right)\right\} \cup \cup$ $\mathcal{Q}^{\prime} \cup\left\{\left\{\operatorname{out}\left(c_{\mathrm{ax}_{i}}, \mathrm{ax}_{i} \phi^{\prime}\right) .0\right\}_{i=j+1}^{n} \cup\{0\}\right\}_{i=1}^{k}$
- $A_{o u t}^{k}\left(\mathcal{Q}^{\prime}\right)=\left\{\left\{\operatorname{out}\left(\xi \rho, \zeta \rho \sigma_{j}\right) \cdot\left(\right.\right.\right.$ Frame $\left.\left._{n}+_{0.5} \operatorname{out}(o k, o k) .0\right)\right\} \cup \mathcal{Q}^{\prime} \cup\{0\}_{i=1}^{k}$
- $A_{+}^{k}\left(\mathcal{Q}^{\prime}\right)=\left\{\left\{\right.\right.$ Frame $_{n}+_{0.5}$ out $\left.\left.(o k, o k) .0\right\}\right\} \cup \mathcal{Q}^{\prime} \cup\{\{0\}\}_{i=1}^{k}$
- $A_{c h^{\prime}}^{j, k}\left(\mathcal{Q}^{\prime}\right)=\left\{\text { out }\left(c_{\mathrm{ax}_{j}}^{\prime}, \mathrm{ax}_{j} \phi^{\prime}\right) \cdot 0\right\}_{i=1}^{j} \cup\left\{\right.$ out $\left.\left(c_{\mathrm{ax}_{j+1}}^{\prime}, \mathrm{ax}_{j+1} \phi^{\prime}\right) \cdot 0|\ldots| \operatorname{out}\left(c_{\mathrm{ax}_{n}}^{\prime}, \mathrm{ax}_{n} \phi^{\prime}\right) \cdot 0\right\} \cup \cup$ $\mathcal{Q}^{\prime} \cup\left\{\{0\}_{i=1}^{n}\right.$
- $A_{o k}^{k}\left(\mathcal{Q}^{\prime}\right)=\left\{\{\operatorname{out}(o k, o k) .0\} \cup \cup \mathcal{Q}^{\prime} \cup\{\{0\}\}_{i=1}^{k}\right.$
where $\sigma_{j}=\left\{\mathrm{ax}_{i} \phi^{\prime} / x_{i}\right\}_{i=1}^{j}$.
Let us denote $\mathcal{A}_{f}^{j, k}=\left\{A_{f}^{i, k}(\mathcal{Q}) \mid \mathcal{Q} \in \mathcal{S} \mathcal{P}_{\ell}\left(\phi^{\prime}, \mathcal{N}_{c h}\right) \wedge f n(\mathcal{Q}) \cap \mathcal{N}_{c h}^{\prime}=\varnothing\right\}$. Similarly, we define $\mathcal{A}_{o u t}^{k}, \mathcal{A}_{+}^{k}, \mathcal{A}_{c h^{\prime}}^{j, k}$ and $\mathcal{A}_{o k}^{k}$. We define a measure function m on processes from $\mathcal{A}_{f}^{j, k}$, $\mathcal{A}_{o u t}^{k}, \mathcal{A}_{+}^{k}, \mathcal{A}_{c h^{\prime}}^{j, k}$ and $\mathcal{A}_{o k}^{k}$ as follows: For all $\mathcal{Q}$,

$$
\begin{array}{ll}
\mathcal{Q} \in \mathcal{A}_{f}^{j, k} \Rightarrow \mathrm{~m}(\mathcal{Q})=(5, j, k) & \mathcal{Q} \in \mathcal{A}_{o u t}^{k} \Rightarrow \mathrm{~m}(\mathcal{Q})=(4, k, 0) \quad \mathcal{Q} \in \mathcal{A}_{+}^{k} \Rightarrow \mathrm{~m}(\mathcal{Q})=(3, k, 0) \\
\mathcal{Q} \in \mathcal{A}_{c h^{\prime}}^{j, k} \Rightarrow \mathrm{~m}(\mathcal{Q})=(2, n-j, k) & \mathcal{Q} \in \mathcal{A}_{o k}^{k} \Rightarrow \mathrm{~m}(\mathcal{Q})=(1, k, 0)
\end{array}
$$

Moreover, we consider a function corr : $\mathcal{S P} \mapsto \mathcal{S P} \mathcal{P}_{\ell}$ such that for all $\left(\mathcal{Q}, \phi^{\prime}\right) \in \mathcal{S} \mathcal{P}_{\ell}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)$ with $f n(\mathcal{Q}) \cap \mathcal{N}_{c h}^{\prime}=\varnothing, \operatorname{corr}\left(A_{f}^{j, k}(\mathcal{Q})\right)=\operatorname{corr}\left(A_{\text {out }}^{k}(\mathcal{Q})\right)=\operatorname{corr}\left(A_{+}^{k}(\mathcal{Q})\right)=\operatorname{corr}\left(A_{c h^{\prime}}^{j, k}(\mathcal{Q})\right)=$ $\operatorname{corr}\left(A_{o k}^{k}(\mathcal{Q})\right)=\left(\mathcal{Q}, \phi^{\prime}\right)$.

Since $\mathcal{P}_{O}^{\prime} \xlongequal{\tau} E_{1}$, we know that there exists an infinite scheme

$$
\begin{aligned}
& \delta_{\mathcal{P}_{0}^{\prime}}=E_{0}^{\rightarrow}+E_{0}^{\top} \\
& E_{0}^{\rightarrow} \xrightarrow{\tau}_{\mathrm{r}} E_{1}^{\rightarrow}+E_{1}^{\top} \\
& \ldots \\
& E_{k}^{\rightarrow} \xrightarrow{\tau}_{\mathrm{r}} E_{k+1}^{\rightarrow}+E_{k+1}^{\top}
\end{aligned}
$$

such that $E_{1}=\sum_{k \in \mathbb{N}} E_{k}^{\top}$.
First notice that $\mathcal{P}_{O}^{\prime}=A_{\text {frame }}^{n, 0}\left(\mathcal{P}^{\prime}\right)$ and $\operatorname{corr}\left(\mathcal{P}_{O}^{\prime}\right)=\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)$. Second, by a simple case analysis, we deduce the following statements for all $\mathcal{Q} \rightarrow D$

- $\mathcal{Q} \in \mathcal{A}_{f}^{j, k}$ implies either $\operatorname{supp}(D) \subseteq \mathcal{A}_{f}^{j-1, k+1} \cup \mathcal{A}_{f}^{j, k-1} \cup \mathcal{A}_{\text {out }}^{k+1}$ and $\operatorname{corr}(D)=\operatorname{corr}\left(\delta_{\mathcal{Q}}\right)$; or $\operatorname{supp}(D) \subseteq \mathcal{A}_{f}^{j, k}$ and $\operatorname{corr}(\mathcal{Q}) \xrightarrow{\tau} \operatorname{corr}(D)$.
- $\mathcal{Q} \in \mathcal{A}_{\text {out }}^{k}$ implies either $\operatorname{supp}(D) \subseteq \mathcal{A}_{\text {out }}^{k-1}$ and $\operatorname{corr}(D)=\operatorname{corr}\left(\delta_{\mathcal{Q}}\right)$; or $\operatorname{supp}(D) \subseteq \mathcal{A}_{+}^{k}$ and $\operatorname{corr}(\mathcal{Q}) \xrightarrow{i n(\xi, \zeta)} \operatorname{corr}(D) ;$ or $\operatorname{supp}(D) \subseteq \mathcal{A}_{\text {out }}^{k}$ and $\operatorname{corr}(\mathcal{Q}) \xrightarrow{\tau} \operatorname{corr}(D)$
- $\mathcal{Q} \in \mathcal{A}_{+}^{k}$ implies either $\operatorname{supp}(D) \subseteq \mathcal{A}_{+}^{k-1} \cup \mathcal{A}_{c h^{\prime}}^{0, k} \cup \mathcal{A}_{o k}^{k}$ and $\operatorname{corr}(D)=\operatorname{corr}\left(\delta_{\mathcal{Q}}\right)$; or $\operatorname{supp}(D) \subseteq \mathcal{A}_{+}^{k}$ and $\operatorname{corr}(\mathcal{Q}) \xrightarrow{\tau} \operatorname{corr}(D)$
- $\mathcal{Q} \in \mathcal{A}_{c h^{\prime}}^{j, k}$ implies either $\operatorname{supp}(D) \subseteq \mathcal{A}_{c h^{\prime}}^{j+1, k} \cup \mathcal{A}_{c h^{\prime}}^{j, k-1}$ and $\operatorname{corr}(D)=\operatorname{corr}\left(\delta_{\mathcal{Q}}\right)$; or $\operatorname{supp}(D) \subseteq \mathcal{A}_{c h^{\prime}}^{j, k}$ and $\operatorname{corr}(\mathcal{Q}) \xrightarrow{\tau} \operatorname{corr}(D)$
- $\mathcal{Q} \in \mathcal{A}_{o k}^{k}$ implies either $\operatorname{supp}(D) \subseteq \mathcal{A}_{o k}^{k-1}$ and $\operatorname{corr}(D)=\operatorname{corr}\left(\delta_{\mathcal{Q}}\right) ;$ or $\operatorname{supp}(D) \subseteq \mathcal{A}_{o k}^{k}$ and $\operatorname{corr}(\mathcal{Q}) \xrightarrow{\tau} \operatorname{corr}(D)$

One of the direct property we deduce from these is that for all $k \in \mathbb{N}$, for all $\alpha \in\{\rightarrow, \top\}$, $\operatorname{supp}\left(E_{k}^{\alpha}\right) \subseteq \bigcup_{k=0}^{n} \bigcup_{j=0}^{n} \mathcal{A}_{f}^{j, k} \cup \mathcal{A}_{o u t}^{k} \cup \mathcal{A}_{+}^{k} \cup \mathcal{A}_{c h^{\prime}}^{j, k} \cup \mathcal{A}_{o k}^{k}$.

We proved that $D_{1} \widehat{o p_{o b s}^{\mathcal{R}_{r}}} E_{1}$. Consider $E_{o k}$ the largest sub-distribution of $E_{1}$ such that for all $\mathcal{P}^{\prime \prime} \in \operatorname{supp}\left(E_{o k}\right), \mathcal{P}_{1} \cup\left\{\left\{P\left\{{ }^{\zeta \phi} / x\right\}\right.\right.$, out $\left.(o k, o k) .0\right\} o p_{o b s}^{\mathcal{R}_{r}} \mathcal{P}^{\prime \prime}$. Notice that $\operatorname{RProb} \mathcal{D}_{\mathcal{R}_{r}}\left(\mathcal{P}_{1} \cup\right.$ $\left.\left\{P\left\{{ }^{\zeta \phi} / x\right\}, \operatorname{out}(o k, o k) .0\right\}, \downarrow o k\right)=1$. Hence, $\operatorname{supp}\left(E_{o k}\right) \subseteq\left\{A_{o k}^{k}\left(\mathcal{Q}^{\prime \prime}\right) \mid\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \mathcal{S P} \mathcal{P}_{\ell}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)\right\}$. Similarly, if we denote $E_{c h^{\prime}}$ the largest sub-distribution of $E_{1}$ such that for all $\mathcal{P}^{\prime \prime} \in$ $\operatorname{supp}\left(E_{c h^{\prime}}\right), \mathcal{P}_{1} \cup\left\{\{P\{\zeta \phi / x\}\} \cup \mathcal{F}\left(\phi, \mathcal{N}_{c h}^{\prime}\right) o p_{o b s}^{\mathcal{R}_{r}} \mathcal{P}^{\prime \prime}\right.$, we obtain that $\operatorname{supp}\left(E_{c h^{\prime}}\right) \subseteq\left\{A_{c h^{\prime}}^{j, k}\left(\mathcal{Q}^{\prime \prime}\right) \mid\right.$ $\left.\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \mathcal{S} \mathcal{P}_{\ell}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)\right\}$. However, $D_{1} o p_{o b s}^{\mathcal{R}_{r}} E_{1}$ implies that $D_{1}\left(\mathcal{P}_{1} \cup\left\{\left\{P\left\{{ }^{\zeta \phi} / x\right\}\right.\right.\right.$, out $\left.\left.\left.(o k, o k) .0\right\}\right\}\right)=$ $0.5 \leq \sum_{\mathcal{P}^{\prime \prime}} E_{o k}\left(\mathcal{P}^{\prime \prime}\right)$ and $D_{1}\left(\mathcal{P}_{1} \cup\left\{\{P\{\zeta \phi \mid x\}\} \cup \mathcal{F}\left(\phi, \mathcal{N}_{c h}^{\prime}\right)\right)=0.5 \leq \sum_{\mathcal{P}^{\prime \prime}} E_{c h^{\prime}}\left(\mathcal{P}^{\prime \prime}\right)\right.$. Since $\operatorname{supp}\left(E_{c h^{\prime}}\right) \cap \operatorname{supp}\left(E_{o k}\right)=\varnothing$, we conclude that $E_{1}=E_{c h^{\prime}}+E_{o k}$ with $\sum_{\mathcal{P}^{\prime \prime}} E_{c h^{\prime}}\left(\mathcal{P}^{\prime \prime}\right)=$ $\sum_{\mathcal{P}^{\prime \prime}} E_{\text {ok }}\left(\mathcal{P}^{\prime \prime}\right)=0.5$. Finally, since no rule (NiL) or (PAR) is applicable on $E_{1}$, we deduce that $\operatorname{supp}\left(E_{c h^{\prime}}\right) \subseteq \mathcal{A}_{c h^{\prime}}^{n, 0}$ and so $\operatorname{supp}\left(E_{c h^{\prime}}\right) \subseteq \mathcal{S P}\left(\phi^{\prime}, \mathcal{N}_{c h}^{\prime}\right)$.

Note that by construction of $E_{c h^{\prime}}, \delta_{\mathcal{P}_{1} \cup\{P\{\zeta \phi / x\}\} \cup \mathcal{F}\left(\phi, \mathcal{N}_{c h}^{\prime}\right)} \widehat{o p_{o b s}^{\mathcal{R}_{r}}} 2 \cdot E$. Thus, by denoting $E=2 \cdot E_{c h^{\prime}}$ and by Lemma 43, we obtain that $D=\pi_{\phi^{\prime}, \mathcal{N}_{c h}^{\prime}}^{p \rightarrow e}\left(\delta_{\mathcal{P}_{1} \cup\{P\{\zeta \phi / x\}\} \cup \mathcal{F}\left(\phi, \mathcal{N}_{c h}^{\prime}\right)}\right) \widehat{R_{o p}}$ $\pi_{\phi^{\prime}, \mathcal{N}_{c h}^{\prime}}^{p \rightarrow e}(E)$.

It remains to show that $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \xrightarrow{i n(\xi, \zeta)}{ }_{\mathrm{r}, \mathrm{N}^{\ell} \ell} \pi_{\phi^{\prime}, \mathcal{N}_{c h}^{\prime}}^{p \rightarrow e}(E)$ : Consider the predicate $\pi^{\mathcal{S}}$ such that $\pi^{\mathcal{S}}(\mathcal{Q})$ holds iff $\mathcal{Q} \subseteq \bigcup_{k=0}^{n} \mathcal{A}_{\text {out }}^{k} \cup \bigcup_{j=1}^{n} \mathcal{A}_{f}^{j, k}$. We also consider the predicates $\pi_{s}^{\rightarrow}$ and $\pi_{c}^{\rightarrow}$ on $\xrightarrow{\tau}$ such that $\pi_{s}^{\rightarrow}(\mathcal{Q} \rightarrow D)$ holds iff $\mathcal{Q} \in \mathcal{A}_{\text {out }}^{k}$ for some $k$ and $\operatorname{supp}(D) \subseteq \mathcal{A}_{+}^{k}$; and $\pi_{c}^{\rightarrow}(\mathcal{Q} \rightarrow D)$ holds iff $\pi^{\mathcal{S}}(\mathcal{Q})$ and either $\operatorname{corr}\left(\delta_{\mathcal{Q}}\right)=\operatorname{corr}(D)$ or $\operatorname{corr}(\mathcal{Q}) \xrightarrow{\tau} \operatorname{corr}(D)$. Notice that $\pi^{\mathcal{S}}, \pi_{c}$ and $\pi_{s}$ satisfy the conditions of Lemma 46. Therefore, $A, A^{\top}, B, B^{\top}, C \in$ $\mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathrm{N}}\right)$ such that

$$
\left(\delta_{\mathcal{P}_{0}^{\prime}} \stackrel{\tau}{\Longrightarrow}_{\mathrm{r}} A+A^{\top}\right) \models \pi_{c} \quad\left(A \xrightarrow{\tau}_{\mathrm{r}} B+B^{\top}\right) \models \pi_{s} \quad B{\underset{\mathrm{r}}{ }}_{\mathrm{T}_{\mathrm{r}}} C
$$

with $E_{1}=C+B^{\top}+A^{\top}$. Note that we already proved that $E_{1}=E_{c h^{\prime}} \dot{+} E_{o k}$ and so we deduce that $A^{\top}=B^{\top}=\varnothing$.

Notice that by definition of $\pi_{s}^{\rightarrow}, A \xrightarrow{\tau} B$ implies $A \xrightarrow{\tau} B$. Moreover, $\pi_{s}(\mathcal{Q} \xrightarrow{\tau} D)$ also implies $\operatorname{corr}(\mathcal{Q}) \xrightarrow{i n(\xi, \zeta)} \operatorname{corr}(D)$. Therefore, $\operatorname{corr}(A) \xrightarrow{i n(\xi, \zeta)} \operatorname{corr}(B)$.

Let us focus on $\left(\delta_{\mathcal{P}_{0}^{\prime}}{ }_{\mathrm{\tau}}^{\Longrightarrow} A\right) \models \pi_{c}$. We define the predicate $\pi_{c}^{\prime}$ such that $\pi_{c}^{\prime}(\mathcal{Q} \rightarrow D)$ holds iff $\operatorname{corr}(\mathcal{Q}) \xrightarrow{\tau}_{\mathrm{N}^{\ell}} \operatorname{corr}(D)$. By construction, notice that $\left(A \xrightarrow{\tau}_{\mathrm{r}, \mathrm{N}} B\right) \models \neg \pi_{c}^{\prime} \wedge \pi_{c} \rightarrow$ implies $\operatorname{corr}(A)=\operatorname{corr}(B)$ and either $A=\varnothing$ or $\mathrm{m}(A)>\mathrm{m}(B)$. Similarly, by construction, $(A{\underset{\rightarrow}{r}, \mathrm{~N}} B) \models \pi_{c}^{\prime} \wedge \pi_{c}^{\rightarrow}$ implies $\operatorname{corr}(A) \xrightarrow{\tau}_{\mathrm{N}^{\ell}} \operatorname{corr}(B)$ and $\mathrm{m}(A)=\mathrm{m}(B)$. This allows us to apply Lemma 49 on $\left(\delta_{\mathcal{P}_{0}^{\prime}}{ }^{\tau}{ }_{\mathrm{r}} A\right) \models \pi_{c}$. Therefore, $\operatorname{corr}\left(\delta_{\mathcal{P}_{0}^{\prime}}\right) \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}^{\ell}} \operatorname{corr}(A)$.

Let us summarize what we have proved so far: $\operatorname{corr}\left(\delta_{\mathcal{P}_{O}^{\prime}}\right) \xrightarrow{\tau}{ }_{\mathrm{r}} \operatorname{corr}(A) \xrightarrow{i n(\xi, \zeta)} \operatorname{corr}(B)$ with $B \xlongequal{\tau}{ }_{\mathrm{r}} E_{1}$ with $\operatorname{supp}(B) \subseteq \bigcup_{k=1}^{n} \mathcal{A}_{+}^{k}$. Let us redefine the predicate $\pi^{\mathcal{S}}$ such that $\pi^{\mathcal{S}}(x)$ holds iff $x \in \bigcup_{k=1}^{n} \mathcal{A}_{+}^{k}$. We redefine $\pi_{c}$ and $\pi_{s}$ such that $\pi_{c}(x \rightarrow D)$ holds when $\pi^{\mathcal{S}}(D)$ and $\operatorname{corr}(x) \xrightarrow{\tau} \operatorname{corr}(D)$; and $\pi_{s}(x \rightarrow D)$ holds when $\operatorname{corr}(D)=\operatorname{corr}\left(\delta_{x}\right)$ and $\mathrm{m}(x)>\mathrm{m}(D)$. By applying Lemma 47 on $B \xlongequal{\tau}{ }_{\mathrm{r}} E_{1}$, we deduce that there exists $\left(B \xlongequal{\tau} B_{1}+B_{1}^{\top}\right) \models \pi_{c}$, $\left(B_{1} \xrightarrow{\tau}_{\mathrm{r}} B_{2}+B_{2}^{\top}\right) \models \pi_{s}, B_{2} \xrightarrow{\tau} B_{3}$ with $E_{1}=B_{3}+B_{1}^{\top}+B_{2}^{\top}$. Once again we know that $E_{1}=E_{c h^{\prime}} \dot{+} E_{o k}$ and so we deduce that $B_{1}^{\top}=\varnothing$.

By definition of $\pi_{c}$, we deduce that $\operatorname{corr}(B) \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}^{\ell}} \operatorname{corr}\left(B_{1}\right)$. Moreover, by definition of $\pi_{s}$, the transition $B_{1} \xrightarrow{\tau}_{\mathrm{r}} B_{2}+B_{2}^{\top}$ correspond to the execution of the probabilistic choice in the process Frame $+_{0.5}$ out $(o k, o k) .0$. Thus, there exist two sub distributions $B_{o k}, B_{c h^{\prime}}$ such that $B_{2}+B_{2}^{\top}=0.5 \cdot B_{o k}+0.5 \cdot B_{c h^{\prime}}, \operatorname{supp}\left(B_{o k}\right) \subseteq \cup_{k=0}^{n} \mathcal{A}_{o k}^{k}, \operatorname{supp}\left(B_{c h^{\prime}}\right) \subseteq \cup_{k=0}^{n} \mathcal{A}_{c h^{\prime}}^{0, k}$ and $\operatorname{corr}\left(B_{1}\right)=\operatorname{corr}\left(B_{o k}\right)=\operatorname{corr}\left(B_{c h^{\prime}}\right)$. By applying Lemma 48, we deduce that $0.5 \cdot B_{o k} \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}^{\circ}}$ $E_{o k}$ and $0.5 \cdot B_{c h^{\prime}} \Longrightarrow_{\mathrm{r}, \mathrm{N}^{\circ}} E_{c h^{\prime}}$, implying that $B_{o k} \xlongequal{\tau}_{\mathrm{r}, \mathrm{N}^{\circ}} 2 \cdot E_{o k}$ and $B_{c h^{\prime}} \xlongequal{\tau}_{\mathrm{r}, \mathrm{N}^{\circ}} 2 \cdot E_{c h^{\prime}}$

We will finally show that $\operatorname{corr}\left(B_{c h^{\prime}}\right) \stackrel{\tau}{\Longrightarrow}{ }_{\mathrm{r}, \mathrm{N}^{\ell}} \operatorname{corr}\left(2 \cdot E_{c h^{\prime}}\right)$ by applying Lemma 49 with predicate $\pi^{\mathcal{S}}$ on $\mathcal{S}_{\mathrm{N}^{o}}$ and predicates $\pi_{a l l}, \pi_{c}$ on $\rightarrow_{\mathrm{N}^{\circ}}$ defined as:

- $\pi^{\mathcal{S}}(x)$ holds iff $x \in \cup_{k=0}^{n} \cup_{j=0}^{n} \mathcal{A}_{c h^{\prime}}^{j, k}$
- $\pi_{c}\left(x \rightarrow_{\mathrm{N}^{\circ}} D\right)$ holds iff $\mathrm{m}(x)=\mathrm{m}(D)$ and $\operatorname{corr}(x) \rightarrow_{\mathrm{N}^{e}} \operatorname{corr}(D)$.
- $\pi_{\text {all }}$ is always true.

This complete the proof of $\delta_{\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)} \xrightarrow{i n(\xi, \zeta)}_{\mathrm{r}, \mathrm{N}^{\mathrm{N}}} \operatorname{corr}\left(2 \cdot E_{c h^{\prime}}\right)=\pi_{\phi^{\prime}, \mathcal{N}_{c h}^{\prime}}^{p \rightarrow e}(E)$.
Let us now consider the case of the output action $a=\operatorname{out}(\xi, \mathrm{ax})$. By definition, $(\mathcal{P}, \phi) \xrightarrow{\text { out }(\xi, \mathrm{ax})}{ }_{\mathrm{N}^{e}} D$ implies that $\mathcal{P}=\mathcal{P}_{1} \cup\{\operatorname{out}(u, t) . P\}, u \doteq \xi \phi, \mathrm{ax}=\mathrm{ax}_{n+1}, \operatorname{Msg}(t)$, $\operatorname{vars}(\xi) \subseteq \operatorname{dom}(\phi)$ and $D=\delta_{\left(\left\{\{P\} \cup \mathcal{P}_{1}, \phi\{a x \mapsto t\}\right)\right.}$. Compare to the input case, we consider a sequence of public name $\mathcal{N}_{c h}^{\prime}$ with one additional channel, i.e. $\mathcal{N}_{c h}^{\prime}=\left[c_{\mathrm{ax}_{i}}^{\prime}\right]_{i=1}^{n+1}$. Moreover, we consider the following process In instead of the process Out:

$$
\begin{aligned}
\text { In } & :=\operatorname{in}\left(c_{\mathrm{ax}_{1}}, x_{1}\right) \ldots \operatorname{in}\left(c_{\mathrm{ax}_{n}}, x_{n}\right) \cdot \operatorname{in}\left(\xi \rho, x_{n+1}\right) \cdot\left(\text { Frame }+_{0.5} \text { out }(o k, o k) .0\right) \\
\text { Frame } & :=\operatorname{out}\left(c_{\mathrm{ax}_{1}}^{\prime}, x_{1}\right) .0|\ldots| \operatorname{out}\left(c_{\mathrm{ax}_{n+1}}^{\prime}, x_{n+1}\right) \cdot 0
\end{aligned}
$$

Thus the initial processes $\mathcal{P}_{O}$ and $\mathcal{P}_{O}^{\prime}$ used in the proof are defined as $\mathcal{P}_{O}=\{\{I n\} \cup$ $\pi_{\phi, \mathcal{N}_{c h}}^{e \rightarrow p}((\mathcal{P}, \phi))$ and $\mathcal{P}_{O}^{\prime}=\left\{\{\operatorname{In}\} \cup \pi_{\phi^{\prime}, \mathcal{N}_{c h}}^{e \rightarrow p}\left(\left(\mathcal{P}^{\prime}, \phi^{\prime}\right)\right)\right.$. Executing the process $\mathcal{P}_{O}$ allows us to
obtain:

$$
\mathcal{P}_{O} \xlongequal{\tau}{ }_{\mathrm{r}} 0.5 \cdot \delta_{\mathcal{P}_{1} \cup\{\{P, \text { out }(o k, o k) .0\}}+0.5 \cdot \delta_{\mathcal{P}_{1} \cup\{P\} \cup \mathcal{F}\left(\phi\left\{\mathrm{ax}_{n+1} \mapsto t\right\}, \mathcal{N}_{c h}^{\prime}\right)}
$$

Then when we analyse the support of $E_{1}$, we consider the following processes:

- $A_{f}^{j, k}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)=\left\{\left\{\operatorname{in}\left(c_{\mathrm{ax}_{j}}, x_{j}\right) \ldots . \operatorname{in}\left(c_{\mathrm{ax}_{n}}, x_{n}\right) . \operatorname{out}\left(\xi \rho \sigma_{j}, x_{n+1}\right) .\left(\right.\right.\right.$ Frame $\left.\left._{j-1}+{ }_{0.5} \operatorname{out}(o k, o k)\right)\right\} \cup \cup$ $\mathcal{Q}^{\prime} \cup\left\{\operatorname{out}\left(c_{\mathrm{ax}_{i}}, \mathrm{ax}_{i} \phi^{\prime}\right) .0\right\}_{i=j+1}^{n} \cup\{0\}_{i=1}^{k}$
- $A_{i n}^{k}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)=\left\{\operatorname{in}\left(\xi \rho, x_{n+1}\right) .\left(\right.\right.$ Frame $\left.\left.\left._{n}+_{0.5} \operatorname{out}(o k, o k) .0\right)\right\} \cup \mathcal{Q}^{\prime} \cup\{0\}\right\}_{i=1}^{k}$
- $A_{+}^{k}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)=\left\{\left\{\right.\right.$ Frame $_{n+1}+_{0.5}$ out $\left.(o k, o k) .0\right\} \cup \cup \mathcal{Q}^{\prime} \cup\{\{0\}\}_{i=1}^{k}$
- $A_{c h^{\prime}}^{j, k}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)=\left\{\left\{\operatorname{out}\left(c_{\mathrm{ax}_{j}}^{\prime}, \operatorname{ax}_{j} \phi^{\prime}\right) .0\right\}_{i=1}^{j} \cup\left\{\operatorname{out}\left(c_{\mathrm{ax}_{j+1}}^{\prime}, \mathrm{ax}_{j+1} \phi^{\prime}\right) .0|\ldots| \operatorname{out}\left(c_{\mathrm{ax}_{n+1}}^{\prime}, \operatorname{ax}_{n} \phi^{\prime}\right) .0\right\} \cup \cup\right.$ $\mathcal{Q}^{\prime} \cup\left\{\{0\}^{n}{ }_{i=1}^{n}\right.$
- $A_{o k}^{k}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)=\left\{\{\operatorname{out}(o k, o k) .0\} \cup \mathcal{Q}^{\prime} \cup\left\{\{0\}_{i=1}^{k}\right.\right.$
where $\sigma_{j}=\left\{{ }^{2} \mathrm{a}_{i} \phi^{\prime} / x_{i}\right\}_{i=1}^{j}$. Notice here that a frame is given as argument since it will be augment once the process $\operatorname{in}\left(\xi \rho, x_{n+1}\right)$ is executed. As such, the set $\mathcal{A}_{f}^{j, k}$ is defined as $\left\{A_{f}^{i, k}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right) \mid\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right) \in \mathcal{S} \mathcal{P}_{\ell}\left(\phi^{\prime}, \mathcal{N}_{c h}\right) \wedge f n(\mathcal{Q}) \cap \mathcal{N}_{c h}^{\prime}=\varnothing\right\}$. Similarly, the correspondence function corr : $\mathcal{S P} \mapsto \mathcal{S} \mathcal{P}_{\ell}$ is defined as for all $\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right) \in \mathcal{S P} \mathcal{P}_{\ell}\left(\phi^{\prime}, \mathcal{N}_{c h}\right)$ with $f n(\mathcal{Q}) \cap$ $\mathcal{N}_{c h}^{\prime}=\varnothing, \operatorname{corr}\left(A_{f}^{j, k}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)\right)=\operatorname{corr}\left(A_{o u t}^{k}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)\right)=\operatorname{corr}\left(A_{+}^{k}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)\right)=\operatorname{corr}\left(A_{c h^{\prime}}^{j, k}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)\right)=$ $\operatorname{corr}\left(A_{o k}^{k}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)\right)=\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)$. The measure function m only differ on $\mathcal{A}_{c h^{\prime}}^{j, k}$ as follows: if $\mathcal{Q} \in \mathcal{A}_{c h^{\prime}}^{j, k}$ then $\mathrm{m}(\mathcal{Q})=(2, n+1-j, k)$. The rest of the proof follows by using the same reasoning. .

## F. 4 Simulation implies observational preorder

For this direction of the equivalence, we define the relation $R_{o p}$ with $o p \in\{\leq, \approx\}$ on multisets of processes as follows: For all $\mathcal{P}, \mathcal{P}^{\prime} \in \mathcal{S P}, \mathcal{P} R_{o p} \mathcal{P}^{\prime}$ if and only if there exist a multiset of processes $\mathcal{P}_{A t t}$, a renaming of variables $\rho$, two extended processes $(\mathcal{Q}, \phi),\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right) \in \mathcal{S} \mathcal{P}_{\ell}$ such that:

- $|\phi|=\left|\phi^{\prime}\right|=n$
- $\operatorname{dom}(\rho) \subseteq \mathcal{N}_{p u b}, \operatorname{img}(\rho) \subseteq \mathcal{N}_{\text {priv }}, \operatorname{img}(\rho) \cap \operatorname{names}\left(\mathcal{Q}, \mathcal{Q}^{\prime}, \phi, \phi^{\prime}\right)=\varnothing$
- $f v\left(\mathcal{P}_{A t t}\right) \subseteq\left\{x_{1}, \ldots, x_{n}\right\}$ and $f n\left(\mathcal{P}_{A t t}\right) \subseteq \mathcal{N}_{p u b}$
- $\mathcal{P}=\mathcal{Q} \rho \cup \mathcal{P}_{A t t}\left\{{ }^{\left\{\mathrm{ax}_{i} \phi\right.} /{ }_{x_{i}}\right\}_{i=1}^{n} \rho$
- $\mathcal{P}^{\prime}=\mathcal{Q}^{\prime} \rho \cup \mathcal{P}_{A t t}\left\{\left\{^{\mathrm{ax}_{i} \phi^{\prime}} / x_{i}\right\}_{i=1}^{n} \rho\right.$
- $(\mathcal{Q}, \phi) o p^{N^{\ell}}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)$

Lemma 51. For all $o p \in\{\leq, \approx\}$, for all $\mathcal{P}, \mathcal{P}^{\prime} \in \mathcal{S P}$, if $\mathcal{P} R_{o p} \mathcal{P}^{\prime}$ then for all closed $\mathcal{P}_{\text {Att }} \in \mathcal{S P}$ such that $f n\left(\mathcal{P}_{A t t}\right) \subseteq \mathcal{N}_{\text {pub }}$ then $\mathcal{P}_{A t t} \cup \mathcal{P} R_{o p} \mathcal{P}_{A t t} \cup \mathcal{P}^{\prime}$.

Proof. Trivial by definition of $R_{o p}$.
Lemma 52. Let $o p \in\{\leq, \approx\}$. Let $D, D^{\prime} \in \mathcal{D}^{\leq 1}\left(\mathcal{S}_{\mathbb{N}^{\ell}}\right)$. Let $n \in \mathbb{N}$. Let $\rho$ be a renaming such that $\operatorname{dom}(\rho) \subseteq \mathcal{N}_{\text {pub }}, \operatorname{img}(\rho) \subseteq \mathcal{N}_{\text {priv }}$ and for all $(\mathcal{P}, \phi) \in \operatorname{supp}(D) \cup \operatorname{supp}\left(D^{\prime}\right)$, $\operatorname{img}(\rho) \cap \operatorname{names}(\mathcal{P}, \phi)=\varnothing$ and $|\phi|=n$. Let $\mathcal{P}_{\text {Att }} \in \mathcal{S P}$ such that $f v\left(\mathcal{P}_{A t t}\right) \subseteq\left\{x_{1}, \ldots, x_{n}\right\}$ and $f n\left(\mathcal{P}_{A t t}\right) \subseteq \mathcal{N}_{p u b}$.

If $D \widehat{o p^{N^{\ell}}} D^{\prime}$ then

Proof. Given a frame $\phi$ of size $n$, we denote by $\sigma_{\phi}$ the substitution $\left\{{ }^{\text {ax }}{ }_{1} \phi / x_{i}\right\}_{i=1}^{n}$. We denote by $E$ and $E^{\prime}$ the sub-distributions $\sum_{(\mathcal{Q}, \phi) \in \operatorname{supp}(D)} D((\mathcal{Q}, \phi)) \cdot \delta_{\mathcal{Q} \rho \cup \mathcal{P}_{A t t} \sigma_{\phi} \rho}$ and $\sum_{(\mathcal{Q}, \phi) \in \operatorname{supp}\left(D^{\prime}\right)}$ $D^{\prime}((\mathcal{Q}, \phi)) \cdot \delta_{\mathcal{Q} \rho \cup \mathcal{P}_{A t t} \sigma_{\phi} \rho}$ respectively. Let $S \subseteq \mathcal{S} \mathcal{P}$. Let us denote $S_{1}=\{(\mathcal{Q}, \phi) \in \operatorname{supp}(D) \mid$ $\left.\left(\mathcal{Q} \rho \cup \mathcal{P}_{A t t} \sigma_{\phi} \rho\right) \in S\right\}$.

Let $S^{\prime}=\left\{\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right) \in \operatorname{supp}\left(D^{\prime}\right) \mid\left(\mathcal{Q} \rho \cup \mathcal{P}_{A t t} \sigma_{\phi} \rho\right) \in S \cap \operatorname{supp}(D)\right.$ and $\left.(\mathcal{Q}, \phi) o p^{\mathbb{N}^{\ell}}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)\right\}$. By definition of $E$, we have:

$$
\begin{aligned}
& E(S)=\sum_{\substack{(\mathcal{Q}, \phi) \in \operatorname{supp}^{(D)} \\
\mathcal{Q} \mathcal{Q} \cup \mathcal{P}_{A t t} \sigma_{\phi} \rho \in S}} D((\mathcal{Q}, \phi)) \\
& =D\left(S_{1}\right) \quad \text { by definition of } S_{1} \\
& \leq D^{\prime}\left(o p^{N^{\ell}}\left(S_{1}\right)\right) \quad \text { by } D \widehat{o p^{N^{\ell}}} D^{\prime} \\
& \leq \sum_{\substack{\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right) \in \operatorname{supp}\left(D^{\prime}\right)}} D^{\prime}\left(\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)\right) \\
& \mid(\mathcal{Q}, \phi) \in S_{1} \wedge(\mathcal{Q}, \phi) o p^{\mathcal{N}^{\ell}}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right) \\
& \leq \sum_{\substack{\left(\mathcal{Q}^{\prime},,^{\prime}\right) \in \operatorname{supp}\left(D^{\prime}\right) \\
\mid\left(\mathcal{Q} \rho \mathcal{P A}_{A t t} \sigma_{\phi} \rho\right) \in S \\
\wedge\left(\mathcal{Q} \rho \cup \mathcal{P}_{A t t} \sigma_{\phi} \rho\right) R_{o p}\left(\mathcal{Q}^{\prime} \rho \cup \mathcal{P}_{A t t} \sigma_{\phi^{\prime}} \rho\right)}} D^{\prime}\left(\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)\right) \quad \text { by definition of } R_{o p} \\
& \leq E^{\prime}\left(R_{o p}(S)\right)
\end{aligned}
$$

This allows us to conclude that $E \widehat{R_{o p}} E^{\prime}$.
Lemma 53. For all $o p \in\{\leq, \approx\}$, for all $\mathcal{P}, \mathcal{P}^{\prime} \in \mathcal{S P}$, if $\mathcal{P} R_{o p} \mathcal{P}^{\prime}$ and $\mathcal{P} \xrightarrow{\tau}_{\mathrm{N}^{o}} D$ then $\mathcal{P} \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}^{\circ}} D^{\prime}$ and $D \widehat{R_{o p}} D^{\prime}\left(\right.$ and $D^{\prime} \widehat{R_{o p}} D$ when $o p=\approx$ ).

Proof. By definition of $\mathcal{P} R_{o p} \mathcal{P}^{\prime}$, we know that there exist $(\mathcal{Q}, \phi),\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right) \in \mathcal{S} \mathcal{P}_{\ell}, \mathcal{P}_{\text {Att }} \in$ $\mathcal{S P}$, a renaming of variables $\rho$ and two substitutions $\sigma, \sigma^{\prime}$ such that $(\mathcal{Q}, \phi) o p^{\mathbb{N}^{\ell}}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)$, $\mathcal{P}=\mathcal{Q} \rho \cup \mathcal{P}_{A t t} \sigma \rho, \mathcal{P}^{\prime}=\mathcal{Q}^{\prime} \rho \cup \mathcal{P}_{a t t} \sigma^{\prime} \rho,|\phi|=\left|\phi^{\prime}\right|, f v\left(\mathcal{P}_{A t t}\right) \subseteq\left\{x_{1}, \ldots, x_{n}\right\}, \sigma=\left\{{ }^{\mathrm{ax}}{ }_{i} \phi / x_{i}\right\}_{i=1}^{n} \rho$, $\sigma^{\prime}=\left\{a^{i} \phi^{\prime} / x_{i}\right\}_{i=1}^{n} \rho, \operatorname{dom}(\rho) \subseteq \mathcal{N}_{\text {pub }}, \operatorname{img}(\rho) \subseteq \mathcal{N}_{\text {priv }}$ and $\operatorname{img}(\rho) \cap \operatorname{names}\left(\mathcal{Q}, \mathcal{Q}^{\prime}\right)=\varnothing$

Let us do a case analysis on the rule applied in $\mathcal{P} \xrightarrow{\tau}_{\mathrm{N}^{\circ}} D$.

 and for all $\left(\mathcal{Q}^{\prime \prime}, \phi\right) \in \operatorname{supp}\left(D_{2}\right), \operatorname{img}(\rho) \cap \operatorname{names}\left(\mathcal{Q}^{\prime \prime}\right)=\varnothing$. By hypothesis, $(\mathcal{Q}, \phi) o p^{\mathrm{N}^{\ell}}$
 $o p=\approx$ ). By the semantics of $\xrightarrow{\tau}_{\mathrm{N}^{e}}$ in Figure 10 and by Lemma 34, we obtain that for all $\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime \prime}\right) \in \operatorname{supp}\left(D_{2}^{\prime}\right), \phi^{\prime}=\phi^{\prime \prime}$ and we can assume w.l.o.g. that $\operatorname{img}(\rho) \cap \operatorname{names}\left(\mathcal{Q}^{\prime \prime}\right)=\varnothing$ (i.e. when the rule (NEW) generates a new private names, we can always pick one that is not in $\operatorname{img}(\rho))$.

Hence, we also deduce that $\mathcal{Q}^{\prime} \rho \Longrightarrow_{\mathrm{r}, \mathrm{N}^{\circ}} \sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}\left(D_{2}^{\prime}\right)} D_{2}^{\prime}\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho}$. Therefore $\mathcal{Q}^{\prime} \rho \cup \mathcal{P}_{A t t} \sigma^{\prime} \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}^{\circ}} \sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}\left(D_{2}^{\prime}\right)} D_{2}^{\prime}\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho \cup \mathcal{P}_{A t t} \sigma^{\prime}}$. Let us denote $D^{\prime}=$ $\sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}\left(D_{2}^{\prime}\right)} D_{2}^{\prime}\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho \cup \mathcal{P}_{A t t} \sigma^{\prime}}$. We conclude by applying Lemma 52 that $D \widehat{R_{o p}} D^{\prime}$ (and $D^{\prime} \widehat{R_{o p}} D$ when $o p=\approx$ ).
Case of a rule solely applied on $\mathcal{P}_{\text {Att }} \sigma$ : In such a case $\mathcal{P}_{A t t} \sigma \xrightarrow{\tau}_{\mathrm{N}^{\circ}} D_{1}$ such that $D=$ $\sum_{\mathcal{P}_{A t t}^{\prime} \in \mathcal{S P}} D_{1}\left(\mathcal{P}_{A t t}^{\prime}\right) \cdot \delta_{\mathcal{Q}^{\prime} \rho \cup \mathcal{P}_{A t t}^{\prime}}$. We first show that there exists a renaming $\rho^{\prime}$ with $\operatorname{dom}\left(\rho^{\prime}\right) \subseteq$ $\mathcal{N}_{\text {pub }}, \operatorname{img}\left(\rho^{\prime}\right) \subseteq \mathcal{N}_{\text {priv }}$ and $\operatorname{img}\left(\rho^{\prime}\right) \cap \operatorname{names}\left(\mathcal{Q}, \mathcal{Q}^{\prime}\right)=\varnothing$ such that:

- for all $\mathcal{P}_{A t t}^{\prime} \in \operatorname{supp}\left(D_{1}\right)$, there exists a multiset of process $\overline{\mathcal{P}_{A t t}^{\prime}}$ such that $\mathcal{P}_{A t t}^{\prime}=$ $\overline{\mathcal{P}_{A t t}^{\prime}}\left\{\mathrm{ax}_{i} \phi / x_{i}\right\}_{i=1}^{n} \rho^{\prime}, f n\left(\mathcal{P}_{A t t}^{\prime \prime}\right) \subseteq \mathcal{N}_{p u b}$ and $f v\left(\mathcal{P}_{A t t}^{\prime \prime}\right) \subseteq\left\{x_{1}, \ldots, x_{n}\right\}$
- $\mathcal{P}_{A t t} \sigma^{\prime} \xrightarrow{\tau}_{\mathrm{N}^{o}} \sum_{\mathcal{P}_{A t t}^{\prime} \in \operatorname{supp}\left(D_{1}\right)} D_{1}\left(\mathcal{P}_{A t t}^{\prime}\right) \cdot \delta_{\overline{\mathcal{P}}_{A t t}^{\prime}\left\{\left\{^{\left\{x_{i} \phi^{\prime}\right.} / x_{i}\right\}_{i=1}^{n} \rho^{\prime}\right.}$

We do a case analysis on the rule applied in $\mathcal{P}_{A t t} \sigma{ }^{\tau}{ }_{\mathrm{N}}{ }^{\circ} D_{1}$. The cases of the rules (NULL), (Par), (Repl), (Choice-1), (Choice-2) and (PChoice) are trivial by taking $\rho^{\prime}=\rho$. Note that in all these cases but (PChoice), $D_{1}$ is in fact a dirac.

Let us now look at the rule (Comm): In such a case, $\mathcal{P}_{\text {Att }}=\{\operatorname{out}(u, t) . P, \operatorname{in}(v, x) \cdot Q\} \cup$ $\mathcal{P}_{A t t, 1}, \mathcal{P}_{A t t}^{\prime}=\{\{P \sigma, Q \sigma\{t \sigma / x\}\}\} \cup \mathcal{P}_{A t t}^{\prime} \sigma, D_{1}=\delta_{\mathcal{P}_{A t t}^{\prime}}, M s g(t \sigma)$ and $u \sigma \doteq v \sigma$. Note that $t \sigma=t \phi \rho, u \sigma=u \phi \rho$ and $v \sigma=v \phi \rho$. Since both $\doteq$ and $\operatorname{Msg}(\cdot)$ are closed under renaming, we deduce that $u \phi \doteq v \phi$ and $\operatorname{Msg}(t \phi)$. Furthermore, $f n(t, u, v) \subseteq \mathcal{N}_{p u b}$ meaning that $t, u, v$ are recipes. Since we know by hypothesis that $(\mathcal{Q}, \phi) o p^{\mathbb{N}^{\ell}}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)$, we deduce that $u \phi \doteq v \phi$ implies $u \phi^{\prime} \doteq v \phi^{\prime}$, and $M s g(t \phi)$ implies $M s g\left(t \phi^{\prime}\right)$. Once again, by the closure under renaming argument, we obtain that $u \phi^{\prime} \rho \doteq v \phi^{\prime} \rho$ and $\operatorname{Msg}\left(t \phi^{\prime} \rho\right)$. This allows us to deduce that $\mathcal{P}_{A t t} \sigma^{\prime} \xrightarrow{\tau}{ }^{\circ} \delta_{\left\{P \sigma^{\prime}, Q \sigma^{\prime}\left\{t \sigma^{\prime} / x\right\}\right\} \cup \mathcal{P}_{A t t}^{\prime}}$, and so we conclude by taking $\rho^{\prime}=\rho$ and $\overline{\mathcal{P}_{A t t}^{\prime}}=\left\{\left\{P, Q\left\{{ }^{t} / x\right\}\right\} \cup \cup \mathcal{P}_{A t t, 1}\right.$.

The cases of the rules (THEN) and (ElSE) are done similarly since the condition to apply the rule only depend on the success or not of an equality $\doteq$.

Finally, let us consider the rule (New): In such a case, $\mathcal{P}_{\text {Att }}=\{$ new $a . P\} \cup \mathcal{P}_{A t t, 1}$, $\mathcal{P}_{A t t}^{\prime}=\left\{\left\{P \sigma\left\{a^{a^{\prime}} / a\right\}\right\} \cup \mathcal{P}_{A t t, 1} \sigma\right.$ and $D_{1}=\delta_{\mathcal{P}_{A t t}^{\prime}}$ where $a^{\prime}$ is fresh. W.l.o.g., we can take $a^{\prime}$ such that $a^{\prime} \notin \operatorname{names}\left(\mathcal{Q}, \mathcal{Q}^{\prime}, \phi, \phi^{\prime}\right)$. We take a new fresh name $a_{p u b} \in \mathcal{N}_{p u b}$ and we conclude by defining $\rho^{\prime}=\rho\left\{a_{p u b} \mapsto a^{\prime}\right\}$ and $\overline{\mathcal{P}_{A t t}^{\prime}}=\left\{\left\{P\left\{a_{p u b} / a\right\}\right\} \cup \mathcal{P}_{A t t, 1}\right.$.

We have therefore proved that:

- $\mathcal{P}_{A t t} \sigma \xrightarrow{\tau}_{N^{o}} \sum_{\mathcal{P}_{A t t}^{\prime} \in \operatorname{supp}\left(D_{1}\right)} D_{1}\left(\mathcal{P}_{A t t}^{\prime}\right) \cdot \delta_{\overline{\mathcal{P}}_{\overline{A t t}}^{\prime}\left\{\mathrm{T}_{i} \phi \mid x_{i}\right\}_{i=1}^{n} \rho^{\prime}}$

$$
\text { - } \mathcal{P}_{A t t} \sigma^{\prime} \xrightarrow{\tau}_{\mathrm{N}^{o}} \sum_{\mathcal{P}_{A t t}^{\prime} \in \operatorname{supp}\left(D_{1}\right)} D_{1}\left(\mathcal{P}_{A t t}^{\prime}\right) \cdot \delta_{\overline{\mathcal{P}}_{A t t}^{\prime}\left\{\left\{^{\left\{x_{i} \phi^{\prime}\right.} / x_{i}\right\}_{i=1}^{n} \rho^{\prime}\right.}
$$

Since $\mathcal{Q} \rho=\mathcal{Q} \rho^{\prime}$ and $\mathcal{Q}^{\prime} \rho=\mathcal{Q}^{\prime} \rho^{\prime}$, we obtain:

- $\mathcal{P}_{A t t} \sigma \cup \mathcal{Q} \rho{\xrightarrow{\tau} \mathbb{N}^{o}} \sum_{\mathcal{P}_{A t t}^{\prime} \in \operatorname{supp}\left(D_{1}\right)} D_{1}\left(\mathcal{P}_{A t t}^{\prime}\right) \cdot \delta_{\left.\mathcal{Q}^{\prime} \cup \overline{\mathcal{P}_{A t t}^{\prime}}{ }^{\left\{\mathrm{Q}_{i} \phi\right.} / x_{i}\right\}_{i=1}^{n} \rho^{\prime}}=D$
- $\mathcal{P}_{A t t} \sigma^{\prime} \cup \mathcal{Q}^{\prime} \rho \xrightarrow{\tau}_{N^{o}} \sum_{\mathcal{P}_{A t t}^{\prime} \in \operatorname{supp}\left(D_{1}\right)} D_{1}\left(\mathcal{P}_{A t t}^{\prime}\right) \cdot \delta_{\mathcal{Q}^{\prime} \rho^{\prime} \cup \overline{\mathcal{P}_{A t t}^{\prime}}}{ }^{\left.\mathrm{ax} \phi^{\prime} \phi^{\prime} / x_{i}\right\}_{i=1}^{n} \rho^{\prime}}$

Note that for all $\mathcal{P}_{A t t}^{\prime} \in \operatorname{supp}\left(D_{1}\right)$, by $(\mathcal{Q}, \phi) o p^{\mathrm{N}^{\ell}}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)$ and by construction of $\rho^{\prime}$ and $\overline{\mathcal{P}_{A t t}^{\prime}}$, we have that:

$$
\mathcal{Q} \rho^{\prime} \cup \overline{\mathcal{P}_{A t t}^{\prime}}\left\{\left\{^{\mathrm{ax}}{ }_{i} \phi / x_{i}\right\}_{i=1}^{n} \rho^{\prime} R_{o p} \mathcal{Q}^{\prime} \rho^{\prime} \cup \overline{\mathcal{P}_{A t t}^{\prime}}\left\{\mathrm{ax}_{i} \phi^{\prime} / x_{i}\right\}_{i=1}^{n} \rho^{\prime}\right.
$$

Note that when $o p=\approx,(\mathcal{Q}, \phi) o p^{\mathrm{N}^{\ell}}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)$ implies $\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right) o p^{\mathrm{N}^{\ell}}(\mathcal{Q}, \phi)$ and so we also have:

$$
\mathcal{Q}^{\prime} \rho^{\prime} \cup \overline{\mathcal{P}_{A t t}^{\prime}}\left\{\mathrm{ax}_{i} \phi^{\prime} / x_{i}\right\}_{i=1}^{n} \rho^{\prime} R \approx \mathcal{Q} \rho^{\prime} \cup \overline{\mathcal{P}_{A t t}^{\prime}}\left\{\mathrm{ax}_{i} \phi / x_{i}\right\}_{i=1}^{n} \rho^{\prime}
$$

By denoting $D^{\prime}=\sum_{\mathcal{P}_{A t t}^{\prime} \in \operatorname{supp}\left(D_{1}\right)} D_{1}\left(\mathcal{P}_{A t t}^{\prime}\right) \cdot \delta_{\mathcal{Q}^{\prime} \rho^{\prime} \cup \overline{\mathcal{P}_{A t t}^{\prime}}\left\{\mathrm{Q}^{\prime} x_{i} \phi^{\prime} / x_{i}\right\}_{i=1}^{n} \rho^{\prime}}$, we conclude that $D \widehat{R_{o p}} D^{\prime}$ and $\mathcal{P}_{A t t} \sigma^{\prime} \cup \mathcal{Q}^{\prime} \rho \Longrightarrow_{\mathrm{r}, \mathrm{N}^{\circ}} D^{\prime}\left(\right.$ and $D^{\prime} \widehat{R_{o p}} D$ when $o p=\approx$ )
Case of rule (Comm) between an output on $\mathcal{Q} \rho$ and an input on $\mathcal{P}_{\text {Att }} \sigma$ : In such a case $\mathcal{Q}=\{\operatorname{out}(u, t) . P\} \cup \cup \mathcal{Q}_{1}, \mathcal{P}_{A t t}=\left\{\{\operatorname{in}(v, x) . Q\} \cup \mathcal{P}_{A t t, 1}, D=\delta_{\{P \rho, Q \sigma\{t \rho / x\}\} \cup \mathcal{P}_{A t t, 1} \sigma \cup \mathcal{Q}_{1} \rho}\right.$, $\operatorname{Msg}(t \rho)$ and $v \sigma \doteq u \rho$. Note that $f n(v) \subseteq \mathcal{N}_{p u b}$ and $f v(v) \subseteq\left\{x_{1}, \ldots, x_{n}\right\}$. If we denote $\rho_{\mathcal{A X}}=\left\{x_{i} \mapsto \mathrm{ax}_{i}\right\}_{i=1}^{n}$, we obtain that $v \rho_{\mathcal{A X}}$ is a recipe with $f v\left(v \rho_{\mathcal{A X}}\right) \subseteq \operatorname{dom}(\phi)$. Note that since $\operatorname{Msg}(\cdot)$ and $\doteq$ are closed by renaming, we deduce from $\operatorname{Msg}(t \rho)$ and $v \sigma \doteq u \rho$ that $\operatorname{Msg}(t)$ and $v \rho_{\mathcal{A X}} \phi \doteq u$. Thus, $(\mathcal{Q}, \phi) \xrightarrow{\text { out }\left(v \rho_{\mathcal{A X}}, \mathrm{ax}_{n+1}\right)} \mathrm{N}^{\ell} \delta_{\left(\{\mathbb{\{}\} \cup \mathcal{Q}_{1}, \phi\left\{\mathrm{ax}_{n+1} \mapsto t\right\}\right)}=D_{1}$.

Let $x_{n+1}$ be a fresh variable. If we define $\phi_{1}=\phi\left\{\mathrm{ax}_{n+1} \mapsto t\right\}, \mathcal{P}_{A t t, 2}=\left\{\left\{Q\left\{x_{n+1} / x\right\}\right\} \cup\right.$ $\mathcal{P}_{A t t, 1}$ and $\sigma_{1}=\left\{{ }^{\mathrm{ax}}{ }_{i} \phi_{1} / x_{i}\right\}_{i=1}^{n+1} \rho$ then we obtain that $D=\delta_{\left(\{P\} \cup \mathcal{Q}_{1}\right) \rho \cup \mathcal{P}_{A t t, 2} \sigma_{1}}$. Notice that $f v\left(\mathcal{P}_{A t t, 2}\right) \subseteq\left\{x_{1}, \ldots, x_{n+1}\right\}$ and $f n\left(\mathcal{P}_{A t t, 2}\right) \subseteq \mathcal{N}_{p u b}$.

By hypothesis, we have $(\mathcal{Q}, \phi) o p^{N^{\ell}}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)$. Thus, there exists $D_{1}^{\prime}$ such that $\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)$ $\xlongequal{\text { out }\left(v \rho_{\mathcal{A X}}, \mathrm{ax} x_{n+1}\right)}{ }_{\mathrm{r}, \mathrm{N}^{\ell}} D_{1}^{\prime}$ and $D_{1} \widehat{o p^{N^{\ell}}} D_{1}^{\prime}$ (and $D_{1}^{\prime} \widehat{o p^{N^{\ell}}} D_{1}$ when $o p=\approx$ ). By definition, there

By the semantics of ${ }^{\tau}{ }_{N^{\ell}}$ in Figure 10 and by Lemma 34 , we obtain that for all $\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime \prime}\right) \in$ $\operatorname{supp}(E), \phi^{\prime}=\phi^{\prime \prime}$ and we can assume w.l.o.g. that $\operatorname{img}(\rho) \cap \operatorname{names}\left(\mathcal{Q}^{\prime \prime}\right)=\varnothing$ (i.e. when the rule (NEw) generates a new private name, we can always pick one that is not in $\operatorname{img}(\rho)$ ). Hence, we also deduce that $\mathcal{Q}^{\prime} \rho \Longrightarrow_{\mathrm{r}, \mathrm{N}^{o}} \sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}(E)} E\left(\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right)\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho}$. Therefore $\mathcal{Q}^{\prime} \rho \cup$ $\mathcal{P}_{A t t} \sigma^{\prime}{ }_{\mathrm{r}, \mathrm{N}^{\circ}} \sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}(E)} E\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho \cup \mathcal{P}_{A t t} \sigma^{\prime}}$.

Note that $D_{1} \widehat{o p^{\mathrm{N}^{\ell}}} D_{1}^{\prime}$ and $D_{1}$ being a distribution imply that $E, F$ and $D_{1}^{\prime}$ are also distributions. Thus for all $\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}(E)$, there exist $u^{\prime}, t^{\prime}, P^{\prime}, \mathcal{Q}^{\prime \prime \prime}$ such that $\mathcal{Q}^{\prime \prime}=\left\{\right.$ out $\left.\left.\left(u^{\prime}, t^{\prime}\right) \cdot P^{\prime}\right\}\right\} \cup \mathcal{Q}^{\prime \prime \prime}$ such that $u^{\prime} \doteq v \rho_{\mathcal{A X}} \phi^{\prime}, M s g\left(t^{\prime}\right)$ and $\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \xrightarrow{\text { out }\left(v \rho_{\mathcal{A X}}, a x_{n+1}\right)}{ }_{N}{ }^{e}$ $\delta_{\left.\left(\left\{P^{\prime}\right\}\right\} \cup \mathcal{Q}^{\prime \prime \prime}, \phi^{\prime}\left\{\mathrm{ax}_{n+1} \mapsto t^{\prime}\right\}\right)}$ with $\left(\left\{\left\{P^{\prime}\right\}\right\} \cup \mathcal{Q}^{\prime \prime \prime}, \phi^{\prime}\left\{\mathrm{ax}_{n+1} \mapsto t^{\prime}\right\}\right) \in \operatorname{supp}(F)$. Since $u^{\prime} \doteq v \rho_{\mathcal{A X}} \phi^{\prime}$ and $M s g\left(t^{\prime}\right)$ imply $u^{\prime} \rho \doteq v \sigma^{\prime}$ and $M s g\left(t^{\prime} \rho\right)$, we deduce that $\mathcal{Q}^{\prime \prime} \rho \cup\left\{\operatorname{in}\left(v \sigma^{\prime}, x\right) \cdot Q \sigma^{\prime}\right\} \cup \mathcal{P}_{A t t, 1} \sigma^{\prime} \xrightarrow{\tau}_{N^{o}}$
 we obtain $\mathcal{Q}^{\prime \prime} \rho \cup\left\{\left\{\operatorname{in}\left(v \sigma^{\prime}, x\right) \cdot Q \sigma^{\prime}\right\} \cup \mathcal{P}_{A t t, 1} \sigma^{\prime} \xrightarrow{\tau}_{\mathrm{N}^{o}} \delta_{\left(\left\{P^{\prime}\right\} \cup \mathcal{Q}^{\prime \prime \prime}\right) \rho \cup \mathcal{P}_{A t t, 2} \sigma_{1}^{\prime}}\right.$.

We have therefore proved that:

$$
\sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}(E)} E\left(\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right)\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho \cup \mathcal{P}_{A t t} \sigma^{\prime}}{ }_{r, N^{o}} \sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime \prime}\right) \in \operatorname{supp}(F)} F\left(\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime \prime}\right)\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho \cup \mathcal{P}_{A t t, 2}\left\{^{\left\{\mathrm{ax}_{i} \phi^{\prime \prime}\right.} / x_{i}\right\}_{i=1}^{n+1} \rho}
$$

Note that $F \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}^{\ell}} D_{1}^{\prime}$. Once again by the semantics of ${\stackrel{\tau}{\mathrm{N}^{e}}}$ in Figure 10 and by Lemma 34 , we can easily show that:

$$
\begin{aligned}
& \sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime \prime}\right) \in \operatorname{supp}(F)} F\left(\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right)\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho \cup \mathcal{P}_{A t t, 2}\left\{\left\{^{\left\{\mathrm{ax}_{i} \phi^{\prime \prime} / x_{i}\right\}_{i=1}^{n+1} \rho}{ }^{\tau}{ }_{\mathrm{r}, \mathrm{~N}^{o}} .\right.\right.} \\
& \sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime \prime}\right) \in \operatorname{supp}\left(D_{1}^{\prime}\right)} D_{1}^{\prime}\left(\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime \prime}\right)\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho \cup \mathcal{P}_{A t t, 2}\left\{\left\{^{2 \mathrm{x}_{i} \phi^{\prime \prime}} / x_{i}\right\}_{i=1}^{n+1} \rho\right.}
\end{aligned}
$$

Let us denote $D^{\prime}=\sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime \prime}\right) \in \operatorname{supp}\left(D_{1}^{\prime}\right)} D_{1}^{\prime}\left(\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime \prime}\right)\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho \cup \mathcal{P}_{A t t, 2}\left\{{ }^{\left\{x_{i} \phi^{\prime \prime}\right.} / x_{i}\right\}_{i=1}^{n+1} \rho}$. We conclude by applying Lemma 52 that $D \widehat{R_{o p}} D^{\prime}$ (and $D^{\prime} \widehat{R_{o p}} D$ when $o p=\approx$ ).
Case of rule (Comm) between an input on $\mathcal{Q} \rho$ and an output on $\mathcal{P}_{\text {Att }} \sigma$ : In such a case $\mathcal{Q}=$ $\{\operatorname{in}(v, x) . Q\} \cup \mathcal{Q}_{1}, \mathcal{P}_{A t t}=\{\operatorname{out}(u, t) . P\} \cup \mathcal{P}_{A t t, 1}, D=\delta_{\{P \sigma, Q \rho\{t \sigma / x\}\} \cup \mathcal{P}_{A t t, 1 \sigma} \cup \mathcal{Q}_{1} \rho}, M s g(t \sigma)$ and $v \rho \doteq u \sigma$. Note that $f n(u, t) \subseteq \mathcal{N}_{\text {pub }}$ and $f v(u, t) \subseteq\left\{x_{1}, \ldots, x_{n}\right\}$. If we denote $\rho_{\mathcal{A X}}=$ $\left\{x_{i} \mapsto \mathrm{ax}_{i}\right\}_{i=1}^{n}$, we obtain that $u \rho_{\mathcal{A X}}$ and $t \rho_{\mathcal{A X}}$ are recipes with $f v\left(u \rho_{\mathcal{A X}}, t \rho_{\mathcal{A X}}\right) \subseteq \operatorname{dom}(\phi)$. Note that since $\operatorname{Msg}(\cdot)$ and $\doteq$ are closed by renaming, we deduce from $\operatorname{Msg}(t \sigma)$ and $v \rho \doteq u \sigma$ that $M s g\left(t \rho_{\mathcal{A X}} \phi\right)$ and $v \doteq u \rho_{\mathcal{A X}} \phi$. Thus, $(\mathcal{Q}, \phi) \xrightarrow{i n\left(u \rho_{\mathcal{A X}}, t \rho_{\mathcal{A X}}\right)}{ }_{N^{\ell}} \delta_{\left(\left\{Q\left\{{ }^{\left.\left.\left.t \rho_{\mathcal{A X}}{ }^{\phi} / x\right\}\right\} \cup \mathcal{Q}_{1}, \phi\right)}\right.\right.\right.}=D_{1}$.

If we define $\mathcal{P}_{A t t, 2}=\{\{P\}\} \cup \mathcal{P}_{A t t, 1}$ then we obtain that $D=\delta_{\left(\left\{Q\left\{{ }^{\left.\left.t \rho_{\mathcal{A X}}{ }^{\phi} / x\right\}\right\}}{ }^{(x)} \cup \mathcal{Q}_{1}\right) \rho \cup \mathcal{P}_{A t t, 2} \sigma\right.\right.}$. Notice that $f v\left(\mathcal{P}_{A t t, 2}\right) \subseteq\left\{x_{1}, \ldots, x_{n}\right\}$ and $f n\left(\mathcal{P}_{A t t, 2}\right) \subseteq \mathcal{N}_{p u b}$.

By hypothesis, we have $(\mathcal{Q}, \phi) o p^{N^{\ell}}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)$. Thus, there exists $D_{1}^{\prime}$ such that $\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)$ $\xlongequal{i n\left(u \rho_{\mathcal{A X}}, t \rho_{\mathcal{A X}}\right)}{ }_{\mathrm{r}, \mathrm{N}^{\ell}} D_{1}^{\prime}$ and $D_{1} \widehat{o p^{N^{\ell}}} D_{1}^{\prime}$ (and $D_{1}^{\prime} \widehat{o p^{N^{\ell}}} D_{1}$ when $o p=\approx$ ). By definition, there

By the semantics of $\xrightarrow{\tau}_{N^{e}}$ in Figure 10 and by Lemma 34 , we obtain that for all $\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime \prime}\right) \in$ $\operatorname{supp}(E), \phi^{\prime}=\phi^{\prime \prime}$ and we can assume w.l.o.g. that $\operatorname{img}(\rho) \cap \operatorname{names}\left(\mathcal{Q}^{\prime \prime}\right)=\varnothing$ (i.e. when the rule (NEW) generates a new private name, we can always pick one that is not in $\operatorname{img}(\rho)$ ).
 $\mathcal{P}_{A t t} \sigma^{\prime}{ }_{\tau}^{\tau} \mathrm{N}^{\circ} \sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}(E)} E\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho \cup \mathcal{P}_{A t t} \sigma^{\prime}}$.

Note that $D_{1} \widehat{o p^{\mathrm{N}^{\ell}}} D_{1}^{\prime}$ and $D_{1}$ being a distribution imply that $E, F$ and $D_{1}^{\prime}$ are also distributions. Thus for all $\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}(E)$, there exist $v^{\prime}, x^{\prime}, Q^{\prime}, \mathcal{Q}^{\prime \prime \prime}$ such that $\mathcal{Q}^{\prime \prime}=\left\{\left\{\operatorname{in}\left(v^{\prime}, x^{\prime}\right) \cdot Q^{\prime}\right\} \cup \cup \mathcal{Q}^{\prime \prime \prime}\right.$ such that $v^{\prime} \doteq u \rho_{\mathcal{A X}} \phi^{\prime}, M \operatorname{sg}\left(t \rho_{\mathcal{A X}} \phi^{\prime}\right)$ and $\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \xrightarrow{i n\left(u \rho_{\mathcal{A X}}, t \rho_{\mathcal{A X}}\right)}{ }_{\mathrm{N}}{ }^{2}$ $\delta_{\left.\left(\left\{Q^{\prime}\left\{\rho_{\mathcal{A X}} \phi^{\prime} / x^{\prime}\right\}\right\}\right\} \cup \mathcal{Q}^{\prime \prime \prime}, \phi^{\prime}\right)}$ with $\left(\left\{Q^{\prime}\left\{\rho_{\mathcal{A X}} \phi^{\prime} / x^{\prime}\right\}\right\} \cup \mathcal{Q}^{\prime \prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}(F)$. Since $v^{\prime} \doteq u \rho_{\mathcal{A X}} \phi^{\prime}$ and $\operatorname{Msg}\left(t \rho_{\mathcal{A} \mathcal{X}} \phi^{\prime}\right)$ imply $v^{\prime} \rho \doteq u \sigma^{\prime}$ and $M s g\left(t \sigma^{\prime}\right)$, we deduce that $\mathcal{Q}^{\prime \prime} \rho \cup\left\{\operatorname{out}\left(u \sigma^{\prime}, t \sigma^{\prime}\right) \cdot P \sigma^{\prime}\right\} \cup$
 $\delta_{\left(\left\{Q^{\prime}\left\{\left\{^{t \mathcal{P}_{\mathcal{X}}}{ }^{\phi^{\prime}} /{ }_{x^{\prime}}\right\}\right\}\right\} \cup \mathcal{Q}^{\prime \prime \prime}\right) \rho \cup \mathcal{P}_{A t t, 2 \sigma^{\prime}} .}$

We have therefore proved that:

$$
\sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}(E)} E\left(\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right)\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho \cup \mathcal{P}_{A t t} \sigma^{\prime}}{\xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{~N}^{o}} \sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}(F)} F\left(\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right)\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho \cup \mathcal{P}_{A t t, 2} \sigma^{\prime}},}
$$

Note that $F \xlongequal{\tau}{ }_{\mathrm{r}, \mathrm{N}^{\ell}} D_{1}^{\prime}$. Once again by the semantics of $\stackrel{\tau}{\rightarrow}_{\mathrm{N}^{\ell}}$ in Figure 10 and by Lemma 34 , we can easily show that:

$$
\sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}(F)} F\left(\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right)\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho \cup \mathcal{P}_{A t t, 2 \sigma^{\prime}}}{\stackrel{\tau}{r}, \mathbb{N}^{\circ}}^{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}\left(D_{1}^{\prime}\right)} D_{1}^{\prime}\left(\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right)\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho \cup \mathcal{P}_{A t t, 2 \sigma^{\prime}}}
$$

Let us denote $D^{\prime}=\sum_{\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right) \in \operatorname{supp}\left(D_{1}^{\prime}\right)} D_{1}^{\prime}\left(\left(\mathcal{Q}^{\prime \prime}, \phi^{\prime}\right)\right) \cdot \delta_{\mathcal{Q}^{\prime \prime} \rho \cup \mathcal{P}_{A t t, 2^{\prime}}}$. We conclude by applying Lemma 52 that $D \widehat{R_{o p}} D^{\prime}$ (and $D^{\prime} \widehat{R_{o p}} D$ when $o p=\approx$ ).

Lemma 54. For all $o p \in\{\leq, \approx\}$, for all $\mathcal{P}, \mathcal{P}^{\prime} \in \mathcal{S} \mathcal{P}$, if $\mathcal{P} R_{o p} \mathcal{P}^{\prime}$ then for all $c \in \mathcal{N}_{\text {pub }}$, $\operatorname{RProb}_{\mathcal{R}_{r}^{o}}(\mathcal{P}, \downarrow c) \leq \operatorname{RProb}_{\mathcal{R}_{r}^{o}}\left(\mathcal{P}^{\prime}, \downarrow c\right)$.

Proof. By Lemma 41, $\operatorname{RProb}_{\mathcal{R}_{r}^{o}}(\mathcal{P}, \downarrow c)=\sup \left\{D(\downarrow c) \mid \delta_{\mathcal{P}} \xlongequal{\tau} D\right.$ with finite support $\}$.
Let $\mathcal{P} \xlongequal{\tau} D$ with finite support. By Lemma 53 and Property 4a of Lemma 37, we deduce that there exists $\mathcal{P}^{\prime} \Longrightarrow_{\mathrm{r}}^{\tau} D^{\prime}$ such that $D \widehat{R_{o p} D^{\prime} \text {. }}$

By definition of $D \widehat{R_{o p}} D^{\prime}$, we know that for all $\mathcal{P}_{1} \in \operatorname{supp}(D), \mathcal{P}_{1}^{\prime} \in \operatorname{supp}\left(D^{\prime}\right)$, there exist $\mathcal{P}_{\text {Att }}$, a renaming of variables $\rho$ and two extended processes $(\mathcal{Q}, \phi)$ and $\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)$ such that:

- $|\phi|=\left|\phi^{\prime}\right|=n$
- $(\mathcal{Q}, \phi) o p^{\mathbb{N}^{\ell}}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)$
- $\mathcal{P}_{1}=\mathcal{Q} \rho \cup \mathcal{P}_{A t t}\left\{{ }^{\mathrm{ax}}{ }_{i} \phi / x_{i}\right\}_{i=1}^{n} \rho$
- $\mathcal{P}_{1}^{\prime}=\mathcal{Q}^{\prime} \rho \cup \mathcal{P}_{A t t}\left\{{ }^{\mathrm{ax}_{i} \phi^{\prime}} /{ }_{x_{i}}\right\}_{i=1}^{n} \rho$

By construction, if $\mathcal{P}_{\text {Att }} \in \downarrow c$ then $\mathcal{P}_{1}, \mathcal{P}_{1}^{\prime} \in \downarrow c$. Otherwise, if $(\mathcal{Q}, \phi) \xrightarrow{\text { out }\left(c, \mathrm{a} \chi_{n+1}\right)} E$ then by Figure 10 , we know that $E$ is a dirac. But $(\mathcal{Q}, \phi) o p^{N^{\ell}}\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)$ implies that there exist $\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right) \xlongequal{\tau}_{\mathrm{r}} F_{1}$ and $F_{1} \xrightarrow{\text { out }(c, \mathrm{ax} n+1)} F_{2}$ and $F_{2} \xlongequal{\tau} E^{\prime}$ such that $E \widehat{o p^{\mathrm{N}^{\ell}}} E^{\prime}$. By definition of $\widehat{o p^{\mathrm{N}^{\ell}}}$ and since $E$ is a dirac, we deduce that $E^{\prime}$ is a distribution, which implies that both $F_{1}$ and $F_{2}$ are distributions. In particular, $F_{1} \xrightarrow{\text { out }\left(c, \mathrm{ax} x_{n+1}\right)} F_{2}$ tells us that $\sum_{\mathcal{Q}^{\prime \prime} \in \downarrow_{c}} F_{1}\left(\mathcal{Q}^{\prime \prime}\right)=1$. Note that the $\tau$ on $\left(\mathcal{Q}^{\prime}, \phi^{\prime}\right)$ carries over $\mathcal{P}_{1}^{\prime}$. Thus, there exists $H$ such that $\mathcal{P}_{1}^{\prime}{ }^{\tau}{ }_{\mathrm{r}} H$ and $H(\downarrow c)=1$.

Finally, let $S=\operatorname{supp}(D) \cap \downarrow c$. Since, $D \widehat{R_{o p}} D^{\prime}$, we deduce that $D(S) \leq D^{\prime}\left(R_{o p}(S)\right)$. As we have just show that for all $\mathcal{P}_{1}^{\prime} \in R_{o p}(S)$, there exists $H$ such that $\mathcal{P}_{1}^{\prime} \xlongequal{\tau}{ }_{\mathrm{r}} H$ with $H(\downarrow c)=1$, we deduce that there exists $D^{\prime \prime}$ such that $D^{\prime} \Longrightarrow_{\mathrm{r}} D^{\prime \prime}$ such that $D(S) \leq D^{\prime}\left(R_{o p}\right.$ $(S)) \leq D^{\prime \prime}(\downarrow c)$.

To summarize, we have show that for all $\mathcal{P} \Longrightarrow_{\mathrm{r}}^{\tau} D$ with finite support, there exists $\mathcal{P}^{\prime} \Longrightarrow_{\mathrm{r}}^{\tau} D^{\prime \prime}$ such that $D(\downarrow c) \leq D^{\prime \prime}(\downarrow c)$. Hence $\sup \left\{D(\downarrow c) \mid \delta_{\mathcal{P}} \Longrightarrow_{\mathrm{r}} D\right.$ with finite support $\} \leq$ $\sup \left\{D(\downarrow c) \mid \delta_{\mathcal{P}^{\prime}} \xlongequal{\tau}_{\mathrm{r}} D\right\}$. We conclude by applying again Lemma 41 .

## F. 5 Main result

Proposition 5. Let $\mathcal{P}, \mathcal{Q}$ two processes in $\mathcal{M} \mathcal{P}$.

$$
\mathcal{P} \leq_{o b s}^{\mathcal{R}_{r}} \mathcal{Q} \quad \text { iff } \quad(\mathcal{P}, \varnothing) \leq_{s i m}^{\mathcal{N}_{e}^{e}}(\mathcal{Q}, \varnothing) \quad \text { and } \quad \mathcal{P} \approx_{o b s}^{\mathcal{R}_{r}} \mathcal{Q} \quad \text { iff } \quad(\mathcal{P}, \varnothing) \approx_{b i}^{\mathcal{N e}^{e}}(\mathcal{Q}, \varnothing)
$$

Proof. The proof of observational preorder (resp. equivalence) implying simulation (resp. bisimulation) is directly given by application of Lemmas 44,45 and 50 .

Lemmas 51,53 and 54 directly gives that simulation (resp. bisimulation) implies $\leq_{o b s}^{r_{1}}$ (resp. $\approx_{o b s}^{\prime r_{1}}$ ). We conclude by Lemma 42 .

## G Non probabilistic processes

## G. 1 Hennessy-Milner's Logical caracterisation

We split the proof of Lemma 12 in two lemmas: Lemmas 55 and 57 below.
Lemma 55. Let $\mathcal{P}$ a non-probabilistic process, $\phi$ a frame. Let $F \in \mathcal{F}$. Let $o k \in \mathcal{N}_{\text {pub }}$ such that ok $\notin f n(\mathcal{P}, \phi, F)$. If $(\mathcal{P}, \phi) \models F$ then there exists a resolution $R=(Y, \operatorname{corr}, r)$, and $s \in Y$ such that $\operatorname{corr}(s)=\left(\mathcal{P} \cup\left\{\left\{A d v_{F,|\phi|}^{o k} \phi\right\}\right)\right.$ and $\operatorname{RProb}_{R}\left(s, \operatorname{corr}^{-1}(\downarrow o k)\right)=1$.

Proof. Let $n=|\phi|$. We do the proof by induction on the structure of the logical formula $F$.
Case $F=\top: A d v_{\top}^{o k} \in \downarrow o k$ hence the result directly holds.
Case $F=a . F^{\prime}$ : we suppose that $(\mathcal{P}, \phi) \models F$. Then by definition of formula validity, we know that there exists a state $(\mathcal{Q}, \psi)$ such that $(\mathcal{P}, \phi) \xrightarrow{\tau} \xrightarrow{*} \xrightarrow{\tau^{*}}(\mathcal{Q}, \psi)$, and $(\mathcal{Q}, \psi) \models F^{\prime}$. Using the induction hypothesis, we can deduce from $(\mathcal{Q}, \psi) \models F^{\prime}$ that there exists a pair $\left(R_{1}, s_{1}\right)$, where $R_{1}=\left(Y_{1}, \operatorname{corr}_{1}, r_{1}\right)$ is a resolution on the NPLTS $\mathrm{N}^{o}, s_{1} \in Y_{1}$ such that $\operatorname{corr}\left(s_{1}\right)=\mathcal{Q} \mid A d v_{F^{\prime}, n^{\prime}}^{o k} \psi$ and $\operatorname{RProb}_{R_{1}}\left(s_{1}, \operatorname{corr}_{1}^{-1}(\downarrow o k)\right)=1\left(\right.$ where $n^{\prime}=n+1$ when $a$ is an output and $n^{\prime}=n$ otherwise).

Moreover, we can deduce from $(\mathcal{P}, \phi) \xrightarrow{\tau} \xrightarrow{* a}{ }^{\tau}(\mathcal{Q}, \psi)$ that $A d v_{F, n}^{o k} \neq 0$ and there exists a sequence of steps:

$$
(\mathcal{P}, \phi) \xrightarrow{\tau}\left(\mathcal{P}_{1}^{\prime}, \phi\right) \ldots \xrightarrow{\tau}\left(\mathcal{P}_{n}^{\prime}, \phi\right) \xrightarrow{a}\left(\mathcal{P}_{1}^{\prime \prime}, \psi\right) \ldots \xrightarrow{\tau}\left(\mathcal{P}_{m}^{\prime \prime}, \psi\right) \xrightarrow{\tau}(\mathcal{Q}, \psi)
$$

Looking at the way we define the adversary $A d v_{F, n}^{o k}$ in Definition 27, we see that we can deduce:

$$
\begin{aligned}
& \left(\mathcal { P } \cup \{ \{ A d v _ { F , n } ^ { o k } \phi \} ) \xrightarrow [ \rightarrow ] { \tau } \left(\mathcal { P } _ { 1 } ^ { \prime } \cup \{ \{ A d v _ { F , n } ^ { o k } \phi \} ) \xrightarrow [ \rightarrow ] { \tau } \ldots \xrightarrow [ \rightarrow ] { \tau } \left(\mathcal{P}_{k}^{\prime} \cup\left\{\left\{A d v_{F, n}^{o k} \phi\right\}\right) \xrightarrow[\rightarrow]{\tau}\right.\right.\right. \\
& \quad\left(\mathcal { P } _ { 1 } ^ { \prime \prime } \cup \{ \{ A d v _ { F ^ { \prime } , n ^ { \prime } } ^ { o k } \psi \} ) \xrightarrow [ \rightarrow ] { \tau } \ldots \xrightarrow { \tau } \left(\mathcal { P } _ { m } ^ { \prime \prime } \cup \{ \{ A d v _ { F ^ { \prime } , n ^ { \prime } } ^ { o k } \psi \} ) \xrightarrow { \tau } \left(\mathcal{Q} \cup\left\{\left\{A d v_{F^{\prime}, n^{\prime}}^{o k} \psi\right\}\right)\right.\right.\right.
\end{aligned}
$$

We build a resolution $R=\left(Y, \operatorname{corr} r\right.$ ) on the NPLTS $\mathrm{N}^{o}$ as follows (our construction is graphically represented in Figure 11):

- $Y=Y_{1} \sqcup\{l(0), \ldots, l(k)\} \sqcup\{q(1), \ldots, q(m)\}$, where $\sqcup$ models disjoint union, and the $l(),. q($.$) are simply two disjoint copies of natural numbers;$
- corr $: Y \rightarrow \mathcal{M P}$ is defined as $\operatorname{corr}(y)=\operatorname{corr}_{1}(y)$ when $y \in Y_{1}, \operatorname{corr}(l(0))=(\mathcal{P} \cup$ $\left.\left\{\left\{A d v_{F, n}^{o k} \phi\right\}\right\}\right), \operatorname{corr}(l(i))=\left(\mathcal{P}_{k}^{\prime} \cup\left\{\left\{A d v_{F, n}^{o k} \phi\right\}\right\}\right)$ for $0<i \leq k ; \operatorname{corr}(q(j))=\left(\mathcal{P}_{j}^{\prime \prime} \cup\right.$ $\left\{\left\{A d v_{F^{\prime}, n^{\prime}}^{o k} \psi\right\}\right)$ for $1 \leq j \leq m$.
- $r: Y \rightarrow \mathcal{D}(Y)$ is defined as $r(y)=r_{1}(y)$ when $y \in Y_{1}, r(l(i))=\delta_{l(i+1)}$ for $0 \leq i \leq$ $k-1, r(l(k))=\delta_{q(1)}, r(q(j))=\delta_{q(j+1)}$ for $1 \leq j \leq m-1, r(q(k))=\delta_{s_{1}}$.

We can check that $R$ is indeed a resolution in the sense of Definition 5 , and that moreover:

$$
\begin{aligned}
\operatorname{RProb}_{R}\left(l(0), \operatorname{corr}^{-1}(\downarrow o k)\right) & =\operatorname{RProb}_{R}\left(s_{1}, \operatorname{corr}_{1}^{-1}(\downarrow o k)\right) \\
& =\operatorname{RProb}_{R_{1}}\left(s_{1}, \operatorname{corr}_{1}^{-1}(\downarrow o k)\right)=1
\end{aligned}
$$

Case $F=F_{1} \wedge F_{2}$ : we suppose that $(\mathcal{P}, \phi) \models F$. Then by definition of formula validity, we know that $(\mathcal{P}, \phi) \models F_{1}$ and $(\mathcal{P}, \phi) \models F_{2}$. By applying the induction hypothesis on $F_{1}$ and $F_{2}$, we obtain two resolution $R_{1}=\left(Y_{1}, \operatorname{corr}_{1}, r_{1}\right), R_{2}=\left(Y_{2}, \operatorname{corr}_{2}, r_{2}\right)$, and $s_{1} \in Y_{1}, s_{2} \in Y_{2}$ with $\operatorname{corr}_{1}\left(s_{1}\right)=\left(\mathcal{P} \cup\left\{\left\{A d v_{F_{1}, n}^{o k} \phi\right\}\right)\right.$ and $\operatorname{corr}_{2}\left(s_{2}\right)=\left(\mathcal{P} \cup\left\{\left\{A d v_{F_{2}, n}^{o k} \phi\right\}\right)\right.$ such that moreover:

$$
\begin{aligned}
& \operatorname{RProb}_{R_{1}}\left(s_{1}, \operatorname{corr}_{1}^{-1}(\downarrow o k)\right)=1 \\
& \operatorname{RProb}_{R_{2}}\left(s_{2}, \operatorname{corr}_{2}^{-1}(\downarrow o k)\right)=1
\end{aligned}
$$

We now build, using the resolution $R_{1}$ and $R_{2}$, a resolution $R$ as represented in Figure 12 ,

- $Y=Y_{1} \sqcup Y_{2} \sqcup\{l(0)\} ;$
- corr $: Y \rightarrow \mathcal{M P}$ is defined as $\operatorname{corr}(y)=\operatorname{corr}_{1}(y)$ when $y \in Y_{1}, \operatorname{corr}(y)=\operatorname{corr}_{2}(y)$ when $y \in Y_{2}, \operatorname{corr}(l(0))=\left(\mathcal{P} \cup\left\{A d v_{F, n}^{o k} \phi\right\}\right)$,
- $r: Y \rightarrow \mathcal{D}(Y)$ is defined as $r(y)=r_{1}(y)$ when $y \in Y_{1}, r(y)=r_{2}(y)$ when $y \in Y_{2}$, $r(l(0))=\frac{1}{2} \delta_{s_{1}}+\frac{1}{2} \delta_{s_{2}}$.

We can check that $R$ is indeed a resolution in the sense of Definition 5, and that moreover:

$$
\begin{aligned}
\operatorname{RProb}_{R}\left(l(0), \operatorname{corr}^{-1}(\downarrow o k)\right) & =\frac{1}{2} \cdot \operatorname{RProb}_{R}\left(s_{1}, \operatorname{corr}^{-1}(\downarrow o k)\right)+\frac{1}{2} \cdot \operatorname{RProb}_{R}\left(s_{2}, \operatorname{corr}^{-1}(\downarrow o k)\right) \\
& =\frac{1}{2} \cdot \operatorname{RProb}_{R}\left(s_{1}, \operatorname{corr}_{1}^{-1}(\downarrow o k)\right)+\frac{1}{2} \cdot \operatorname{RProb}_{R}\left(s_{2}, \operatorname{corr}_{2}^{-1}(\downarrow o k)\right) \\
& =1
\end{aligned}
$$

This allows us to conclude.
Lemma 56. Let $(\mathcal{P}, \phi)$ be a non-probabilistic extended process. Let $F \in \mathcal{F}$. If $(\mathcal{P}, \phi) \xrightarrow{\tau}{ }^{*}$ $\left(\mathcal{P}^{\prime}, \phi\right)$ and $\left(\mathcal{P}^{\prime}, \phi\right) \models F$ then $(\mathcal{P}, \phi) \models F^{\prime}$.

Figure 11: The resolution $R$ for the formula $a \cdot F^{\prime}$.

Figure 12: The resolution $R$ for the formula $F_{1}^{\prime} \wedge F_{2}^{\prime}$.

Proof. By induction on the structure of $F$ and by noticing that if $\left(\mathcal{P}^{\prime}, \phi\right) \xrightarrow{a}\left(\mathcal{Q}, \phi^{\prime}\right)$ in the LTS $\mathrm{L}^{\ell}$ then we also have $(\mathcal{P}, \phi) \xrightarrow{a}\left(\mathcal{Q}, \phi^{\prime}\right)$ in the LTS $\mathrm{L}^{\ell}$.

Lemma 57. Let $\mathcal{P}$ a non-probabilistic process, $\phi$ a frame. Let $F \in \mathcal{F}$. Let $o k \in \mathcal{N}_{p u b}$ such that ok $\notin f n(\mathcal{P}, \phi, F)$. If there exists a pair $(R, s)$ with $R=(Y, \operatorname{corr}, r) \in \mathcal{R}_{\mathrm{nr}}^{o}$, such that $\operatorname{corr}(s)=\left(\mathcal{P} \cup\left\{\left\{A d v_{F,|\phi|}^{o k} \phi\right\}\right)\right.$ and $\operatorname{RProb}_{R}\left(s, \operatorname{corr}^{-1}(\downarrow o k)\right)=1$ then $(\mathcal{P}, \phi) \models F$.

Proof. Let $n=|\phi|$. We do the proof by induction on the structure of $F$.
Case $F=T$ : we can see immediately that the result holds as the formula $T$ holds for all extended processes.
Case $F=a . F^{\prime}:$ Since $\operatorname{RProb}_{R}\left(s, \operatorname{corr}^{-1}(\downarrow o k)\right)=1$ and ok $\notin f n(\mathcal{P}, \phi, F)$, we deduce that $A d v_{F, n}^{o k} \neq 0$ and $A d v_{F, n}^{o k} \notin \downarrow o k$. Thus, using Lemma 23 and the fact that $\mathcal{P}$ is a nonprobabilistic process and the fact that $R$ is a non-randomized resolution, we deduce that there exist $\mathcal{P}_{1}, \ldots, \mathcal{P}_{k}, \mathcal{Q}, \phi^{\prime}$ and the following sequence

$$
s \xrightarrow{\tau} \delta_{s_{1}} \quad s_{1} \xrightarrow{\tau} \delta_{s_{2}} \quad \ldots s_{k-1} \xrightarrow{\tau} \delta_{s_{k}} \quad s_{k} \xrightarrow{\tau} \delta_{s_{a}}
$$

such that

- for all $i \in\{1, \ldots k\}, \operatorname{corr}\left(s_{i}\right)=\mathcal{P}_{i} \cup\left\{\left\{A d v_{F, n}^{o k} \phi\right\}\right.$
- $\mathcal{P} \xrightarrow{\tau} \delta_{\mathcal{P}_{1}}$
- for all $i \in\{1, \ldots, k-1\}, \mathcal{P}_{i} \xrightarrow{\tau} \delta_{\mathcal{P}_{i+1}}$
- $\operatorname{corr}\left(s_{a}\right)=\mathcal{Q} \cup\left\{\left\{A d v_{F^{\prime},\left|\phi^{\prime}\right|}^{o k} \phi^{\prime}\right\}\right.$
- $\left(\mathcal{P}_{k}, \phi\right) \xrightarrow{a} \delta_{\left(\mathcal{Q}, \phi^{\prime}\right)}$
- $\operatorname{RProb}_{R}\left(s_{a}, \operatorname{corr}^{-1}(\downarrow o k)\right)=1$

Note that here, $k$ can be equal to 0 and in that case $s \xrightarrow{\tau} \delta_{s_{a}}$. We deduce that $(\mathcal{P}, \phi) \xrightarrow{a}$ $\left(\mathcal{Q}, \phi^{\prime}\right)$ in the LTS $\mathrm{L}^{\ell}$. Using our inductive hypothesis on $F^{\prime}$ and the pair ( $R, s_{a}$ ), we deduce obtain that $\left(\mathcal{Q}, \phi^{\prime}\right) \models F^{\prime}$. By definition of the validity of a formula, we conclude that $(\mathcal{P}, \phi) \models a . F^{\prime}$.
Case $F=F_{1} \wedge F_{2}$ : Since $A d v_{F, n}^{o k}=A d v_{F_{1}, n}^{o k}+_{\frac{1}{2}} A d v_{F_{2}, n}^{o k}, A d v_{F, n}^{o k} \notin \downarrow o k$. Hence, using Lemma 23 and the fact that $\mathcal{P}$ is a non-probabilistic process and the fact that $R$ is a non-randomized resolution, we deduce from $\operatorname{RProb}_{R}\left(s, \operatorname{corr}^{-1}(\downarrow o k)\right)=1$ that there exist $\mathcal{P}_{1}, \ldots, \mathcal{P}_{k}, \mathcal{Q}, \phi^{\prime}$ and the following sequence

$$
s \xrightarrow{\tau} \delta_{s_{1}} \quad s_{1} \xrightarrow{\tau} \delta_{s_{2}} \quad \ldots s_{k-1} \xrightarrow{\tau} \delta_{s_{k}} \quad s_{k} \xrightarrow{\tau} \frac{1}{2} \delta_{s_{a_{1}}}+\frac{1}{2} \delta_{s_{a_{2}}}
$$

such that

- for all $i \in\{1, \ldots k\}, \operatorname{corr}\left(s_{i}\right)=\mathcal{P}_{i} \cup\left\{\left\{A d v_{F, n}^{o k} \phi\right\}\right.$
- $\mathcal{P} \xrightarrow{\tau} \delta_{\mathcal{P}_{1}}$
- for all $i \in\{1, \ldots, k-1\}, \mathcal{P}_{i} \xrightarrow{\tau} \delta_{\mathcal{P}_{i+1}}$
- $\operatorname{corr}\left(s_{a_{1}}\right)=\mathcal{P}_{k} \cup\left\{\left\{A d v_{F_{1}, n}^{o k} \phi\right\}\right.$
- $\operatorname{corr}\left(s_{a_{2}}\right)=\mathcal{P}_{k} \cup\left\{\left\{A d v_{F_{2}, n}^{o k} \phi\right\}\right.$
- $\operatorname{RProb}_{R}\left(s_{a_{1}}, \operatorname{corr}^{-1}(\downarrow\right.$ ok $\left.)\right)=1$
- $\operatorname{RProb}_{R}\left(s_{a_{2}}, \operatorname{corr}^{-1}(\downarrow o k)\right)=1$

By applying our inductive hypothesis on $F_{1}$ and the pair $\left(R, s_{a_{1}}\right)$, we obtain $\left(\mathcal{P}_{k}, \phi\right) \models F_{1}$. Similarly, we also obtain $\left(\mathcal{P}_{k}, \phi\right) \models F_{2}$. As $(\mathcal{P}, \phi) \xrightarrow{\tau}{ }^{*}\left(\mathcal{P}_{k}, \phi\right)$, we conclude by applying Lemma 56 that $(\mathcal{P}, \phi) \models F_{1} \wedge F_{2}$.

Lemma 12. Let $\mathcal{P} \in \mathcal{M} \mathcal{P}^{\mathrm{np}}$ and $o k \in \mathcal{N}_{\text {pub }}$ such that $o k \notin f n(\mathcal{P})$. For all formula $F \in \mathcal{F}$, we have

$$
(\mathcal{P}, \varnothing) \models F \quad \text { iff } \quad \operatorname{RProb}_{\mathcal{R}_{\mathrm{r}}}\left(\mathcal{P} \cup\left\{\left\{A d v_{F, 0}^{o k}\right\}, \downarrow o k\right)=1\right.
$$

Proof. Direct from Lemmas 19,55 and 57 .

## G. 2 Proposition 6

Lemma 58. Let $(\mathcal{P}, \phi)$ and ( $\mathcal{P}^{\prime}, \phi^{\prime}$ ) be two extended processes such that $\operatorname{dom}(\phi)=$ $\operatorname{dom}\left(\phi^{\prime}\right)$. Let $A \in \mathcal{M P}$ such that $f n(A) \subseteq \mathcal{N}_{\text {pub }}$ and $\operatorname{fv}(A) \subseteq \operatorname{dom}(\phi)$. If $\mathcal{P} \cup A \phi \rightarrow^{*} \mathcal{Q}$ then there exists $\left(\mathcal{P}_{1}, \phi_{1}\right) \in \mathcal{S} \mathcal{P}_{\ell}$, an adversarial process $A_{1}$ for $\operatorname{dom}\left(\phi_{1}\right)$ and a trace $w$ such that $\mathcal{Q}=\mathcal{P}_{1} \cup A_{1} \phi_{1},(\mathcal{P}, \phi) \xrightarrow{w}\left(\mathcal{P}_{1}, \phi_{1}\right)$ and for all recipes $\xi, \zeta$, if $\operatorname{vars}(\xi, \zeta) \subseteq \operatorname{dom}\left(\phi_{1}\right)$ and $\xi \phi_{1} \doteq \zeta \phi_{1}$ then

$$
\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \xrightarrow{w}\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right) \rightarrow_{\xi^{?}=\zeta}\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right) \text { implies } \mathcal{P}^{\prime} \cup A \phi^{\prime} \rightarrow^{*} \mathcal{P}_{1}^{\prime} \cup A_{1} \phi_{1}^{\prime}
$$

Proof. We prove this lemma by induction on the length of the derivation $\mathcal{P} \cup A \phi \rightarrow^{*} \mathcal{Q}$.
Base case $\ell=0$ : In such a case, $\mathcal{Q}=\mathcal{P} \cup A \phi$. We take $w=\varepsilon$ and $A_{1}=A$. Let $\xi, \zeta$ be recipes such that $\operatorname{vars}(\xi, \zeta) \subseteq \operatorname{dom}\left(\phi^{\prime}\right)$ and $\xi \phi \doteq \zeta \phi$. We conclude by noticing that $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \xrightarrow{\varepsilon}\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right) \rightarrow_{\xi=\zeta}^{?}\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right)$ implies $\phi^{\prime}=\phi_{1}^{\prime}$ and $\mathcal{P}^{\prime} \rightarrow^{*} \mathcal{P}_{1}^{\prime}$. Therefore, $\mathcal{P}^{\prime} \cup A \phi \rightarrow^{*}$ $\mathcal{P}_{1}^{\prime} \cup A_{1} \phi_{1}^{\prime}$.
Inductive step $\ell>0$ : In such a case, we have $\mathcal{P} \cup A \phi \rightarrow^{*} \mathcal{Q}_{2} \rightarrow \mathcal{Q}$ where the length of the derivation $\mathcal{P} \cup A \phi \rightarrow^{*} \mathcal{Q}_{2}$ is strictly smaller than $\ell$. We can apply our inductive hypothesis to obtain that there exist $\left(\mathcal{P}_{2}, \phi_{2}\right) \in \mathcal{S} \mathcal{P}_{\ell}$, an adversarial process $A_{2}$ for $\operatorname{dom}\left(\phi_{2}\right)$ and a trace $w_{2}$ such that $\mathcal{Q}_{2}=\mathcal{P}_{2} \cup A_{2} \phi_{2},(\mathcal{P}, \phi) \xrightarrow{w_{2}}\left(\mathcal{P}_{2}, \phi_{2}\right)$ and for all recipes $\xi^{\prime}$, $\zeta^{\prime}$, if $\operatorname{vars}\left(\xi^{\prime}, \zeta^{\prime}\right) \subseteq \operatorname{dom}\left(\phi_{2}\right)$ and $\xi^{\prime} \phi_{2} \doteq \zeta^{\prime} \phi_{2}$ then

$$
\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \stackrel{w_{2}}{\Longrightarrow}\left(\mathcal{P}_{2}^{\prime}, \phi_{2}^{\prime}\right) \rightarrow_{\xi^{\prime} \text { ? } \zeta^{\prime}}\left(\mathcal{P}_{2}^{\prime}, \phi_{2}^{\prime}\right) \text { implies } \mathcal{P}^{\prime} \cup A \phi^{\prime} \rightarrow^{*} \mathcal{P}_{2}^{\prime} \cup A_{2} \phi_{2}^{\prime}
$$

By taking $\xi^{\prime}=\zeta^{\prime} \in \mathcal{N}_{\text {pub }}$, we have that $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \stackrel{w_{2}}{\Longrightarrow}\left(\mathcal{P}_{2}^{\prime}, \phi_{2}^{\prime}\right)$ implies $\mathcal{P}^{\prime} \cup A \phi^{\prime} \rightarrow^{*} \mathcal{P}_{2}^{\prime} \cup A_{2} \phi_{2}^{\prime}$.
We do a case analysis on the rule applied in $\mathcal{P}_{2} \cup A_{2} \phi_{2} \rightarrow \mathcal{Q}$.
Case of an internal reduction on $\mathcal{P}_{2}$ : In such a case $\mathcal{P}_{2} \rightarrow \mathcal{P}_{1}$ and $\mathcal{P}_{Q}=\mathcal{P}_{1} \cup A_{2} \phi_{2}$. Let $A_{1}=A_{2}, \phi_{1}=\phi_{2}$ and $w=w_{2}$. Note that $\mathcal{P}_{2} \rightarrow \mathcal{P}_{1}$ implies $\left(\mathcal{P}_{2}, \phi_{2}\right) \rightarrow_{\tau}\left(\mathcal{P}_{1}, \phi_{1}\right)$ hence $(\mathcal{P}, \phi) \xrightarrow{w}\left(\mathcal{P}_{1}, \phi_{1}\right)$.

Let $\xi, \zeta$ be recipes such that $\operatorname{vars}(\xi, \zeta) \subseteq \operatorname{dom}\left(\phi_{1}\right)$. If $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \xrightarrow{w}\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right) \rightarrow_{\xi=\frac{?}{=}}\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right)$ then we can directly rely on our inductive hypothesis to conclude.

Case of an internal reduction on $A_{2} \phi_{2}$ : In such a case, there exists an adversarial process $A_{1}$ such that $A_{2} \phi_{2} \rightarrow A_{1} \phi_{2}$ and $\mathcal{P}_{Q}=\mathcal{P}_{1} \cup A_{1} \phi_{2}$. To define the trace we need to consider, let us look at the rule $A_{2} \phi_{2} \rightarrow A_{1} \phi_{2}$.

- Rule Then: In such a case, $A_{2}=A^{\prime} \cup\{$ if $u=v$ then $P$ else $Q\}$ and $A_{1}=A^{\prime} \cup\{\{P\}$. We define $w=w_{2} .(u \stackrel{?}{=} v)$.
- Rule Else: In such a case, $A_{1}=A^{\prime} \cup\{$ if $u=v$ then $P$ else $Q\}$ and $A_{1}=A^{\prime} \cup\{\{Q\}$. We define $w=w_{2} \cdot(u \stackrel{?}{\neq} v)$.
- Otherwise, we define $w=w_{2}$

Let $\phi_{1}=\phi_{2}$ and $\mathcal{P}_{1}=\mathcal{P}_{2}$. In the case of the rule Then (resp. Else), $A_{2} \phi_{2} \rightarrow A_{1} \phi_{2}$ implies that $u \phi_{2} \doteq v \phi_{2}\left(\right.$ resp. $\left.u \phi_{2} \neq v \phi_{2}\right)$. Hence $\left(\mathcal{P}_{2}, \phi_{2}\right) \rightarrow_{(u=v)}^{?}\left(\mathcal{P}_{1}, \phi_{1}\right)$ (resp. $\left(\mathcal{P}_{2}, \phi_{2}\right) \rightarrow_{(u \neq v)}^{?}$ $\left.\left(\mathcal{P}_{1}, \phi_{1}\right)\right)$ and so $(\mathcal{P}, \phi) \xrightarrow{w}\left(\mathcal{P}_{1}, \phi_{1}\right)$.

Let us now take $\xi, \zeta$ recipes such that $\operatorname{vars}(\xi, \zeta) \subseteq \operatorname{dom}\left(\phi_{1}\right)$ and $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \xrightarrow{w_{2}}\left(\mathcal{P}_{2}^{\prime}, \phi_{2}^{\prime}\right) \rightarrow_{a}$ $\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right) \rightarrow_{\xi \stackrel{?}{\xi} \zeta}\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right)$ with $a$ being either $(u \stackrel{?}{=} v)$ or $(u \stackrel{?}{\neq} v)$ or $\tau$ following the rule applied on $A_{2} \phi_{2} \rightarrow A_{1} \phi_{2}$. If $a=\tau$ then we trivially have that $\left(\mathcal{P}_{2}^{\prime}, \phi_{2}^{\prime}\right)=\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right)$ and $A_{2} \phi_{2}^{\prime} \rightarrow A_{1} \phi_{1}^{\prime}$. Hence, $\mathcal{P}_{2}^{\prime} \cup A_{2} \phi_{2}^{\prime} \rightarrow \mathcal{P}_{2}^{\prime} \cup A_{1} \phi_{1}^{\prime}$ and so the result holds.

If $a=(u \stackrel{?}{=} v)($ resp. $(u \neq v))$ then $\left(\mathcal{P}_{2}^{\prime}, \phi_{2}^{\prime}\right) \rightarrow_{a}\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right)$ implies that $\left(\mathcal{P}_{2}^{\prime}, \phi_{2}^{\prime}\right)=\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right)$ and $u \phi_{1}^{\prime} \doteq v \phi_{1}^{\prime}$ (resp. $u \phi_{1}^{\prime} \neq v \phi_{1}^{\prime}$ ). Hence, $A_{2} \phi_{2}^{\prime} \rightarrow A_{1} \phi_{1}^{\prime}$ which allows us to conclude.

Case of the rule (Comm) between $\mathcal{P}_{2}$ (input) and $A_{2} \phi_{2}$ (output): In such a case, we have $\mathcal{P}_{2}=\mathcal{P}_{3} \cup\left\{\{\operatorname{in}(c, x) . P\}\right.$ and $A_{2}=A_{3} \cup\left\{\{\operatorname{out}(u, v) . Q\}\right.$ with $\operatorname{Msg}\left(v \phi_{2}\right), u \phi_{2} \doteq c$, $\mathcal{P}_{1}=\mathcal{P}_{3} \cup\left\{\left\{P\left\{x \rightarrow v \phi_{2}\right\}\right\}\right\}$ and $A_{1}=A_{3} \cup\left\{\{Q\}\right.$. Therefore by denoting $\phi_{1}=\phi_{2}$, we have $\left(\mathcal{P}_{2}, \phi_{2}\right) \rightarrow_{\text {in }(u, v)}\left(\mathcal{P}_{1}, \phi_{1}\right)$. We define $w=w_{2} . i n(u, v)$.

Let us now take $\xi, \zeta$ recipes such that $\operatorname{vars}(\xi, \zeta) \subseteq \operatorname{dom}\left(\phi_{1}\right)$ and $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \xrightarrow{w_{2}}\left(\mathcal{P}_{2}^{\prime}, \phi_{2}^{\prime}\right)$ $\rightarrow_{\text {in }(u, v)}\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right) \rightarrow_{\xi^{\underline{?}} \zeta}\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right)$. By definition, we deduce that $\phi_{1}^{\prime}=\phi_{2}^{\prime}, \mathcal{P}_{2}^{\prime}=\mathcal{P}_{3}^{\prime} \cup$ $\left\{\operatorname{in}\left(c^{\prime}, x\right) . P^{\prime}\right\}, \mathcal{P}_{1}^{\prime}=\mathcal{P}_{3}^{\prime} \cup\left\{\left\{P^{\prime}\left\{x \rightarrow v \phi_{1}^{\prime}\right\}\right\}\right\}, c^{\prime} \doteq u \phi_{1}^{\prime}$ and $\operatorname{Msg}\left(v \phi_{1}^{\prime}\right)$. This allows us to conclude that $\mathcal{P}_{2}^{\prime} \cup A_{2} \phi_{2}^{\prime} \rightarrow \mathcal{P}_{1}^{\prime} \cup A_{1} \phi_{1}^{\prime}$.
Case of the rule (Comm) between $\mathcal{P}_{2}$ (output) and $A_{2} \phi_{2}$ (input): In such a case, we have $\mathcal{P}_{2}=\mathcal{P}_{3} \cup\{$ out $(c, t) . P\}$ and $A_{2}=A_{3} \cup\left\{\right.$ in $\left.\left(u, \mathrm{ax}_{n+1}\right) . Q\right\}$ (w.l.o.g. we rename the variable to $\mathrm{ax}_{n+1}$ if $\left.\left|\operatorname{dom}\left(\phi_{1}\right)\right|=n\right)$ with $\operatorname{Msg}(t), c \doteq u \phi_{1}, \mathcal{P}_{1}=\mathcal{P}_{3} \cup\left\{\{P\}\right.$ and $A_{1}=A_{3} \cup\{Q\{x \rightarrow t\}\}$.

As $\operatorname{Msg}(t)$ and $c \doteq u \phi_{1}$, we can notice that $\left(\mathcal{P}_{2}, \phi_{2}\right) \rightarrow_{\text {out }\left(u, \mathrm{ax}_{n+1}\right)}\left(\mathcal{P}_{3} \cup\left\{\{P\}, \phi_{2}\left\{\mathrm{ax}_{n+1} \mapsto t\right\}\right)\right.$. By defining $w=w_{2}$.out $\left(u, \mathrm{ax}_{n+1}\right), \phi_{1}=\phi_{2}\left\{\mathrm{ax}_{n+1} \mapsto t\right\}$, we have $(\mathcal{P}, \phi) \xrightarrow{w}\left(\mathcal{P}_{1}, \phi_{1}\right)$.

Let us now take $\xi, \zeta$ recipes such that $\operatorname{vars}(\xi, \zeta) \subseteq \operatorname{dom}\left(\phi_{1}\right)$ and $\left(\mathcal{P}^{\prime}, \phi^{\prime}\right) \xrightarrow{w_{2}}\left(\mathcal{P}_{2}^{\prime}, \phi_{2}^{\prime}\right)$ $\rightarrow_{\text {out }\left(u, \mathrm{ax}_{n+1}\right)}\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right) \rightarrow_{\xi^{?}=\zeta}\left(\mathcal{P}_{1}^{\prime}, \phi_{1}^{\prime}\right)$. By definition, $\mathcal{P}^{\prime}=\mathcal{P}_{3}^{\prime} \cup\left\{\operatorname{out}\left(c^{\prime}, t^{\prime}\right) . P^{\prime}\right\}, \operatorname{Msg}\left(t^{\prime}\right)$, $c^{\prime} \doteq u \phi_{1}^{\prime}, \mathcal{P}_{1}^{\prime}=\mathcal{P}_{3}^{\prime} \cup\left\{\left\{P^{\prime}\right\}\right.$ and $\phi_{1}^{\prime}=\phi_{2}^{\prime}\left\{\mathrm{ax}_{n+1} \mapsto t^{\prime}\right\}$. This allows us to obtain $\mathcal{P}_{2}^{\prime} \cup A_{2} \phi_{2}^{\prime} \rightarrow$ $\mathcal{P}_{1}^{\prime} \cup A_{1} \phi_{1}^{\prime}$.

Proposition 6. Let $\mathcal{P}, \mathcal{Q} \in \mathcal{M} \mathcal{P}^{\mathrm{np}}$.

$$
(\mathcal{P}, \varnothing) \leq_{t r}(\mathcal{Q}, \varnothing) \quad \text { iff } \quad \begin{aligned}
& \forall A d v \in \mathcal{M} \mathcal{P}^{\mathrm{np}} \text { s.t. } f n(A d v) \subseteq \mathcal{N}_{p u b} . \forall c \in \mathcal{N}_{p u b} . \\
& \quad \operatorname{RProb}_{\mathcal{R}}(\mathcal{P} \cup A d v, \downarrow c) \leq \operatorname{RProb}_{\mathcal{R}}(\mathcal{Q} \cup A d v, \downarrow c)
\end{aligned}
$$

Proof. To show that may-testing implies trace equivalence, we rely on Lemma 12, Indeed, a trace $w=a_{1} \ldots a_{n}$ can be seen as a formula $F=a_{1} \cdot a_{2} \ldots a_{n}$. T. In particular, $(\mathcal{P}, \varnothing) \xrightarrow{w}$ $\left(\mathcal{P}_{1}, \phi_{1}\right)$ if and only if $(\mathcal{P}, \varnothing) \models F$. Hence, by taking ok $\in \mathcal{N}_{p u b}$ such that ok $\notin f n(w, \mathcal{P}, \mathcal{Q})$, we can apply Lemma 12 to obtain that $\operatorname{RProb}_{\mathcal{R}_{\mathrm{r}}}\left(\mathcal{P} \cup A d v_{F, 0}^{o k}, \downarrow o k\right)=1$. By hypothesis, we deduce that $\left.\operatorname{RProb}_{\mathcal{R}_{\mathrm{r}}} \mathcal{\mathcal { Q }} \cup A d v_{F, 0}^{o k}, \downarrow o k\right)=1$ and so $(\mathcal{Q}, \varnothing) \models F$ once again by Lemma 12 , This allows us to conclude that $(\mathcal{Q}, \varnothing) \xrightarrow{w}\left(\mathcal{Q}_{1}, \phi_{1}^{\prime}\right)$.

To show that trace equivalence implies may-testing. Let us consider a non-probabilisitic $A \in \mathcal{M P}$ such that $f n(A) \subseteq \mathcal{N}_{p u b}$. Let $c \in \mathcal{N}_{\text {pub }}$.

Assume that $\operatorname{RProb}_{\mathcal{R}_{n r}^{o}}(\mathcal{P} \cup A, \downarrow c) \neq 0$ (otherwise the result trivially holds). Thus $\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}^{o}}(\mathcal{P} \cup A, \downarrow c)=1$ and so $\mathcal{P} \cup A d v \rightarrow \mathcal{P}^{\prime} \in \downarrow c$. By Lemma 58, there exists $\left(\mathcal{P}_{1}, \phi_{1}\right) \in$ $\mathcal{S P}{ }_{\ell}$, and adversarial process $A d v_{1}$ for $\operatorname{dom}\left(\phi_{1}\right)$ and a trace $w$ such that $\mathcal{P}^{\prime}=\mathcal{P}_{1} \cup A d v_{1} \phi_{1}$, $(\mathcal{P}, \varnothing) \xrightarrow{w}\left(\mathcal{P}_{1}, \phi_{1}\right)$ and for all recipes $\xi, \zeta$, if $\operatorname{vars}(\xi, \zeta) \subseteq \operatorname{dom}\left(\phi_{1}\right)$ and $\xi \phi_{1} \doteq \zeta \phi_{1}$ then

$$
\begin{equation*}
(\mathcal{Q}, \varnothing) \xrightarrow{w}\left(\mathcal{Q}_{1}, \phi_{1}^{\prime}\right) \rightarrow_{\xi=\zeta}\left(\mathcal{Q}_{1}, \phi_{1}^{\prime}\right) \text { implies } \mathcal{Q} \cup A d v \rightarrow^{*} \mathcal{Q}_{1} \cup A d v_{1} \phi_{1}^{\prime} \tag{20}
\end{equation*}
$$

If $A d v_{1} \phi_{1} \in \downarrow c$ then $A d v_{1}=A d v_{2} \cup\{\operatorname{out}(u, t) . P\}$ with $u \phi_{1} \doteq c$. Consider the trace $w^{\prime}=w \cdot(u \stackrel{?}{=} c)$. We thus have $(\mathcal{P}, \varnothing) \xrightarrow{w^{\prime}}\left(\mathcal{P}_{1}, \phi_{1}\right)$. Since $(\mathcal{P}, \varnothing) \leq_{t r}(\mathcal{Q}, \varnothing)$ then there exists $(\mathcal{Q}, \varnothing) \xrightarrow{w \cdot\left(u^{?} c\right)}\left(\mathcal{Q}_{2}, \phi_{2}^{\prime}\right)$. Therefore, we have $(\mathcal{Q}, \varnothing) \xrightarrow{w}\left(\mathcal{Q}_{1}, \phi_{1}^{\prime}\right) \rightarrow_{u \underline{?}}^{\underline{?_{c}}}\left(\mathcal{Q}_{1}, \phi_{1}^{\prime}\right) \xrightarrow{\varepsilon}$ $\left(\mathcal{Q}_{2}, \phi_{2}^{\prime}\right)$. We deduce that $\mathcal{Q} \cup A \rightarrow{ }^{*} \mathcal{Q}_{1} \cup A_{1} \phi_{1}^{\prime}$ and $u \phi_{1}^{\prime} \doteq c$. Therefore, $A_{1} \phi_{1}^{\prime} \in \downarrow c$ and so $\mathcal{Q}_{1} \cup A_{1} \phi_{1}^{\prime} \in \downarrow c$. This allows us to conclude that $\operatorname{RProb}_{\mathcal{R}_{\mathrm{n}}}(\mathcal{Q} \cup A, \downarrow c)=1$.
If $\mathcal{P}_{1} \in \downarrow c$ then $\mathcal{P}_{1}=\mathcal{P}_{2} \cup\{$ out $(u, t) . P\}$ with $u \doteq c$ and $\operatorname{Msg}(t)$. Hence $\left(\mathcal{P}_{1}, \phi_{1}\right) \rightarrow_{\text {out }\left(c, a x_{n+1}\right)}$ $\left.\left(\mathcal{P}_{2} \cup\{P\}\right\}, \phi_{1}\left\{\mathrm{ax}_{n+1} \mapsto t\right\}\right)$. Since $(\mathcal{P}, \varnothing) \leq_{t r}(\mathcal{Q}, \varnothing)$ then there exists $(\mathcal{Q}, \varnothing) \xrightarrow{\text { w.out }\left(c, \mathrm{ax}_{n+1}\right)}$ $\left(\mathcal{Q}_{3}, \phi_{3}^{\prime}\right)$. Therefore, $(\mathcal{Q}, \varnothing) \xrightarrow{w}\left(\mathcal{Q}_{1}, \phi_{1}^{\prime}\right) \rightarrow_{\text {out }\left(c, \mathrm{ax} \mathrm{x}_{n+1}\right)}\left(\mathcal{Q}_{2}, \phi_{2}^{\prime}\right) \xrightarrow{\varepsilon}\left(\mathcal{Q}_{3}, \phi_{3}^{\prime}\right)$. But $\left(\mathcal{Q}_{1}, \phi_{1}^{\prime}\right)$ $\rightarrow_{\text {out }\left(c, \mathrm{ax}_{n+1}\right)}\left(\mathcal{Q}_{2}, \phi_{2}^{\prime}\right)$ implies that $\mathcal{Q}_{1}=\mathcal{Q}^{\prime} \cup\left\{\operatorname{out}\left(u^{\prime}, t^{\prime}\right) . P^{\prime}\right\}$ with $c \doteq u^{\prime}$ and $\operatorname{Msg}\left(t^{\prime}\right)$. Hence $\mathcal{Q}_{1} \in \downarrow c$. By applying Equation (20) with $\xi=\zeta=c$, we deduce that $\mathcal{Q} \cup A d v \rightarrow^{*}$ $\mathcal{Q}_{1} \cup A d v_{1} \phi_{1}^{\prime}$ which allows us to conclude that $\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}}(\mathcal{Q} \cup A, \downarrow c)=1$.

## H Fully probabilistic processes

Lemma 16. Let $o k \in \mathcal{N}_{p u b}$. Let $(\mathcal{P}, \phi)$ be a purely probabilistic process. Let $A d v$ be a fully determinate adversarial process such that $f v(A d v) \subseteq \operatorname{dom}(\phi)$.

$$
\begin{aligned}
\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathbb{N}^{o}\right)}(\mathcal{P} \cup A d v \phi, \downarrow o k)= & \operatorname{RProb}_{\mathcal{R n r}^{( }\left(\mathbb{N}^{o}\right)}(\mathcal{P}, \downarrow o k)+\left(1-\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathbb{N}^{\circ}\right)}(\mathcal{P}, \downarrow o k)\right) \times \\
& \left.\sum_{(\alpha, w) \in T r^{o k}(\operatorname{Adv},|\operatorname{dom}(\phi)|)} \alpha \cdot \operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathcal{N}^{\ell}\right)}(\mathcal{P}, \phi), w\right)
\end{aligned}
$$

Proof. Using the property of maximal schedulers of Proposition 10, we know that there exists a maximal scheduler $(\operatorname{corr}, R)$ in $\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}^{o}\right)$ such that $\operatorname{RProb}_{\left.\mathcal{R n r}^{( } \mathrm{N}^{o}\right)}(\mathcal{P} \cup A d v \phi, \downarrow o k)=$ $\operatorname{RProb}_{R}\left(s, \operatorname{corr}^{-1}(\downarrow o k)\right)$ where $\operatorname{corr}(s)=\mathcal{P} \cup A d v \phi$.

Moreover we can suppose that corr $_{R}$ is simply the identity. It is because, we can see that there always exists a maximal resolution where corr ${ }_{\mathrm{R}}$ is the identity. Hence, we obtain:

$$
\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{\circ}\right)}(\mathcal{P} \cup A d v \phi, \downarrow o k)=\operatorname{RProb}_{R}(\mathcal{P} \cup A d v \phi, \downarrow o k)
$$

We will show in fact that from $R$, we can build a maximal resolution in $\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}^{\ell}\right)$, that we denote $\mathrm{B}_{\ell}(R)$ such that:

$$
\begin{aligned}
\operatorname{RProb}_{R}(\mathcal{P} \cup A d v \phi, \downarrow o k)= & \operatorname{RProb}_{\mathcal{R n r}^{\left(N^{o}\right)}}(\mathcal{P}, \downarrow o k)+\left(1-\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathbb{N}^{o}\right)}(\mathcal{P}, \downarrow o k)\right) \times \\
& \left.\sum_{(\alpha, w) \in T r^{o k}(\operatorname{Adv},|\operatorname{dom}(\phi)|)} \alpha \cdot \operatorname{Prob}_{\mathrm{B}_{\ell}(R)}(\mathcal{P}, \phi), w\right)
\end{aligned}
$$

Finally, as we only consider finite processes without replication, if we restrict the sets of $R$ to the processes reachabable from $\mathcal{P} \cup A d v \phi$, i.e. $\mathcal{P} \cup A d v \phi \rightarrow^{*} \mathcal{P}^{\prime}$ then $R$ is finite. Thus:

$$
\operatorname{RProb}_{R}(s, \mathcal{T})= \begin{cases}1 & \text { if } s \in \mathcal{T} \\ 0 & \text { if } s \notin \mathcal{T} \wedge \operatorname{trans}(s)=\star \\ \sum_{u \in \operatorname{supp}(D)} D(u) \cdot \operatorname{RProb}_{R}(u, \mathcal{T}) \quad \text { if } s \notin \mathcal{T} \wedge \operatorname{trans}(s)=D\end{cases}
$$

We do a proof by induction on the sub-scheduler starting from $\mathcal{P} \cup A d v \phi$.
Case $\mathcal{P} \cup A d v \phi \in \downarrow o k$ : In such a case, either there exists out $(u, v) ; P \in \mathcal{P}$ such that $u \doteq o k$ or $A d v=\operatorname{out}\left(u^{\prime}, v^{\prime}\right) ; A d v^{\prime}$ with $u^{\prime} \phi \doteq o k$. In the former case, we deduce that for any maximal scheduler $R^{\prime}$ starting from $\mathcal{P}, \operatorname{RProb}_{R^{\prime}}(\mathcal{P}, \downarrow o k)=1$. By taking $\mathrm{B}_{o}(R)=R^{\prime}$ and $\mathrm{B}_{\ell}(R)$ any maximal scheduler starting from $(\mathcal{P}, \phi)$, we conclude. In the latter case, we have by construction that $\operatorname{Tr}^{o k}(\operatorname{Adv} \phi,|\operatorname{dom}(\phi)|)=\left\{\left(p_{i},\left(u^{\prime} \neq o k\right) \cdot i n\left(u^{\prime}, \mathrm{ax}_{n+1}\right) \cdot w_{i}\right)\right\}_{i=1}^{m} \cup$ $\left\{\left(1, u^{\prime} \stackrel{?}{=} o k\right)\right\}$ when $\operatorname{Tr}^{o k}(A d v, n)=\left\{\left\{\left(p_{i}, w_{i}\right)\right\}_{i=1}^{m}\right.$. As $u^{\prime} \phi \doteq o k$, we deduce that for all $i \in\{1, \ldots, m\}, \operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}(\mathbb{N})}\left((\mathcal{P}, \phi),\left(u^{\prime} \neq o k\right) . i n\left(u, \mathrm{ax}_{n+1}\right) . w_{i}\right)=0$. Hence, by taking any maximal scheduler $\mathrm{B}_{\ell}(R)$, we have:

$$
\sum_{(\alpha, w) \in T r^{o k}(\operatorname{Adv},|\operatorname{dom}(\phi)|)} \alpha \cdot \operatorname{Prob}_{\mathrm{B}_{\ell}(R)}((\mathcal{P}, \phi), w)=\operatorname{Prob}_{\mathrm{B}_{\ell}(R)}\left((\mathcal{P}, \phi),\left(u^{\prime} \stackrel{?}{=} o k\right)\right)=1
$$

By taking any maximal scheduler $\mathrm{B}_{o}(R)$ and by denoting $\beta=\operatorname{RProb}_{\mathrm{B}_{o}(R)}(\mathcal{P}, \downarrow$ ok), we have:

$$
\begin{aligned}
\operatorname{RProb}_{R}(\mathcal{P} \cup A d v \phi, \downarrow o k) & =\beta+(1-\beta) * \sum_{(\alpha, w) \in T r^{o k}(A d v,|d o m(\phi)|)} \alpha \cdot \operatorname{Prob}_{\mathrm{B}_{\ell}(R)}((\mathcal{P}, \phi), w) \\
& =\beta+(1-\beta)=1
\end{aligned}
$$

Case $\mathcal{P} \cup A d v \phi \notin \downarrow$ ok and $\operatorname{trans}(\mathcal{P} \cup A d v \phi)=\star$ : As $R$ is maximal, we deduce that there is no possible transition on $\mathcal{P} \cup A d v \phi$. Hence, all processes in $\mathcal{P}$ starts by an input or an output (no $\tau$ transition) and either $A d v=0$ or $A d v=\operatorname{in}(c, x) ; A d v^{\prime}$ or $A d v=\operatorname{out}(c, u) ; A d v^{\prime}$ with $c \phi \neq c_{i}$ for all $i \in\{1, \ldots, n\}$. Moreover, when $A d v=\operatorname{out}(c, u) ; A d v^{\prime}, c \phi \neq o k$. By construction, we deduce that for all $(\alpha, w) \in \operatorname{Tr}^{o k}(\operatorname{Adv},|\operatorname{dom}(\phi)|), \operatorname{Prob}_{\mathcal{R}_{n r}\left(N^{\ell}\right)}((\mathcal{P}, \phi), w)=$ 0 . Hence by taking any maximal scheduler as $\mathrm{B}_{\ell}(R)$, we deduce that:

$$
\sum_{(\alpha, w) \in T r^{o k}(\operatorname{Adv},|\operatorname{dom}(\phi)|)} \alpha \cdot \operatorname{Prob}_{\mathrm{B}_{\ell}(R)}((\mathcal{P}, \phi), w)=0
$$

Moreover, since all processes in $\mathcal{P}$ starts by an input or an output (no $\tau$ transition) and they have distinct channels, we deduce that for any maximal scheduler $\mathrm{B}_{o}(R)$ from $\mathcal{P}$ with transition function trans ${ }^{\prime}$, we have $\operatorname{trans}^{\prime}(\mathcal{P})=\star$. Hence, $\operatorname{RProb}_{\mathrm{B}_{o}(R)}(\mathcal{P}, \downarrow o k)=0$ which allows us to conclude.
Case $\mathcal{P} \cup\{\{A d v \phi\} \notin \downarrow$ ok and $\operatorname{trans}(\mathcal{P} \cup\{\{A d v \phi\})=D$ : In such a case, we have four possibilities with respect to the transition $\operatorname{trans}(\mathcal{P} \cup\{\{\operatorname{Adv} \phi\}\})=D$ :

- $\tau$ transition on $\mathcal{P}$ : In such a case, we have either $D=\delta_{\mathcal{Q} \cup\{A d v \phi\}}$ where $\mathcal{P} \xrightarrow{\tau} \mathcal{Q}$ is either conditional or a name restriction; or $\mathcal{P}=\left\{\left\{P_{1}+{ }_{p} P_{2}\right\} \cup \mathcal{P}^{\prime}\right.$ and $D=p$. $\delta_{\mathcal{Q}_{1} \cup\{\{A d v \phi\}}+(1-p) \cdot \delta_{\mathcal{Q}_{2} \cup\{\{A d v \phi\}}$ with $\mathcal{Q}_{1}=\left\{\left\{P_{1}\right\} \cup \cup \mathcal{P}^{\prime}\right.$ and $\mathcal{Q}_{2}=\left\{\left\{P_{2}\right\} \cup \cup \mathcal{P}^{\prime}\right.$.
In the first case, by definition, $\operatorname{RProb}_{R}\left(\mathcal{Q} \cup\{\{A d v \phi\}, \downarrow o k)=\operatorname{RProb}_{R}(\mathcal{P} \cup\{\{A d v \phi\}, \downarrow\right.$ $o k)$. Moreover, by applying our inductive hypothesis, we deduce that there exist a scheduler $R_{\ell}$ such that

$$
\begin{aligned}
\operatorname{RProb}_{R}(\mathcal{Q} \cup\{A d v \phi\}, \downarrow o k)= & \operatorname{RProb}_{\mathcal{R}_{n r}\left(\mathbb{N}^{o}\right)}(\mathcal{Q}, \downarrow o k)+\left(1-\operatorname{RProb}_{\mathcal{R}_{\text {nr }}\left(\mathbb{N}^{o}\right)}(\mathcal{Q}, \downarrow o k)\right) \times \\
& \sum_{(\alpha, w) \in T r^{r o k}(A d v,|d o m(\phi)|)} \alpha \cdot \operatorname{Prob}_{R_{\ell}}((\mathcal{Q}, \phi), w)
\end{aligned}
$$

By taking the maximal scheduler $\mathrm{B}_{\ell}(R)$ that connects $(\mathcal{P}, \phi)$ to $(\mathcal{Q}, \phi)$ by the transition $(\mathcal{P}, \phi) \xrightarrow{\tau} \delta_{(\mathcal{Q}, \phi)}$ (and behaves as $R_{\ell}$ everywhere else), we deduce that for all $(\alpha, w) \in \operatorname{Tr}^{o k}(A d v,|\operatorname{dom}(\phi)|), \operatorname{Prob}_{R_{\ell}}((\mathcal{Q}, \phi), w)=\operatorname{Prob}_{\mathrm{B}_{\ell}(R)}((\mathcal{P}, \phi), w)$. Similarly, by Proposition 10, $\operatorname{RProb}_{\mathcal{R n r}\left(\mathrm{N}^{\circ}\right)}\left(\mathcal{Q}, \downarrow\right.$ ok) $=\operatorname{RProb}_{R^{\prime}}\left(\mathcal{Q}, \downarrow\right.$ ok) for some $R^{\prime}$ maximal. By taking the maximal scheduler $R^{\prime \prime}$ that connects $\mathcal{P}$ to $\mathcal{Q}$ by the transition $\mathcal{P} \xrightarrow{\tau} \delta_{\mathcal{Q}}$ (and behaves as $R^{\prime}$ everywhere else), we deduce that $\operatorname{RProb}_{R^{\prime}}(\mathcal{Q}, \downarrow$ ok $)=$ $\operatorname{RProb}_{R^{\prime \prime}}(\mathcal{P}, \downarrow o k)=\operatorname{RProb}_{\mathcal{R}_{n r}\left(\mathbb{N}^{\circ}\right)}(\mathcal{P}, \downarrow o k)$. This allows us to conclude that.

Consider the second case i.e., $\mathcal{P}=\left\{\left\{P_{1}+{ }_{p} P_{2}\right\}\right\} \cup \mathcal{P}^{\prime}$ and $D=p \cdot \delta_{\mathcal{Q}_{1} \cup\{A d v \phi\}}+(1-p)$. $\delta_{\mathcal{Q}_{2} \cup\{A d v \phi\}}$. In that case, $\operatorname{RProb}_{R}\left(\mathcal{P} \cup\{\{A d v \phi\}, \downarrow o k)=p \cdot \operatorname{RProb}_{R}\left(\mathcal{Q}_{1} \cup\{\{A d v \phi\}, \downarrow\right.\right.$ $o k)+(1-p) \cdot \operatorname{RProb}_{R}\left(\mathcal{Q}_{2} \cup\{\{A d v \phi\}, \downarrow o k)\right.$. Moreover, $(\mathcal{P}, \phi) \xrightarrow{\tau} p \cdot \delta_{\left(\mathcal{Q}_{1}, \phi\right)}+(1-p) \cdot \delta_{\left(\mathcal{Q}_{2}, \phi\right)}$.
By inductive hypothesis, for all $i \in\{1,2\}$, there exist schedulers $R_{1}, R_{2}$ such that:

$$
\begin{aligned}
\operatorname{RProb}_{R}\left(\mathcal{Q}_{i} \cup\{\{A d v \phi\}, \downarrow o k)=\right. & \operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}\left(\mathcal{Q}_{i}, \downarrow o k\right)+\left(1-\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}\left(\mathcal{Q}_{i}, \downarrow o k\right)\right) \times \\
& \sum_{(\alpha, w) \in T r^{o k}(\operatorname{Adv},|\operatorname{dom}(\phi)|)} \alpha \cdot \operatorname{Prob}_{R_{i}}\left(\left(\mathcal{Q}_{i}, \phi\right), w\right)
\end{aligned}
$$

Actually, since by Proposition 11, all maximal resolutions on $\mathrm{N}^{\ell}$ lead to the same probability of reaching a trace, we can suppose $R_{1}=R_{2}$. By taking the scheduler $\mathrm{B}_{\ell}(R)$ that connects ( $\left.\mathcal{P}, \phi\right)$ to $\left(\mathcal{Q}_{1}, \phi\right)$ with probability $p$ and $(\mathcal{P}, \phi)$ to $\left(\mathcal{Q}_{2}, \phi\right)$ with probability $1-p$, (and behaves as $R_{1}=R_{2}$ elsewhere) we deduce that for all $(\alpha, w) \in \operatorname{Tr}^{o k}(A d v,|d o m(\phi)|), \operatorname{Prob}_{\mathrm{B}_{\ell}(R)}((\mathcal{P}, \phi), w)=p \cdot \operatorname{Prob}_{\mathrm{B}_{\ell}(R)}\left(\left(\mathcal{Q}_{1}, \phi\right), w\right)+$ $(1-p) \cdot \operatorname{Prob}_{\mathrm{B}_{\ell}(R)}\left(\left(\mathcal{Q}_{2}, \phi\right), w\right)=p \cdot \operatorname{Prob}_{R_{1}}\left(\left(\mathcal{Q}_{1}, \phi\right), w\right)+(1-p) \cdot \operatorname{Prob}_{R_{2}}\left(\left(\mathcal{Q}_{2}, \phi\right), w\right)$. Similarly, we have that $\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}^{\circ}\right)}(\mathcal{P}, \downarrow o k)=p \cdot \operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{N}^{\circ}\right)}\left(\mathcal{Q}_{1}, \downarrow o k\right)+(1-p)$. $\operatorname{RProb}_{\mathcal{R}_{\text {nr }}\left(N^{\circ}\right)}\left(\mathcal{Q}_{2}, \downarrow o k\right)$.
To summarize, we have

$$
\begin{aligned}
& -\sum_{(\alpha, w) \in T r^{o k}(A d v,|\operatorname{dom}(\phi)|)} \alpha \cdot \operatorname{Prob}_{\mathrm{B}_{\ell}(R)}((\mathcal{P}, \phi), w)=p \cdot \beta_{1}+(1-p) \cdot \beta_{2} \\
& -\beta_{i}=\sum_{(\alpha, w) \in T T^{o k}(A d v,|\operatorname{dom}(\phi)|)} \alpha \cdot \operatorname{Prob}_{R_{i}}\left(\left(\mathcal{Q}_{i}, \phi\right), w\right) \text { for } i=1,2 \\
& -\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{\circ}\right)}(\mathcal{P}, \downarrow o k)=p \cdot \gamma_{1}+(1-p) \cdot \gamma_{2} \\
& -\gamma_{i}=\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{\circ}\right)}\left(\mathcal{Q}_{i}, \downarrow o k\right) \text { for } i=1,2
\end{aligned}
$$

 $\{A d v \phi\}, \downarrow o k)=p \cdot\left(\beta_{1}+\gamma_{1}\right)+(1-p) \cdot\left(\beta_{2}+\gamma_{2}\right)=\left(p \cdot \beta_{1}+(1-p) \cdot \beta_{2}\right)+\left(p \cdot \gamma_{1}+(1-p) \cdot \gamma_{2}\right)$, we conclude.

- Probabilistic choice on $A d v \phi$ : In such a case, $A d v=A d v_{1}+_{p} A d v_{2}$ and $T r^{o k}\left(A d v_{1}+_{p}\right.$ $\left.A d v_{2}, n\right)=\left\{\left\{\left(p \cdot p_{k}^{1}, w_{k}^{1}\right)\right\}_{k=1}^{n_{1}} \cup\left\{\left\{\left((1-p) \cdot p_{k}^{2}, w_{k}^{2}\right)\right\}_{k=1}^{n_{2}}\right.\right.$ when $\operatorname{Tr}^{o k}\left(A d v_{i}, n\right)=\left\{\left(p_{k}^{i}, w_{k}^{i}\right)\right\}_{k=1}^{n_{i}}$ for $i=1,2$. Moreover, by definition:
$\operatorname{RProb}_{R}(\mathcal{P} \cup\{\{A d v \phi\}\}, \downarrow o k)=p \cdot \operatorname{RProb}_{R}\left(\mathcal{P} \cup\left\{\left\{A d v_{1} \phi\right\}\right\}, \downarrow o k\right)+(1-p) \cdot \operatorname{RProb}_{R}\left(\mathcal{P} \cup\left\{\left\{A d v_{2} \phi\right\}\right\}, \downarrow o k\right)$

By inductive hypothesis, for all $i \in\{1,2\}$, there exist two maximal schedulers $R_{1}, R_{2}$ such that:

$$
\begin{aligned}
\operatorname{RProb}_{R}\left(\mathcal{P} \cup\left\{\left\{A d v_{i} \phi\right\}, \downarrow o k\right)=\right. & \operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}(\mathcal{P}, \downarrow o k)+\left(1-\operatorname{RProb}_{\mathcal{R n r}\left(\mathrm{N}^{o}\right)}(\mathcal{P}, \downarrow o k)\right) \times \\
& \left.\sum_{k=1}^{n_{i}} p_{k}^{i} \cdot \operatorname{Prob}_{R_{i}}(\mathcal{P}, \phi), w_{k}^{i}\right)
\end{aligned}
$$

Note that thanks to our lemma on maximal resolutions, we can in fact suppose that $R_{1}=R_{2}$ since $\operatorname{Prob}_{R_{1}}\left((\mathcal{P}, \phi), w^{\prime}\right)=\operatorname{Prob}_{R_{2}}\left((\mathcal{P}, \phi), w^{\prime}\right)$ for all $w^{\prime}$. Let us take $\mathrm{B}_{\ell}(R)=R_{1}$. Thus, we obtain that:

$$
\begin{aligned}
\operatorname{RProb}_{R}(\mathcal{P} \cup\{\{A d v \phi\}, \downarrow o k)= & \operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}(\mathcal{P}, \downarrow o k)+\left(1-\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}(\mathcal{P}, \downarrow o k)\right) \times \\
& \left.\left(p \cdot \sum_{k=1}^{n_{1}} p_{k}^{1} \cdot \operatorname{Prob}_{\mathrm{B}_{\ell}(R)}\right)(\mathcal{P}, \phi), w_{k}^{1}\right)+ \\
& \left.(1-p) \cdot \sum_{k=1}^{n_{2}} p_{k}^{2} \cdot \operatorname{Prob}_{\mathrm{B}_{\ell}(R)}\left((\mathcal{P}, \phi), w_{k}^{2}\right)\right)
\end{aligned}
$$

Since $\operatorname{Tr}^{o k}\left(A d v_{1}+{ }_{p} A d v_{2}, n\right)=\left\{\left\{\left(p \cdot p_{k}^{1}, w_{k}^{1}\right)\right\}_{k=1}^{n_{1}} \cup\left\{\left\{\left((1-p) \cdot p_{k}^{2}, w_{k}^{2}\right)\right\}_{k=1}^{n_{2}}\right.\right.$, we conclude.

- Name restriction on $A d v \phi$ : In such a case, $A d v=$ new $a ; A d v^{\prime}$ with $\operatorname{Tr}^{o k}(A d v, n)=$ $T r^{o k}\left(A d v^{\prime}\left\{{ }^{b} / a\right\}, n\right)$ and $b \in \mathcal{N}_{p u b}$ fresh. Moreover, by definition:

$$
\operatorname{RProb}_{R}\left(\mathcal{P} \cup\{\{A d v \phi\}, \downarrow o k)=\operatorname{RProb}_{R}\left(\mathcal{P} \cup\left\{\left\{A d v^{\prime}\left\{{ }^{b} / a\right\} \phi\right\}, \downarrow o k\right)\right.\right.
$$

By applying the inductive hypothesis on $\mathcal{P} \cup\left\{\left\{A d v^{\prime}\left\{{ }^{b} / a\right\} \phi\right\}\right.$, we directly conclude.

- Conditional branching on $A d v \phi$. We focus on the case where the transition corresponds to the rule Then (the case of the rule Else is similar). Thus $A d v=$ if $u=$ $v$ then $A d v_{1}$ else $A d v_{2}$ and $T r^{o k}$ (if $u=v$ then $A d v_{1}$ else $\left.A d v_{2}, n\right)=\left\{\left\{\left(p_{k}^{1},(u \stackrel{?}{=} v) \cdot w_{k}^{1}\right)\right\}_{k=1}^{n_{1}} \cup\right.$ $\left\{\left(p_{k}^{2},(u \neq v) \cdot w_{k}^{2}\right)\right\}_{k=1}^{n_{2}}$. Since the rule THEN was applied, we have that $u \phi \doteq v \phi$. Hence, for all $k \in\left\{1, \ldots, n_{2}\right\}, \operatorname{Prob}_{\mathcal{R}_{\mathrm{nr}}\left(\mathbb{N}^{\ell}\right)}\left((\mathcal{P}, \phi),(u \neq v) . w_{k}^{2}\right)=0$ and for all $k \in\left\{1, \ldots, n_{1}\right\}, \operatorname{Prob}_{\mathcal{R}_{n r}\left(N^{\ell}\right)}\left((\mathcal{P}, \phi), w_{k}^{1}\right)=\operatorname{Prob}_{\mathcal{R}_{n r}\left(\mathbb{N}^{\ell}\right)}\left((\mathcal{P}, \phi),(u \stackrel{?}{=} v) . w_{k}^{1}\right)$. By applying our inductive hypothesis on $\mathcal{P} \cup\left\{\left\{A d v_{1} \phi\right\}\right.$, we directly conclude.
- Internal communication with output on $A d v \phi$ and input on $\mathcal{P}$ : In such a case, $A d v=$ out $(u, v) ; A d v^{\prime}$ and $\operatorname{Tr}^{o k}(A d v, n)=\left\{\left(p_{i},(u \neq o k) . i n(u, v) \cdot w_{i}\right)\right\}_{i=1}^{m} \cup\{(1, u \stackrel{?}{=} o k)\}$ when $\operatorname{Tr}^{o k}\left(A d v^{\prime}, n\right)=\left\{\left(p_{i}, w_{i}\right)\right\}_{i=1}^{m}$. Moreover, $\mathcal{P}=\mathcal{P}^{\prime} \cup\{\operatorname{in}(c, x) ; P\}$ with $u \phi \doteq c$. Finally, we deduce that $D=\delta_{\mathcal{Q} \cup\left\{A d v^{\prime} \phi\right\}}$ where $\mathcal{Q}=\mathcal{P}^{\prime} \cup\{\{P\{v \phi / x\}\}$. Hence, by definition, we deduce that:

$$
\operatorname{RProb}_{R}(\mathcal{P} \cup\{\{A d v \phi\}\}, \downarrow o k)=\operatorname{RProb}_{R}\left(\mathcal{Q} \cup\left\{\left\{A d v^{\prime} \phi\right\}, \downarrow o k\right)\right.
$$

Note that since $\mathcal{P} \cup A d v \phi \notin \downarrow o k$, we know that $o k \neq c$ and so $o k \neq c$. Thus, by definition of the labeled semantics, we have $(\mathcal{P}, \phi) \xrightarrow{(o k \neq u) \cdot i n(u, v)}(Q, \phi)$. By applying our inductive hypothesis, we deduce that there exist a scheduler $R_{\ell}$ such that

$$
\begin{aligned}
\operatorname{RProb}_{R}\left(\mathcal{Q} \cup\left\{\left\{A d v^{\prime} \phi\right\}, \downarrow o k\right)=\right. & \operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{\circ}\right)}(\mathcal{Q}, \downarrow o k)+\left(1-\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{\circ}\right)}(\mathcal{Q}, \downarrow o k)\right) \times \\
& \sum_{(\alpha, w) \in T^{o k}\left(A d v^{\prime},|\operatorname{dom}(\phi)|\right)} \alpha \cdot \operatorname{Prob}_{R_{\ell}}((\mathcal{Q}, \phi), w)
\end{aligned}
$$

Recall that $o k \neq c$. Hence, by definition of purely probabilisitic processes, $\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(N^{o}\right)}(\mathcal{Q}, \downarrow$ $o k)=\operatorname{RProb}_{\mathcal{R}_{n r}\left(\mathrm{~N}^{\circ}\right)}(\mathcal{P}, \downarrow o k)$.
By taking the scheduler $\mathrm{B}_{\ell}(R)$ that connect $(\mathcal{P}, \phi)$ to $(\mathcal{Q}, \phi)$ by the transitions $(\mathcal{P}, \phi) \xrightarrow{i n(u, v)}(\mathcal{Q}, \phi)$ and then executes $R_{\ell}$, we deduce that for all $i \in\{1, \ldots, m\}$, $\operatorname{Prob}_{R_{\ell}}\left((\mathcal{Q}, \phi), w_{i}\right)=\operatorname{Prob}_{\mathrm{B}_{\ell}(R)}((\mathcal{P}, \phi),(o k \neq u) \cdot i n(u, v) . w)$ which allows us to conclude.

- Internal communication with input on $A d v \phi$ and output on $\mathcal{P}$ : In such a case,
$A d v=\operatorname{in}(u, x) ; A d v^{\prime}$ and $\operatorname{Tr}^{o k}(A d v, n)=\left\{\left(p_{i},(u \neq o k) . o u t\left(u, \mathrm{ax}_{n+1}\right) \cdot w_{i}\right)\right\}_{i=1}^{m}$ when $\left.\operatorname{Tr}^{o k}\left(A d v^{\prime}, n+1\right)=\left\{\left(p_{i}, w_{i}\right)\right\}\right\}_{i=1}^{m}$. Moreover, $\mathcal{P}=\mathcal{P}^{\prime} \cup\{$ out $(c, v) ; P\}$ with $u \phi \doteq c$. Finally, we deduce that $D=\delta_{\mathcal{Q} \cup\left\{A d v^{\prime} \phi^{\prime}\right\}}$ where $\mathcal{Q}=\mathcal{P}^{\prime} \cup\left\{\{P\}\right.$ and $\phi^{\prime}=\phi\left\{\mathrm{ax}_{n+1} \mapsto v\right\}$. Hence, by definition, we deduce that:

$$
\operatorname{RProb}_{R}\left(\mathcal{P} \cup\{\{A d v \phi\}, \downarrow o k)=\operatorname{RProb}_{R}\left(\mathcal{Q} \cup\left\{\left\{A d v^{\prime} \phi^{\prime}\right\}\right\}, \downarrow o k\right)\right.
$$

Note that since $\mathcal{P} \cup A d v \phi \notin \downarrow o k$, we know that $o k \neq c$ and so $o k \neq c$. Thus, by definition of the labeled semantics, we have $(\mathcal{P}, \phi) \xrightarrow{\left(o k^{2} \neq u\right) . \text { out }\left(u, \mathrm{ax}_{n}+1\right)} \delta_{\left(Q, \phi^{\prime}\right)}$. By applying our inductive hypothesis, we deduce that there exists a scheduler $R_{\ell}$ such that

$$
\begin{aligned}
\operatorname{RProb}_{R}\left(\mathcal{Q} \cup\left\{\left\{A d v^{\prime} \phi^{\prime}\right\}\right\}, \downarrow o k\right)= & \operatorname{RProb}_{\mathcal{R}_{n r}\left(N^{o}\right)}(\mathcal{Q}, \downarrow o k)+\left(1-\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(\mathrm{~N}^{o}\right)}(\mathcal{Q}, \downarrow o k)\right) \times \\
& \sum_{(\alpha, w) \in T r^{o k}\left(A d v^{\prime},\left|\operatorname{dom}\left(\phi^{\prime}\right)\right|\right)} \alpha \cdot \operatorname{Prob}_{R_{\ell}}\left(\left(\mathcal{Q}, \phi^{\prime}\right), w\right)
\end{aligned}
$$

Recall that $o k \neq c$. Hence, by definition of purely probabilisitic processes, $\operatorname{RProb}_{\mathcal{R}_{\mathrm{nr}}\left(N^{o}\right)}(\mathcal{Q}, \downarrow$ $o k)=\operatorname{RProb}_{\mathcal{R}_{\text {nr }}\left(\mathrm{N}^{\circ}\right)}(\mathcal{P}, \downarrow o k)$.
By taking the scheduler $\mathrm{B}_{\ell}(R)$ that connect $(\mathcal{P}, \phi)$ to $\left(\mathcal{Q}, \phi^{\prime}\right)$ by the transition $(\mathcal{P}, \phi) \xrightarrow{\text { out }\left(u, \mathrm{ax}_{n+1}\right)}\left(\mathcal{Q}, \phi^{\prime}\right)$ and then executes $R_{\ell}$, we deduce that for all $i \in\{1, \ldots, m\}$, $\operatorname{Prob}_{R_{\ell}}\left(\left(\mathcal{Q}, \phi^{\prime}\right), w_{i}\right)=\operatorname{Prob}_{\mathrm{B}_{\ell}(R)}\left((\mathcal{P}, \phi),(o k \neq u) . \operatorname{out}\left(u, \mathrm{ax}_{n+1}\right) . w_{i}\right)$ which allows us to conclude.
