Abstract

Cyclic induction is a powerful reasoning technique that can soundly stop the proof development and make the proof experience successful. In the setting of first-order logic with inductive definitions (FOL_{ID}) , cyclic proofs can be built automatically by the CYCLIST prover but their implementations are error-prone and the human validation may be tedious. On the other hand, cyclic induction is not yet integrated in certifying proof environments that support first-order logic and inductive definitions, as Isabelle and Coq.

We propose a solution to check in Coq the cyclic proofs produced by E-CYCLIST, an extension of CYCLIST that implements a more efficient soundness validation method, by using the very general Noetherian induction principle integrated in Coq. Our work is based on a methodology already used successfully for certifying formula-based Noetherian induction proofs. The advantages of our approach are threefold:

- I) The certification of cyclic FOL_{ID} proofs is *mechanical*. The user can validate with Coq every single step from the the E-CYCLIST proofs, as well as the induction arguments, and identify errors in a very precise way. - II) The Coq users can also perform cyclic induction *directly*. Coq functions are provided to help them to deal with the induction part. - III) There is a great potential for automation. The methodology has already been used to automatically convert implicit induction proofs, as those built by the SPIKE prover, to Coq scripts.

Certification of FOL_{ID} Cyclic Proofs

1 Introduction

9

2

10 11

12 13 14

15

16 In the setting of first-order logic with inductive definitions (FOL_{ID}), cyclic 17 induction reasoning can be used as a sound argument for stopping the expan-18 sion of some proof nodes during the proof process. CLKID^{ω} [3, 4] is the 19 standard inference system able to perform it. It extends the sequent-based LK 20 proof system [8] with rules that process equalities and inductive predicates. It 21 can build finite tree derivations called *cyclic pre-proofs* that may have special 22 23 leaves called *buds*, i.e., nodes that are labelled by sequents already occurring 24 in the derivation. Hence, it it possible to associate to each bud a unique node 25 labelled by the same sequent, called *companion*. The bud-companion relations 26 may introduce cycles, leading to infinite paths in the pre-proofs.

27 CYCLIST [5] is the *de facto* theorem prover that implements CLKID^{ω} to 28 automatize the FOL_{ID} cyclic reasoning. When displayed to the user, a pre-29 proof is represented in an indented text form. Fig. 1 partially illustrates a proof 30 state built for some sequent $N(x), N(y) \vdash Q(x, y)$. The nodes are prefixed by 31 naturals that increment in chronological order, starting by 0 for the root node. 32 On the right-hand side of each sequent is displayed additional information 33 related to the inference rule applied on the sequent, as well as the list of the 34 naturals of the nodes labelled by the sequents built by the application of the 35 rule, if any. An exception is done for the Backl rule that applies on a bud 36 sequent. In this case, the list has only the companion node. To highlight the 37 bud-companion relation from the figure, we employed a red arrow that starts 38 from the bud node 13 and points to its companion node 0. It introduces a cycle 39 that can be visited by infinite paths, e.g., [0, 2, 4, 5, 7, 8, 0, 2, ...]. 40 41

0: N_1(x) /\ N_2(y) - Q_1(x,y) (N L.Unf.) [1,2] 1: N_1(x) /\ N_3(0) - Q_1(x,0) (Q R.Unf.) [3] 3: N_1(x) /\ N_3(0) - T (Id) 2: N_1(x) /\ N_2(z) /\ N_3(s(z)) - Q_1(x,s(z)) (Q R.Unf.) [4] 4: N_1(x) /\ N_2(z) /\ N_3(s(z)) - Q_1(x,z) /\ P_2(x) (R.And) [5,6] 5: N_1(x) /\ N_2(z) /\ N_3(s(z)) - Q_1(x,z) (Weaken) [7] 7: N_1(x) /\ N_2(z) - Q_1(x,z) (Subst) [8]
8: N_1(x) /\ N_2(y) - Q_1(x,y) (Backl) [0]
÷

Fig. 1: Indented representation of a derivation tree in CYCLIST.

The inductive atoms from each sequent are indexed in order to track their evolution in a derivation tree. The inductive antecedent atoms (IAAs), found on the left-hand side of the '|-' sign of a sequent, are crucial for checking the soundness of a pre-proof. It is a non-trivial process that consists in verifying some global trace condition. The idea is to associate a trace to every infinite path p from a cyclic pre-proof, built from IAAs occurring in the sequents labelling the nodes from p, then show that progress steps happen infinitely

- 65

Certification of FOL_{ID} Cyclic Proofs 3

often. The standard way to check the global trace condition is by using a 14 15 complete procedure, based on an exponential complement operation for Büchi 16 automata [9], that was implemented in CYCLIST. Later [11, 13], a polynomial-17 time but incomplete ordering-based procedure has been proposed for checking 18 cyclic pre-proofs built for a variant of CLKID^{ω} that was also implemented in 19 an extension of CYCLIST, referred to as E-CYCLIST [15]. Even if the theoretical 20 results underlying the two checking procedures seem to be well accepted by 21 the theorem proving community, their implementations are error-prone and 22 the human validation may be tedious. Hence, the need for mechanical solutions 23 for certifying FOL_{ID} cyclic reasoning.

24 In this paper, we provide a convenient way to mechanically certify 25 E-CYCLIST sound pre-proofs, referred to as *proofs*, using the Coq proof assis-26 tant [16]. The main idea comes from the observation that Coq can represent 27 sequents as first-order formulas and reproduce the first-order reasoning, define 28 and manipulate inductive predicates, and perform induction reasoning by the 29 means of the Noetherian induction principle. In other words, the logic under-30 lying Coq is enough expressive to reproduce FOL_{ID} specifications and every 31 single pre-proof step. The most technical part consists in converting the sound-32 33 ness arguments used for cyclic induction into Coq script based on Noetherian 34 induction. For this, we consider the ordering-based procedure implemented in 35 E-CYCLIST to associate to each critical node n, as the companions involved 36 in cycles, a *measure value* (weight) consisting of a multiset of IAAs from the 37 sequent labelling n. These weights will help Coq to define a Noetherian (well-38 founded) induction ordering to be used in the Coq scripts for showing by 39 Noetherian induction that the measures decrease along the cycles. The way 40 the Noetherian induction arguments are built is given by a methodology [12] 41 developed to certify with Coq formula-based Noetherian induction reasoning, 42 as that presented in the implicit induction proofs produced with the SPIKE 43 theorem prover [14]. In the paper, it helped to successfully certify the E-44 CYCLIST proofs of all the FOL_{ID} examples included in the official distribution 45 of CYCLIST, as well as the 2-Hydra problem [2]. 46

Our approach presents two other advantages. Firstly, we give evidence that the Coq users can *directly* perform cyclic induction reasoning. Beyond the existing examples, we provide a set of Coq functions that help them to define the Noetherian induction ordering and to deal with the cyclic induction reasoning. Secondly, there is room for automation; in the past, the methodology was used to completely automatically convert SPIKE proofs to Coq scripts [12].

53 The rest of the paper has five sections and one appendix with two sections. 54 Section 2 presents as a running example a pre-proof built for one of the 55 non-trivial FOL_{ID} examples taken from the official distribution of CYCLIST. 56 Section 3 shows how to convert the pre-proof to Coq script. The machin-57 ery for checking whether the pre-proof is a proof and the translation of the 58 induction reasoning part are described in the next two sections. The sound-59 ness checking procedure implemented in E-CYCLIST and the measure values 60 for the running example are presented in Section 4. The general procedure for 61

4 Certification of FOL_{ID} Cyclic Proofs

building the Noetherian induction arguments from a cyclic proof, as well as its application on the CYCLIST pre-proof, are given in Section 5. The last section concludes and gives directions for future work. The appendix completes the Coq script from Section 3 with the induction reasoning part, as produced with our methodology and provides the missing proofs from Section 4.

2 A case study: the 'P and Q' example

The following example, taken from the official distribution of CYCLIST, is known as 'P and Q' [17]. The notations are those used by E-CYCLIST to define the inductive predicate symbols N, P and Q over the function symbols 0 and s (the 'successor' function):

 $N \{ P \{ true \Rightarrow N(0) | \\ N_1(x) \Rightarrow N(s(x)) \\ \}; P \{ true \Rightarrow P(0) | \\ P_1(x) \& Q_2(x, s(x)) \Rightarrow P(s(x)) \\ \}; P_1(x) \& Q_2(x, s(x)) \Rightarrow P(s(x)) \\ \}; P \{ true \Rightarrow P(0) | \\ P_1(x) \& Q_2(x, s(x)) \Rightarrow P(s(x)) \\ \}; P \{ true \Rightarrow P(0) | \\ P_1(x) \& Q_2(x, s(x)) \Rightarrow P(s(x)) \\ \}; P \{ true \Rightarrow P(0) | \\ P_1(x) \& Q_2(x, s(x)) \Rightarrow P(s(x)) \\ \}; P \{ true \Rightarrow P(0) | \\ P_1(x) \& Q_2(x, s(x)) \Rightarrow P(s(x)) \\ \}; P \{ true \Rightarrow P(0) | \\ P_1(x) \& Q_2(x, s(x)) \Rightarrow P(s(x)) \\ \}; P \{ true \Rightarrow P(0) | \\ P_1(x) \& Q_2(x, s(x)) \Rightarrow P(s(x)) \\ \}; P \{ true \Rightarrow P(0) | \\ P$

Q {

$$true \Rightarrow Q(x,0) \mid$$

$$Q_1(x,y) \& P_2(x) \Rightarrow Q(x,s(y))$$
};

The predicate N(x) checks whether x is a natural number, while the predicate P(x) and Q(x, y) [18] are mutually defined. E-CYCLIST can prove the sequent $N_1(x), N_2(y) \vdash Q_1(x, y)$, saying that Q(x, y) holds whenever x and y are naturals. Here, we have used the interpretation of a sequent in firstorder logic, according to which the conjunction of its antecedents implies the disjunction of its *succedents* (the atoms found on the rhs of \vdash). Several induction systems succeeded to prove it in different logical settings [17, 3, 12]. Its E-CYCLIST pre-proof is given in Fig. 2.

Certification of FOL_{ID} Cyclic Proofs 5

13 14 The proof of $N_1(x)$, $N_2(y) \vdash Q_1(x, y)$ starts by instantiating y by 0 and s(z)15 with the rule (L.Unf.), where z is a fresh variable. In FOL_{ID}, the instantiation 16 schema is built from the definition of inductive predicate symbols, in our case 17 N, by instantiating the arguments of one of the IAAs headed by N, in our case 18 $N_2(y)$. For Node 2, $N_2(z)$ was added as IAA from the unfolding of $N_3(s(z))$ 19 using the second axiom defining N. The (R.Unf.) rule unfolds the conclusion 20 of the sequent labelling Node 1, i.e., $Q_1(x,0)$, with the first axiom defining Q 21 to get a sequent that is validated by the (Id) rule; E-CYCLIST will not try 22 to expand further valid sequents. For Node 2, $Q_1(x, s(z))$ is unfolded by the 23 second axiom defining Q to get a conjunction in the succedent part. After the 24 application of the LK-rule ($\wedge R$), denoted as (R.And), the weakening LK-rule 25 (Wk), denoted by (Weaken), is applied on the sequent labelling Node 5, then 26 rename Node 7 by (Subst) to the root sequent. E-CYCLIST considers that 27 Node 8 is a bud and stops its development. For Node 6, (L.Unf.) is applied to 28 instantiate the argument x of $N_1(x)$, then the conclusions of the two resulting 29 sequents are unfolded using the definition of P. The sequent labelling Node 30 11 is true, while that labelling Node 12 has a conjunction as conclusion. E-31 CYCLIST prefers to apply again (L.Unf.) to instantiate s(y) given as argument 32 33 to $N_4(s(y))$. (Ex Falso) rule concludes that the sequent labelling Node 13 is 34 true because it has s(y) = 0 (a false atom) in the antecedent part. The atom 35 $Q_2(y, s(y))$ from the conclusion of the sequent labelling Node 14 unfolds, then 36 (Weaken) is applied before renaming with (SUBST) in order to get a bud whose 37 companion is Node 4. The derivation tree is a pre-proof because no other node 38 can be expanded. 39

Compared with other proof scenarios from [17, 3, 12], the E-CYCLIST preproof is not the most effective. For example, one could have omitted the last (L.Unf.) step which only adds the already present N(y) to the antecedent part of the sequent labelling Node 12.

In the next section, we present the Coq translation of the resulting preproof.

3 The Coq script of the pre-proof

50 The Coq specifications are typed. To cope with the untyped CYCLIST specifi-51 cation, we assume that there is a *unique* type variable *T*. It serves as a domain 52 definition for the function symbols denoted by *zero* (for 0) and *succ* (for *s*), 53 also defined as variables, as well as for the inductive predicates **P** and **Q**: 54

```
55
         Variable T: Set.
56
          Variable zero: T.
57
          Variable succ: T \rightarrow T.

Coq informs that the proof is incomplete and lists the two remaining goals to be proved. They correspond to the sequents labelling Nodes 7 and 16 in the pre-proof listed in Fig. 2.

In the next section, we explain why that the pre-proof from Fig. 2 is a proof using the soundness checking procedure implemented in E-CYCLIST.

4 The soundness checking procedure

A cyclic *proof* is a cyclic pre-proof that satisfies the global trace condition discussed in the introductory part. To build a trace for an infinite path p, we have to assign a trace value for each of its nodes. We start by choosing an IAA from the sequent labelling the first node in p. For the next nodes in p, we proceed recursively. We associate to a node n one of the IAAs from its labelling sequent by following a *cause effect* rule that is: either i) the same trace value t for the previous node in p, or ii) the IAA resulting from the unfolding of tduring the application of an (L.UNF.) that uses t. The last case corresponds to a *progress point*. The global trace condition holds if, for each infinite path, the case ii) occurs infinitely often.

Example 1 For the pre-proof from Fig. 2, there are three cases to build infinite paths:

1. by following the nodes $0, 2, 4, 5, 6, 7, 8, 0, \dots$ The corresponding trace is $N_2 y$, $N_2 z$, $N_2 y$, $N_2 y$,...¹ The progress point is underlined.

2. by following the nodes 4, 6, 10, 12, 14, 15, 16, 17, 4, The corresponding trace is N_1x , N_1x , N_1y , N_1y , N_1y , N_1y , N_1y , N_1y , N_1x , N_1x ,

¹For sake of simplicity, the parentheses are omitted.

13	
14	
15	3. by infinitely intertwining finite parts from the paths presented in the first
16	and the second cases. The trace along this path is built from the IAAs
17	indexed by 1. The underlined IAA from the second case occurs infinitely
18	often.
19	The reader may also consult Example 5.2.2 from [2] presenting a different
20	$CLKID^{\omega}$ proof of the 'P and O' conjecture
21	CLIAID proof of the T and & conjecture.
22	
23	The soundness checking procedure implemented in E-CYCLIST was
24	described in [11, 13]. It provides <i>sufficient</i> conditions to satisfy the global trace
25	condition. Its two main steps are detailed in the following.
26	. 0
27	1. The normalisation step.

A pre-proof represented by the derivation tree \mathcal{T} is transformed into a forest of connected derivation trees for which i) all companions are root nodes, ii) the root of \mathcal{T} is among the root nodes, and iii) every path p leading a root r to a bud b, called rb-path and denoted by $r \to b$, ends with a (Subst)-step which is also the unique (Subst)-step in p.

Example 2 The result of the normalisation operation generates two trees with the roots 0 and 4, where the node 4 is duplicated twice in the tree with root 0. Once, to perform a stuttering step by applying a (Subst)-step with the identity substitution. The other time, to separate from the main tree the subtree rooted by it, followed by the creation of a new bud-companion relation. The normalised pre-proof is given in Fig. 3:

Fig. 3: The normalisation of the pre-proof from Fig. 2.

It can be noticed that every infinite path in the E-CYCLIST pre-proof are also reproduced in its normal form, by duplicating the node 4, and vice-versa, by deleting the occurrences introduced during the normalisation step.

12 Certification of FOL_{ID} Cyclic Proofs

2. The ordering and derivability constraints step.

The next step is to associate to each root r, from a cycle of the normalized pre-proof, a measure value in terms of a multiset of IAAs from the sequent labelling r such that some derivability and ordering constraints are satisfied. The *derivability constraints* consist in checking that, for any rb-path p found in a cycle, every IAA from the measure value of the root companion of its bud can be derived from some IAA of the measure value of its root, according to some trace following p.

Example 3 For our example, we list all traces following the rb-paths found in cycles:

- $0 \to 4''$: i) $N_1 x, N_1 x, N_1 x, N_1 x$ (=), ii) $N_2 y, \underline{N_2 z}, N_2 z, N_2 z$ (>), and iii) $N_2 y, N_3 sz, N_3 sz, N_3 sz$ (=),
- $4 \rightarrow 8$: i) $N_1 x, N_1 x, N_1 x, N_1 x$ (=), ii) $N_2 z, N_2 z, N_2 z, N_2 y$ (=), and
- 4 \rightarrow 17: i) $N_1x, N_1x, N_1y, N_1y, N_1y, N_1y, N_1y, N_1x$ (>),
 - ii) $N_1x, N_1x, N_4sy, N_4sy, N_4y, N_4y, N_4y, N_2z$ (>), and
 - iii) $N_1x, N_1x, N_4sy, N_4sy, N_5sy, N_5sy, N_3sy, N_3sz$ (=).

Each trace $A_r, ..., A_b$ following any of the rb-paths from Example 3 was annotated by (>) if it has at least one progress point; the progress points are underlined. We say that A_r is 'greater than' A_b , denoted as $A_r > A_b$. The traces with no progress points are annotated by (=). In this case, A_r and A_b are said to be *equal*. An *infinitely progressing trace* has infinite progress points.

Recall that the global trace condition requires that, for any infinite path 40 p of the pre-proof, there is an infinitely progressing trace starting from some 41 42 point of p. On the other hand, p can be represented in the normal form of the 43 pre-proof as an infinite concatenation of rb-paths starting from some point. 44 We will show that this condition is ensured if, for each rb-path $r \to b$ of p, we 45 have $M(r) >_{mul} M(c(b))$, where c(b) is the companion of b and M(r) (resp., 46 M(c(b)) is the measure value for r (resp., c(b)). The ordering $>_{mul}$ is the 47 trace-based multiset extension of >, i.e., $M(r) >_{mul} M(c(b))$ if the equal IAAs 48 from M(r) and M(c(b)) are deleted, to get M(r)' and M(c(b))', and either i) 49 M(c(b))' is empty and M(r)' is not empty, or ii) for each IAA $a \in M(c(b))'$ 50 there is an IAA $b \in M(r)'$ such that b > a. This definition of $>_{mul}$ was 51 firstly introduced in [15] and is a substitution-free version of the $<_{\pi}$ -derivability 52 relations used in [11, 13]. 53

54

55 Example 4 In Fig. 4, only the indexes of the IAAs are listed but one can notice 56 that the heuristics implemented in E-CYCLIST [15] proposed (a permutation of) 57 $\{N_1x, N_1x, N_2y, N_2y\}$ and $\{N_1x, N_1x, N_2z, N_2z, N_3sz\}$ as measure values for the 58 nodes 0 and 4, respectively. In the same figure, the links of IAAs from buds to roots 59 are checked, for each rb-path. For the rb-path $0 \rightarrow 4''$, M(4'') is M(4) since 4 is the 60 companion of 4'' and includes the IAAs indexed by 1, 2 and 3. The link of each of 61 them to the IAAs from M(0) are as follows:

27 28 **Theorem 1** (soundness) The global trace condition holds for a pre-proof if each rbpath $r \to b$ belonging to a cycle from its normalized pre-proof satisfies $M(r) >_{mul}$ M(c(b)).

5 Building Noetherian induction proofs from cyclic proofs

In the following, we will take advantage of the fact that the measure values assigned to the roots help also to represent the pre-proofs as Noetherian induction proofs for which the induction ordering is defined using the measure values for the roots, as computed in the previous section. We will use the (first-order) formula-based instance of the Noetherian induction principle [10]:

 $(\forall m \in \mathcal{E}, (\forall k \in \mathcal{E}, k < m \Rightarrow k) \Rightarrow m) \Rightarrow (\forall p \in \mathcal{E}, p),$

29 where \mathcal{E} is a set of first-order formulas and < is a Noetherian induction order-30 ing defined over first-order formulas which forbids infinite strictly decreasing 31 sequences of formulas. The principle states that any formula k from \mathcal{E} can be 32 used as induction hypothesis in the proof of another formula m from \mathcal{E} , as long 33 as k is smaller than m. 34

In our setting, \mathcal{E} is the set of (the first-order logic representation of) root 35 sequents and < the multiset extension $<^{wf}_{mul}$ of a Noetherian ordering $<^{wf}$ 36 37 over the IAAs from the root sequents. The link between Noetherian induction 38 reasoning and cyclic reasoning is based on the notion of $\langle p_i - derivability$ intro-39 duced in [11, 13]. The idea is to use the measure values for the root sequents 40 as computed by E-CYCLIST. Given an rb-path $r \to b$, let δ be the substitu-41 tion used in the (Subst)-step of $r \to b$ and θ the *cumulative substitution* for 42 $r \rightarrow b$, i.e., the composition of all substitutions instantiating IAAs along $r \rightarrow b$ 43 in (L.Unf.)-steps. It can be noticed that if $l_1 \in M(r)$ and $l_2 \in M(c(b))$ such 44 that $l_1 = l_2$, then $l_1 \delta \equiv l_2 \theta$, where \equiv is the syntactic equality. For the case 45 when $l_1 > l_2$, we have to show that $l_1 \delta <^{wf} l_2 \theta$. We further denote by σ_{id} the 46 identity substitution. 47

49 *Example 5* For the running example, the measure value computed by E-CYCLIST 50 for the root 0 (resp., 4) are $\{Nx, Nx, Ny, Ny\}$ (resp., $\{Nx, Nx, Nz, Nz, Nsz\}$). In 51 practice, one can consider that all the inductive predicate symbols are equivalent, 52 hence the measure values for the roots are multisets built only from their arguments. 53 The measure value for the root 0 (resp., 4) becomes $\{x, x, y, y\}$ (resp., $\{x, x, z, z, sz\}$). 54

The ordering constraints checking the validity of the rb-paths are:

- $0 \to 4'': \{x, x, z, z, sz\}[\sigma_{id}] <_{mul}^{wf} \{x, x, y, y\}[\{y \mapsto sz\}],$ $4 \to 8: \{x, x, y, y\}[\{y \mapsto z\}] <_{mul}^{wf} \{x, x, z, z, sz\}[\sigma_{id}], and$

•
$$4 \to 17$$
: $\{x, x, z, z, sz\}[\{x \mapsto y; z \mapsto y\}] <_{mul}^{wf} \{x, x, z, z, sz\}[\{x \mapsto sy\}],$

where the indexes for the inductive predicates are omitted.

They are satisfied if $<^{wf}$ is a multiset path ordering (mpo) [1] built from any precedence over the symbols $\{s, 0\}$.

10		
11		
12	Certifi	$cation of FOL_{ID} Cyclic Proofs 15$
13		<i>f</i>
14	We say that the rb-path $r \to b$ is va	lid if $M(c(b))[\delta] <_{mul}^{w_J} M(r)[\theta]$. In the
15	Noetherian induction setting, $M(c(b))[\delta]$	plays the role of <i>induction hypothesis</i>
16	and $M(r)[\theta]$ that of the <i>induction concl</i>	usion.
17	If every rb-path from a cycle of a m	normalized pre-proof resulting from a
18	pre-proof \mathcal{P} is valid is sufficient to cond	clude that \mathcal{P} is a cyclic proof, even if
19	$<_{mul}^{wf}$ is not Noetherian [11, 13].	
20		
21	In order to certify with Coq the I	Noetherian induction reasoning from
22	FOL_{ID} pre-proofs, we apply the certific	ation methodology for formula-based
23	Noetherian induction proofs [12]. First	ly, the mpo and its multiset exten-
24	sion, denoted by less, are defined using	the Coccinelle library [6, 7]. To each
25	function symbol from the Cog specificat	ion corresponds a Coccinelle function
26	symbol with an arity status and index:	
27	Symbol with an arty, status and mach	Definition status $(f:\mathbf{symb}) :=$
28	Inductive symb : Set :=	match f with
29	id 0	$id 0 \Rightarrow rpo Mul$
30	id S	$ id S \Rightarrow rpo Mu $
3⊥ 20		end
3∠ 22	•	
22 21	Definition arity (f: symb) :=	Definition index (f: symb) :=
24 25	match f with	match f with
35	$ id_0 \Rightarrow term_spec.Free \ 0$	$ id0 \Rightarrow 2$
30	$ id_S \Rightarrow term_spec.Free \ 1$	$ id_S \Rightarrow 3$
38	end.	end.
39	The function <i>model nat</i> translates C	og terms to Coccinelle terms:
40		
41	Variable model nat $T \rightarrow term$	
42	Axiom model nat 0 : model nat zero = (Term id () nil)
43	Axiom model nat succ: $\forall (u1: T)$	nodel nat (succ $u1$) = (Term id S
44	((model nat u1)::nil))	
45		
46	The above equalities can be used for	rewriting during the proofs:
47		
48	Hint Rewrite model_nat_0 model_nat_	succ : model_nat.
49	Ltac $rewrite_model :=$ autorewrite wi	th model_nat.
50	The axiom stating the freeness of 0	and <i>succ</i> is required to reproduce the
51	reasoning behind the application of the	(Ex Falso) rule:
52	O TIT	
53	Axiom zero different from succ: $\forall x_i$ (ze	$ero = succ \ x) \rightarrow False$
54		
55	If the pre-proof has several non-sing	ieton strongly connected components
56	(SUUS), one should define a precedence v	w.r.t. their processing order, such that
57	the SCC S_1 is treated after the SCC S_2	2 If S_1 depends on S_2 . For each SCC,
58	several steps should be performed. They	are illustrated for the unique SCC S
59	from the running example:	
60		
6 L		

Springer Nature 2021 LATEX template 9 10 11 16 Certification of FOL_{ID} Cyclic Proofs 12 13 1. attach a measure value to each root from S inside a *functional* to ensure 14 15 that whenever the root formula is instantiated the mesure value is also 16 instantiated with the same substitution: 17 Definition type_LF_0_4 := $T \rightarrow T \rightarrow (\text{Prop} \times (\text{List.list term})).$ 18 Definition F_0 : type_LF_0_4:= (fun $u1 \ u2 \Rightarrow$ (N $u1 \rightarrow$ N $u2 \rightarrow$ Q u119 u2, $((model_nat \ u1)::(model_nat \ u1)::(model_nat \ u2)::(model_nat \ u2)::(mo$ 20 u2):: nil))).21 22 Definition F_4: type_LF_0_4:= (fun $u1 u2 \Rightarrow$ (N $u1 \rightarrow$ N $u2 \rightarrow$ N (succ 23 $u^{2} \rightarrow \mathbf{Q} u^{1} u^{2} \wedge \mathbf{P} u^{1}$, ((model_nat u^{1})::(model_nat u^{1})::(model_nat u^{1})) 24 u2):: (model_nat u2):: (model_nat (succ u2)):: nil))). 25 2. define the list of functionals: 26 27 Definition $LF_0_4 := [F_0, F_4]$. 28 3. define and prove the main lemma by reproducing the parts rooted by 29 the root nodes in the pre-proof.³ The main lemma validates the applica-30 tion conditions for the formula-based instance of the Noetherian induction 31 principle: 32 Lemma main_0_4 : \forall F, ln F LF_0_4 \rightarrow \forall u1, \forall u2, (\forall F', ln F' LF_0_4 \rightarrow 33 34 $\forall e1, \forall e2, \mathsf{less}(\mathsf{snd}(F' e1 e2))(\mathsf{snd}(F u1 u2)) \rightarrow \mathsf{fst}(F' e1 e2)) \rightarrow \mathsf{fst}$ 35 $(F \ u1 \ u2).$ 36 4. prove all formulas from the list of functionals as the all_true conjecture, 37 using the main lemma and the Noetherian induction principle integrated in 38 Coq: 39 Theorem all_true: $\forall F$, $\ln F \ LF_0_4 \rightarrow \forall u1: T, \forall u2: T, fst (F u1 u2)$. 40 41 5. finally, prove the root conjectures as direct consequences of all_true: 42 Theorem true_0: $\forall x y, \mathbf{N} x \rightarrow \mathbf{N} y \rightarrow \mathbf{Q} x y$. 43 Theorem true_4: $\forall x y$, $\mathbf{N} x \rightarrow \mathbf{N} y \rightarrow \mathbf{N} (succ y) \rightarrow \mathbf{Q} x y \wedge \mathbf{P} x$. 44 45 This completes the goal set in Section 3 to finish the proof of true_0. 46 47 5.1 Other examples 48 49 The certification procedure has also been successfully used for checking the 50 other E-CYCLIST proofs from [15], based on the FOL_{ID} examples from 51 the standard distribution of CYCLIST and the 2-Hydra problem [2]. For 52 convenience, the axioms for the inductive predicates used in the examples are: 53 54 $O \{$ $E \{$ $R \{$ 55 $true \Rightarrow E(0) \mid \qquad E_1(x) \Rightarrow O(s(x))$ $true \Rightarrow R(0, x) \mid$ 56 57 $O_1(x) \Rightarrow E(s(x)) \};$ $R_1(x,0) \Rightarrow R(s(x),0) \mid$ 58 $R_1(s(s(x)), y) \Rightarrow R(s(x), s(y))$ }; 59 }; 60 61

63 64

62

 $^{^{3}}$ The full Coq proof script of the main lemma is given in Appendix A.

 $ADD \{$

 $\begin{array}{ll} D \left\{ \begin{array}{ccc} p \left\{ & p \left\{ & \\ N_{1}(x) \Rightarrow ADD(0, x, x) \mid & true \Rightarrow p(0, 0) \mid \\ ADD_{1}(x, y, z) \Rightarrow ADD(s(x), y, s(z)) & true \Rightarrow p(s(0), 0) \mid \\ \end{array} \right. \\ \left. \right\} ; & true \Rightarrow p(x, s(0)) \mid \\ p_{1}(x, y) \Rightarrow p(s(x), s(s(y))) \mid \\ p_{1}(s(y), y) \Rightarrow p(0, s(s(y))) \mid \\ p_{1}(s(x), x) \Rightarrow p(s(s(x)), 0) \\ \end{array} \right\} ; \\ \end{array}$

The inductive predicates E, O, and ADD refer to the even and odd numbers, as well as to the addition on naturals, respectively. R is an inductive predicate given as example in CYCLIST and p formalizes the 2-Hydra problem.

Table 1 contains some statistics about the certification of a dozen of E-CYCLIST proofs. The columns show, from left to right, the number of the problem as it figures in the standard distribution of CYCLIST (excepting for the 2-Hydra problem listed at the bottom line), and related to the normalized E-CYCLIST pre-proof: its number of SCCs, its root sequents and their measure values.⁴

An important part of the Coq script built for the running example was shared with the Coq script for the other examples, as the definition of the Coccinelle orderings.⁵. The main intellectual energy was spent to prove the main lemmas.

In some cases, the translation of the application of (L.Unf.) using an IAA of the form N(s(x)) requires an axiom stating the injectivity of succ:

Axiom succ_is_injective: $\forall x y$, (succ x = succ y) $\rightarrow x = y$.

6 Conclusions and future work

We have adapted a general procedure for certifying formula-based Noetherian induction reasoning to check with Coq FOL_{ID} cyclic proofs, as those produced by the E-CYCLIST prover. Given a cyclic proof of a sequent S, the output is the Coq script proving a bunch of theorems and lemmas among which there is the formula representing S in first-order logic. The deductive part of the main lemma translates the steps from the cyclic proof. Some of them are converted to Coq script in a one-to-one translation. Others, like the unfolding of a conjunct in a (R.Unf.) step, may require more than one Coq proof steps. In fact, Coq is enough powerful to translate *any* E-CYCLIST inference step. For the translation of classical proof steps, the axiom of excluded middle is required

 $^{^4 \}rm The$ full Coq specifications and proof scripts are archived and can be downloaded from https://drive.google.com/file/d/1E3_kO72mgAzZexEjHbbL8_nrf4LkAMIG.

B The missing proofs from Section 4

B.1 Proof of Lemma 1

Proof Let us assume two adjacent rb-paths $r_1 \to b_1$ and $r_2 \to b_2$ in a cycle such that r_2 is the companion of b_1 , $M(r_1) >_{mul} M(c(b_1))$, and $M(r_2) >_{mul} M(c(b_2))$. We will try to prove that $M(r_1) >_{mul} M(c(b_2))$.

22 Certification of FOL_{ID} Cyclic Proofs

Since the roots/buds are repeated infinitely along the cycle, none of their measure values should be empty. If, by contradiction, we assume that a measure value is empty, there exists an rb-path $r \to b$ in the cycle such that M(r) is empty. But there is no $\langle mul$ such that M(r) > M(c(b)).

18 We show that there should be a trace along the path $[r_1, \ldots, b_1, r_2, \ldots, b_2]$. Since 19 $M(c(b_2))$ is not empty, let $l_3 \in M(c(b_2))$. By the definition of $<_{mul}$, there exists an 20 IAA $l_2 \in M(r_2)$ such that $l_2 > l_3$ or $l_2 = l_3$. A similar reasoning can be applied on 21 l_2 as for l_3 to conclude that there is $l_1 \in M(r_1)$ such that $l_1 > l_2$ or $l_1 = l_2$. Hence, 22 the trace is $l_1, \ldots, l_2, l_2, \ldots, l_3$.

Finally, we check whether $M(r_1) >_{mul} M(c(b_2))$. As previously, for each IAA $l_3 \in M(c(b_2))$ there is an IAA $l_2 \in M(r_2)$ such that $l_2 > l_3$ or $l_2 = l_3$, and an IAA $l_1 \in M(r_1)$ such that $l_1 > l_2$ or $l_1 = l_2$. We perform a case analysis on the comparison results between l_2 and l_3 , as well as l_1 and l_2 :

- if $l_2 > l_3$ and $l_1 > l_2$, then $l_1 > l_3$;
- if $l_2 > l_3$ and $l_1 = l_2$, then $l_1 > l_3$;
- if $l_2 = l_3$ and $l_1 > l_2$, then $l_1 > l_3$;
- if $l_2 = l_3$ and $l_1 = l_2$, then $l_1 = l_3$.

We show that $M(r_1) >_{mul} M(c(b_2))$ when there is at least one $l_3 \in M(c(b_2))$ for which it exists $l_1 \in M(r_1)$ such that $l_1 > l_3$. After the pairwise deletion of equal IAAs from $M(r_1)$ and $M(c(b_2))$, to get $M(r_1)'$ and $M(c(b_2))'$, we have that $l_3 \in M(c(b_2))'$, $l_1 \in M(r_1)'$ and $l_1 > l_3$. By the definition of $>_{mul}$, we have that $M(r_1) >_{mul} M(c(b_2))$, because the same reasoning can be done for any other IAA from $M(c(b_2))'$ as for l_3 .

If for all $l_3 \in M(c(b_2))$, there exists $l_1 \in M(r_1)$ such that $l_3 = l_1$, then it exists $l_2 \in M(r_2)$ such that $l_1 = l_2$ and $l_2 = l_3$. Since $M(r_2) >_{mul} M(c(b_2))$, after the pairwise deletion of IAAs from $M(r_2)$ and $M(c(b_2))$, to get $M(r_2)'$ and $M(c(b_2))'$, we have that $M(c(b_2))'$ is empty and $M(r_2)'$ is not empty. Similarly, since $M(r_1) >_{mul} M(c(b_1))$, we have that $M(c(b_1))'$ is empty and $M(r_1)'$ is not empty. We conclude that after the pairwise deletion of IAAs from $M(r_1)$ and $M(c(b_2))$, to get $M(r_1)'$ and $M(c(b_2))'$, we have that $M(c(b_2))'$ is empty and $M(r_1)'$ is not empty. Hence $M(r_1) >_{mul} M(c(b_2))$, as required.

B.2 Proof of Theorem 1

49 *Proof* Let \mathcal{P} be a pre-proof and p_0 an infinite path in \mathcal{P} . Let p be the infinite path 50 from the normalized pre-proof of \mathcal{P} built from p_0 by duplicating the nodes as shown 51 during the normalization process. By construction, the path p is built starting from 52 some point only from the concatenations of rb-paths from cycles from the normalized 53 pre-proof. Since the number of roots is finite in \mathcal{P} , there is a root r in p that occurs 54 infinitely often in p. Hence, there is an infinite sub-path p' of p of the form $[r, \ldots, r, \ldots]$ 55 which can be represented as the infinite concatenation of finite sub-paths $[r, \ldots, b]$, 56 where r is the companion of b and r occurs only once in each sub-path. Each such sub-path is built from a finite number of concatenations of rb-paths of the form 57 $[r_1, \ldots, b_1]$ for which $M(r_1) >_{mul} M(c(b_1))$. Since $<_{mul}$ is transitive, by Lemma 1, 58 we have that $M(r) >_{mul} M(c(b))$ for each sub-path $[r, \ldots, r, \ldots, b]$. Since M(r) is 59 not empty, for the same reasons as presented in the proof of Lemma 1, there is a 60 trace following p'. 61

9	Springer Nature 2021 $IATEX$ template
10	
11	
12	Certification of FOL_{ID} Cyclic Proofs 23
13	
14	By contradiction, we assume that the number of progress points in all the traces
15	along p' is finite. Since the cardinality of the trace measures for each root in p' is
16	finite, there is a sub-path $[r, \ldots, b]$ defined as above whose traces have no progress
17	points and satisfies $M(r) >_{mul} M(c(b))$. After the pairwise deletion of equal IAAs
18	from $M(r)$ and $M(c(0))$, to get $M(r)$ and $M(c(0))$, we perform a case analysis by
19	considering whether $M(c(0))$ is empty or not.
20	• $M(c(b))'$ is not empty. By the definition of $>_{mul}$, there is an IAA $l \in$
21	$M(c(b))'$ for which there is an IAA $l' \in M(r)'$ such that $l' > l$. Hence, the
22	trace leading l' to l has at least one progress point. Contradiction.
23	• $M(c(b))'$ is empty. By a similar reasoning as given in the proof of Lemma 1.
24	The cardinality of $M(r)$ is greater than that of $M(c(b))$ But $M(r) =$
25	M(c(h)) because r is the companion of h Contradiction again
26	M(c(0)) because r is the companion of 0 . Constant of 0 , again.
27	Since there is a trace along p' that has an infinite number of progress points,
28	p has also an infinitely progressing trace starting from some point. Since p_0 can be
29	built from p by deleting the extra nodes added during the normalisation process, it
30	has an infinitely progressing trace starting from some point, too.
31	We conclude that \mathcal{P} satisfies the global trace condition.
