Abstract. Automata, Resolution, and Cut-elimination are three methods to prove the decidability of provability in various logics. The goal of this paper is to understand the relation between these three methods, using Alternating pushdown systems as a unifying example. To this aim, we propose a new Resolution based saturation method for Polarized sequent calculus modulo theory and its associated cut-elimination theorem. We then show how it can be used to prove the decidability of Alternating pushdown systems.

1 Introduction

Cut-elimination and the construction of a finite-state automaton recognizing the provable propositions are two methods to prove the decidability of provability in inference systems. For instance, Kleene has proved the decidability of classical and constructive propositional logic by proving first a cut-elimination theorem for these logics and then the finiteness of the search space for a cut-free proof of a given proposition [16]. In contrast, A. Bouajjani, J. Esparza, and O. Maler, have proved the decidability of reachability in Alternating pushdown systems by constructing a finite-state automaton recognizing the inverse reachable configurations [3].

In previous work [11] we have shown that this methodological difference between cut-elimination and the construction of an automaton is not so strong as it looks: for each Alternating pushdown system, a Natural-Deduction style inference system can be defined, such that the inverse reachability in this Alternating pushdown system is reduced to the provability in the inference system, which in turn can be proved decidable, using a saturation algorithm and a cut-elimination theorem. However, the inference system, the saturation algorithm, and the cut-elimination theorem, presented in [11] are somehow *ad hoc*, as they are specific to Alternating pushdown systems. This raises the question of the possibility to prove this decidability result using already known inference systems, such as Polarized sequent calculus modulo theory [9, 10], and already known saturation algorithm and cut-elimination theorem.

A saturation algorithm for Polarized sequent calculus modulo theory has been presented in previous work [4]. This saturation algorithm transforms a rewrite

system into a set of clauses, saturates this set of clauses with Ordered resolution with selection and transforms back the saturated set of clauses into a rewrite system.

Interestingly enough, the decidability of Alternating pushdown systems has also been proved independently, using a saturation by Resolution method to transform Alternating pushdown systems into automata [12, 14, 7, 13, 8].

So, [11] relates cut-elimination and automata, [4] relates cut-elimination and Resolution, and [12, 14, 7, 13, 8] relate Resolution and automata

The goal of this paper is to understand the relation between these three methods, using Alternating pushdown systems as a unifying example. The method presented in this paper also extends that presented in [5]. The saturation algorithm of [4] uses only a particular case of Ordered resolution with selection, where only one negative literal can be selected in each clause. In this paper, we generalize the method of [4] to full Ordered resolution with selection. Then, we apply this general method to a formalization of Alternating pushdown systems.

We show, in Section 2, how to express Alternating pushdown systems in Polarized sequent calculus modulo theory. The saturation algorithm is defined in Section 3. We finally apply this saturation algorithm to prove the decidability of inverse reachability in Alternating pushdown systems in Section 4.

2 Alternating pushdown systems in Polarized sequent calculus modulo theory

2.1 Alternating pushdown systems

Definition 1 (State, word, configuration). *Consider a language \mathcal{L} in monadic predicate logic, containing a finite number of predicate symbols, called states, a finite number of function symbols, called stack symbols, and a constant ε , called the empty word. A closed term in \mathcal{L} , also called a word, has the form $\gamma_1(\gamma_2 \dots (\gamma_n(\varepsilon)))$ where $\gamma_1, \dots, \gamma_n$ are stack symbols. A closed atomic proposition, also called a configuration, has the form $P(w)$ where P is a state and w a word.*

Definition 2 (Alternating pushdown systems). *An Alternating pushdown system consists of a finite set of rules of the form*

pop

$$Q(\gamma(x)) \leftrightarrow \{P_1(x), \dots, P_n(x)\}$$

empty

$$Q(\varepsilon) \leftrightarrow \emptyset$$

push

$$Q(x) \leftrightarrow \{P_1(\gamma(x)), P_2(x), \dots, P_n(x)\}$$

and neutral

$$Q(x) \leftrightarrow \{P_1(x), \dots, P_n(x)\}$$

It defines a transition system between finite sets of closed atomic propositions: for all finite set S of closed atomic propositions and all word w

- a pop rule $Q(\gamma(x)) \leftrightarrow \{P_1(x), \dots, P_n(x)\}$ defines a transition

$$\{Q(\gamma(w))\} \cup S \leftrightarrow \{P_1(w), \dots, P_n(w)\} \cup S$$

- an empty rule $Q(\varepsilon) \leftrightarrow \emptyset$ defines a transition

$$\{Q(\varepsilon)\} \cup S \leftrightarrow S$$

- a push rule $Q(x) \leftrightarrow \{P_1(\gamma(x)), P_2(x), \dots, P_n(x)\}$ defines a transition

$$\{Q(w)\} \cup S \leftrightarrow \{P_1(\gamma(w)), P_2(w), \dots, P_n(w)\} \cup S$$

- a neutral rule $Q(x) \leftrightarrow \{P_1(x), \dots, P_n(x)\}$ defines a transition

$$\{Q(w)\} \cup S \leftrightarrow \{P_1(w), \dots, P_n(w)\} \cup S$$

A closed atomic proposition $P(w)$ is *inverse reachable*, written $P(w) \in Pre^*(\emptyset)$, if $\{P(w)\} \leftrightarrow^* \emptyset$, where, as usual, the relation \leftrightarrow^* is the reflexive-transitive closure of the relation \leftrightarrow .

The decidability of such a system is not obvious as, for instance, the push rule

$$P(x) \leftrightarrow \{P(a(x))\}$$

transforms the set $\{P(a(\varepsilon))\}$ successively into $\{P(a(a(\varepsilon)))\}$, $\{P(a(a(a(\varepsilon))))\}$, $\{P(a(a(a(a(\varepsilon))))\}$, and so on.

2.2 Polarized sequent calculus modulo theory

Polarized sequent calculus modulo theory [9, 10] is an extension of sequent calculus, where axioms are replaced by rewrite rules, for instance the axiom $P \Rightarrow (Q \wedge R)$ can be replaced by the rewrite rule $P \longrightarrow_- (Q \wedge R)$. Rules are classified into positive and negative, according to the occurrences of the proposition to which they can apply. Then, the deduction rules are modified to allow the reduction of a proposition at any time.

Definition 3 (Polarized rewrite system). A rewrite rule is a pair $P \longrightarrow A$ where P is an atomic proposition and A an arbitrary proposition. A rewrite system is a set of rewrite rules. A polarized rewrite system $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$ is a pair of rewrite systems. The rules of \mathcal{R}_- are called negative and those of \mathcal{R}_+ positive.

Definition 4 (Polarized rewriting). Let $\mathcal{R} = \langle \mathcal{R}_-, \mathcal{R}_+ \rangle$ be a polarized rewrite system. The one step negative and positive rewriting relations, \longrightarrow_- and \longrightarrow_+ , are defined as follows.

- If $P \longrightarrow A$ is a rule of \mathcal{R}_s and σ is a substitution then $\sigma P \longrightarrow_s \sigma A$, where s is either $-$ or $+$.
- If $A \longrightarrow_s A'$ then $\neg A \longrightarrow_s \neg A'$, where \neg swaps $-$ and $+$.
- If $(A \longrightarrow_s A'$ and $B = B')$ or $(A = A'$ and $B \longrightarrow_s B')$, then $A \wedge B \longrightarrow_s A' \wedge B'$ and $A \vee B \longrightarrow_s A' \vee B'$.
- If $(A \longrightarrow_s A'$ and $B = B')$ or $(A = A'$ and $B \longrightarrow_s B')$, then $A \Rightarrow B \longrightarrow_s A' \Rightarrow B'$.
- If $A \longrightarrow_s A'$ then $\forall x A \longrightarrow_s \forall x A'$ and $\exists x A \longrightarrow_s \exists x A'$.

As usual, the relation \longrightarrow_s^* is the reflexive-transitive closure of the relation \longrightarrow_s .

Definition 5 (Polarized sequent calculus modulo theory). Let $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$ be a polarized rewrite system. Languages, terms, and propositions of Polarized sequent calculus modulo $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$, are like those of Predicate logic. The deduction rules (Figure 1) are those of the usual sequent calculus parametrized by the polarized rewrite system $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$.

For instance, the usual rule of sequent calculus

$$\frac{\Gamma \vdash C, \Delta \quad \Gamma \vdash D, \Delta}{\Gamma \vdash C \wedge D, \Delta} \wedge\text{-right}$$

is transformed into

$$\frac{\Gamma \vdash C, \Delta \quad \Gamma \vdash D, \Delta}{\Gamma \vdash A, \Delta} \wedge\text{-right} \quad \text{if } A \longrightarrow_+^* (C \wedge D)$$

Provability is preserved (also when considering only cut-free proofs) if the right-hand sides of rewrite rules is replaced by equivalent propositions. This can be used to simplify rewrite rules, using for instance De Morgan's rules.

Definition 6 (Right-equivalent rewrite rules). Two rewrite rules $P \longrightarrow A$ and $P \longrightarrow B$ are right-equivalent if the proposition $\forall x_1 \dots \forall x_n (A \Leftrightarrow B)$ is a provable in Predicate logic, where x_1, \dots, x_n are the free variables of A and B .

Two rewrite systems are right-equivalent if for each rule in one system, there is a right-equivalent rule in the other. This extends to polarized rewrite systems in the obvious way.

Lemma 1. Given two polarized rewrite systems $\langle \mathcal{R}_-, \mathcal{R}_+^1 \rangle$ and $\langle \mathcal{R}_-, \mathcal{R}_+^2 \rangle$ that are right-equivalent, a sequent $\Gamma \vdash \Delta$ can be proved (resp. proved without cut) modulo $\langle \mathcal{R}_-, \mathcal{R}_+^1 \rangle$ if and only if it can be proved (resp. proved without cut) modulo $\langle \mathcal{R}_-, \mathcal{R}_+^2 \rangle$.

Proof. See Appendix A. □

Definition 7 (Simplification). *The simplification $A \downarrow$ of a proposition A is obtained by pushing the negations inside A .*

$$\begin{array}{lll}
(\neg \top) \downarrow = \perp & (\neg(A \wedge B)) \downarrow = (\neg A) \downarrow \vee (\neg B) \downarrow & (A \wedge B) \downarrow = A \downarrow \wedge B \downarrow \\
\top \downarrow = \top & (\neg(A \vee B)) \downarrow = (\neg A) \downarrow \wedge (\neg B) \downarrow & (A \vee B) \downarrow = A \downarrow \vee B \downarrow \\
(\neg \perp) \downarrow = \top & (\neg \forall x A) \downarrow = \exists x ((\neg A) \downarrow) & (\forall x A) \downarrow = \forall x (A \downarrow) \\
\perp \downarrow = \perp & (\neg \exists x A) \downarrow = \forall x ((\neg A) \downarrow) & (\exists x A) \downarrow = \exists x (A \downarrow) \\
(\neg \neg A) \downarrow = A \downarrow & &
\end{array}$$

This definition extends to rewrite rules $(P \longrightarrow A) \downarrow = P \longrightarrow (A \downarrow)$ and to rewrite systems and polarized rewrite systems in the obvious way.

Lemma 2. *Given a polarized rewrite systems $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$ and its simplification $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle \downarrow$, a sequent $\Gamma \vdash \Delta$ can be proved (resp. proved without cut) modulo $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$ if and only if it can be proved (resp. proved without cut) modulo $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle \downarrow$.*

Proof. Corollary of Lemma 1, since the simplification leads to equivalent propositions. \square

2.3 Alternating pushdown systems in Polarized sequent calculus modulo theory

To express Alternating pushdown systems in Polarized sequent calculus modulo theory, we must replace each transition rule of an Alternating pushdown system by a rewrite rule. Let us start with an example.

Example 1. Consider the Alternating pushdown system formed with the rules

$$\begin{array}{ll} P(\varepsilon) \leftrightarrow \emptyset & Q(b(x)) \leftrightarrow \{P(x)\} \\ R(a(x)) \leftrightarrow \{Q(x)\} & S(x) \leftrightarrow \{R(a(x))\} \end{array}$$

The pop rules $R(a(x)) \leftrightarrow \{Q(x)\}$ and $Q(b(x)) \leftrightarrow \{P(x)\}$ and the empty rule $P(\varepsilon) \leftrightarrow \emptyset$ that permit to build the derivation

$$\{R(a(b(\varepsilon)))\} \leftrightarrow \{Q(b(\varepsilon))\} \leftrightarrow \{P(\varepsilon)\} \leftrightarrow \emptyset$$

are transformed into positives rule $R(a(x)) \longrightarrow_+ Q(x)$, $Q(b(x)) \longrightarrow_+ P(x)$, and $P(\varepsilon) \longrightarrow_+ \top$. This way, the proposition $R(a(b(\varepsilon)))$ rewrites positively to \top , and it has the proof in Polarized sequent calculus modulo theory

$$\frac{}{\vdash R(a(b(\varepsilon)))} \top\text{-right}$$

A push rule such as $S(x) \leftrightarrow \{R(a(x))\}$ could be transformed into the positive rule $S(x) \longrightarrow_+ R(a(x))$. This way, the proposition $S(b(\varepsilon))$ would rewrite positively to \top as well, and would have a trivial proof, built with the \top -right rule. However, we prefer to transform it into the negative rule $R(a(x)) \longrightarrow_- S(x)$, in order to let the proposition $S(b(\varepsilon))$ have the proof

$$\frac{\frac{}{\vdash R(a(b(\varepsilon)))} \top\text{-right} \quad \frac{}{R(a(b(\varepsilon))) \vdash S(b(\varepsilon))} \text{axiom}}{\vdash S(b(\varepsilon))} \text{cut}$$

but no cut-free proof, reflecting the fact that the derivation

$$\{S(b(\varepsilon))\} \leftrightarrow \{R(a(b(\varepsilon)))\} \leftrightarrow \{Q(b(\varepsilon))\} \leftrightarrow \{P(\varepsilon)\} \leftrightarrow \emptyset$$

contains a “cut”: a subsequence formed with a push rule followed by a pop rule. With the rewrite rules we have so far, this cut cannot be eliminated because the critical pair

does not close. But, it can be eliminated if we add either the rule $S(x) \longrightarrow_+ Q(x)$ or the rule $Q(x) \longrightarrow_- S(x)$, both representing the neutral rule $S(x) \leftrightarrow \{Q(x)\}$. Again, we shall take the negative rule, so that the closed atomic proposition $S(b(\varepsilon))$ has a proof

$$\frac{\frac{}{\vdash Q(b(\varepsilon))} \top\text{-right} \quad \frac{}{Q(b(\varepsilon)) \vdash S(b(\varepsilon))} \text{axiom}}{\vdash S(b(\varepsilon))} \text{cut}$$

but no cut-free proof, reflecting the fact that the derivation

$$\{S(b(\varepsilon))\} \leftrightarrow \{Q(b(\varepsilon))\} \leftrightarrow \{P(\varepsilon)\} \leftrightarrow \emptyset$$

still contains a “cut”: a subsequence formed with a neutral rule followed by a pop rule. With the rewrite rules we have so far, this cut cannot be eliminated because the critical pair

does not close. But, it can be eliminated if we add the rule $S(b(x)) \longrightarrow_+ P(x)$ which represents the pop rule $S(b(x)) \leftrightarrow \{P(x)\}$.

Once these two rules have been added, the proposition $S(b(\varepsilon))$ rewrites positively to \top , $S(b(\varepsilon)) \longrightarrow_+ P(\varepsilon) \longrightarrow_+ \top$, and hence it has the cut-free proof

$$\frac{}{\vdash S(b(\varepsilon))} \top\text{-right}$$

More generally, we shall see that with these two extra rules, every provable proposition has a cut-free proof and that the existence of a cut-free proof is decidable.

This example leads to the following definition.

Definition 8 (Expression of Alternating pushdown systems). *Let \mathcal{P} be an Alternating pushdown system, we define the rewrite system $\mathcal{R}(\mathcal{P})$ as follows:*

- a pop rule $Q(\gamma(x)) \leftrightarrow \{P_1(x), \dots, P_n(x)\}$ is expressed as the rewrite rule

$$Q(\gamma(x)) \longrightarrow_+ P_1(x) \wedge \dots \wedge P_n(x)$$

- an empty rule $Q(\varepsilon) \leftrightarrow \emptyset$ as the rewrite rule

$$Q(\varepsilon) \longrightarrow_+ \top$$

- a push rule $Q(x) \leftrightarrow \{P_1(\gamma(x)), P_2(x), \dots, P_n(x)\}$ as the rewrite rule

$$P_1(\gamma(x)) \longrightarrow_- \neg P_2(x) \vee \dots \vee \neg P_n(x) \vee Q(x)$$

- a neutral rule $Q(x) \leftrightarrow \{P_1(x), \dots, P_n(x)\}$ with $n \geq 1$ as the n rewrite rules

$$P_i(x) \longrightarrow_- \neg P_1(x) \vee \dots \vee \neg P_{i-1}(x) \vee \neg P_{i+1}(x) \dots \vee \neg P_n(x) \vee Q(x)$$

- and a neutral rule $Q(x) \leftrightarrow \emptyset$ as the rewrite rule

$$Q(x) \longrightarrow_+ \top$$

Lemma 3. *Let \mathcal{P} be an Alternating pushdown system and $\mathcal{R} = \mathcal{R}(\mathcal{P})$ be its expression as a rewrite system. If $S \leftrightarrow^* \emptyset$ in \mathcal{P} , then for all A in S , the sequent $\vdash A$ has a proof in Polarized sequent calculus modulo \mathcal{R} .*

Proof. By induction on the structure of the derivation from S to \emptyset .

- If $S = \{Q(w)\} \cup S'$ and the first step of the derivation from S to \emptyset transforms S into $\{P_1(\gamma(w)), P_2(w), \dots, P_n(w)\} \cup S'$ with a push rule, then by induction hypothesis all the propositions of S' have proofs in the Polarized sequent calculus modulo \mathcal{R} , and the propositions $P_1(\gamma(w)), P_2(w), \dots, P_n(w)$ have proofs $\pi_1, \pi_2, \dots, \pi_n$ in the Polarized sequent calculus modulo \mathcal{R} . The rewrite system \mathcal{R} contains the rule

$$P_1(\gamma(x)) \longrightarrow_- \neg P_2(x) \vee \dots \vee \neg P_n(x) \vee Q(x)$$

We build the following proof of $Q(w)$

$$\frac{\frac{\frac{\pi_1}{\vdash P_1(\gamma(w))} \quad \frac{\frac{\frac{\pi_2}{\vdash P_2(w)}}{\vdash P_2(w), Q(w)} \text{w-right}}{\neg P_2(w) \vdash Q(w)} \neg\text{-left} \quad \dots \quad \frac{\frac{\frac{\pi_n}{\vdash P_n(w)}}{\vdash P_n(w), Q(w)} \text{w-right}}{\neg P_n(w) \vdash Q(w)} \neg\text{-left} \quad \frac{Q(w) \vdash Q(w)}{\text{axiom}} \vee\text{-left}}{\frac{P_1(\gamma(w)) \vdash Q(w)}{\text{cut}}}}{\vdash Q(w)} \text{cut}$$

- If $S = \{Q(w)\} \cup S'$ and the first step of the derivation from S to \emptyset transforms S into $\{P_1(w), P_2(w), \dots, P_n(w)\} \cup S'$ with a non nullary neutral rule, then by induction hypothesis all the propositions of S' have proofs in the Polarized sequent calculus modulo \mathcal{R} and the propositions $P_1(w), P_2(w), \dots, P_n(w)$ have proofs $\pi_1, \pi_2, \dots, \pi_n$ in the Polarized sequent calculus modulo \mathcal{R} . The polarized rewrite system \mathcal{R} contains the rule

$$P_1(x) \longrightarrow_- \neg P_2(x) \vee \dots \vee \neg P_n(x) \vee Q(x)$$

We build the following proof of $Q(w)$

$$\frac{\frac{\frac{\pi_1}{\vdash P_1(w)} \quad \frac{\frac{\frac{\pi_2}{\vdash P_2(w)}}{\vdash P_2(w), Q(w)} \text{w-right}}{\neg P_2(w) \vdash Q(w)} \neg\text{-left} \quad \dots \quad \frac{\frac{\frac{\pi_n}{\vdash P_n(w)}}{\vdash P_n(w), Q(w)} \text{w-right}}{\neg P_n(w) \vdash Q(w)} \neg\text{-left} \quad \frac{Q(w) \vdash Q(w)}{\text{axiom}}}{\frac{P_1(w) \vdash Q(w)}{\text{cut}} \quad \frac{Q(w) \vdash Q(w)}{\text{v-left}}}}{\vdash Q(w)} \text{cut}$$

- If $S = \{Q(w)\} \cup S'$ and the first step of the derivation from S to \emptyset transforms S into S' with a nullary neutral rule, then by induction hypothesis all the propositions of S' have proofs. The polarized rewrite system \mathcal{R} contains the rule

$$Q(x) \longrightarrow_+ \top$$

We build the following proof of $Q(w)$

$$\frac{}{\vdash Q(w)} \top\text{-right}$$

- The cases of the pop and empty rules are similar.

3 Ordered resolution with selection and cut-elimination

We now want to define a saturation algorithm, that transforms a polarized rewrite system into an equivalent *saturated* polarized rewrite system and prove that if a polarized rewrite system \mathcal{R} is saturated, then the Polarized sequent calculus modulo \mathcal{R} has the cut-elimination property. Instead of saturating a polarized rewrite system by closing the critical pairs one by one, we shall use a more powerful method [4]: transform a polarized rewrite system into a set of clauses, saturate this set of clauses with Ordered resolution with selection and transform back the saturated set of clauses into a polarized rewrite system. Note that in general, saturating using Ordered resolution with selection may not terminate, so that not all rewrite systems can be completed that way. However, we will see cases where saturation is guaranteed to terminate.

3.1 Ordered resolution with selection

Ordered resolution with selection is a refinement of Resolution parametrized by a Noetherian ordering and a selection function. We recall its definition.

Definition 9 (Literal, Clause). *A proposition is a literal if it is either atomic or the negation of an atomic proposition. A clause is a disjunction of literals.*

If A is a proposition containing the free variables x_1, \dots, x_n , we write $\bar{\forall}A$ for the proposition $\forall x_1 \dots \forall x_n A$.

Definition 10 (Clause form). *To each proposition A , we associate a set of clauses $\mathcal{C}(A)$ such that A is equivalent to $\bigwedge_{C \in \mathcal{C}(A)} \bar{\forall}C$. The actual definition of \mathcal{C} is not relevant here, see for instance [18].*

Definition 11 (Maximal atomic proposition). Given an ordering \succ on atomic propositions, an atomic proposition A is said to be maximal in a clause C if for all atomic propositions B in C , $B \not\succeq A$.

Definition 12 (Selection function). A selection function is a function \mathcal{S} that associates to each clause C a set $\mathcal{S}(C)$ of negative literals of C .

We often indicate the selected literals just by underlining them; for instance, in the clause $\neg P \vee \neg Q \vee \neg R \vee S$, if \mathcal{S} selects $\neg P$ and $\neg R$, we write the clause $\underline{\neg P} \vee \neg Q \vee \underline{\neg R} \vee S$.

Definition 13 (Ordered resolution with selection). Ordered resolution with selection [2, Section 4.3] ($ORS_{\mathcal{S}}^{\succ}$) is a refinement of Resolution parametrized by

- an ordering \succ on atomic propositions that is well-founded, stable by substitution, and total on ground atomic propositions,
- and a selection function \mathcal{S} .

It consists in restricting the literals on which the Resolution rule can be applied: if $\mathcal{S}(C)$ is not empty, then only the literals in $\mathcal{S}(C)$ can be used; otherwise, only the maximal literals with respect to \succ can be used.

The inference rule of $ORS_{\mathcal{S}}^{\succ}$ is the following:

$$\frac{\neg A_1 \vee \dots \vee \neg A_k \vee D \quad A_1^1 \vee \dots \vee A_1^{n_1} \vee C_1 \quad \dots \quad A_k^1 \vee \dots \vee A_k^{n_k} \vee C_k}{\sigma(D \vee C_1 \vee \dots \vee C_k)} \text{Resolution}$$

- σ is the most general unifier to the simultaneous unification problems $A_i^1 = \dots = A_i^{n_i} = A_i$ for $1 \leq i \leq k$;
- - either $\mathcal{S}(\neg A_1 \vee \dots \vee \neg A_k \vee D) = \{\neg A_1, \dots, \neg A_k\}$, with $k \geq 1$;
 - or $\mathcal{S}(\neg A_1 \vee \dots \vee \neg A_k \vee D) = \emptyset$, $k = 1$ and $\sigma(\neg A_1)$ is maximal in $\sigma(\neg A_1 \vee D)$;
- $\mathcal{S}(A_i^1 \vee \dots \vee A_i^{n_i} \vee C_i) = \emptyset$ for all $1 \leq i \leq k$;
- and each $\sigma(A_i^j)$ is maximal in $\sigma(A_i^1 \vee \dots \vee A_i^{n_i} \vee C_i)$.

Definition 14 (Saturated). A set of clauses \mathcal{C} is saturated if no clause can be added by applying the Resolution rule.

Remark 1. The results presented here hold also if one considers saturation up to redundancies, more precisely up to compositeness [1], where inferred clauses can be discarded from the saturation if they follow from smaller clauses.

Besides, if \mathcal{C} and \mathcal{D} are two sets of clauses and \mathcal{C} is saturated, then in a derivation of \perp from \mathcal{C}, \mathcal{D} , we can forbid applying a rule between clauses from \mathcal{C} only, because this would yield a clause that is already in \mathcal{C} .

3.2 Building clauses from polarized rewrite systems

Definition 15 (Transforming polarized rewrite systems into sets of clauses). Let \mathcal{R} be a polarized rewrite system. Let Γ be the set of propositions containing, for each negative rewrite rule $P \rightarrow_- A$ in \mathcal{R} , the proposition $\bar{\forall}(P \Rightarrow A)$ and, for each positive rewrite rule $P \rightarrow_+ A$ in \mathcal{R} , the proposition $\bar{\forall}(A \Rightarrow P)$. The set of clauses $\Phi(\mathcal{R})$ associated to the polarized rewrite system \mathcal{R} is the set $\bigcup_{B \in \Gamma} \mathcal{C}(B)$.

Lemma 4. *Let \mathcal{R} be a polarized rewrite system and Γ be as in Definition 15. Let $\{C_1, \dots, C_n\} = \Phi(\mathcal{R})$ be the set of clauses associated to \mathcal{R} . Let D be a proposition. Then, the sequent $\vdash D$ is provable in Polarized sequent calculus modulo \mathcal{R} if and only if the sequent $\Gamma \vdash D$ is provable in Predicate logic if and only if the sequent $\forall C_1, \dots, \forall C_n \vdash D$ is provable in Predicate logic.*

Proof. The first equivalence is proved in [9, 10]. The second is the correctness of the clause form.

Example 2. Continuing Example 1, the polarized rewrite system

$$\begin{array}{ll} P(\varepsilon) \longrightarrow_+ \top & Q(b(x)) \longrightarrow_+ P(x) \\ R(a(x)) \longrightarrow_+ Q(x) & R(a(x)) \longrightarrow_- S(x) \end{array}$$

is transformed into the set of clauses

$$\begin{array}{ll} P(\varepsilon) & \neg P(x) \vee Q(b(x)) \\ \neg Q(x) \vee R(a(x)) & \neg R(a(x)) \vee S(x) \end{array}$$

The rewrite rule saturation step of Example 1, that generates the rewrite rule $Q(x) \longrightarrow_- S(x)$ closing the critical pair

is the application of the Ordered resolution rule —with an ordering \succ such that $R(a(x)) \succ Q(x)$, $R(a(x)) \succ S(x)$ — to two clauses $\neg Q(x) \vee R(a(x))$ and $\neg R(a(x)) \vee S(x)$, that yields the clause $\neg Q(x) \vee S(x)$. Then, in this clause, we need to consider the negative literal $\neg Q(x)$ as "maximal", so that we can apply the Resolution rule to the clauses $\neg Q(x) \vee S(x)$ and $\neg P(x) \vee Q(b(x))$ to generate the clause $S(b(x)) \vee \neg P(x)$ corresponding to the rule $S(b(x)) \longrightarrow_+ P(x)$ of Example 1. To do so, we must use the selection function to select the negative literal $\neg Q(x)$ in the clause $\neg Q(x) \vee S(x)$ corresponding to a neutral rule.

3.3 Building polarized rewrite systems from clauses using Ordered resolution with selection

In [4], we have presented an algorithm that transforms a set of clauses \mathcal{C} into a polarized rewrite system \mathcal{R} , such that Polarized sequent calculus modulo \mathcal{R} has the cut-elimination property. More precisely, this algorithm first saturates this set of clauses \mathcal{C} , with Ordered resolution with selection, into an equivalent set of clauses \mathcal{C}' . If this saturation terminates, the algorithm generates the polarized rewrite system \mathcal{R} , from the saturated set \mathcal{C}' . However [4] only addressed a restricted form of Ordered resolution with selection, where in each clause, at most one literal is selected. So, in this section, we start by generalizing the main theorem of [4] to full Ordered resolution with selection.

Definition 16 (Polarized rewrite system associated to a set of clauses).

Given an ordering \succ on atomic propositions and a selection function \mathcal{S} , we define a function $\Psi_{\mathcal{S}}^{\succ}$ that associates, to each set of clauses \mathcal{C} , the following polarized rewrite system $\Psi_{\mathcal{S}}^{\succ}(\mathcal{C})$: for each clause C of \mathcal{C} ,

- if $\mathcal{S}(C) \neq \emptyset$, then for all $\neg Q \in \mathcal{S}(C)$, we add a rule

$$Q \longrightarrow_{-} \forall y_1 \dots \forall y_n (C \setminus \neg Q)$$

- if $\mathcal{S}(C) = \emptyset$, then

- for all maximal negative literals $\neg Q$ in C , we add a rule

$$Q \longrightarrow_{-} \forall y_1 \dots \forall y_n (C \setminus \neg Q)$$

- for all maximal positive literals Q in C , we add a rule

$$Q \longrightarrow_{+} (\neg \forall y_1 \dots \forall y_n (C \setminus Q)) \downarrow$$

where $C \setminus L$ is the clause C without the literal L and y_1, \dots, y_n are the variables that are free in C but not in Q .

Lemma 5. *The transformation $\Psi_{\mathcal{S}}^{\succ}$ is a right inverse (in terms of logical equivalence) of the function Φ of Definition 15: for all set S of clauses, $\Phi(\Psi_{\mathcal{S}}^{\succ}(S))$ is logically equivalent to S .*

Proof. If a clause $\neg Q \vee C$ leads to a rule $Q \longrightarrow_{-} \forall y_1 \dots \forall y_n C$ (either because $\neg Q$ is selected or maximal), then Definition 15 first consider the proposition $A = \forall x_1 \dots \forall x_m (Q \Rightarrow \forall y_1 \dots \forall y_n C)$ where x_1, \dots, x_m are the free variables of Q . This proposition is logically equivalent to $\forall (\neg Q \vee C)$, so $\mathcal{A}(A)$ is also equivalent to it.

If a clause $Q \vee C$ leads to a rule $Q \longrightarrow_{+} (\neg \forall y_1 \dots \forall y_n C) \downarrow$, then Definition 15 first consider the proposition $B = \forall x_1 \dots \forall x_m ((\neg \forall y_1 \dots \forall y_n C) \downarrow \Rightarrow Q)$ where x_1, \dots, x_m are the free variables of Q . This proposition is logically equivalent to $\forall (Q \vee C)$, so $\mathcal{A}(B)$ is also equivalent to it. \square

Note that it is not a left inverse (because the left-hand side of the original rules are not necessarily selected or maximal in the clauses).

Example 3. Consider the polarized rewrite system containing the rules $P \longrightarrow_{-} Q \wedge R$ and $P \longrightarrow_{+} \top$. The proposition Q has no cut-free proof, but it has the proof

$$\frac{\frac{\frac{}{\vdash P} \top\text{-right}}{\vdash P} \quad \frac{\frac{\overline{Q, R \vdash Q} \text{ axiom}}{P \vdash Q} \wedge\text{-left}}{\vdash Q} \text{ cut}}{\vdash Q} \text{ cut}}{\vdash Q} \text{ cut}$$

The set of clauses associated to this rewrite system is $\{\neg P \vee Q, \neg P \vee R, P\}$. If we consider an order such that $R \succ Q \succ P$, and a selection function selecting

$\neg P$ in both clauses, then Resolution generates the clauses Q and R and the produced rewrite system is

$$\begin{array}{lll} P \longrightarrow_- Q & P \longrightarrow_+ \top & R \longrightarrow_+ \top \\ P \longrightarrow_- R & Q \longrightarrow_+ \top & \end{array}$$

In contrast, if, with the same order, selection does not select any negative literal, Resolution does not generate any clause, and the produced rewrite system is

$$Q \longrightarrow_+ P \quad R \longrightarrow_+ P \quad P \longrightarrow_+ \top$$

The proposition Q has a cut-free proof in both cases, but the two rewrite systems are quite different. This example also shows that it is not completely obvious to saturate directly the rewrite system and add such rules as a way to close the critical pair

Example 4. Continuing on Examples 1 and 2, using the order and selection function defined there, the clause $P(\varepsilon)$, $\neg P(x) \vee Q(b(x))$, $\neg Q(x) \vee R(a(x))$, and $\neg R(a(x)) \vee S(x)$ of the initial system translate respectively to the rewrite rules

$$\begin{array}{ll} P(\varepsilon) \longrightarrow_+ \top & Q(b(x)) \longrightarrow_+ P(x) \\ R(a(x)) \longrightarrow_+ Q(x) & R(a(x)) \longrightarrow_- S(x) \end{array}$$

and the clause $\neg Q(x) \vee S(x)$ and $\neg P(x) \vee S(b(x))$ added during saturation translate respectively to the rewrite rules

$$Q(x) \longrightarrow_- S(x) \quad S(b(x)) \longrightarrow_+ P(x)$$

To generalize the main theorem of [4] linking saturation with cut elimination, we introduce another variant of Resolution, with a binary resolution rule and an explicit factoring rule.

Definition 17 (Binary resolution and factoring).

$$\frac{P \vee C \quad \neg Q \vee D}{\sigma(C \vee D)} \text{ Binary Resolution} \quad \frac{P \vee Q \vee C}{\sigma(P \vee C)} \text{ Factoring}$$

where σ is the most general unifier of P and Q .

Theorem 1 (Cut-elimination). *If $\mathcal{C} = \{C_1, \dots, C_n\}$ is a saturated set of clauses and A is an arbitrary proposition, then the following are equivalent:*

1. the sequent $\vdash A$ is provable in the Polarized sequent calculus modulo $\Psi_S^>(\mathcal{C})$;
2. the sequent $\forall C_1, \dots, \forall C_n \vdash A$ is provable in Predicate logic;
3. the empty clause can be derived in $ORS_S^>$ from $\mathcal{C}, \mathcal{C}(\neg A)$, with, at each step, at least one of the premises not in \mathcal{C} ;

4. the empty clause can be derived in the Binary Resolution and Factoring system from $\mathcal{C}, \mathcal{C}(\neg A)$, with, at each step, at least one of the premises not in \mathcal{C} (so Factoring is applied only to clauses outside \mathcal{C});
5. the sequent $\mathcal{C}(\neg A) \vdash$ has a cut-free proof in the Polarized sequent calculus modulo $\Psi_S^\succ(\mathcal{C})$;
6. the sequent $\vdash A$ has a cut-free proof in the Polarized sequent calculus modulo $\Psi_S^\succ(\mathcal{C})$.

Proof. – 1 \Rightarrow 2: By Lemma 5 $\Phi(\Psi_S^\succ(\mathcal{C}))$ is logically equivalent to \mathcal{C} . Therefore, this is a consequence of Lemma 4.

– 2 \Rightarrow 3: ORS_S^\succ is refutationally complete. Furthermore, if a set of clauses \mathcal{C} is saturated, and $\mathcal{C}, \mathcal{C}(\neg A)$ is unsatisfiable, there exists a derivation of the empty clause from $\mathcal{C}, \mathcal{C}(\neg A)$ in which every instance of the Resolution rule has at least one premise not in \mathcal{C} (otherwise the conclusion is already in \mathcal{C} because it is saturated).

– 3 \Rightarrow 4: We translate the derivation in ORS_S^\succ into a derivation in the Binary resolution and factoring system. Given an instance of the Resolution rule with the notations of Definition 13, at least one of $\neg A_1 \vee \dots \vee \neg A_k \vee D$ or $A_1^1 \vee \dots \vee A_i^{n_i} \vee C_i$ for $1 \leq i \leq k$ is not in \mathcal{C} . Without loss of generality, we can assume that this premise is either $\neg A_1 \vee \dots \vee \neg A_k \vee D$ or $A_1^1 \vee \dots \vee A_1^{n_1} \vee C_1$. Then, the Resolution rule is translated as follows, where $A'_i = \sigma A_i = \sigma A_i^1 = \dots = \sigma A_i^{n_i}$:

First we obtain $\neg A'_2 \vee \dots \vee \neg A'_k \vee \sigma D \vee \sigma C_1$ from $\neg A_1 \vee \dots \vee \neg A_k \vee D$ and $A_1^1 \vee \dots \vee A_1^{n_1} \vee C_1$:

$$\frac{\frac{\frac{\neg A_1 \vee \dots \vee \neg A_k \vee D \quad A_1^1 \vee \dots \vee A_1^{n_1} \vee C_1}{\neg A'_2 \vee \dots \vee \neg A'_k \vee \sigma D \vee \sigma A_1^2 \vee \dots \vee \sigma A_1^{n_1} \vee \sigma C_1} \text{Binary resolution}}{\neg A_1 \vee \dots \vee \neg A_k \vee D \quad \frac{\dots}{\neg A'_2 \vee \dots \vee \neg A'_k \vee \sigma D \vee A'_1 \vee \sigma C_1} \text{Factoring}} \text{Factoring}}{\frac{\neg A'_2 \vee \dots \vee \neg A'_k \vee \sigma D \vee \neg A'_2 \vee \dots \vee \neg A'_k \vee \sigma D \vee \sigma C_1}{\neg A'_2 \vee \dots \vee \neg A'_k \vee \sigma D \vee \sigma C_1} \text{Binary resolution}} \text{Factoring}}$$

Similarly we can obtain $\neg A'_3 \vee \dots \vee \neg A'_k \vee \sigma D \vee \sigma C_1 \vee \sigma C_2$ from $\neg A'_2 \vee \dots \vee \neg A'_k \vee \sigma D \vee \sigma C_1$ and $A_2^1 \vee \dots \vee A_2^{n_2} \vee C_2$, and so on until we get $\sigma D \vee \sigma C_1 \vee \dots \vee \sigma C_k$.

As we can remark, at most one of the premises of each inference rule belongs to \mathcal{C} .

- 4 \Rightarrow 5: We translate the derivation into a cut-free proof of $\mathcal{C}(\neg A)$ modulo the rewrite system $\Psi_S^\succ(\mathcal{C})$ associated with the saturated set of clause \mathcal{C} , exactly as it is described in the proof of Lemma 11 of [4].
- 5 \Rightarrow 6: A cut-free proof of $\vdash A$ modulo $\Psi_S^\succ(\mathcal{C})$ can be obtained from the cut-free proof of $\mathcal{C}(\neg A) \vdash$ modulo $\Psi_S^\succ(\mathcal{C})$ as shown in [15].
- 6 \Rightarrow 1: trivial. □

Corollary 1. *If \mathcal{C} is saturated, then the cut rule is admissible in Polarized sequent calculus modulo $\Psi_S^\succ(\mathcal{C})$.* □

4 An application to the decidability of Alternating pushdown systems

The goal of this section is to prove the decidability of reachability in pushdown systems (Theorem 2) by using to the result of Section 3. We have shown in Section 2 how to express an Alternating pushdown system \mathcal{P} as a polarized rewrite system $\mathcal{R}(\mathcal{P})$. When we express this rewrite system as a set of clauses $\Phi(\mathcal{R}(\mathcal{P}))$, we obtain *Pushdown clauses*.

Definition 18 (Pushdown clause). Pushdown clauses are clauses of the following form:

$\neg Q_1(x) \vee \dots \vee \neg Q_n(x) \vee P(\gamma(x))$	<i>pop</i>	<i>where n may be zero</i>
$P(\varepsilon)$	<i>empty</i>	
$\neg P_1(\gamma(x)) \vee \neg P_2(x) \vee \dots \vee \neg P_n(x) \vee Q(x)$	<i>push</i>	
$\neg Q_1(x) \vee \dots \vee \neg Q_n(x) \vee P(x)$	<i>neutral</i>	<i>where $n \geq 1$</i>
$P(x)$	<i>arbitrary</i>	

Note that we distinguish the clauses coming from neutral rules with at least one premise (neutral clauses) and those coming from neutral rules with no premise (arbitrary clauses).

Definition 19 (Coherent). Let \mathcal{P} be an Alternating pushdown system. A clause C of the form $\neg P_1 \vee \dots \vee \neg P_n \vee Q$ is said to be coherent with the Alternating pushdown system \mathcal{P} if for all substitutions σ , such that σC is closed, if $\{\sigma P_1\} \leftrightarrow^* \emptyset$, ..., $\{\sigma P_n\} \leftrightarrow^* \emptyset$ in \mathcal{P} , then $\{\sigma Q\} \leftrightarrow^* \emptyset$ in \mathcal{P} .

Lemma 6. Let \mathcal{P} be an Alternating pushdown system, all the clauses of $\Phi(\mathcal{R}(\mathcal{P}))$ are coherent with \mathcal{P} .

Proof. Assume, for instance, that $\Phi(\mathcal{R}(\mathcal{P}))$ contains a pop clause $\neg Q_1(x) \vee \dots \vee \neg Q_n(x) \vee P(\gamma(x))$. In this case, the polarized rewrite system $\mathcal{R}(\mathcal{P})$ contains the rule $P(\gamma(x)) \rightarrow_+ Q_1(x) \wedge \dots \wedge Q_n(x)$ and the Alternating pushdown system \mathcal{P} contains the rule $P(\gamma(x)) \leftrightarrow \{Q_1(x), \dots, Q_n(x)\}$. Thus, this clause is coherent with \mathcal{P} .

The other cases are similar. □

Definition 20 (Ordering). Let \prec be the Knuth-Bendix Ordering [17] with an arbitrary total precedence and the same weight for each symbol.

Note that $P(\gamma(x)) \succ Q(x)$ regardless the predicate symbols P and Q and that \prec is total on closed atomic propositions. Any order satisfying these two conditions could be used instead.

Definition 21 (Selection). Consider a selection function S that selects all the negative literals in neutral clauses, and nothing in pop, empty, push, and arbitrary clauses.

A clause C such that $S(C) \neq \emptyset$ is a neutral clause. A clause C such that $S(C) = \emptyset$ and C has a negative maximal literal is a push clause. A clause C such that $S(C) = \emptyset$ and C has a positive maximal literal is either a pop clause, an empty clause, or an arbitrary clause.

Thus, when applying the Resolution rule to Pushdown clauses (Definition 18) the clause with the negative literals can either be a push clause or a neutral clause, and those with the positive literals can be pop, empty, or arbitrary clauses.

If the clause with negative literals is a push clause, the clause with positive literals can be a pop clause or an arbitrary clause, but not an empty clause, because ε and $\gamma(x)$ do not unify. Thus, the resolution rule specializes into the two rules

$$\frac{\neg Q_1(\gamma(x)) \vee \neg Q_2(x) \vee \dots \vee \neg Q_m(x) \vee R(x) \quad \neg P_1(x) \vee \dots \vee \neg P_n(x) \vee Q_1(\gamma(x))}{\neg Q_2(x) \vee \dots \vee \neg Q_m(x) \vee \neg P_1(x) \vee \dots \vee \neg P_n(x) \vee R(x)} \text{push-pop}$$

$$\frac{\neg Q_1(\gamma(x)) \vee \neg Q_2(x) \vee \dots \vee \neg Q_m(x) \vee R(x) \quad Q_1(x)}{\neg Q_2(x) \vee \dots \vee \neg Q_m(x) \vee R(x)} \text{push-arbitrary}$$

If the clause with negative literals is a neutral clause, then the clauses with positive literals are a mix of pop, empty, and arbitrary clauses. There cannot be both pop and empty clauses, because ε and $\gamma(x)$ do not unify, so they are either a mix of at least one pop clause and some arbitrary clauses, a mix of at least one empty clause and some arbitrary clauses, or arbitrary clauses only. Thus, the resolution rule specializes into the three rules

$$\frac{\frac{\frac{\frac{\neg Q_1(x) \vee \dots \vee \neg Q_k(x) \vee \neg Q_{k+1}(x) \vee \dots \vee \neg Q_m(x) \vee R(x)}{\neg P_1^1(x) \vee \dots \vee \neg P_{n_1}^1(x) \vee Q_1(\gamma(x))} \dots}{\neg P_1^k(x) \vee \dots \vee \neg P_{n_k}^k(x) \vee Q_k(\gamma(x))} \dots}{Q_{k+1}(x)} \dots}{Q_m(x)} \text{neutral-pop}}{\neg P_1^1(x) \vee \dots \vee \neg P_{n_1}^1(x) \vee \dots \vee \neg P_1^k(x) \vee \dots \vee \neg P_{n_k}^k(x) \vee R(\gamma(x))} \text{neutral-pop}$$

$$\frac{\frac{\neg Q_1(x) \vee \dots \vee \neg Q_k(x) \vee \neg Q_{k+1}(x) \vee \dots \vee \neg Q_m(x) \vee R(x) \quad Q_1(\varepsilon) \quad \dots \quad Q_k(\varepsilon) \quad Q_{k+1}(x) \quad \dots \quad Q_m(x)}{R(\varepsilon)} \text{neutral-empty}}{\neg Q_1(x) \vee \dots \vee \neg Q_m(x) \vee R(x) \quad Q_1(x) \quad \dots \quad Q_m(x)} \text{neutral-empty}$$

$$\frac{\frac{\neg Q_1(x) \vee \dots \vee \neg Q_m(x) \vee R(x) \quad Q_1(x) \quad \dots \quad Q_m(x)}{R(x)} \text{neutral-arbitrary}}{\neg Q_1(x) \vee \dots \vee \neg Q_m(x) \vee R(x) \quad Q_1(x) \quad \dots \quad Q_m(x)} \text{neutral-arbitrary}$$

These rules are similar to the saturation rules of [11], with one exception: if we have the clauses $P(x)$ and $\neg P(\gamma(x)) \vee Q(x)$, [11] produces first the *pop* clause $P(\gamma(x))$ then $Q(x)$, while Ordered resolution with selection produces $Q(x)$ directly, with the push-arbitrary rule.

Lemma 7. *The Resolution rule applied to Pushdown clauses always produces Pushdown clauses, and terminates, on a saturated set, after a finite number of steps.*

Proof. In the five cases above, the produced clause is a Pushdown clause. Given a finite language, the number of possible Pushdown clauses is finite, hence the saturation process terminates.

Lemma 8. *Consider an Alternating pushdown system \mathcal{P} . The set of clauses that are coherent with \mathcal{P} is closed by the Resolution rule.*

Proof. Consider $k + 1$ clauses that are coherent with the Alternating pushdown system \mathcal{P} :

$$\begin{aligned} & \neg P_1 \vee \dots \vee \neg P_k \vee \neg Q_1 \vee \dots \vee \neg Q_n \vee R \\ & \quad \neg S_1^1 \vee \dots \vee \neg S_1^{n_1} \vee P'_1 \\ & \quad \dots \\ & \quad \neg S_k^1 \vee \dots \vee \neg S_k^{n_k} \vee P'_k \end{aligned}$$

With σ the simultaneous most general unifier of $P_i = P'_i$ for all $1 \leq i \leq k$, Resolution infers the clause C

$$\neg \sigma Q_1 \vee \dots \vee \neg \sigma Q_n \vee \neg \sigma S_1^1 \vee \dots \vee \neg \sigma S_1^{n_1} \vee \dots \vee \neg \sigma S_k^1 \vee \dots \vee \neg \sigma S_k^{n_k} \vee \sigma R$$

Let τ be a substitution such that τC is closed.

Assume $\{\tau \sigma Q_1\} \leftrightarrow^* \emptyset, \dots, \{\tau \sigma Q_n\} \leftrightarrow^* \emptyset, \{\tau \sigma S_1^1\} \leftrightarrow^* \emptyset, \dots, \{\tau \sigma S_k^{n_k}\} \leftrightarrow^* \emptyset$.

For all $1 \leq i \leq k$, as the clause $i + 1$ is coherent with \mathcal{P} , $\{\tau \sigma P'_i\} \leftrightarrow^* \emptyset$. Thus, as the first clause is coherent with \mathcal{P} , $\{\tau \sigma R\} \leftrightarrow^* \emptyset$. \square

Proposition 1. *Consider an Alternating pushdown system \mathcal{P} , its expression \mathcal{R} ($= \mathcal{R}(\mathcal{P})$) as a polarized rewrite system, the translation \mathcal{C} ($= \Phi(\mathcal{R})$) of this polarized rewrite system as a set of clauses, the saturation \mathcal{C}' of \mathcal{C} , the polarized rewrite system \mathcal{R}' ($= \Psi_{\mathcal{S}}^{\mathcal{C}'}(\mathcal{C}')$) associated to \mathcal{C}' , and the polarized rewrite system \mathcal{R}'' composed of the positive rules of \mathcal{R}' .*

Let $R(w)$ be a closed atomic proposition. Then if $\{R(w)\} \leftrightarrow^ \emptyset$ in \mathcal{P} , the sequent $\vdash R(w)$ has a cut-free proof in the Polarized sequent calculus modulo \mathcal{R}'' .*

Proof. If $\{R(w)\} \leftrightarrow^* \emptyset$ in \mathcal{P} , then by Lemma 3, the sequent $\vdash R(w)$ has a proof in Polarized sequent calculus modulo \mathcal{R} . By Lemma 4, the sequent $\overline{\forall} \mathcal{C} \vdash R(w)$ is provable in Predicate logic. By soundness of Resolution, $\overline{\forall} \mathcal{C}' \vdash R(w)$ has a proof in Predicate logic. By Theorem 1, the sequent $\vdash R(w)$ has a cut-free proof in Polarized sequent calculus modulo \mathcal{R}' .

As all the positive rules of \mathcal{R}' , coming from the pop, empty, and arbitrary clauses, have the form

$$\begin{aligned} Q(\gamma(x)) & \longrightarrow_+ P_1(x) \wedge \dots \wedge P_n(x) \\ Q(\varepsilon) & \longrightarrow_+ \top \\ Q(x) & \longrightarrow_+ \top \end{aligned}$$

and all occurrences of atomic propositions in the right-hand side of these rules are positive, a cut-free proof of a sequent of the form $\vdash R(w)$ in \mathcal{R}' only uses positive rules. Thus, the sequent $\vdash R(w)$ has a cut-free proof in Polarized sequent calculus modulo \mathcal{R}'' . \square

We now want to prove the converse of Proposition 1: cut-free proofs in Polarized sequent calculus modulo \mathcal{R}'' can be translated back to derivations in \mathcal{P} .

Lemma 9. *Let \mathcal{R}'' be a polarized rewrite system containing rules of the form*

$$\begin{array}{l} Q(\gamma(x)) \longrightarrow_+ P_1(x) \wedge \dots \wedge P_n(x) \\ Q(\varepsilon) \longrightarrow_+ \top \end{array} \qquad Q(x) \longrightarrow_+ \top$$

and let $R(w)$ be an atomic proposition such that $\vdash R(w)$ has a cut-free proof in Polarized sequent calculus modulo \mathcal{R}'' . Then $R(w) \longrightarrow_+^* T$ where T is a conjunction of propositions \top .

Proof. By induction on the structure of w . As $\vdash R(w)$ has a cut-free proof, the proposition is reducible. If it reduces in one step to \top , then we take $T = \top$. Otherwise $w = \gamma(w')$ and $R(w)$ reduces to $S_1(w') \wedge \dots \wedge S_n(w')$. As $S_1(w') \wedge \dots \wedge S_n(w')$ has a cut-free proof, so do $S_1(w')$, ..., $S_n(w')$. By induction hypotheses, these propositions rewrite to a conjunction of propositions \top . Thus, so does $R(w)$. \square

Proposition 2. *Consider $\mathcal{P}, \mathcal{R}, \mathcal{C}, \mathcal{C}', \mathcal{R}'$ and \mathcal{R}'' as in Proposition 1. Let $R(w)$ be a closed atomic proposition. Then if the sequent $\vdash R(w)$ has a cut-free proof in the Polarized sequent calculus modulo \mathcal{R}'' , then $\{R(w)\} \hookrightarrow^* \emptyset$ in \mathcal{P} .*

Proof. From Lemma 6 and 8, all clauses of \mathcal{C}' are coherent with \mathcal{P} . Thus, for all rewrite rules of \mathcal{R}'' of the form

$$Q(\gamma(x)) \longrightarrow_+ P_1(x) \wedge \dots \wedge P_n(x)$$

if $\{P_1(w)\} \hookrightarrow^* \emptyset, \dots, \{P_n(w)\} \hookrightarrow^* \emptyset$, then $\{Q(\gamma(w))\} \hookrightarrow^* \emptyset$. In the same way, for all rewrite rules of \mathcal{R}'' of the form

$$Q(\varepsilon) \longrightarrow_+ \top$$

$\{Q(\varepsilon)\} \hookrightarrow^* \emptyset$ and for all rewrite rules of \mathcal{R}'' of the form

$$Q(x) \longrightarrow_+ \top$$

and for all w , $\{Q(w)\} \hookrightarrow^* \emptyset$.

From Lemma 9, $R(w)$ rewrites in \mathcal{R}'' to a proposition T that is a conjunction of propositions \top . We conclude with a simple induction on the structure of the rewrite sequence from $R(w)$ to T . \square

Theorem 2 (Decidability). *Consider $\mathcal{P}, \mathcal{R}, \mathcal{C}, \mathcal{C}', \mathcal{R}'$ and \mathcal{R}'' as in Proposition 1. The set of atomic propositions $R(w)$ that have a proof in the Polarized sequent calculus modulo \mathcal{R}'' is decidable.*

Proof. The system \mathcal{R}'' contains rules of the form

$$\begin{array}{l} Q(\gamma(x)) \longrightarrow_+ P_1(x) \wedge \dots \wedge P_n(x) \\ Q(\varepsilon) \longrightarrow_+ \top \\ Q(x) \longrightarrow_+ \top \end{array}$$

and the Polarized sequent calculus modulo \mathcal{R}'' has the cut-elimination property.

We design an algorithm that proceeds by induction on the structure of w . If $R(w)$ is irreducible, then it does not have a proof. If it reduces in one step to \top then it has a proof. Otherwise $w = \gamma(w')$ and $R(w)$ reduces in one step to $S_1(w') \wedge \dots \wedge S_n(w')$. The proposition $R(w)$ is provable if and only if $S_1(w')$, ..., $S_n(w')$ are provable. We apply the algorithm recursively to these propositions. \square

Example 5. Consider the system with the transition rules

$$\begin{array}{lll} P(a(x)) \leftrightarrow \{P(x), Q(x)\} & P(b(x)) \leftrightarrow \{S(x)\} & Q(b(x)) \leftrightarrow \emptyset \\ Q(a(x)) \leftrightarrow \{S(x)\} & R(x) \leftrightarrow \{P(a(x))\} & S(x) \leftrightarrow \emptyset \end{array}$$

We have $\{R(a(b(\varepsilon)))\} \leftrightarrow^* \emptyset$.

This system is expressed in Polarized sequent calculus modulo theory by the polarized rewrite system

$$\begin{array}{lll} P(a(x)) \longrightarrow_+ P(x) \wedge Q(x) & P(b(x)) \longrightarrow_+ S(x) & Q(b(x)) \longrightarrow_+ \top \\ Q(a(x)) \longrightarrow_+ S(x) & P(a(x)) \longrightarrow_- R(x) & S(x) \longrightarrow_+ \top \end{array}$$

This polarized rewrite system is expressed by the Pushdown clauses \mathcal{C}

$$\begin{array}{lll} \neg P(x) \vee \neg Q(x) \vee P(a(x)) & \neg S(x) \vee P(b(x)) & Q(b(x)) \\ \neg S(x) \vee Q(a(x)) & \neg P(a(x)) \vee R(x) & S(x) \end{array}$$

Applying the Resolution rule to the clauses of \mathcal{C} yields the saturated system \mathcal{C}' that contains the clauses of \mathcal{C} and the following three new clauses

$$\frac{\neg P(x) \vee \neg Q(x) \vee R(x) \quad \neg S(x) \vee R(b(x))}{\neg P(x) \vee \neg Q(x) \vee \neg S(x) \vee R(a(x))}$$

From the set \mathcal{C}' , we derive the following polarized rewrite system

$$\begin{array}{lll} P(a(x)) \longrightarrow_+ P(x) \wedge Q(x) & P(b(x)) \longrightarrow_+ S(x) & Q(b(x)) \longrightarrow_+ \top \\ Q(a(x)) \longrightarrow_+ S(x) & P(a(x)) \longrightarrow_- R(x) & S(x) \longrightarrow_+ \top \\ P(x) \longrightarrow_- \neg Q(x) \vee R(x) & Q(x) \longrightarrow_- \neg P(x) \vee R(x) & \\ R(a(x)) \longrightarrow_+ P(x) \wedge Q(x) \wedge S(x) & R(b(x)) \longrightarrow_+ S(x) & \end{array}$$

In this polarized rewrite system, the proposition $R(a(b(\varepsilon)))$ reduces to the proposition $\top \wedge \top \wedge \top$ and has the cut free proof

$$\frac{\frac{\frac{}{\vdash \top} \top\text{-right} \quad \frac{}{\vdash \top} \top\text{-right}}{\vdash \top} \wedge\text{-right}}{\vdash R(a(b(\varepsilon)))}$$

A Proof of Lemma 1

To prove Lemma 1, we introduce Polarized unfolding sequent calculus, a sequent calculus that is equivalent to Polarized sequent calculus modulo theory and that was first introduced by Burel and Kirchner [6]. Inference rules of Polarized unfolding sequent calculus are presented in Figure 2. In contrast with Polarized sequent calculus modulo, the application of rewrite rules is performed only through the use of two extra inference rules, namely the unfolding-left and unfolding-right rules. Also, weakening and contraction rules are made admissible by integrating them in the inference rules where they are needed.

Lemma 10. *Given a polarized rewrite system $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$, a sequent is provable (resp. provable without cut) in Polarized unfolding sequent calculus for $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$ iff it is provable (resp. provable without cut) in Polarized sequent calculus modulo $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$.*

Proof. This is Proposition 7 of [6]. \square

We can therefore consider provability in Polarized unfolding sequent calculus. Therefore, in the remainder of this section, “a sequent can be proved in $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$ ” means that it can be proved in Polarized unfolding sequent calculus.

Lemma 11. *If a sequent $\Gamma, A \vdash \Delta$ can be proved without cut and without unfolding rules, and $\Gamma \vdash A, \Delta$ can be proved without cut, then $\Gamma \vdash \Delta$ can be proved without cut.*

Dually, if a sequent $\Gamma, A \vdash \Delta$ can be proved without cut, and $\Gamma \vdash A, \Delta$ can be proved without cut and without unfolding rules, then $\Gamma \vdash \Delta$ can be proved without cut.

Proof. This lemma does not hold in general without the hypothesis of absence of unfolding rules in at least one of the premises.

We can follow the proof of Proposition 39 of [6] to eliminate the cut

$$\frac{\Gamma, A \vdash \Delta \quad \Gamma \vdash A, \Delta}{\Gamma \vdash \Delta} \text{cut}$$

Since one the two branches does not contain unfolding rules, we will never reach the only problematic case when we have

$$\frac{\frac{\Gamma, A, B \vdash \Delta}{\Gamma, A \vdash \Delta} \text{unfolding-left} \quad \frac{\Gamma \vdash A, C, \Delta}{\Gamma \vdash A, \Delta} \text{unfolding-right}}{\Gamma \vdash \Delta} \text{cut}$$

\square

Lemma 12. *Let $\forall x_1 \dots \forall x_n (A \Rightarrow B)$ be a tautology in Predicate logic, and σ a substitution. If the sequent $\Gamma \vdash A, \Delta$ can be proved in $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$ then the sequent $\Gamma \vdash B, \Delta$ can be proved in $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$.*

Dually, if the sequent $\Gamma, B \vdash \Delta$ can be proved without cut in $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$ then the sequent $\Gamma, A \vdash \Delta$ can be proved without cut in $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$.

$$\begin{array}{c}
\overline{\Gamma, A \vdash A, \Delta} \text{ axiom} \\
\frac{\Gamma, A \vdash \Delta \quad \Gamma \vdash A, \Delta}{\Gamma \vdash \Delta} \text{ cut} \\
\overline{\Gamma \vdash \top, \Delta} \top\text{-right} \\
\overline{\Gamma, \perp \vdash \Delta} \perp\text{-left} \\
\frac{\Gamma \vdash A, \Delta}{\Gamma, \neg A \vdash \Delta} \neg\text{-left} \\
\frac{\Gamma, A \vdash \Delta}{\Gamma \vdash \neg A, \Delta} \neg\text{-right} \\
\frac{\Gamma, A, B \vdash \Delta}{\Gamma, A \wedge B \vdash \Delta} \wedge\text{-left} \\
\frac{\Gamma \vdash A, \Delta \quad \Gamma \vdash B, \Delta}{\Gamma \vdash A \wedge B, \Delta} \wedge\text{-right} \\
\frac{\Gamma, A \vdash \Delta \quad \Gamma, B \vdash \Delta}{\Gamma, A \vee B \vdash \Delta} \vee\text{-left} \\
\frac{\Gamma \vdash A, B, \Delta}{\Gamma \vdash A \vee B, \Delta} \vee\text{-right} \\
\frac{\Gamma, \forall x A, (t/x)A \vdash \Delta}{\Gamma, \forall x A \vdash \Delta} \langle x, A, t \rangle \forall\text{-left} \\
\frac{\Gamma \vdash A, \Delta}{\Gamma \vdash \forall x A, \Delta} \langle x, A \rangle \forall\text{-right if } x \notin FV(\Gamma \Delta) \\
\frac{\Gamma, A \vdash \Delta}{\Gamma, \exists x A \vdash \Delta} \langle x, A \rangle \exists\text{-left if } x \notin FV(\Gamma \Delta) \\
\frac{\Gamma \vdash (t/x)A, \exists x A, \Delta}{\Gamma \vdash \exists x A, \Delta} \langle x, A, t \rangle \exists\text{-right} \\
\frac{\Gamma, \sigma P, \sigma A \vdash \Delta}{\Gamma, \sigma P \vdash \Delta} \langle P \rightarrow A, \sigma \rangle \text{ unfolding-left if } P \text{ atomic and } P \rightarrow_- A \\
\frac{\Gamma \vdash \sigma P, \sigma A, \Delta}{\Gamma \vdash \sigma P, \Delta} \langle P \rightarrow A, \sigma \rangle \text{ unfolding-right if } P \text{ atomic and } P \rightarrow_+ A
\end{array}$$

Fig. 2. Polarized unfolding sequent calculus for $\langle \mathcal{R}_-, \mathcal{R}_+ \rangle$

Proof. Since $\forall x_1 \dots \forall x_n (A \Rightarrow B)$ is a tautology, by completeness of the sequent calculus, the sequent $\sigma A \vdash \sigma B$ has a proof without cut and without unfolding rules, and by admissibility of weakening [6, Lemma 2], $\Gamma, \sigma A \vdash \sigma B, \Delta$ has such a proof too. We conclude using Lemma 11. \square

Lemma 13. *If $P \longrightarrow A$ and $P \longrightarrow B$ are right-equivalent, then a sequent $\Gamma \vdash \Delta$ is provable without cut in $\langle \mathcal{R}_- \cup \{P \longrightarrow A\}, \mathcal{R}_+ \rangle$ (resp. in $\langle \mathcal{R}_-, \mathcal{R}_+ \cup \{P \longrightarrow A\} \rangle$) iff it is provable without cut in $\langle \mathcal{R}_- \cup \{P \longrightarrow B\}, \mathcal{R}_+ \rangle$ (resp. in $\langle \mathcal{R}_-, \mathcal{R}_+ \cup \{P \longrightarrow B\} \rangle$).*

Proof. By duality, we only need to prove one direction.

By induction on the proof of $\Gamma \vdash \Delta$. Almost all cases are simple applications of the induction hypothesis. The only interesting cases are the unfolding rules. Suppose we have a proof ending with

$$\frac{\Gamma, \sigma P, \sigma A \vdash \Delta}{\Gamma, \sigma P \vdash \Delta} \langle P \longrightarrow A, \sigma \rangle \text{ unfolding-left}$$

in $\langle \mathcal{R}_- \cup \{P \longrightarrow A\}, \mathcal{R}_+ \rangle$. By induction hypothesis, we have a proof of $\Gamma, \sigma P, \sigma A \vdash \Delta$ in $\langle \mathcal{R}_- \cup \{P \longrightarrow B\}, \mathcal{R}_+ \rangle$. Using Lemma 12, we have a proof of $\Gamma, \sigma P, \sigma B \vdash \Delta$ in $\langle \mathcal{R}_- \cup \{P \longrightarrow B\}, \mathcal{R}_+ \rangle$. We can therefore build the proof

$$\frac{\Gamma, \sigma P, \sigma B \vdash \Delta}{\Gamma, \sigma P \vdash \Delta} \langle P \longrightarrow B, \sigma \rangle \text{ unfolding-left}$$

in $\langle \mathcal{R}_- \cup \{P \longrightarrow B\}, \mathcal{R}_+ \rangle$. \square

Lemma 14. *Given two polarized rewrite systems $\langle \mathcal{R}_-^1, \mathcal{R}_+^1 \rangle$ and $\langle \mathcal{R}_-^2, \mathcal{R}_+^2 \rangle$ that are right-equivalent, a sequent $\Gamma \vdash \Delta$ can be proved (resp. proved without cut) modulo $\langle \mathcal{R}_-^1, \mathcal{R}_+^1 \rangle$ if and only if it can be proved (resp. proved without cut) modulo $\langle \mathcal{R}_-^2, \mathcal{R}_+^2 \rangle$.*

Proof. By repetitively applying Lemma 13 on right-equivalent pairs of rewrite rules. \square
