## Context and objectives

Multiple sclerosis patients often present **hyper-intense T2-w lesions** in the spinal cord. The **severe imbalance** between background and lesion classes poses a major challenge for Deep Learning segmentation methods. We aim at investigating the following strategies to help mitigating this issue:

- careful selection of the **loss function**
- adjustment** of the conventional 0.5-thresholding

## Dataset

- 161 T2-w cervical and thoracic MRI were acquired in 13 different sites from 108 subjects.
- Trained **neurologists** and **radiologists** performed manual segmentations, validated by a senior expert.
- Data splits were generated by assigning **each subject** to a single set while **balancing the lesion load** (Fig.1).

Fig. 1 Boxplots for lesion number and volume in the training (62 MRI scans), validation (13), thr-optimization (14) and unseen set (26, 46 with no MS lesions are not included here). Points are jittered to improve visualization.

## Methods

- Images were **reoriented** and **resampled** to 0.5mm isotropic using linear interpolation.
- The **Spinal Cord Toolbox<sup>1</sup> (SCT)** was used for detecting spinal cord centerline.
- 3D patches** (48x48x48) were extracted along the centerline for model training using a **3D-Unet** architecture<sup>2,3</sup>.
- Data augmentation** techniques such as patch overlapping, random mirroring, and 90° rotation were employed during the 300-epoch training.
- Overlapping patches** were used for prediction with different **thresholding values**, and a **thr-optimization** subset was used to optimize binarization thresholds.
- The model was evaluated on an **unseen test set** and compared with the SOTA method (SCT).

Table 1. Lesion- and voxel-wise F1 scores, and patient-level sensitivity and specificity (median (mean  $\pm$  std)) for models trained with the binary cross-entropy (BCE), Dice (SCT), Focal Tversky and Tversky losses. Metrics obtained on the unseen test set.

Loss	L-F1	V-F1 (Dice)	P-sensitivity	P-specificity
BCE	0.27 (0.28 $\pm$ 0.3)	0.33 (0.29 $\pm$ 0.24)	0.58	0.24
SCT	0.38 (0.34 $\pm$ 0.32)	0.39 (0.35 $\pm$ 0.25)	0.62	<b>0.33</b>
F. Tversky	0.26 (0.28 $\pm$ 0.28)	0.31 (0.31 $\pm$ 0.25)	0.65	0.22
Tversky	<b>0.4 (0.34<math>\pm</math>0.31)</b>	<b>0.41 (0.33<math>\pm</math>0.24)</b>	<b>0.65</b>	0.26

## Results

- Small changes in threshold lead to a larger change in **voxel-F1 score** for BCE and Dice (SCT) losses (Fig.2).
- Tversky-based losses seem more stable with threshold changes.
- Highest median L-F1 and V-F1 scores (40%) for Tversky loss compared to SOTA SCT with Dice loss (38%, Table 1).
- Example of segmentation output between Dice and Tversky loss on unseen test data with optimized threshold (Fig.3).

Fig. 2. Boxplots of voxel-wise F1 score for BCE, SCT, Focal Tversky and Tversky losses at each decision threshold value. One point corresponds to one image.

Fig. 3. Original image (a), overlaid by a reference lesion mask (b), and segmentations with the Tversky (c) and Dice (d) losses. FN, FP and TP voxels appear in white, red and green respectively.

## Conclusion

**Tversky Index**-based losses and a minimal **adjustment of the decision threshold** can yield less dispersed and higher median scores than more standard settings (Dice loss + 0.5 thr).<sup>1</sup>
