#### Abstract

Establishing equivalence and refinement relations between programs is an important mean for verifying their correctness. By establishing that the behaviours of a modified program simulate those of the source one, simulation relations formalise the desired relationship between a specification and an implementation, two equivalent implementations, or a program and its optimised implementation. This article discusses a notion of simulation between open automata, which are symbolic behavioural models for communicating systems. Open automata may have holes modelling elements of their context, and can be composed by instantiation of the holes. This allows for a compositional approach for verification of their behaviour. We define a simulation between open automata that may or may not have the same holes, and show under which conditions these refinements are preserved by composition of open automata.

## Raffinements des Automates Ouverts

Résumé : Vérifier la correction d'un programme est une tâche complexe souvent réalisée de manière progressive en établissant une relation entre les comportements de deux programmes. La relation de simulation, qui met en corespondance une spécification et une implémentation, ou un programme et sa version raffinée, permet d'assurer la correction. Cet article introduit et discute d'une relation entre des programmes représentés sous la forme d'automates ouverts, un modèle comportemental symbolique pour les systèmes de communication. Établir des relations d'équivalence et de raffinement sur les automates ouverts permet une approche compositionnelle pour vérifier leur comportement. L'aspect compositionnel des automates ouverts provient des trous, qui représentent des éléments du contexte. La composition de deux automates consiste à instancier un trou d'un automate avec l'autre automate. Dans cet article, nous définissons une relation de raffinement entre les automates ouverts qui peuvent avoir ou non les mêmes trous, sur le modèle des simulations. Nous montrons ensuite dans quelles conditions la composition d'automates ouverts préserve cette relation.

## 1 Introduction

Compositional design is a highly convenient approach for specifying and verifying large systems. Automata are often used as the basic formalism for this approach, but most automata definitions allow only the specifications of finite closed systems. These systems can be verified efficiently, but programming often consists in writing systems that should be interfaced with others, and with potentially unbound behaviours. We investigate in our works the reasoning on open symbolic systems, with a strong focus on compositionality of properties. More precisely, we say that a system is open if it contains a "hole" to be filled by another system. Open systems are typically composition operators [15] or componentised systems where some of the components are yet to be provided [6. This form of composition is more complex to handle than top-level interaction usually found in process algebra, as the behaviour of each entity in the system is parameterised both by classical symbolic variables and by process variables.

The refinement concept plays an important role in software engineering. In addition to helping to cope with the complexity of requirements and design, refinement provides a foundation for ensuring system correctness. The correctness of a system can be established by proving, that a system refines its specification with the idea that some properties of the specification are preserved in the refined system. Refinement entails that one system can be considered as a more precise version of another one that is considered to be the specification. The refined model features all the specified behaviours with more concrete details. From a formal point of view, refinement is a mathematical relations between a specification and its implementation, with trace inclusion or simulation being frequently used relations [20, 18 .

In this article, we design a simulation theory for open symbolic systems. We build a very generic theory that should allow us to reason on simulation-based verification for most concurrent systems, as our base theory merely relies on automata parameterised by both variables and processes. As we shall see, our composition of automata is also very generic to account for any interaction mechanism found in concurrent systems. While our contribution is theoretical, it establishes the foundations for to the verification of any compositionally designed system, like component systems, algorithmic skeletons.

Open automata (that we abbreviate OA) were defined as a way to provide a semantics for open parameterised hierarchical labelled transition systems (abbreviated LTS). They were proposed as a theoretical foundation for parametrised automata used in verification tools and called pNets. An OA [15] is similar to a classical automaton but with variables and holes. Variables make automata symbolic and allow them to encode infinite state systems. Holes enable the composition of automata: an automaton with a hole is an operator that takes another automaton as parameter and reacts to the actions it emits; the composed automaton is an automaton where the behaviour of one "process parameter" of the main automaton has been provided. Due to their the generic nature, the notion of OA model is quite abstract but we already illustrated previously how to derive OAs for process algebra operators [15] or for component systems [6, 5].

In previous works [6, 22] a bisimulation relation was defined for OA and open parameterised hierarchical LTSs. It exhibited good properties concerning bisimulation, but refinement relations were not studied. In this article we go further to define a theory of simulation for OA. The simulation relation we introduce in the paper is based on the notion of simulation, in a similar way to that defined in classical automata theory [19, 8]. It possesses the common behaviourpreserving property: all the behaviour of the abstract specification must be followed by its (complex) implementation but additional behaviours may exist. However we also ensure that a whole scenario, made of several steps, of the specification can also be simulated by the refined system, which is slightly richer than the traditional simulation relation and allows us to obtain a compositionality result.

Our contribution in this paper is the definition of a simulation relation for OA that has the following characteristics:

- Classical simulation characterisation but also an additional criteria ensuring that simulation does not introduce deadlocks when following a trace from the simulated automaton.
- Good properties relatively to composition: we prove that composition preserves the simulation relation.
- Ability to take into account both composition and transitivity: this is a challenge because composition changes the set of holes of the OA and simulation takes into account the actions of the holes.
The simulation relation is introduced in two steps. First we define a simulation that relates two automata with the same holes, which allows us to focus on the automaton aspect. Second we introduce a relation that relates two automata with different sets of holes, which allows us to take into account the open nature of OA, and to deal with composition. Properties of the simulation are stated and proven on the second, more general version of the relation, thus also being valid for the first simpler simulation relation.

This paper is organized as follows. Section 2 recalls the definition of OA and defines their composition. We then define a simulation relation for OA, first only considering two automata with the same set of holes in Section 3 and generalize it to automata with a different set of holes in Section 4 . Section 5 is dedicated to formalize and prove basic properties of the simulation defined, including the proof that simulation is a preorder and has nice composability properties. In Section 6 we review related works, and Section 7 concludes the paper.

## 2 Open Automata and their Composition

This section presents our notations and the principles of automata. Except for minor changes in the notations, compared to previous works [6] the only new contribution is the definition of a composition operator for OA.

### 2.1 Preliminaries and notations

Families of values (equivalent to maps) will be noted $x_{i}^{i \in I},\left\{i_{\mapsto} x_{i} \mid i \in I\right\}$, or $\left\{i \leftarrow x_{i} \mid i \in I\right\}$, depending on what is more convenient (e.g. $i \leftarrow x_{i}$ is used for maps that are used as substitution). Statements like $\exists c_{j}^{j \in J}$ defines both $J$ and the mapping $j_{\mapsto} c_{j}$. The disjoint union on sets is noted $\uplus$. Disjoint union is also used on maps. There are several ways of ensuring a union is disjoint, we will indifferently either suppose sets are disjoint or rename conflicting objects (useful for variables). In a formula, a quantifier followed by a finite set will be used as a shorthand for the quantification on every variable in the set: $\forall\left\{a_{1}, \ldots, a_{n}\right\}, \exists\left\{b_{1}, \ldots, b_{m}\right\}, P$ means $\forall a_{1}, \ldots, \forall a_{n}, \exists b_{1}, \ldots, \exists b_{m}, P$.

Our expression algebra $E$ is the disjoint union of terms, actions, and formulas $E=\mathcal{T} \uplus \mathcal{A} \uplus \mathcal{F}$. $\mathcal{T}$ and $\mathcal{A}$ are term algebras. The set of formulas $\mathcal{F}$ contain at least first order formulas and equality ${ }^{1}$ over $\mathcal{T}$ and $\mathcal{A}$. For $e \in E$, $\operatorname{vars}(e)$ is the set of variables in $e$ that are not bound by a binder. An expression is closed if $\operatorname{vars}(e)=\varnothing$. The set $\mathcal{P}$ denotes values which is a subset of closed terms. $\mathcal{F}_{V}$ is the set of formulas $f$ that only uses variables in $V$, i.e., the formulas such that $\operatorname{vars}(f) \subseteq V$. The parallel substitution of variables in $e$ by a map $\psi: V \rightarrow \mathcal{T}$ is denoted $e\{\psi\}$.

We suppose given a decidable satisfiability relation on closed formulas, denoted $\vdash f$. We will use two variants of the satisfiability relation:

[^1]- The satisfiability of a formula $f \in \mathcal{F}$ under some valuation $\sigma: V \rightarrow \mathcal{P}$ is defined as follows: $\sigma \vdash f \Longleftrightarrow \vdash \exists \operatorname{vars}(f\{\sigma \sigma), f\{\sigma\}$
- The satisfiability of a formula $f \in \mathcal{F}$ with some variable set $V$ as context is defined as follows: $V \vdash f \Longleftrightarrow \vdash \forall V, \exists(\operatorname{vars}(f) \backslash V), f$

### 2.2 Open Automata (OA)

OA are labelled transition systems with variables that can be used to compose other automata: they are made of transitions that are dependent on the actions of "holes", a composition operation consists in filling a hole with another automaton to obtain a more complex automaton. The variables makes the OA symbolic, and the holes allow for a partial definition of the behaviour.

Definition 1 (Open transition, Open automaton). An open automaton is a tuple $\left\langle S, s_{0}, V, \sigma_{0}, J, T\right\rangle$ with $S$ a set of states, $s_{0} \in S$ the initial state, $V$ the finite set of variable names, $\sigma_{0}: V \rightarrow \mathcal{P}$ the initial valuation of variables, $J$ the set of hole names and $T$ the set of open transitions.

An open transition is a tuple $\frac{\beta_{j}^{j \in J^{\prime}}, g, \psi}{s \xrightarrow[\longrightarrow]{\alpha} s^{\prime}}$ with $s, s^{\prime} \in S$ the source and target states, $\alpha \in \mathcal{A}$ the produced action, $J^{\prime} \subseteq J$ the holes involved in the transition, $\beta_{j} \in \mathcal{A}$ the actions of the holes, $g \in \mathcal{F}$ the guard and $\psi: V \rightarrow \mathcal{T}$ the variable assignments. To be well-formed, an open transition should use only variables of the automaton and variables appearing in the involved actions, formally:

$$
\begin{array}{r}
\operatorname{vars}(g) \subseteq \operatorname{vars}(\alpha) \cup \bigcup_{j \in J^{\prime}} \operatorname{vars}\left(\beta_{j}\right) \cup V \\
\forall v \in V \cdot \operatorname{vars}(\psi(v)) \subseteq \operatorname{vars}(\alpha) \cup \bigcup_{j \in J^{\prime}} \operatorname{vars}\left(\beta_{j}\right) \cup V
\end{array}
$$

A pair consisting of a state and a valuation is called a configuration (of the automaton). We use two operators to access pieces of information of the OA.

Definition 2 (Out-transition, Transition variables). Let $V$ be the variable names of a considered automaton, $T$ its transitions and $r$ one of its states. $\mathrm{OT}_{T}(r) \subset T$ are called the out-transitions of the state $r$. When the set $T$ is clear from the context, it will be omitted. The local variables of a transition vars $(t)$ are all variables appearing in transition $t$ except the variables of the automaton.

$$
\mathrm{OT}_{T}(r)=\left\{\left.\frac{\beta_{j}^{j \in J^{\prime}}, g, \psi}{s \xrightarrow{\alpha} s^{\prime}} \in T \right\rvert\, s=r\right\} \quad \operatorname{vars}\left(\frac{\beta_{j}^{j \in J^{\prime}}, g, \psi}{s \xrightarrow{\alpha} s^{\prime}}\right)=\left(\operatorname{vars}(\alpha) \cup \bigcup_{j \in J^{\prime}} \operatorname{vars}\left(\beta_{j}\right)\right) \backslash V
$$

Example 1 (prod-cons). As a running example, we consider a classical producer-consumer pair interacting through FIFO buffer, named prod-cons. Fig. 1 reflects the overall structure of the system involving a producer process, a consumer process and an orchestrator that coordinates their activities.

The OA modelling the behaviour of such a system using an unbounded circular/ring buffer is depicted in Fig. 2. The automaton has a single state with two holes: $P$ and $Q$ that are the two interacting processes. l (as last) indicates the next available position for enqueuing an element and $f$ (as first) is the position that contains the next element to be dequeued. The buffer reacts to a push from P and enqueues it. Similarly, whenever $Q$ pops an element, it dequeues it. Additionally, whenever $Q$ produces an item, it is exposed as an external observable print action. When any process do its internal computation, it is exposed externally as unobservable action $\tau$.

The example uses several kinds of data. Variable m holds a message (we can leave the message type abstract here). We additionally use arrays of messages with a syntax of the form M[l] for

Figure 1: Structure of the example. Each box corresponds to a process whose ports are the actions it can perform. The actions observable by the environment are push, which indicates the enqueuing of an element, pop which indicates the dequeuing, and print which indicates the production of results.

Figure 2: OA for the prod-cons system using FIFO circular buffer.
array accesses; $M$ is an array of $N$ elements, from 0 to $N-1$. Finally, we use addition and modulo operation (\%) on integers.

Open automata composition. OA are partially specified automata, the partiality arises from the holes. A hole can be seen as a port in which we can plug an OA. The plugging operation is called composition. The composition of OA was already implicitly defined by the means of composition on pNets in previous work [15]. We provide here a (new) direct definition of composition for OA.

Definition 3 (Composition of OA). Let $A_{c}=\left\langle S_{c}, s_{0 c}, V_{c}, \sigma_{0 c}, J_{c}, T_{c}\right\rangle$ be an OA and $k$ one of its holes, $k \in J_{c}$. Let $A_{p}=\left\langle S_{p}, s_{0 p}, V_{p}, \sigma_{0 p}, J_{p}, T_{p}\right\rangle$ be another $O A$, the composition $A_{c}\left[A_{p} / k\right]$ that fills the hole $k$ of the context $O A A_{c}$ with the parameter $O A A_{p}$ is defined as follows:

$$
A_{c}\left[A_{p} / k\right]::=\left\langle S_{c} \times S_{p},\left(s_{0 c}, s_{0 p}\right), V_{c} \uplus V_{p}, \sigma_{0 c} \uplus \sigma_{0 p}, J_{p} \uplus J_{c} \backslash\{k\}, T\right\rangle
$$

with

$$
\begin{aligned}
T= & \left\{\left.\frac{\beta_{j}^{j \in J_{p}^{\prime} \uplus J_{c}^{\prime}}, g_{c} \wedge g_{p} \wedge \alpha_{p}=\beta_{k}, \psi_{c} \uplus \psi_{p}}{\left(s_{c}, s_{p}\right) \xrightarrow{\alpha_{c}}\left(s_{c}^{\prime}, s_{p}^{\prime}\right)} \right\rvert\, \frac{\beta_{j}^{j \in J_{c}^{\prime} \uplus\{k\}}, g_{c}, \psi_{c}}{s_{c} \xrightarrow{\alpha_{c}} s_{c}^{\prime}} \in T_{c}, \frac{\beta_{j}^{j \in J_{p}^{\prime}}, g_{p}, \psi_{p}}{s_{p} \xrightarrow{\alpha_{p}} s_{p}^{\prime}} \in T_{p}\right\} \\
& \cup\left\{\left.\frac{\beta_{j}^{j \in J_{c}^{\prime}}, g_{c}, \psi_{c}}{\left(s_{c}, s_{p}\right) \xrightarrow{\alpha_{c}}\left(s_{c}^{\prime}, s_{p}\right)} \right\rvert\, \frac{\beta_{j}^{j \in J_{c}^{\prime}}, g_{c}, \psi_{c}}{s_{c} \xrightarrow{\alpha_{c}} s_{c}^{\prime}} \in T_{c}, k \notin J_{c}^{\prime}, s_{p} \in S_{p}\right\}
\end{aligned}
$$

Figure 3: (Left) A producer. It produces one item at a time and pushes it. (Right) A consumer. It pops an item, does some work and pushes the result.

Figure 4: OA for prod-cons[P/producer].

The first OA decides when the second can evolve by involving its hole in a transition: the action emitted when $A_{p}$ makes a transition is synchronised with the action of the hole $k$ in transitions of $A_{c}$.

Example 2. Fig. 3 shows a producer automaton and a consumer automaton that can be used to fill the holes $P$ and $Q$ of prod-cons defined in Example 1.

The OA on Fig. 4 is the composition of the system in Fig. 2 and the producer in Fig. 3 (left). The composition consists of two states (the product of the states of both automata). The transitions from one state to another come from the synchronisation of the transitions of the encompassing automaton with those of the producer filling the hole P. Transitions involving $\mathbb{Q}$ remain unchanged.

### 2.3 Relations between Open Automata

Establishing semantic equivalences and simulation relations between different OA requires to compare their states. For this purpose, we suppose that the variables of the two OA are disjoint (a renaming of variables may have to be applied before comparing OA states).

Definition 4 (Relation on open automata configurations). Suppose $V_{1}$ and $V_{2}$ are disjoint. $A$ relation on configurations of two $O A\left\langle S_{1}, s_{01}, V_{1}, \sigma_{01}, J_{1}, T_{1}\right\rangle$ and $\left\langle S_{2}, s_{02}, V_{2}, \sigma_{02}, J_{2}, T_{2}\right\rangle$ is a function $\mathcal{R}: S_{1} \times S_{2} \rightarrow \mathcal{F}_{V_{1} \uplus V_{2}}$.

The idea is that two states are related depending on the satisfiability of the expression relying their variables, i.e., if the variables of the OA verify a certain formula. In other words, to each pair of states is attached a boolean formula that may refer to the variables of each of the two OA, stating whether the two states are related or not. Additionally, we say that the relation $\mathcal{R}$ relates the initial states of the automata if: $\sigma_{01} \uplus \sigma_{02} \vdash \mathcal{R}\left(s_{01}, s_{02}\right)$.

### 2.4 A Bisimulation for Open Automata

Bisimulation between OA was defined in [6. We show below the principles of this bisimulation. We first recall the usual definition of bisimulation. Bisimulation can be defined as follows for standard transition systems:

Definition 5 (Classical Bisimulation). A bisimulation is a relation $\mathcal{R}$ such that if $s \mathcal{R} t$ then:

$$
\begin{array}{lrrl}
\forall l s^{\prime}, s \xrightarrow{l} s^{\prime} \Longrightarrow \exists t^{\prime} . s^{\prime} \mathcal{R} t^{\prime} \wedge t \xrightarrow{l} t^{\prime} & & s & \mathcal{R} \\
\text { and conversely } & t \\
\forall l t^{\prime}, t \xrightarrow{l} t^{\prime} \Longrightarrow \exists s^{\prime} . s^{\prime} \mathcal{R} t^{\prime} \wedge s \xrightarrow{l} s^{\prime} & \text { i.e. } & l \downarrow & \\
\downarrow l
\end{array}
$$

$s$ and $t$ are bisimilar, written $s \sim t$ iff there is a bisimulation relation $\mathcal{R}$ such that $s \mathcal{R} t$
A bisimulation relation relates pair of states and ensures that any behaviour of one automaton can be performed by the other one while staying in relation. We informally explain here the symbolic nature of the bisimulation for OA and the related complexity of its definition. The presence of holes in fact raises no strong difficulty but the variables must be handled carefully. Consider the two following simple OA:

We should be able to consider these two OA as bisimilar. Both can input any $\beta(x)$ input on their hole and stores the value of $x$, emitting $\alpha(x)$ along the transition. The difference is the way $x$ is stored. We can then define a configuration relation $\mathcal{R}$ such that $\mathcal{R}\left(s, s_{2}\right)$ is true and $\mathcal{R}\left(t, t_{2}\right)$ holds when $z \geqslant 0$ and $y=z$, while $\mathcal{R}\left(t^{\prime}, t_{2}\right)$ holds when $z<0$ and $y=-z$. This illustrates relation on configurations, but also shows that bisimulation on OA is more complex than in the classical case. Indeed, we need two transitions on the left OA to simulate a single one on the right OA. We should check that these two transitions cover all the cases accepted by the right hand side OA, and of course that destination states are in relation. Formally, FH-bisimulation is defined as follows [6]:

Definition 6 (Strong FH-bisimulation).
Suppose $\left\langle S_{1}, s_{01}, V_{1}, \sigma_{01}, J_{1}, T_{1}\right\rangle$ and $\left\langle S_{2}, s_{02}, V_{2}, \sigma_{02}, J_{2}, T_{2}\right\rangle$ are $O A$ with identical holes of the same sort, with disjoint sets of variables ( $V_{1} \cap V_{2}=\varnothing$ ).

Then $\mathcal{R}$, a relation on configurations of $O A$, is an FH-bisimulation if and only if for any states $s \in S_{1}$ and $t \in S_{2}$, we have the following:

- For any open transition $O T$ in $T_{1}: \frac{\beta_{j}^{j \in J^{\prime}}, g_{O T}, \psi_{O T}}{s \xrightarrow{\alpha} s^{\prime}}$ there exists an indexed set of open transitions $O T_{x}^{x \in X} \subseteq T_{2}: \frac{\beta_{j x}^{j \in J_{x}}, g_{O T_{x}}, \psi_{O T_{x}}}{t \xrightarrow{\alpha_{x}} t_{x}}$ such that $\forall x . J^{\prime}=J_{x}$ and there exists Pred $_{s^{\prime}, t_{x}}$ such that $\left(s^{\prime}, t_{x} \mid\right.$ Pred $\left._{s^{\prime}, t_{x}}\right) \in \mathcal{R}$ and

$$
\mathcal{R}(s, t) \wedge g_{O T} \Longrightarrow \quad \bigvee_{x \in X}\left(\forall j . \beta_{j}=\beta_{j x} \wedge g_{O T_{x}} \wedge \alpha=\alpha_{x} \wedge \mathcal{R}\left(s^{\prime}, t_{x} \psi_{O T} \uplus \psi_{O T_{x}}\right)\right)
$$

- and symmetrically any open transition from $t$ in $T_{2}$ can be covered by a set of transitions from $s$ in $T_{1}$.

Two automata are bisimilar if there exists a strong FH-bisimulation $\mathcal{R}$ that relates their initial states.

Note that this definition matches an open transition $t_{1}$ to a family of covering open transitions $t_{2 x}^{x \in X}$. Intuitively, this means that for every pair of related states $\left(s_{1}, s_{2}\right)$ of the two automata, and for every transition of the first automaton from $s_{1}$, there is a set of matching transitions of the second automaton from $s_{2}$ such that the produced action match, the actions of the same holes and the successors are related after variable update. Technically, the following sections do not rely on the definition of strong bisimulation on OA, but they follow the same principles and in particular the same way to faithfully simulate an open transition by a set of other open transitions.

### 2.5 Reachability

We finally define a new predicate abstracting state reachability for OA, it allows us to reason on reachable states in an automaton. It can be seen as an abstraction of the reachable states under the form of a predicate that must stay verified along the execution of the OA.

Definition 7 (Reachability). For any $O A A=\left\langle S, s_{0}, V, \sigma_{0}, J, T\right\rangle$, a reachability predicate $\checkmark_{A}$ : $S \rightarrow \mathcal{F}_{V}$ is any predicate on states that is valid on initial state, and preserved across transitions:

$$
\sigma_{0} \vdash \checkmark_{A}\left(s_{0}\right) \wedge \quad \forall t=\frac{\beta_{j}^{j \in J^{\prime}}, g, \psi}{s \xrightarrow{\alpha} s^{\prime}} \in T, \operatorname{vars}(t) \vdash\left(\checkmark_{A}(s) \wedge g \Longrightarrow \checkmark_{A}\left(s^{\prime}\right)\{\psi\}\right)
$$

Reachability takes into account all paths, and can over-approximate the reachable configurations. From an automation point of view, finding the most precise reachability predicate for a given automaton is not decidable because of the symbolic nature of OA, but only an overapproximation is necessary.

## 3 Simulation for Automata with the Same Holes

Similarly to FH-bisimulation [6] we are interested in finding simulation relations between configurations of two OA that contain variables and holes. When dealing with open systems it is common to define simulation in terms of a simulation relation. We rely on a classical notion of simulation inspired from [6]. The idea is to consider two configurations related by a relation; if one state can do a transition, then the other can also make this transition. Like for bisimulation, a simulation relation characterises when two states are related, and this characterisation is expressed as a predicate on the variables of the two automata. Simulation defines conditions on a relation $\mathcal{R}$ such that $\mathcal{R}\left(s_{1}, s_{2}\right)$ is a predicate (possibly involving variables of the automata) that is true when the state $s_{1}$ of $A_{1}$ simulates the state $s_{2}$ of $A_{2}$.

However here we want to build a simulation relation that also guarantees that no deadlock is introduced when refining the automaton. This property is quite frequent in simulation relation, and referred to as lack of new deadlocks [18] or complete simulation [21. The notion of deadlock should however be specialised to our OA. Indeed, the possible transitions are better characterised by the guards of the outgoing transitions from a given state, rather than the simple existence of a transition. We thus define a deadlock reduction criterion based on how the outgoing transitions are guarded. As such, a simulation does not introduce deadlocks if in the conditions where no
transition is possible in the refined automaton, no transition were already possible in the more general one. More formally, for any pair of states $s_{1}$ and $s_{2}$ we introduce a criterion of the form:

$$
\left.\forall\left(s_{1}, s_{2}\right) \in S_{1} \times S_{2}, V_{1} \uplus V_{2} \vdash \mathcal{R}\left(s_{1}, s_{2}\right) \wedge \neg\left(\bigvee_{t_{1} \in \mathrm{OT}\left(s_{1}\right)} \operatorname{guard}\left(t_{1}\right)\right) \Longrightarrow \underset{t_{2} \in \mathrm{OT}\left(s_{2}\right)}{ } \operatorname{guard}\left(t_{2}\right)\right)
$$

Which can be rewritten as:

$$
\forall\left(s_{1}, s_{2}\right) \in S_{1} \times S_{2}, V_{1} \uplus V_{2} \vdash \mathcal{R}\left(s_{1}, s_{2}\right) \Longrightarrow\left(\bigvee_{t_{1} \in \mathrm{OT}\left(s_{1}\right)} \operatorname{guard}\left(t_{1}\right)\right) \vee \neg\left(\bigvee_{t_{2} \in \mathrm{OT}\left(s_{2}\right)} \operatorname{guard}\left(t_{2}\right)\right)
$$

Both statements being equivalent, as each of them may reveal more intuitive than the other in different situations, we use them interchangeably. We can now state the definition of simulation between OA that have the same set of holes.
Definition 8 (Hole-equal simulation). Consider two $O A$ with identical set of holes: $A_{1}=$ $\left\langle S_{1}, s_{01}, V_{1}, \sigma_{01}, J_{1}, T_{1}\right\rangle$ and $A_{2}=\left\langle S_{2}, s_{02}, V_{2}, \sigma_{02}, J_{2}, T_{2}\right\rangle$ where $J_{1}=J_{2}$, the relation on configurations $\mathcal{R}: S_{1} \times S_{2} \rightarrow \mathcal{J}_{V_{1} \uplus V_{2}}$ is a hole-equal simulation from $A_{1}$ to $A_{2}$ if the following conditions hold :
(1) $\sigma_{01} \uplus \sigma_{02} \vdash \mathcal{R}\left(s_{01}, s_{02}\right)$
(2) $\forall\left(s_{1}, s_{2}\right) \in S_{1} \times S_{2}$,

$$
\begin{aligned}
& \forall t_{1}=\begin{array}{c}
\stackrel{\beta_{1 j}^{j \in J}, g_{1}, \psi_{1}}{s_{1} \xrightarrow[\alpha_{1}]{\ldots} \ldots \ldots} s_{1}^{\prime}
\end{array} \in \mathrm{OT}\left(s_{1}\right) . \quad \exists\left(t_{2 x}=\stackrel{\beta_{2 x j}^{j \in J}, g_{2 x}, \psi_{2 x}}{s_{2} \xrightarrow{\alpha_{2 x}} s_{2 x}^{\prime} \ldots}\right)^{x \in X} \in \mathrm{OT}\left(s_{2}\right) . \\
& V_{1} \uplus V_{2} \uplus \operatorname{vars}\left(t_{1}\right) \uplus \bigcup_{x} \operatorname{vars}\left(t_{2 x}\right) \vdash \\
& \\
& \mathcal{R}\left(s_{1}, s_{2}\right) \wedge g_{1} \Longrightarrow \bigvee_{x \in X}\binom{\alpha_{2 x}=\alpha_{1} \wedge \bigwedge_{j \in J} \beta_{2 x j}=\beta_{1 j} \wedge}{g_{2 x} \wedge \mathcal{R}\left(s_{1}^{\prime}, s_{2 x}^{\prime}\right)\left\{\psi_{2 x} \uplus \psi_{1}\right\}}
\end{aligned}
$$

(3) Deadlock reduction:

$$
\forall\left(s_{1}, s_{2}\right) \in S_{1} \times S_{2}, V_{1} \uplus V_{2} \vdash \mathcal{R}\left(s_{1}, s_{2}\right) \Longrightarrow\left(\bigvee_{t_{1} \in \mathrm{OT}\left(s_{1}\right)} \operatorname{guard}\left(t_{1}\right)\right) \vee \neg\left(\bigvee_{t_{2} \in \mathrm{OT}\left(s_{2}\right)} \operatorname{guard}\left(t_{2}\right)\right)
$$

If there is a hole-equal simulation from $A_{1}$ to $A_{2}$, then we say that $A_{2}$ simulates $A_{1}$; we denote it $A_{2} \leqslant A_{1}$.

The first and second conditions coincide with the natural way to prove inductively that an automaton simulates another by starting with the initial state. The third condition ensures that simulation prevents the introduction of deadlocks. Our definition captures a simple simulation for OA with the same holes that is more expressive than a strict simulation since it matches a transition with a family of transitions. For example, with such a relation we are able to check the simulation between two OA that differ by duplicated states, removed duplicated transitions, reinforced guards, different variables, etc. We will show in Section 5 that this simulation relation has good properties in terms of transitivity, compositionality, and reflexivity.
Example 3. To illustrate the simulation of $O A$, we consider a variation on the prod-cons example. Namely, we suppose that the two processes $P$ and $Q$ communicate through a one-place buffer. Fig. 5 shows the OA modelling this simpler version of the system, that we refer to as simprod-cons. We can easily check that this automaton simulates the one of Fig. 园. Indeed, one can see that $\mathcal{R}=\left\{\left(r_{0}, s_{0}\right) \mapsto l=f,\left(r_{0}, s_{1}\right) \mapsto f=l+1 \% N\right\}$ is a simulation relation. It follows that prod-cons $\leqslant$ simprod-cons.

The simulation relation defined above is insufficient in the setting of composition which is the main advantage of the OA-based approach. Indeed, it should be possible to refine an automaton by filling its hole, providing a concrete view of a part of the application that was not specified originally. More generally, it should be possible to relate automata that do not have the same holes because composition is a crucial part of system specification. However, filling holes can result in a system with more or less holes than the original system because the plugged subsystem can contain itself many holes. Next section defines a more powerful simulation relation able to reason on automata with different sets of holes.

## 4 A Simulation Relation that Takes Holes into Account

This section extends the preceding relation to automata where the set of holes is not the same. This is particularly useful to state whether the automaton after composition is a simulation of the original automaton or not. Indeed, when composing the set of holes changes. Being able to compare automata with only some of their holes in common seems useful in general.

One major challenge in the extension of simulation to different sets of holes is to maintain a form of transitivity while being able to take into account the actions of some of the holes. A naive definition of simulation would ensure that only the holes that are identical in the two OA are taken into account in the simulation. Unfortunately, considering all the common holes does not ensure transitivity of the simulation for the following reason. If $A_{1}$ simulates $A_{2}$ and $A_{2}$ simulates $A_{3}$, and one hole $j$ appears in $A_{3}$ and in $A_{1}$ but not in $A_{2}$ then we have no guarantee on the way $A_{1}$ and $A_{3}$ take the actions of this hole into account, thus a simulation between and $A_{1}$ and $A_{3}$ would require conditions involving actions of the hole $j$ which cannot be ensured. The way we solve this issue is to remember in the simulation relation which holes have been compared. This makes the relation parameterised by a subset of the set of holes that belong to the two automata that we want to take into account. This way, in the example above, we would have no guarantee on actions the hole $j$ by transitivity but can state a simulation relation with guarantees on the actions of the other holes.

In the following definition we add a parameter $H$ which is the set of holes tracked by the simulation relation and adapt the definition by ignoring actions of the holes that are not in $H$.

Definition 9 (Hole-tracking simulation). For two $O A$
$A_{1}:=\left\langle S_{1}, s_{01}, J_{1}, V_{1}, \sigma_{01}, T_{1}\right\rangle$ and $A_{2}:=\left\langle S_{2}, s_{02}, J_{2}, V_{2}, \sigma_{02}, T_{2}\right\rangle, A_{1}$ is a simulation of $A_{2}$ tracking holes $H$, noted $A_{1} \leqslant_{H} A_{2}$, with $H \subseteq J_{1} \cap J_{2}$, if there is a relation on configurations $\mathcal{R}:\left(S_{1} \times S_{2}\right) \rightarrow \mathcal{F}_{V_{1} \uplus V_{2}}$ such that:
(1) $\sigma_{01} \uplus \sigma_{02} \vdash \mathcal{R}\left(s_{01}, s_{02}\right)$

Figure 5: The simprod-cons OA: the system using one-place buffer.
(2) $\forall\left(s_{1}, s_{2}\right) \in S_{1} \times S_{2}$,

$$
\begin{aligned}
& \forall \frac{\beta_{1 j}^{j \in J_{1}^{\prime}}, g_{1}, \psi_{1}}{s_{1} \xrightarrow[\alpha_{1}]{\prime} s_{1}^{\prime}} \in \mathrm{OT}\left(s_{1}\right), \exists\left(\frac{\beta_{2 x j}^{j \in J_{2 x}^{\prime}}, g_{2 x}, \psi_{2 x}}{s_{2} \xrightarrow{\alpha_{2 x}} s_{2 x}^{\prime}} \in \mathrm{OT}\left(s_{2}\right)\right)^{x \in X}, \\
& \quad\left(\forall x \in X, J_{2 x}^{\prime} \cap H=J_{1}^{\prime} \cap H\right) \wedge \\
& V_{1} \uplus V_{2} \uplus \operatorname{vars}\left(t_{1}\right) \vdash \\
& \qquad\left(\mathcal { R } ( s _ { 1 } , s _ { 2 } ) \wedge g _ { 1 } \Longrightarrow \bigvee _ { x \in X } \left(\begin{array}{c}
\left.\left.\alpha_{1}=\alpha_{2 x} \wedge \bigwedge_{j \in J_{2 x}^{\prime} \cap H}^{\substack{\prime}} \begin{array}{l}
\beta_{1 j}=\beta_{2 x j} \wedge \\
g_{2 x} \wedge \mathcal{R}\left(s_{1}^{\prime}, s_{2 x}^{\prime}\right)\left\{\psi_{1} \uplus \psi_{2 x}\right\}
\end{array}\right)\right)
\end{array}\right.\right.
\end{aligned}
$$

(3) Deadlock reduction:

$$
\forall\left(s_{1}, s_{2}\right) \in S_{1} \times S_{2}, V_{1} \uplus V_{2} \vdash \mathcal{R}\left(s_{1}, s_{2}\right) \Longrightarrow\left(\bigvee_{t_{1} \in \mathrm{OT}\left(s_{1}\right)} \operatorname{guard}\left(t_{1}\right)\right) \vee \neg\left(\bigvee_{t_{2} \in \mathrm{OT}\left(s_{2}\right)} \operatorname{guard}\left(t_{2}\right)\right)
$$

Note that every action of the holes outside $H$ is unconstrained according to the simulation relation.

Property 1 (Relating simulations). Hole-equal simulation is a particular case of hole-tracking simulation when $J_{1}=J_{2}=H$.

Example 4. Consider the automata of Examples 1 and 3. As we saw above, prod-cons $\leqslant$ simprod-cons, therefore prod-cons $\leqslant_{\{p, q\}}$ simprod-cons.

Property 2 (Tracked holes). By construction, if an automaton is the simulation of another one, it is also a simulation by tracking less holes.

$$
A_{1} \leqslant_{H} A_{2} \wedge H^{\prime} \subseteq H \Longrightarrow A_{1} \leqslant_{H^{\prime}} A_{2}
$$

Now that we have a simulation relation that takes both variable parameters and process parameters into account, we would like to ensure that it has properties one would expect for a simulation relation.

## 5 Properties of our Simulation Relations

Before reasoning on the properties of simulation, we need to introduce one additional notion that characterises when the composition of two automata does not introduce new blocked transitions.

### 5.1 Non-blocking Composition

Unfortunately, the deadlock reduction property in the definition of simulation is not compositional: the composition operator can itself introduce a deadlock. In other words, when filling the hole of two related automata with a third one, even if there is a deadlock reduction between the two original automata, there might not be a deadlock reduction in the composed ones. The same problem may arise when two related automata are composed in the same hole of a third one.

This creates a conflict between deadlock reduction and the properties involving composition. We call non-blocking composition a composition that can safely be used to compose OA that are involved in a deadlock reducing relation.

Definition 10 (Non-blocking composition). Consider two $O A$ :
$A_{1}:=\left\langle S_{1}, s_{01}, V_{1}, \sigma_{01}, J_{1}, T_{1}\right\rangle$ and $A_{2}:=\left\langle S_{2}, s_{02}, V_{2}, \sigma_{02}, J_{2}, T_{2}\right\rangle$. Let $A$ be the $O A$ resulting from the composition $A=A_{1}\left[A_{2} / k\right]=\left\langle S, s_{0}, V, \sigma_{0}, J, T\right\rangle$. The composition $A_{1}\left[A_{2} / k\right]$ is non-blocking if A has a reachability predicate such that, for each reachable configuration, if there is a possible transition in $A_{1}$ then there is a possible transition in $A$ :

$$
\forall s=\left(s_{1}, s_{2}\right) \in S, V \uplus \biguplus_{t \in \mathrm{OT}\left(s_{1}\right)} \operatorname{vars}(t) \vdash\left(\checkmark_{A}(s) \wedge \bigvee_{t \in \mathrm{OT}\left(s_{1}\right)} \operatorname{guard}(t) \Longrightarrow \bigvee_{t \in \mathrm{OT}(s)} \operatorname{guard}(t)\right)
$$

Like in the definition of simulation (Definition 8) we use guards to ensure that the transition can occur. In general, one would not want to only consider non-blocking composition as it may reveal a bit restrictive, but it is the best necessary condition that can be identified for compositionality of simulation. It will be used to prove composition theorems given below. In absence of non-blocking composition, simulation may also be checked specifically for a given composed automaton.

### 5.2 Properties

We now state the properties of our simulation, their proofs can be found in the appendices. We express these properties in terms of hole-tracking simulation because, thanks to Property 11 all the properties of hole-tracking simulation are also valid for hole-equal simulation. The first crucial theorem of simulation is that it is a preorder on the set of OA. This latter enables stepwise refinement.

Theorem 1 (Simulation is a preorder). Hole-tracking simulation is reflexive and transitive: it is a preorder on the set of $O A$.

Proof sketch. The relation $\leqslant_{H}$ is reflexive, $A \leqslant_{H} A$. This is shown by considering the relation $\mathcal{R}$ such that $\mathcal{R}\left(s_{1}, s_{2}\right) \triangleq s_{1}=s_{2} \wedge \bigwedge_{v \in \operatorname{vars}\left(s_{1}\right)} v=v$ we can prove the conditions for Definition 9 . Appendix A presents the proof of transitivity. It is done classically by identifying the relation between $A_{1}$ and $A_{3}$ that is a simulation. What is less classical is the definition of this relation because it is a boolean formula. For each couple of states $s_{1}$ and $s_{3}$ of $A_{1}$ and $A_{3}$ we build a formula that defines the simulation. To do this, we take the disjunction of formulas relating $s_{1}$ and $s_{3}$, and passing by all states $s_{2}$ of $A_{2}$. More precisely, we define a relation of the following form:

$$
\mathcal{R}_{13}\left(s_{1}, s_{3}\right)=\bigvee_{s_{2} \in S_{2}}\left(\mathcal{R}_{12}\left(s_{1}, s_{2}\right) \wedge \mathcal{R}_{23}\left(s_{2}, s_{3}\right)\right)
$$

We then prove that this relation is a simulation, according to Definition 9
The next theorem states that if two automata are in simulation relation and the same automaton is placed in the same hole of the two automata, then the simulation is preserved. This is the first step toward proving that simulation is compositional in the sense that it is sufficient to prove simulation for the composed automata separately to obtain a simulation relation.

Theorem 2 (Context refinement). Let $A_{1}, A_{2}$ and $A_{3}$ be three $O A$ with $A_{1} \leqslant_{H} A_{2}$. Let $J_{3}$ be the set of holes of $A_{3}$ and suppose that $k \in H$. Suppose additionally that $A_{1}\left[A_{3} / k\right]$ is non-blocking. We have:

$$
A_{1}\left[A_{3} / k\right] \leqslant_{J_{3} \uplus H \backslash\{k\}} A_{2}\left[A_{3} / k\right]
$$

Proof sketch. The proof relies on a simulation relation that we consider is the one that makes $A_{1}$ and $A_{2}$ similar, complemented with identity of configurations for $A_{3}$. Then, by construction, all transitions of the composed automaton $A_{1}\left[A_{3} / k\right]$ are specified by open transitions of $A_{1}$. For the transitions that do not involve hole $k$, the transition of $A_{1}\left[A_{3} / k\right]$ is the same and simulation between $A_{1}$ and $A_{2}$ allows us to conclude directly. If the hole $k$ is involved the considered relation implies that valuations in $A_{3}$ are equal (i.e., the value for each variable are the same in both valuations), after a transition we should obtain "equal" valuations because post-conditions are deterministic.

Example 5. Consider again the prod-cons and simprod-cons automata given in the examples above. Since prod-cons $\leqslant\{P, Q\}$ simprod-cons, then according to Theorem 2, we have prod-cons[producer $/ P] \leqslant\{Q\}$ simprod-cons[producer $/ P]$.
The automaton of prod-cons[producer/P] is shown in Fig. 4. The automaton resulting from the composition of simprod-cons and producer is bigger and not shown here.

Theorem 3 (Congruence). Let $A_{1}, A_{2}$ and $A_{3}$ be three $O A$ with $A_{2} \leqslant_{H} A_{3}$. Let $J_{1}$ be the set of holes of $A_{1}$ and suppose that $k \in J_{1}$. Suppose additionally that the composition $A_{1}\left[A_{2} / k\right]$ is non-blocking. We have:

$$
A_{1}\left[A_{2} / k\right] \leqslant_{J_{1} \uplus H \backslash\{k\}} A_{1}\left[A_{3} / k\right]
$$

Consequently, as the simulation is transitive we can compose the previous theorems and state the following:

Theorem 4 (Composability). Let $A_{1}, A_{2}, A_{3}$ and $A_{4}$ be four $O A$ with $A_{1} \leqslant{ }_{H} A_{2}$ and $A_{3} \leqslant_{H^{\prime}}$ $A_{4}$. Suppose that $k \in H$. We have:

$$
A_{1}\left[A_{3} / k\right] \leqslant_{H \uplus H^{\prime} \backslash\{k\}} A_{2}\left[A_{4} / k\right]
$$

Example 6. As an example of the use of this theorem, if we design a refined version of the producer process of Example 2 called Refproducer. According to Theorem 4, we have prod-cons[producer $/ P] \leqslant\{Q\}$ simprod-cons[Refproducer $/ P]$.

Note that the substitution operation can be extended to a multiple substitution that fills several holes at the same time, and the theorems can be adapted accordingly.

## 6 Related Work

The origins of refinement are in the approach of programming that aims to provide solid foundations for building correct programs [12. Many work contributed to the development of elaborated notions of refinement in various area (e.g. [7, 1, 10, [8]). In the context of process algebra, refinement between processes can be defined in terms of simulations relation (e.g. ([17, 20]). However, the concept of simulations presented so far has focused on the refinement of systems that are inherently closed, i.e., systems which are bounded and without environment,

The simulation ensures the preservation of safety properties as deadlock-freeness and, more generally, all linear temporal logic properties [1, 18. The difference between the existing refinement principles have been studied in [13], for example the authors explain in what sense failure semantics is different from (bi)simulation in the compared systems and properties ensured. In this paper we particularly focus on the compositionality of simulation-based refinement.

There are not a lot of works that study refinement for open systems. Defining refinement of open systems as trace inclusion is addressed as a notion of subtyping in type theory (e.g.
[14, (9). The definition of refinement is based on a connection between session types and communicating automata theories - a notion of session automata based on Communicating Finite-State Machines, that are used for modelling processes communicating through FIFO channels. The refinement of open systems is also defined in terms of alternating simulation [4, 3. Alternating simulation is originating from the game theory [2], it allows the study of relation between individual components by viewing them as alternating transition systems. In particular, a refinement of game-based automata expresses that the refined component can offer more services (input actions) and fewer service demands (output actions). However, the composition of such automata may lead to illegal states, where one automaton issues an output that is not acceptable as input in the other one. The theory of alternating simulation provides an optimistic approach to compute compatibility between automata based on the fact that each automaton expects the other to provide legal inputs, i.e., two components can be composed if there is an environment where they can work together. Our approach has some commonalities with the above mentioned simulation [3]: both are process-oriented approaches even if they are not based on the same notion of simulation, and both include in the model how to compose and interact with processes that are accepted as parameters. Nevertheless, they differ in that our approach focuses on the compositional properties of the simulation, and not on the fact that entities can be composed.

Previous works on OA focused on equivalence relations compatible with composition. In [16, a computable bisimulation is introduced, while in 6] a weak version of the bisimulation is introduced. In this paper we tackle the refinement relation in the form of simulation, as is the case for the corresponding relations on labelled transition systems [8. Unlike the standard simulation we deal with symbolic and open models. In [23], the authors exploit transition systems to reason about the systems that are partially specified by using variables, making the state space potentially infinite.

Some work target component-based refinement with the concern of preserving deadlock freedom (e.g. [11, 18]). These works are not concerned with the theory of open symbolic systems, and therefore do not focus on the same modularity as we do, in particular we provide preservation of refinement by composition.

## 7 Conclusion

In this article we investigated the notion of refinement for a symbolic and open model: open automata. OA are convenient for compositional software verification. Indeed, OA model parallel systems that are parameterised both by the use of variables and by the possibility to compose automata. The formalism supports compositional specification through the simulation paradigm. In this paper, we introduce a refinement relation between open automata. It relies on a simulation relation between the two automata; it specifies that the refined process must follow the behaviour of the simulated one. We finally showed that simulation is a preorder that is preserved by composition, both when filling a hole and when placing automata in comparable contexts.

## A Proof of Transitivity for Refinement (Theorem 1)

$$
\text { If } A_{1} \leqslant_{H} A_{2} \text { and } A_{2} \leqslant_{H^{\prime}} A_{3} \text {, then } A_{1} \leqslant_{H \cap H^{\prime}} A_{3} .
$$

Proof. If $A_{1} \leqslant_{H} A_{2}$ then there is $\mathcal{R}_{12}$ a relation between states of $A_{1}$ and of $A_{2}$; If $A_{2} \leqslant H_{H^{\prime}} A_{3}$ then there is $\mathcal{R}_{23}$ a relation between states of $A_{2}$ and of $A_{3}$. We build a relation between states of $A_{1}$ and of $A_{3}$ as follows: for each pair of states $s_{1}, s_{3}$, for each state $s_{2}$ such that $\mathcal{R}_{12}$ relates $s_{1}$ and $s_{2}$, and $\mathcal{R}_{23}$ relates $s_{2}$ and $s_{3}$. Let $\mathcal{R}_{13}$ be the relation:

$$
\mathcal{R}_{13}\left(s_{1}, s_{3}\right)=\bigvee_{s_{2} \in S_{2}}\left(\mathcal{R}_{12}\left(s_{1}, s_{2}\right) \wedge \mathcal{R}_{23}\left(s_{2}, s_{3}\right)\right)
$$

We will show that $A_{1} \leqslant H_{H H^{\prime}} A_{3}$ by exhibiting $\mathcal{R}_{13}$ as a hole-tracking simulation of $A_{1}$ by $A_{3}$.

We have to prove that the relation $\mathcal{R}_{13}$ satisfies the three conditions of the definition of a refinement of OA.

1. Firstly, we have to $\mathcal{R}_{13}$ satisfies initial configurations:

$$
\sigma_{01} \uplus \sigma_{03} \vdash \mathcal{R}_{13}\left(s_{01}, s_{03}\right)
$$

By knowing that substitutions only have an effect on the variables of the OA they belong to, they also produce terms containing only variables of the OA they belong to. We have:

$$
\begin{aligned}
&\left(\sigma_{01} \uplus \sigma_{02} \vdash \mathcal{R}_{12}\left(s_{01}, s_{02}\right)\right) \wedge\left(\sigma_{02} \uplus \sigma_{03} \vdash \mathcal{R}_{23}\left(s_{02}, s_{03}\right)\right) \Longrightarrow \\
& \mathcal{R}_{12}\left(s_{01}, s_{02}\right)\left\{\sigma_{01} \uplus \sigma_{02}\right\} \wedge \mathcal{R}_{23}\left(s_{02}, s_{03}\right)\left\{\sigma_{02} \uplus \sigma_{03}\right\} \Longrightarrow \\
& \mathcal{R}_{12}\left(s_{01}, s_{02}\right)\left\{\sigma_{01} \uplus \sigma_{02} \uplus \sigma_{03}\right\} \wedge \mathcal{R}_{23}\left(s_{02}, s_{03}\right)\left\{\sigma_{01} \uplus \sigma_{02} \uplus \sigma_{03}\right\} \Longrightarrow \\
& \underbrace{\left.\Longrightarrow \mathcal{R}_{01}, s_{03}\right)}_{\mathcal{R}_{12}\left(s_{01}, s_{02}\right) \wedge \mathcal{R}_{23}\left(s_{02}, s_{03}\right)}\left\{\sigma_{01} \uplus \sigma_{02} \uplus \sigma_{03}\right\}
\end{aligned}
$$

Since $\sigma_{02}$ has no effect on variables of $s_{01}$ and $s_{03}$ thus we get the expected result.
2. Secondly, we need to prove that for any open transition $t_{1}$ in $T_{1}$ originating from $s_{1}$ :

$$
\frac{\beta_{1 j}^{j \in J_{1}^{\prime}}, g_{1}, \psi_{1}}{s_{1} \xrightarrow{\alpha_{1}} s_{1}^{\prime}} \in \mathrm{OT}\left(s_{1}\right)
$$

there exists an indexed family of OTs originating from $s_{3}$ :

$$
\begin{aligned}
& V_{1} \uplus V_{3} \uplus \operatorname{vars}\left(t_{1}\right) \vdash \\
& \qquad\left(R_{13}\left(s_{1}, s_{3}\right) \wedge g_{1} \Longrightarrow \varliminf_{z \in Z}\binom{\alpha_{1}=\alpha_{3 z} \wedge}{\begin{array}{c}
j \in J_{3 z}^{\prime} \wedge\left(H \cap H^{\prime}\right) \\
g_{3 z} \wedge R_{12}\left(s_{1}^{\prime}, s_{3 z}^{\prime}\right)\left\{\psi_{1} \uplus \psi_{3 z}\right\}
\end{array}}\right)
\end{aligned}
$$

The proof of this simulation step follows the same principles as the one given in [6] for the proof of transitivity of bisimulation ${ }^{2}$ It relies on the fact that one open transition of $A_{1}$ is simulated by a family of open transitions of $A_{2}$, and one open transition of $A_{2}$ is simulated by a family of open transitions of $A_{3}$. Transitivity leads to a doubly indexed family of simulating open transition.

[^2]3. Lastly, we have to prove the satisfaction of the deadlock reduction condition. To build $\mathcal{R}_{13}$ we need to rely on the disjunction of all possible paths to relate $s_{1}$ and $s_{3}$, which leads to
$$
\mathcal{R}_{13}\left(s_{1}, s_{3}\right)=\bigvee_{p \in P}\left(\mathcal{R}_{12}\left(s_{1}, s_{2 p}\right) \wedge \mathcal{R}_{23}\left(s_{2 p}, s_{3}\right)\right)
$$

Consider any $\left(s_{1}, s_{3}\right) \in \mathcal{R}_{13}$ there is a set of states $\left(s_{2 p}\right)^{p \in P}$ of $A_{2}$ relating $s_{1}$ and $s_{3}$. First, according to the relation between $A_{1}$ and $A_{2} \mathrm{OA}$, for all $\left(s_{1}, s_{2 p}\right) \in S_{1} \times S_{2}$ we have:

$$
\left.V_{1} \uplus V_{2} \vdash \mathcal{R}_{12}\left(s_{1}, s_{2 p}\right) \quad \Longrightarrow \quad \bigvee_{t_{1} \in \mathrm{OT}\left(s_{1}\right)} \operatorname{guard}\left(t_{1}\right) \vee \underset{t_{2 p} \in \mathrm{OT}\left(s_{2_{p}}\right)}{\vee} \operatorname{guard}\left(t_{2 p}\right)\right)
$$

Second, according to the relation between $A_{2}$ and $A_{3} \mathrm{OA}$, for all $\left(s_{2 p}, s_{3}\right) \in S_{2} \times S_{3}$ we have:

$$
V_{2} \uplus V_{3} \vdash \mathcal{R}_{23}\left(s_{2 p}, s_{3}\right) \quad \Longrightarrow \quad \bigvee_{t_{1} \in \mathrm{OT}\left(s_{2 p}\right)} \operatorname{guard}\left(t_{2 p}\right) \vee \underset{t_{3} \in \mathrm{OT}\left(s_{3}\right)}{\neg\left(\bigvee_{2} \operatorname{guard}\left(t_{3}\right)\right)}
$$

With the conjunction of both, we get:

$$
V_{1} \uplus V_{2} \uplus V_{3} \vdash \mathcal{R}_{12}\left(s_{1}, s_{2 p}\right) \wedge \mathcal{R}_{23}\left(s_{2 p}, s_{3}\right) \Longrightarrow \underset{t_{1} \in \mathrm{OT}\left(s_{1}\right)}{\bigvee_{1} \operatorname{guard}\left(t_{1}\right) \vee \neg\left(\bigvee_{t_{3} \in \mathrm{OT}\left(s_{3}\right)} \operatorname{guard}\left(t_{3}\right)\right)}
$$

This is valid for all $s_{2 p} \in\left(s_{2 p}\right)^{p \in P}$, then we have:

$$
\begin{aligned}
V_{1} \uplus V_{2} \uplus V_{3} \vdash \underbrace{\bigvee_{p \in P}\left(R_{12}\left(s_{1}, s_{2 p}\right) \wedge R_{23}\left(s_{2 p}, s_{3}\right)\right)}_{R_{13}\left(s_{1}, s_{3}\right)} & \Longrightarrow \\
& \left(\bigvee_{t_{1} \in \mathrm{OT}\left(s_{1}\right)} \operatorname{guard}\left(t_{1}\right)\right) \vee \neg\left(\bigvee_{t_{3} \in \mathrm{OT}\left(s_{3}\right)}^{\left.\operatorname{guard}\left(t_{3}\right)\right)}\right.
\end{aligned}
$$

By removing the $A_{2}$ variables that have not effect on $A_{2}$ et $A_{3}$, we get the desired result:

$$
V_{1} \uplus V_{3} \vdash \mathcal{R}_{13}\left(s_{1}, s_{3}\right) \quad \Longrightarrow \quad\left(\bigvee_{t_{1} \in \mathrm{OT}\left(s_{1}\right)} \operatorname{guard}\left(t_{1}\right)\right) \vee \underset{t_{3} \in \mathrm{OT}\left(s_{3}\right)}{\left.\neg \operatorname{guard}\left(t_{3}\right)\right)}
$$

## B Proof of Context Refinement (Theorem 2)

Suppose that $A_{1} \leqslant_{H} A_{2}, k \in H$ and that $A_{1}\left[A_{3} / k\right]$ is non-blocking. We have:

$$
A_{1}\left[A_{3} / k\right] \leqslant_{J_{3} \uplus H \backslash\{k\}} A_{2}\left[A_{3} / k\right]
$$

Pictorially, the theorem states the following result:

Proof. Let us denote by $A_{13}$ (resp. $A_{23}$ ) the OA resulting from $A_{1}\left[A_{3} / k\right]$ (resp. $A_{2}\left[A_{3} / k\right]$ ), to prove the theorem it is sufficient to prove that there exists a relation between states of the two OA that satisfies the conditions of Definition 9

We denote $A_{1}=\left\langle S_{1}, s_{01}, J_{1}, V_{1}, \sigma_{01}, T_{1}\right\rangle$ and $A_{2}:=\left\langle S_{2}, s_{02}, J_{2}, V_{2}, \sigma_{02}, T_{2}\right\rangle$ and $A_{3}=\left\langle S_{3}, s_{03}, J_{3}, V_{3}, \sigma_{03}, T_{3}\right\rangle$. The proof requires to rename the variables of one instance of the two $A_{3}$ automata to avoid clashes in variable names (this is required by the definition of refinement). In practice we will use superscripts ${ }^{1}$ and ${ }^{2}$ to distinguish elements of the two instances of $A_{3}$.

Let $\mathcal{R}$ be the refinement relation relating states of $A_{1}$ and $A_{2}$. Let us denote with $t^{1}$ and $t^{2}$ the elements of $A_{1}$ and $A_{2}$ respectively. Consider any two states $s_{13}=\left(s_{1}, s_{3}^{1}\right)$ and $s_{23}=\left(s_{2}, s_{3}^{2}\right)$ ( $s_{3}^{1}$ and $s_{3}^{2}$ are the same with renaming). We define a relation $\mathcal{R}^{\prime}$ relating states of $s_{13}$ and $s_{23}$ as follows:

$$
\mathcal{R}^{\prime}\left(s_{13}, s_{23}\right)=\mathcal{R}\left(s_{1}, s_{2}\right) \wedge \checkmark_{A_{13}}\left(s_{13}\right) \wedge \bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \wedge s_{3}^{1}=s_{3}^{2}
$$

We want to prove that $\left(\mathcal{R}^{\prime}, H \uplus J_{3} \backslash\{k\}\right)$ is a hole-tracking simulation of $A_{13}$ and $A_{23}$. In the following we denote $H^{\prime}=H \cup J_{3} \backslash\{k\}$.

1. First, we have to prove the relation for initial states:

$$
\sigma_{013} \uplus \sigma_{023} \vdash \mathcal{R}^{\prime}\left(s_{013}, s_{023}\right)
$$

with $\sigma_{013}=\sigma_{01} \uplus \sigma_{03}^{1}, \sigma_{023}=\sigma_{02} \uplus \sigma_{03}^{2}, s_{013}=\left(s_{01}, s_{03}^{1}\right)$, and $s_{023}=\left(s_{02}, s_{02}^{2}\right)$.
By using the fact that $\mathcal{R}$ relates initial configurations of $A_{1}$ and $A_{2}$, we have: $\left(\sigma_{01} \uplus \sigma_{02} \vdash \mathcal{R}\left(s_{01}, s_{02}\right)\right)$.
Considering that initial valuations $\sigma_{03}^{1}$ and $\sigma_{03}^{2}$ associate the same values to the "same" variables modulo renaming, so the following holds:

$$
\left(\bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \wedge s_{3}^{1}=s_{3}^{2}\right)\left\{\left\{\sigma_{03}^{1} \uplus \sigma_{03}^{2}\right\}\right\} .
$$

Additionally, because the domains of the substitution function are disjoint, the substitution function has an effect only on the related elements, we get:

$$
\begin{aligned}
& \left(\sigma_{01} \uplus \sigma_{02} \vdash \mathcal{R}\left(s_{01}, s_{02}\right)\right) \\
\Longrightarrow & \mathcal{R}\left(s_{01}, s_{02}\right)\left\{\sigma_{01} \uplus \sigma_{02}\right\} \wedge\left(\bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \wedge s_{3}^{1}=s_{3}^{2}\right)\left\{\left\{\sigma_{03}^{1} \uplus \sigma_{03}^{2}\right\}\right\} \\
\Longrightarrow & \left(\mathcal{R}\left(s_{01}, s_{02}\right) \wedge \bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \wedge s_{3}^{1}=s_{3}^{2}\right)\left\{\left\{\sigma_{01} \uplus \sigma_{02} \uplus \sigma_{03}^{1} \uplus \sigma_{03}^{2} \uplus \sigma_{013}\right\}\right\} \\
\Longrightarrow & \sigma_{013} \uplus \sigma_{023} \vdash \mathcal{R}^{\prime}\left(s_{013}, s_{023}\right)
\end{aligned}
$$

The last step comes from the additional fact that $\checkmark_{A_{13}}\left(s_{013}\right)$.
2. Second, we need to prove for any open transition $t_{13}$ in $T_{13}$ originating from $s_{13}$ :

$$
\frac{\beta_{13 j}^{j \in J_{13}^{\prime}}, g_{13}, \psi_{13}}{s_{13} \xrightarrow{\alpha_{13}} s_{13}^{\prime}} \in \mathrm{OT}\left(s_{13}\right)
$$

there exists an indexed family $t_{23 x}$ of OTs originating from $s_{23}$ that simulate it:

$$
\left(\frac{\beta_{23 x j}^{j \in J_{33 x}^{\prime}, g_{23 x}, \psi_{23 x}}}{s_{23} \xrightarrow[232 x]{ } s_{23 x}^{\prime}} \in \mathrm{OT}\left(s_{23}\right)\right)^{x \in X}
$$

such that $\left(\forall x \in X, J_{23 x}^{\prime} \cap H^{\prime}=J_{13}^{\prime} \cap H^{\prime}\right)$ and
$V_{13} \uplus V_{23} \uplus \operatorname{vars}\left(t_{13}\right) \vdash$

$$
\mathcal{R}^{\prime}\left(s_{13}, s_{23}\right) \wedge g_{13} \Longrightarrow \bigvee_{x \in X}\binom{\alpha_{13}=\alpha_{23 x} \wedge \bigwedge_{j \in J_{23 x}^{\prime} \cap H^{\prime}} \beta_{13 j}=\beta_{23 x j} \wedge}{g_{23 x} \wedge \mathcal{R}^{\prime}\left(s_{13}^{\prime}, s_{23 x}^{\prime}\right)\left\{\psi_{13} \uplus \psi_{23 x}\right\}}
$$

Recall that by definition of composition and OA refinement we have:

$$
\begin{aligned}
& V_{13}=V_{1} \uplus V_{3}^{1} \text { and } V_{23}=V_{2} \uplus V_{3}^{2} \\
& H^{\prime} \subseteq J_{3} \uplus\left(J_{1} \cap J_{2}\right) \backslash\{k\}=\left(J_{3} \uplus J_{1} \backslash\{k\}\right) \cap\left(J_{3} \uplus J_{2} \backslash\{k\}\right)
\end{aligned}
$$

First of all, we have by hypothesis $A_{1} \leqslant_{H} A_{2}$, then for any open transition $t_{1}$ in $T_{1}$ originating from $s_{1}$ :

$$
\frac{\beta_{1 j}^{j \in J_{1}^{\prime}}, g_{1}, \psi_{1}}{s_{1} \xrightarrow[\alpha_{1}]{\longrightarrow} s_{1}^{\prime}} \in \mathrm{OT}\left(s_{1}\right)
$$

there exists an indexed family of OTs originating from $s_{2}$ :

$$
\left(\frac{\beta_{2 x j}^{j \in J_{2 x}^{\prime}}, g_{2 x}, \psi_{2 x}}{s_{2} \xrightarrow[2 x]{ } s_{2 x}^{\prime}} \in \mathrm{OT}\left(s_{2}\right)\right)^{x \in X}
$$

such that $\forall x \in X, J_{2 x}^{\prime} \cap H=J_{1}^{\prime} \cap H$ and

$$
\begin{align*}
& V_{1} \uplus V_{2} \uplus \operatorname{vars}\left(t_{1}\right) \vdash \\
& \mathcal{R}\left(s_{1}, s_{2}\right) \wedge g_{1} \Longrightarrow \bigvee_{x \in X}\binom{\alpha_{1}=\alpha_{2 x} \wedge \bigwedge_{\substack{\left.j \in J_{2,}^{\prime} \wedge H \\
s_{1}, s_{2 x}^{\prime}\right)}} \beta_{1 j}=\beta_{2 x j} \wedge}{\left.g_{2 x} \wedge \mathcal{R} \uplus \psi_{1} \uplus\right\}} \tag{*}
\end{align*}
$$

Consider any transition $t_{13}$ in $A_{13}$. Based on the definition of composition $t_{13}$ can be obtained from two different cases, we will consider the two cases separately.

First case: Both automata perform a transition. The transition $t_{13}$ is obtained by the composition of transitions $t_{1}=\frac{\beta_{1 j}^{j \in J_{1}^{\prime}}, g_{1}, \psi_{1}}{s_{1} \xrightarrow{\alpha_{1}} s_{1}^{\prime}} \in \mathrm{OT}\left(s_{1}\right)$ and

$$
t_{3}^{1}=\frac{\left(\beta_{3 j}^{1}\right)^{j \in J_{3}^{1 /}}, g_{3}^{1}, \psi_{3}^{1}}{s_{3}^{1} \xrightarrow[3]{\alpha_{3}^{1}} s_{3}^{11^{1}}} \in \mathrm{OT}\left(s_{3}^{1}\right) \quad \text { when } k \in J_{1}^{\prime}
$$

The result is:

$$
t_{13}=\frac{\beta_{1 j}^{j \in J_{1}^{\prime} \backslash\{k\}} \uplus\left(\beta_{j 3}^{1}\right)^{j \in J_{3}^{1 \prime}}, g_{1} \wedge g_{3}^{1} \wedge \alpha_{3}^{1}=\beta_{1 k}, \psi_{1} \uplus \psi_{3}^{1}}{\left(s_{1}, s_{3}^{1}\right) \xrightarrow{\alpha_{1}}\left(s_{1}^{\prime}, s_{3}^{1 \prime}\right)} \quad \text { where } k \in J_{1}^{\prime}
$$

We then obtain a family of OTs by the simulation of $A_{1}$ by $A_{2}$ (as stated above). By hypothesis we have $k \in H$, so in the case where $k \in J_{1}^{\prime}$, we deduce that $k \in J_{2 x}^{\prime}$ we can then build a family of OTs $t_{23 x}^{x \in X}$ with the same transitions of $A_{3}$ (up to renaming) as those used to build $t_{13}$.

$$
t_{23 x}=\left(\frac{\beta_{2 x j}^{j \in J_{2 x}^{\prime} \backslash\{k\}} \uplus\left(\beta_{3 j}^{2}\right)^{j \in J_{3}^{2 \prime}}, g_{2 x} \wedge g_{3}^{2} \wedge \alpha_{3}^{2}=\beta_{2 x k}, \psi_{2 x} \uplus \psi_{3}^{2}}{\left(s_{2}, s_{3}^{2}\right) \xrightarrow{\alpha_{2 x}}\left(s_{2 x}^{\prime}, s_{3}^{2 \prime}\right)}\right)^{x \in X}
$$

Recall that in this case $k \in J_{1}^{\prime}$, so $\forall x \in X$ we have

$$
\begin{aligned}
& J_{23 x}^{\prime} \cap H^{\prime}=\left(\left(J_{2 x}^{\prime} \backslash\{k\}\right) \uplus J_{3}^{2 \prime}\right) \cap\left(H \uplus J_{3} \backslash\{k\}\right) \\
&=\left(\left(J_{2 x}^{\prime} \cap\left(H \uplus J_{3}\right)\right) \uplus\left(J_{3}^{2 \prime} \cap\left(H \uplus J_{3}\right)\right)\right) \backslash\{k\} \\
&=\left(\left(J_{2 x}^{\prime} \cap H\right) \uplus\left(J_{3}^{2 \prime} \cap J_{3}\right)\right) \backslash\{k\} \\
& \quad \text { since } J_{3} \cap J_{2 x}^{\prime}=\varnothing \text { and } H \cap J_{3}^{2 \prime}=\varnothing \\
&=\left(\left(J_{2 x}^{\prime} \cap H\right) \uplus J_{3}^{2 \prime}\right) \backslash\{k\} \text { since } J_{3}^{2 \prime} \subseteq J_{3} \\
&=\left(\left(J_{1}^{\prime} \cap H\right) \uplus J_{3}^{\prime \prime}\right) \backslash\{k\} \quad \text { since } J_{3}^{1 \prime}=J_{3}^{2 \prime} \text { and } J_{1}^{\prime} \cap H=J_{2 x}^{\prime} \cap H \\
&=\left(\left(J_{1}^{\prime} \cap H\right) \uplus\left(J_{3}^{1 \prime} \cap J_{3}\right)\right) \backslash\{k\} \text { since } J_{3}^{1 \prime} \subseteq J_{3} \\
&=\left(J_{1}^{\prime} \cap\left(J_{3} \uplus H\right)\right) \uplus\left(\left(J_{3}^{1 \prime} \cap\left(J_{3} \uplus H\right)\right) \backslash\{k\}\right. \\
& \quad \text { since } J_{3} \cap J_{1}^{\prime}=\varnothing \text { and } H \cap J_{3}^{1 \prime}=\varnothing \\
&=\left(\left(J_{1}^{\prime} \uplus J_{3}^{1 \prime}\right) \backslash\{k\}\right) \cap\left(\left(J_{3} \uplus H\right) \backslash\{k\}\right) \\
&= J_{13}^{\prime} \cap H^{\prime}
\end{aligned}
$$

In this case the composition gives:

$$
g_{13} \Leftrightarrow g_{1} \wedge g_{3}^{1} \wedge \alpha_{3}^{1}=\beta_{1 k} \text { and } g_{23 x} \Leftrightarrow g_{2 x} \wedge g_{3}^{2} \wedge \alpha_{3}^{2}=\beta_{2 x k}
$$

As $k \in H$ we have $\beta_{1 k}=\beta_{2 x k}$ then we deduce:

$$
g_{3}^{1} \wedge \alpha_{3}^{1}=\beta_{1 k} \Leftrightarrow g_{3}^{2} \wedge \alpha_{3}^{2}=\beta_{2 x k}
$$

The proof of the rest is based on the following facts:
(a) By construction of $t_{13}$ and $t_{23 x}$ we have $\alpha_{13}=\alpha_{1}$ and $\alpha_{23 x}=\alpha_{2 x}$. So we deduce: $\alpha_{1}=\alpha_{2 x} \Rightarrow \alpha_{13}=\alpha_{23 x}$.
(b) By composition we have also:
$\beta_{13 j}^{j \in J_{13}^{\prime}}=\beta_{1 j}^{j \in J_{1}^{\prime} \backslash\{k\}} \uplus\left(\beta_{3 j}^{1}\right)^{j \in J_{3}^{1 \prime}}$ and $\beta_{23 x j}^{j \in J_{23}^{\prime}}=\beta_{2 x j}^{j \in J_{2 x}^{\prime} \backslash\{k\}} \uplus\left(\beta_{3 j}^{2}\right)^{j \in J_{3}^{2 \prime}}$
Therefore, we have for all $j \in J_{13}^{\prime}$ (recall that $J_{13}^{\prime}=J_{23}^{\prime}$ ):

$$
\beta_{13 j}=\beta_{23 x j} \Rightarrow\left(j \in J_{1}^{\prime} \wedge \beta_{1 j}=\beta_{2 x j}\right) \vee\left(j \in J_{3}^{1 \prime} \wedge \beta_{3 j}^{1}=\beta_{3 j}^{2}\right)
$$

(c) Considering $\beta_{3 j}^{1}$ and $\beta_{3 j}^{2}$ are the same (up to renaming) we have:
$V_{3}^{1} \uplus V_{3}^{2} \uplus \operatorname{vars}\left(t_{13}\right) \vdash \bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \Longrightarrow \bigwedge_{j \in J_{3}^{2 \prime}} \beta_{3 j}^{1}=\beta_{3 j}^{2}$

Then we compose by disjunction with the following hypothesis (part of formula $(*)$ ).
$V_{1} \uplus V_{2} \uplus \operatorname{vars}\left(t_{1}\right) \vdash \bigwedge \beta_{1 j}=\beta_{2 x j}$

$$
j \in J_{2 x}^{\prime} \cap H
$$

$$
\begin{aligned}
& V_{1} \uplus V_{2} \uplus V_{3}^{1} \uplus V_{3}^{2} \uplus \operatorname{vars}\left(t_{13}\right) \vdash \bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \Longrightarrow \bigwedge_{j \in J_{2 x}^{\prime} \cap H} \beta_{1 j}=\beta_{2 x j} \vee \bigwedge_{j \in J_{3}^{2 \prime}} \beta_{3 j}^{1}=\beta_{3 j}^{2} \\
& \Rightarrow V_{13} \uplus V_{23} \uplus \operatorname{vars}\left(t_{13}\right) \vdash \bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \Longrightarrow \bigwedge_{j \in\left(J_{2 x}^{\prime} \cap H\right) \uplus J_{3}^{2 \prime}} \beta_{13 j}=\beta_{23 x j} \\
& \Rightarrow V_{13} \uplus V_{23} \uplus \operatorname{vars}\left(t_{13}\right) \vdash \bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \Longrightarrow \bigwedge_{j \in\left(\left(J_{2 x}^{\prime} \cap H\right) \uplus J_{3}^{2 \prime}\right) \backslash\{k\}} \beta_{13 j}=\beta_{23 x j} \\
& \Rightarrow V_{13} \uplus V_{23} \uplus \operatorname{vars}\left(t_{13}\right) \vdash \bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \Longrightarrow \bigwedge_{j \in\left(J_{23 x}^{\prime} \cap H^{\prime}\right)} \beta_{13 j}=\beta_{23 x j}
\end{aligned}
$$

We can extend the valuation context of the variables to cover the variables of the transitions $t_{3}$ and the variables in $V_{3}^{1}$ and $V_{3}^{2}$ in the formula (*). By using the statements resulting from the cases (a), (b) and (c), we get:

$$
\begin{aligned}
& V_{13} \uplus V_{23} \uplus \operatorname{vars}\left(t_{13}\right) \vdash \\
& \mathcal{R}\left(s_{1}, s_{2}\right) \wedge\left(g_{1} \wedge g_{3}^{1} \wedge \alpha_{3}^{1}=\beta_{1 k}\right) \wedge \bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \Longrightarrow \\
& \bigvee_{x \in X}\binom{\alpha_{13}=\alpha_{23 x} \wedge \bigwedge_{\substack{ \\
j \in\left(J_{23 x}^{\prime} \cap H^{\prime}\right) \\
g_{2 x} \wedge \mathcal{R}\left(s_{1}^{\prime}, s_{2 x}^{\prime}\right)\left\{\psi_{1} \uplus \psi_{2 x}\right\}}}=\beta_{23 x j} \wedge}{g_{1}} \wedge g_{3}^{2} \wedge \alpha_{3}^{2}=\beta_{2 x k}
\end{aligned}
$$

That can be re-written as follows:

$$
\begin{aligned}
& V_{13} \uplus V_{23} \uplus \operatorname{vars}\left(t_{13}\right) \vdash \\
& \mathcal{R}\left(s_{1}, s_{2}\right) \wedge g_{13} \wedge \bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \Longrightarrow \bigvee_{x \in X}\binom{\alpha_{13}=\alpha_{23 x} \wedge \bigwedge_{j \in J_{23 x}^{\prime} \wedge H^{\prime}} \beta_{13 j}=\beta_{23 x j} \wedge}{g_{23 x} \wedge \mathcal{R}\left(s_{1}^{\prime}, s_{2 x}^{\prime}\right)\left\{\psi_{1} \uplus \psi_{2 x}\right\}}
\end{aligned}
$$

Moreover, we have for any transition $t_{3}$ in $A_{3}$ relating $s_{3}$ and $s_{3}^{\prime}$ the following:

$$
V_{13} \uplus V_{23} \uplus \operatorname{vars}\left(t_{13}\right) \vdash \bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \wedge s_{3}^{1}=s_{3}^{2} \Longrightarrow \bigwedge_{v_{3} \in V_{3}} \psi_{13}\left(v_{3}^{1}\right)=\psi_{13}\left(v_{3}^{2}\right) \wedge s_{3}^{1 \prime}=s_{3}^{2 \prime}
$$

Furthermore, according to the Definition 7 (reachability applied to the composed automaton $\left.A_{1}\left[A_{3} / k\right]\right)$ we have, for all $t_{13} \in T_{13}$ :

$$
\operatorname{vars}\left(t_{13}\right) \vdash\left(\checkmark_{A_{13}}\left(s_{13}\right) \wedge g_{13} \Longrightarrow \checkmark_{A_{13}}\left(s_{13}^{\prime}\right)\left\{\left\{\psi_{13}\right\}\right)\right.
$$

Thus, we get:

$$
\left.\begin{array}{rl}
V_{13} \uplus V_{23} \uplus \operatorname{vars}\left(t_{1}\right) & \cap \operatorname{vars}\left(t_{13}\right) \vdash \\
\mathcal{R}\left(s_{1}, s_{2}\right) & \wedge g_{13} \wedge \checkmark_{A_{13}}\left(s_{13}\right) \wedge \bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \wedge s_{3}^{1}=s_{3}^{2} \Longrightarrow \\
\bigvee_{x \in X}\left(\begin{array}{l}
\alpha_{13}=\alpha_{23 x} \wedge \\
\wedge \bigwedge_{A_{13}}\left(s_{13}^{\prime}\right)\left\{\bigwedge_{23 x}^{\prime} \cap H_{13}^{\prime}\right\} \wedge \\
\beta_{13 j}=\beta_{23 x j} \wedge g_{23 x} \wedge \mathcal{R}\left(s_{1}^{\prime}, s_{2 x}^{\prime}\right)\left\{\psi_{1} \uplus \psi_{2 x}\right\} \\
v_{3} \in V_{3}
\end{array}\right)=v_{313}^{1}\left(v_{3}^{2}\right) \wedge s_{3}^{1 \prime}=s_{3}^{2 \prime}
\end{array}\right) .
$$

From the two previous formulas, we get:

$$
\left.\left.\begin{array}{rl}
V_{13} \uplus V_{23} \uplus \operatorname{vars}\left(t_{13}\right) & \vdash \\
\mathcal{R}\left(s_{1}, s_{2}\right) & \wedge g_{13}
\end{array}\right) \checkmark_{A_{13}\left(s_{13}\right)} \wedge \bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \wedge s_{3}^{1}=s_{3}^{2} \Longrightarrow \quad \begin{array}{l}
\left.\alpha_{13}=\alpha_{23 x} \wedge \bigwedge_{\substack{j \in J_{23 x}^{\prime} \cap H^{\prime}}}^{\beta_{13 j}=\beta_{23 x j} \wedge g_{23 x} \wedge \checkmark_{A_{13}}\left(s_{13}^{\prime}\right)\left\{\psi_{13}\right\} \wedge} \begin{array}{r}
\mathcal{R}\left(s_{1}^{\prime}, s_{2 x}^{\prime}\right)\left\{\psi_{1} \uplus \psi_{2 x}\right\}
\end{array}\right) \wedge \bigwedge_{v_{3} \in V_{3}} \psi_{13}\left(v_{3}^{1}\right)=\psi_{13}\left(v_{3}^{2}\right) \wedge s_{3}^{1 \prime}=s_{3}^{2 \prime}
\end{array}\right) .
$$

Because of the independence of the substitution domains, we simplify and get the expected formula:

$$
\begin{aligned}
& V_{13} \uplus V_{23} \uplus \operatorname{vars}\left(t_{13}\right) \vdash \\
& \qquad \mathcal{R}^{\prime}\left(s_{13}, s_{23}\right) \wedge g_{13} \Longrightarrow \bigvee_{x \in X}\binom{\alpha_{13}=\alpha_{23 x} \wedge \bigwedge_{\substack{j \in J_{23 x}^{\prime} \wedge H^{\prime} \\
g_{23 x} \wedge \mathcal{R}^{\prime}\left(s_{13}^{\prime}, s_{23 x}^{\prime}\right)\left\{\left\{\psi_{13} \uplus \psi_{23 x}\right\}\right.}} \beta_{13 j}=\beta_{23 x j} \wedge}{g_{20}}
\end{aligned}
$$

Second case: Only the encompassing automaton performs a transition. $t_{13}$ is obtained by the transition $t_{1}=\frac{\beta_{1 j}^{j \in J_{1}^{\prime}}, g_{1}, \psi_{1}}{s_{1} \xrightarrow{\alpha_{1}} s_{1}^{\prime}}$ alone with the state $s_{3}^{1}$ unchanged, if $k \notin J_{1}^{\prime}$

$$
t_{13}=\frac{\beta_{1 j}^{j \in J_{1}^{\prime}}, g_{1}, \psi_{1}}{\left(s_{1}, s_{3}^{1}\right) \xrightarrow{\alpha_{1}}\left(s_{1}^{\prime}, s_{3}^{1}\right)}
$$

As stated above, from the simulation of $A_{1}$ by $A_{2}$ we get a family of OTs $t_{2 x}^{x \in X}$. The composition of this family of OTs with the same transitions of $A_{3}$ (up to renaming) as those used to build $t_{13}$ produces a family of OTs $t_{23 x}^{x \in X}$ in the form:

$$
t_{23 x}=\left(\frac{\beta_{2 x}^{j \in J_{2 x}^{\prime}}, g_{2 x}, \psi_{2 x}}{\left(s_{2}, s_{3}^{2}\right) \xrightarrow{\alpha_{2 x} \longrightarrow}\left(s_{2 x}^{\prime}, s_{3}^{2}\right)}\right)^{x \in X}
$$

By hypothesis we have $k \in H$, since $k \notin J_{1}^{\prime}$, we deduce $k \notin J_{2 x}^{\prime}$.
$\forall x \in X$ we have:

$$
\begin{aligned}
J_{23 x}^{\prime} \cap H^{\prime} & =J_{2 x}^{\prime} \cap\left(J_{3} \uplus H \backslash\{k\}\right) \\
& =\left(J_{2 x}^{\prime} \cap H\right) \text { since } J_{2 x}^{\prime} \cap J_{3}=\varnothing \wedge k \notin J_{2 x}^{\prime} \\
& =\left(J_{1}^{\prime} \cap H\right) \text { since } J_{1}^{\prime} \cap H=J_{2 x}^{\prime} \cap H \\
& =\left(J_{13}^{\prime} \cap H^{\prime}\right) \text { since } J_{3} \cap J_{1}^{\prime}=\varnothing \wedge k \notin J_{1}^{\prime}
\end{aligned}
$$

The proof of the rest of the formula follows the same steps as the previous case the only argument that change is that by composition we obtain: $g_{13}$ is the same as $g_{1}$ and $g_{23 x}$ is the same as $g_{2 x}$ and the actions of $\alpha_{13}$, resp. $\alpha_{23 x}$, is the same as $\alpha_{1}$, resp. $\alpha_{2 x}$. Similarly $\beta_{13 j}$ and $\beta_{23 x j}$ that are the same as $\beta_{1 j}$ and $\beta_{2 x j}$ respectively. We also apply the reachability definition but only on the automaton $A_{1}$
3. Lastly, we have to prove the satisfaction of the deadlock reduction condition, i.e., for all $\left(s_{13}, s_{23}\right) \in S_{13} \times S_{23}$

By hypothesis the composition $A_{1}\left[A_{3} / k\right]$ is non-blocking, then according to the Definition 10 we have for all state $s_{13}$ :

$$
V_{13} \uplus \biguplus_{t_{1} \in \mathrm{OT}\left(s_{1}\right)}^{+\operatorname{vars}\left(t_{1}\right)} \vdash\left(\checkmark_{A_{13}\left(s_{13}\right)} \wedge \bigvee_{t_{1} \in \mathrm{OT}\left(s_{1}\right)} \operatorname{guard}\left(t_{1}\right)\right) \quad \Longrightarrow \quad \bigvee_{t_{13} \in \mathrm{OT}\left(s_{13}\right)} \operatorname{guard}\left(t_{13}\right)
$$

From this we can infer:

Furthermore, from the second hypothesis stating that $A_{1} \leqslant{ }_{H} A_{2}$, we have for all $\left(s_{1}, s_{2}\right) \in$ $S_{1} \times S_{2}$

$$
V_{1} \uplus V_{2} \vdash \mathcal{R}\left(s_{1}, s_{2}\right) \wedge \quad \neg\left(\bigvee_{t_{1} \in \mathrm{OT}\left(s_{1}\right)} \operatorname{guard}\left(t_{1}\right)\right) \quad \Longrightarrow \quad \neg\left(\bigvee_{t_{2} \in \mathrm{OT}\left(s_{2}\right)}^{\left.\operatorname{guard}\left(t_{2}\right)\right)}\right.
$$

From the two previous formula can deduce:

$$
\begin{aligned}
& V_{13} \uplus V_{2} \uplus \biguplus_{t_{1} \in \mathrm{OT}\left(s_{1}\right)} \operatorname{vars}\left(t_{1}\right) \vdash \\
& R\left(s_{1}, s_{2}\right) \wedge \neg\left(\bigvee_{t_{13} \in \mathrm{OT}\left(s_{13}\right)} \operatorname{guard}\left(t_{13}\right)\right) \Longrightarrow \neg\left(\bigvee_{t_{2} \in \mathrm{OT}\left(s_{2}\right)} \operatorname{guard}\left(t_{2}\right)\right) \vee \neg \checkmark_{A_{13}}\left(s_{13}\right)
\end{aligned}
$$

By definition of the composition of open automata, each guard of automaton $A_{23}$ is of the form $\operatorname{guard}\left(t_{23}\right)=\operatorname{guard}\left(t_{2}\right) \wedge t$, thus we have:

$$
V_{23} \quad \vdash \quad \underset{t_{1} \in \mathrm{OT}\left(s_{2}\right)}{\neg\left(\bigvee_{\operatorname{lar}} \operatorname{guard}\left(t_{2}\right)\right)} \quad \Longrightarrow \quad \underset{t_{23} \in \mathrm{OT}\left(s_{23}\right)}{\neg\left(\bigvee_{23} \operatorname{guard}\left(t_{23}\right)\right)}
$$

From the two previous formula and by introducing the following tautology

$$
\begin{aligned}
\left(\bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2}\right. & \left.\wedge s_{3}^{1}=s_{3}^{2}\right), \text { we get: } \\
V_{13} \uplus V_{23} & \vdash \underbrace{\mathcal{R}\left(s_{1}, s_{2}\right) \wedge \checkmark_{A_{13}}\left(s_{13}\right) \wedge\left(\bigwedge_{v_{3} \in V_{3}} v_{3}^{1}=v_{3}^{2} \wedge s_{3}^{1}=s_{3}^{2}\right)}_{\mathcal{R}^{\prime}\left(s_{13}, s_{23}\right)} \wedge \neg \bigvee_{t_{13} \in \mathrm{OT}\left(s_{13}\right)} \operatorname{guard}\left(t_{13}\right) \\
& \Longrightarrow\left(\begin{array}{c}
\left.\neg \bigvee_{t_{23} \in \mathrm{OT}\left(s_{23}\right)} \operatorname{guard}^{2}\left(t_{23}\right) \vee \neg \checkmark_{A_{13}}\left(s_{13}\right)\right) \wedge \checkmark_{A_{13}}\left(s_{13}\right) \Longrightarrow \underset{t_{23} \in \mathrm{OT}\left(s_{23}\right)}{ } \text { guard }\left(t_{23}\right)
\end{array}\right.
\end{aligned}
$$

which gives the expected result.

## C Proof of Congruence (Theorem 3)

Suppose $A_{2} \leqslant_{H} A_{3}$ and $k \in H$. and the composition $A_{1}\left[A_{2} / k\right]$ is non-blocking. We have:

$$
A_{1}\left[A_{2} / k\right] \leqslant J_{1} \uplus H \backslash\{k\} \quad A_{1}\left[A_{3} / k\right]
$$

Pictorially, the theorem states the following result:

Proof. Let us denote by $A_{12}$ (resp. $A_{13}$ ) the OA resulting from $A_{1}\left[A_{2} / k\right]$ (resp. $A_{1}\left[A_{3} / k\right]$ ), to prove the theorem it is sufficient to prove that there exists a relation between states of the two OA that satisfies the conditions of the Definition (9,

We denote $A_{1}=\left\langle S_{1}, s_{01}, J_{1}, V_{1}, \sigma_{01}, T_{1}\right\rangle$ and $A_{2}=\left\langle S_{2}, s_{02}, J_{2}, V_{2}, \sigma_{02}, T_{2}\right\rangle$ and $A_{3}=\left\langle S_{3}, s_{03}, J_{3}, V_{3}, \sigma_{03}, T_{3}\right\rangle$.
Let $R$ be the refinement relation relating states of $A_{2}$ and $A_{3}$. Let us denote with $t^{2}$ and $t^{3}$ the elements of $A_{2}$ and $A_{3}$ respectively. Consider any two states $s_{12}=\left(s_{1}^{1}, s_{2}\right)$ and $s_{13}=\left(s_{1}^{2}, s_{3}\right)$ ( $s_{1}^{1}$ and $s_{1}^{2}$ are the same with renaming). We define a relation $\mathcal{R}^{\prime}$ relating states of $s_{12}$ and $s_{13}$ as follows:

$$
\mathcal{R}^{\prime}\left(s_{12}, s_{13}\right)=\mathcal{R}\left(s_{2}, s_{3}\right) \wedge \checkmark_{A_{12}}\left(s_{12}\right) \wedge \bigwedge_{v_{1} \in V_{1}} v_{1}^{1}=v_{1}^{2} \wedge s_{1}^{1}=s_{1}^{2}
$$

Let us denote $H^{\prime}=H \cup J_{1} \backslash\{k\}$. We want to prove that $\left(\mathcal{R}^{\prime}, H^{\prime}\right)$ is a hole-tracking simulation of $A_{12}$ and $A_{13}$. As for the previous proof we deal with cases:

1. First, we have to prove the relation for initial states:

$$
\sigma_{012} \uplus \sigma_{013} \vdash \mathcal{R}^{\prime}\left(s_{012}, s_{013}\right)
$$

with $\sigma_{012}=\sigma_{01}^{1} \uplus \sigma_{03}, \sigma_{013}=\sigma_{01}^{2} \uplus \sigma_{03}, s_{012}=\left(s_{01}^{1}, s_{02}\right)$, and $s_{013}=\left(s_{01}^{2}, s_{03}\right)$. The proof of this point is similar to that of Theorem 2.
2. Second, we need to prove for any OT $t_{12}$ in $T_{12}$ originating from $s_{12}$

$$
\frac{\beta_{12 j}^{j \in J_{12}^{\prime}}, g_{12}, \psi_{12}}{s_{12} \xrightarrow{\alpha_{12}} s_{12}^{\prime}} \in \mathrm{OT}\left(s_{12}\right)
$$

there exists an indexed family $t_{13 x}$ of OTs originating from $s_{13}$ that simulates it:

$$
\left(\frac{\beta_{13 j}^{j \in J_{13 x}^{\prime}}, g_{13 x}, \psi_{13 x}}{s_{13} \xrightarrow{\alpha_{13 x}} s_{13 x}^{\prime}} \in \mathrm{OT}\left(s_{13}\right)\right)^{x \in X}
$$

such that $\left(\forall x \in X, J_{13 x}^{\prime} \cap H^{\prime}=J_{12}^{\prime} \cap H^{\prime}\right)$ and

$$
\begin{aligned}
& V_{12} \uplus V_{13} \uplus \operatorname{vars}\left(t_{12}\right) \vdash \\
& \qquad \mathcal{R}^{\prime}\left(s_{12}, s_{13}\right) \wedge g_{12} \Longrightarrow \bigvee_{x \in X}\binom{\alpha_{12}=\alpha_{13 x} \wedge \bigwedge_{j \in J_{13 x}^{\prime} \cap H^{\prime}} \beta_{12 j}=\beta_{13 x j} \wedge}{g_{13 x} \wedge \mathcal{R}^{\prime}\left(s_{12}^{\prime}, s_{13 x}^{\prime}\right)\left\{\psi_{12} \uplus \psi_{13 x}\right\}}
\end{aligned}
$$

By definition of composition and OA refinement we have:

$$
\begin{aligned}
& V_{12}=V_{1}^{1} \uplus V_{3} \text { and } V_{13}=V_{1}^{2} \uplus V_{3} \\
& H^{\prime}=H \uplus J_{1} \backslash\{k\} \subseteq J_{1} \uplus\left(J_{2} \cap J_{3}\right) \backslash\{k\}=\left(J_{1}^{1} \uplus J_{2} \backslash\{k\}\right) \cap\left(J_{1}^{2} \uplus J_{3} \backslash\{k\}\right) \\
& \quad=J_{12} \cap J_{13}
\end{aligned}
$$

We have by hypothesis $A_{2} \leqslant_{H} A_{3}$, then for any open transition $t_{2}$ in $T_{2}$ originating from $s_{2}$ :

$$
\frac{\beta_{2 j}^{j \in J_{2}^{\prime}}, g_{2}, \psi_{2}}{s_{2} \xrightarrow{\alpha_{2}} s_{2}^{\prime}} \in \mathrm{OT}\left(s_{2}\right)
$$

there exists an indexed family of OTs originating from $s_{3}$ :

$$
\left(\frac{\beta_{3 x j}^{j \in J_{3 x}^{\prime}}, g_{3 x}, \psi_{3 x}}{s_{3} \xrightarrow[3 x x]{\prime} s_{3 x}^{\prime}} \in \mathrm{OT}\left(s_{3}\right)\right)^{x \in X}
$$

such that $\forall x \in X, J_{3 x}^{\prime} \cap H=J_{2}^{\prime} \cap H$ and

$$
\begin{align*}
& V_{2} \uplus V_{3} \uplus \operatorname{vars}\left(t_{2}\right) \vdash \\
& \qquad \mathcal{R}\left(s_{2}, s_{3}\right) \wedge g_{2} \Longrightarrow \bigvee_{x \in X}\binom{\alpha_{2}=\alpha_{3 x} \wedge \bigwedge_{j \in J_{3 x}^{\prime} \wedge H} \beta_{2 j}=\beta_{3 x j} \wedge}{g_{3 x} \wedge \mathcal{R}\left(s_{2}^{\prime}, s_{3 x}^{\prime}\right)\left\{\psi_{2} \uplus \psi_{3 x}\right\}} \tag{*}
\end{align*}
$$

Consider any transition $t_{12}$ in $A_{12}$. Based on the definition of the composition $t_{12}$ can be obtained from two different cases, we will consider the two cases separately.

First case: Both automata perform a transition. The transition $t_{12}$ is obtained by the composition of transition $t_{2}=\frac{\beta_{2 j}^{j \in J_{2}^{\prime}}, g_{2}, \psi_{2}}{s_{2} \xrightarrow{\alpha_{2}} s_{2}^{\prime}}$ and a transition

$$
t_{1}^{1}=\frac{\left(\beta_{1 j}^{1}\right)^{j \in J_{1}^{\prime \prime}}, g_{1}^{1}, \psi_{1}^{1}}{s_{1}^{1} \xrightarrow{\alpha_{1}^{1}} s_{1}^{\prime^{\prime}}} \quad \text { when } k \in J_{1}^{1^{\prime}}
$$

The result:

$$
t_{12}=\frac{\beta_{1 j}^{1 j \in J_{1}^{1 \prime} \backslash\{k\}} \uplus\left(\beta_{2 j}\right)^{j \in J_{2}^{\prime}}, g_{1}^{1} \wedge g_{2} \wedge \alpha_{1}^{1}=\beta_{2 k}, \psi_{1}^{1} \uplus \psi_{2}}{\left(s_{1}^{1}, s_{2}\right) \xrightarrow{\alpha_{1}^{1}}\left(s_{1}^{1 \prime}, s_{2}^{\prime}\right)} \quad \text { where } k \in J_{1}^{1^{\prime}}
$$

We then obtain a family of OTs by the simulation of $A_{2}$ by $A_{3}$ (as stated above). By hypothesis we have $k \in H$, so in the case where $k \in J_{1}^{1^{\prime}}$, we deduce that $k \in J_{3 x}^{\prime}$ we can then build a family of OTs $t_{13 x}^{x \in X}$ with the same transition, up to renaming, as the one used to build $t_{12}$ (i.e., $t_{1}^{1}$ ), where $s_{1}^{2^{\prime}}$ is the same as $s_{1}^{1^{\prime}}$ up to renaming.

$$
t_{13 x}=\left(\frac{\left(\beta_{1 j}^{2}\right)^{j \in J_{1}^{2 \prime}} \uplus \beta_{3 x j}^{j \in J_{3 x}^{\prime} \backslash\{k\}}, g_{3 x} \wedge g_{1}^{2} \wedge \alpha_{1}^{2}=\beta_{3 x k}, \psi_{3 x} \uplus \psi_{1}^{2}}{\left(s_{1}^{2}, s_{3}\right) \xrightarrow{\alpha_{1}^{2}}\left(s_{1}^{2^{\prime}}, s_{3 x}^{\prime}\right)}\right)^{x \in X}
$$

Recall that in this case $k \in J_{1}^{1^{\prime}}$, so $\forall x \in X$ we have:

$$
\begin{aligned}
& J_{13 x}^{\prime} \cap H^{\prime}=\left(\left(J_{3 x}^{\prime} \backslash\{k\}\right) \uplus J_{1}^{2 \prime}\right) \cap\left(H \uplus J_{1} \backslash\{k\}\right) \\
&=\left(\left(J_{3 x}^{\prime} \cap\left(H \uplus J_{1}\right)\right) \uplus\left(J_{1}^{2 \prime} \cap\left(H \uplus J_{1}\right)\right)\right) \backslash\{k\} \\
&=\left(\left(J_{3 x}^{\prime} \cap H\right) \uplus\left(J_{1}^{2 \prime} \cap J_{1}\right)\right) \backslash\{k\} \\
& \quad \text { since } J_{1} \cap J_{3 x}^{\prime}=\varnothing \text { and } H \cap J_{1}^{2 \prime}=\varnothing \\
&=\left(\left(J_{3 x}^{\prime} \cap H\right) \uplus J_{1}^{2 \prime}\right) \backslash\{k\} \text { since } J_{1}^{2 \prime} \subseteq J_{1} \\
&=\left(\left(J_{2}^{\prime} \cap H\right) \uplus J_{1}^{1 \prime}\right) \backslash\{k\} \\
& \quad \text { since } J_{1}^{1 \prime}=J_{1}^{2 \prime} \text { and } J_{2}^{\prime} \cap H=J_{3 x}^{\prime} \cap H \\
&=\left(\left(J_{2}^{\prime} \cap H\right) \uplus\left(J_{1}^{1 \prime} \cap J_{1}\right)\right) \backslash\{k\} \text { since } J_{1}^{1 \prime} \subseteq J_{1} \\
&=\left(J_{2}^{\prime} \cap\left(J_{1} \uplus H\right)\right) \uplus\left(\left(J_{1}^{1 \prime} \cap\left(J_{1} \uplus H\right)\right) \backslash\{k\}\right. \\
& \quad \text { since } J_{1} \cap J_{2}^{\prime}=\varnothing \text { and } H \cap J_{1}^{1 \prime}=\varnothing \\
&=\left(\left(J_{2}^{\prime} \uplus J_{1}^{1 \prime}\right) \backslash\{k\}\right) \cap\left(\left(J_{1} \uplus H\right) \backslash\{k\}\right) \\
&= J_{12}^{\prime} \cap H^{\prime}
\end{aligned}
$$

In this case the composition gives:

$$
g_{12} \Leftrightarrow g_{1}^{1} \wedge g_{2} \wedge \alpha_{1}^{1}=\beta_{2 k} \text { and } g_{13 x} \Leftrightarrow g_{1}^{2} \wedge g_{3 x} \wedge \alpha_{1}^{2}=\beta_{3 x k}
$$

As $k \in H$ we have $\alpha_{1}^{1}=\alpha_{1}^{2}$ then we deduce:

$$
g_{1}^{1} \wedge \alpha_{1}^{1}=\beta_{2 k} \Leftrightarrow g_{1}^{2} \wedge \alpha_{1}^{2}=\beta_{3 x k}
$$

The proof of the rest is based on the following facts:
(a) By construction of $t_{12}$ and $t_{13 x}$ we have $\alpha_{12}=\alpha_{1}^{1}$ and $\alpha_{13 x}=\alpha_{1}^{2}$. Since $\alpha_{1}^{1}$ and $\alpha_{1}^{2}$ are the same (up to renaming) we deduce: $\alpha_{12}=\alpha_{13 x}$.
(b) By composition we have also:
$\beta_{12 j}^{j \in J_{12}^{\prime}}=\left(\beta_{1 j}^{1}\right)^{j \in J_{1}^{\prime \prime} \backslash\{k\}} \uplus\left(\beta_{2 j}\right)^{j \in J_{2}^{\prime}}$ and $\beta_{13 x j}^{j \in J_{13}^{\prime}}=\left(\beta_{1 j}^{2}\right)^{j \in J_{1}^{2 \prime} \backslash\{k\}} \uplus \beta_{3 x j}^{j \in J_{3 x}^{\prime} \backslash\{k\}}$
Therefore, we have for all $j \in J_{12}^{\prime}$ (recall that $J_{12}^{\prime}=J_{13}^{\prime}$ ):

$$
\beta_{12 j}=\beta_{13 x j} \Rightarrow\left(j \in J_{1}^{1 \prime} \wedge \beta_{1 j}^{1}=\beta_{1 j}^{2}\right) \vee\left(j \in J_{2}^{\prime} \wedge \beta_{2 j}=\beta_{3 x j}\right)
$$

(c) Considering $\beta_{1 j}^{1}$ and $\beta_{1 j}^{2}$ are the same (up to renaming) we have:

$$
V_{1}^{1} \uplus V_{1}^{2} \uplus \operatorname{vars}\left(t_{12}\right) \vdash \bigwedge_{v_{1} \in V_{1}} v_{1}^{1}=v_{1}^{2} \Longrightarrow \bigwedge_{j \in J_{1}^{2 \prime}} \beta_{1 j}^{1}=\beta_{1 j}^{2}
$$

We compose by disjunction with the following hypothesis (part of formula (*)).
$V_{2} \uplus V_{3} \uplus \operatorname{vars}\left(t_{2}\right) \vdash \bigwedge_{j \in J_{3 x}^{\prime} \cap H} \beta_{2 j}=\beta_{3 x j}$

$$
\begin{aligned}
V_{2} \uplus & V_{3} \uplus V_{1}^{1} \uplus V_{1}^{2} \uplus \operatorname{vars}\left(t_{12}\right) \vdash \bigwedge_{v_{1} \in V_{1}} v_{1}^{1}=v_{1}^{2} \\
& \Longrightarrow V_{12} \uplus V_{13} \uplus \operatorname{vars}\left(t_{12}\right) \vdash \bigwedge_{v_{1} \in V_{1}} v_{1}^{1}=v_{1}^{2} \\
& \Longrightarrow \bigwedge_{j \in J_{3 x}^{\prime} \cap H} \beta_{2 j}=\beta_{3 x j} \vee \bigwedge_{j \in\left(J_{3 x}^{\prime} \cap H\right) \uplus J_{1}^{2 \prime}} \beta_{1 j}^{1}=\beta_{1 j}^{2} \\
& \beta_{12 j}=\beta_{13 x j} \\
& \Rightarrow V_{13} \uplus \operatorname{vars}\left(t_{12}\right) \vdash \bigwedge_{v_{1} \in V_{1}} v_{1}^{1}=v_{1}^{2}
\end{aligned} V_{12} \uplus \bigwedge_{j \in\left(\left(J_{3 x}^{\prime} \cap H\right) \uplus J_{1}^{2 \prime}\right) \backslash\{k\}} \beta_{12 j}=\beta_{13 x j}{\operatorname{vars}\left(t_{12}\right) \vdash \bigwedge_{v_{1} \in V_{1}} v_{1}^{1}=v_{1}^{2}}_{\Longrightarrow \bigwedge_{j \in\left(J_{13 x}^{\prime} \cap H^{\prime}\right)} \beta_{12 j}=\beta_{13 x j}}
$$

We can extend the valuation context of the variables to cover the variables of the transitions $t_{1}$ and variables $V_{1}^{1}$ and $V_{1}^{2}$ in the formula (*). By using the statements resulting from the cases (a), (b) and (c), we get:
$V_{13} \uplus V_{13} \uplus \operatorname{vars}\left(t_{12}\right) \vdash$

$$
\begin{aligned}
\mathcal{R}\left(s_{2}, s_{3}\right) \wedge\left(g_{2} \wedge g_{1}^{1} \wedge \alpha_{1}^{1}=\beta_{2 k}\right) & \wedge \bigwedge_{v_{1} \in V_{1}} v_{1}^{1}=v_{1}^{2} \Longrightarrow \\
& \bigvee_{x \in X}\binom{\alpha_{12}=\alpha_{13 x} \wedge \bigwedge_{j \in\left(J_{3 x x}^{\prime} \cap H^{\prime}\right)} \beta_{12 j}=\beta_{13 x j} \wedge}{g_{3 x} \wedge \mathcal{R}\left(s_{2}^{\prime}, s_{3 x}^{\prime}\right)\left\{\psi_{2} \uplus \psi_{3 x}\right\}} \wedge g_{1}^{2} \wedge \alpha_{1}^{2}=\beta_{3 x k}
\end{aligned}
$$

That can be re-written as follows:
$V_{12} \uplus V_{13} \uplus \operatorname{vars}\left(t_{12}\right) \vdash$

$$
\mathcal{R}\left(s_{2}, s_{3}\right) \wedge g_{12} \wedge \bigwedge_{v_{1} \in V_{1}} v_{1}^{1}=v_{1}^{2} \Longrightarrow \bigvee_{x \in X}\binom{\alpha_{12}=\alpha_{13 x} \wedge \bigwedge_{\substack{ \\j \in J_{13 x}^{\prime} \cap H^{\prime} \\ \beta_{12}}} \beta_{12 j}=\beta_{13 x j} \wedge}{g_{13 x} \wedge \mathcal{R}\left(s_{2}^{\prime}, s_{3 x}^{\prime}\right)\left\{\psi_{2} \uplus \psi_{3 x}\right\}}
$$

Moreover, we have for any transition $t_{1}$ in $A_{1}$ relating $s_{1}^{1}$ and $s_{1}^{1^{\prime}}$ the following:

$$
V_{12} \uplus V_{13} \uplus \operatorname{vars}\left(t_{12}\right) \vdash
$$

$$
\bigwedge_{v_{1} \in V_{1}} v_{1}^{1}=v_{1}^{2} \wedge s_{1}^{1}=s_{1}^{2} \Longrightarrow \bigwedge_{v_{1} \in V_{1}} \psi_{12}\left(v_{1}^{1}\right)=\psi_{13 x}\left(v_{1}^{2}\right) \wedge s_{1}^{1 \prime}=s_{1}^{2 \prime}
$$

From the two previous formula, we get:

$$
\begin{aligned}
& V_{12} \uplus V_{13} \uplus \operatorname{vars}\left(t_{12}\right) \vdash \\
& R\left(s_{2}, s_{3}\right) \wedge g_{12} \wedge \bigwedge_{v_{1} \in V_{1}} v_{1}^{1}=v_{1}^{2} \wedge s_{1}^{1}=s_{1}^{2} \Longrightarrow \\
& \bigvee_{x \in X}\binom{\alpha_{12}=\alpha_{13 x} \wedge \bigwedge_{j \in J_{13 x}^{\prime} \cap H^{\prime}} \beta_{12 j}=\beta_{13 x j} \wedge g_{13 x} \wedge}{R\left(s_{2}^{\prime}, s_{3 x}^{\prime}\right)\left\{\begin{array}{l}
\left\{\psi_{2} \uplus \psi_{3 x}\right\}
\end{array}\right\} \bigwedge_{v_{1} \in V_{1}} \psi_{12}\left(v_{1}^{1}\right)=\psi_{13 x}\left(v_{1}^{2}\right) \wedge s_{1}^{1 \prime}=s_{1}^{2 \prime}}
\end{aligned}
$$

Furthermore, according to the Definition 7 (reachability, applied to the composed automaton $\left.A_{1}\left[A_{2} / k\right]\right)$ we have, for all $t_{12} \in T_{12}$ :

$$
\operatorname{vars}\left(t_{12}\right) \vdash\left(\checkmark_{A_{12}}\left(s_{12}\right) \wedge g_{12} \Longrightarrow \checkmark_{A_{12}}\left(s_{12}^{\prime}\right)\left\{\psi_{12}\right\}\right)
$$

Thus, we get:

$$
\begin{aligned}
& V_{12} \uplus V_{13} \uplus \operatorname{vars}\left(t_{12}\right) \vdash \\
& \mathcal{R}\left(s_{2}, s_{3}\right) \wedge g_{12} \wedge \checkmark_{A_{12}}\left(s_{12}\right) \wedge \bigwedge_{v_{1} \in V_{1}} v_{1}^{1}=v_{1}^{2} \wedge s_{1}^{1}=s_{1}^{2} \Longrightarrow \\
& \\
& \bigvee_{x \in X}\binom{\alpha_{12}=\alpha_{13 x} \wedge \bigwedge_{j \in J_{13 x}^{\prime} \cap H^{\prime}}\left(\beta_{12 j}=\beta_{13 x j} \wedge g_{13 x} \wedge\right.}{\mathcal{R}\left(s_{2}^{\prime}, s_{3 x}^{\prime}\right)\left\{\begin{array}{l}
\left\{\psi_{2} \uplus \psi_{3 x}\right\} \wedge \checkmark_{A_{12}}\left(s_{12}^{\prime}\right)\left\{\psi_{12}\right\} \\
\wedge \bigwedge_{v_{1} \in V_{1}} \psi_{12}\left(v_{1}^{1}\right)=\psi_{13 x}\left(v_{1}^{2}\right) \wedge s_{1}^{1 \prime}=s_{1}^{2 \prime}
\end{array}\right)}
\end{aligned}
$$

Because of the independence of the substitution domains, we simplify and get the expected formula:

$$
\begin{aligned}
& V_{12} \uplus V_{13} \uplus \operatorname{vars}\left(t_{12}\right) \vdash \mathcal{R}^{\prime}\left(s_{12}, s_{13}\right) \wedge g_{12} \Longrightarrow \\
& \bigvee_{x \in X}\left(\begin{array}{l}
\left.\alpha_{12}=\alpha_{13 x} \wedge \bigwedge_{j \in J_{13 x}^{\prime} \cap H^{\prime}} \beta_{12 j}=\beta_{13 x j} \wedge g_{13 x} \wedge \mathcal{R}^{\prime}\left(s_{12}^{\prime}, s_{13 x}^{\prime}\right)\left\{\psi_{12} \uplus \psi_{13 x}\right\}\right)
\end{array}\right)
\end{aligned}
$$

Second case: Only the encompassing automaton performs a transition. $t_{12}$ is obtained by the transition $t_{1}^{1}=\frac{\left(\beta_{1 j}^{1}\right)^{j \in J_{1}^{\prime \prime}}, g_{1}^{1}, \psi_{1}^{1}}{s_{1}^{1} \xrightarrow[1]{\alpha_{1}^{1}} s_{1}^{1^{\prime}}}$ alone with the state $s_{2}$ unchanged, if $k \notin J_{1}^{1^{\prime}}$

$$
t_{12}=\frac{\left(\beta_{1 j}^{1}\right)^{j \in J_{1}^{1 \prime}}, g_{1}^{1}, \psi_{1}^{1}}{\left(s_{1}^{1}, s_{2}\right) \xrightarrow{\alpha_{1}^{1}}\left(s_{1}^{1^{\prime}}, s_{2}\right)}
$$

The hole is not involved we can define $t_{13}$ with the same transition $t_{1}$ of $A_{1}$ (where elements of $t_{1}$ are the same as above modulo renaming of variables):

$$
t_{13}=\frac{\left(\beta_{1 j}^{2}\right)^{j \in J_{1}^{2 \prime}}, g_{1}^{2}, \psi_{1}^{2}}{\left(s_{1}^{1}, s_{3}\right) \xrightarrow{\alpha_{1}^{2}}\left(s_{1}^{2^{\prime}}, s_{3}\right)}
$$

We thus take $\left(t_{13 x}\right)^{x \in X}=\left\{t_{13}\right\} . \forall x \in X$ we have $J_{13 x}^{\prime}=J_{1}^{2 \prime}$ and trivially:

$$
\begin{aligned}
J_{13 x}^{\prime} \cap H^{\prime} & =J_{1}^{2 \prime} \cap\left(J_{1} \uplus H \backslash\{k\}\right) \\
& =J_{1}^{1 \prime} \cap\left(J_{1} \uplus H \backslash\{k\}\right) \text { since } J_{1}^{2 \prime}=J_{1}^{1 \prime} \\
& =\left(J_{12}^{\prime} \cap H^{\prime}\right)
\end{aligned}
$$

Moreover, we have by definition

$$
\mathcal{R}^{\prime}\left(s_{12}, s_{13}\right)=\mathcal{R}\left(s_{2}, s_{3}\right) \wedge \checkmark_{A_{12}}\left(s_{12}\right) \wedge \bigwedge_{v_{1} \in V_{1}} v_{1}^{1}=v_{1}^{2} \wedge s_{1}^{1}=s_{1}^{2}
$$

Thus, because transitions $t_{1}^{1}$ and $t_{1}^{2}$ are the same:

$$
\mathcal{R}^{\prime}\left(s_{12}, s_{13}\right) \Longrightarrow \underbrace{\mathcal{R}\left(s_{2}, s_{3}\right) \wedge \checkmark_{A_{12}}\left(s_{12}\right) \wedge \bigwedge_{v_{1} \in V_{1}} v_{1}^{1}=v_{1}^{2} \wedge s_{1}^{1^{\prime}}=s_{1}^{2^{\prime}}}_{\mathcal{R}^{\prime}\left(s_{12}^{\prime}, s_{13}^{\prime}\right)}
$$

Moreover, we have the following:
$V_{12} \uplus V_{13} \uplus \operatorname{vars}\left(t_{12}\right) \vdash$

$$
\bigwedge_{v_{1} \in V_{1}} v_{1}^{1}=v_{1}^{2} \wedge s_{1}^{1}=s_{1}^{2} \Longrightarrow \bigwedge_{v_{1} \in V_{1}} \psi_{12}\left(v_{1}^{1}\right)=\psi_{13}\left(v_{1}^{2}\right) \wedge s_{1}^{1 \prime}=s_{1}^{2 \prime}
$$

Furthermore, according to the Definition 7 (reachability, applied to the composed automaton $A_{1}$ ) we have, for all $t_{12} \in T_{12}$ :

$$
\operatorname{vars}\left(t_{12}\right) \vdash\left(\checkmark_{A_{12}}\left(s_{12}\right) \wedge g_{12} \Longrightarrow \checkmark_{A_{12}}\left(s_{12}^{\prime}\right)\left\{\left\{\psi_{12}\right\}\right)\right.
$$

Because $\alpha_{12}$ and $\alpha_{13}$ are the same, and also $\beta_{12}$ and $\beta_{13}$ are the same (modulo renaming of variables), we deduce from the above the expected formula (instantiated with $X$ a singleton):

$$
\begin{aligned}
V_{12} \uplus V_{13} \uplus \operatorname{vars}\left(t_{12}\right) & \vdash \mathcal{R}^{\prime}\left(s_{12}, s_{13}\right) \wedge g_{12} \Longrightarrow \\
& \left(\alpha_{12}=\alpha_{13} \wedge \bigwedge_{j \in J_{13}^{\prime} \cap H^{\prime}} \beta_{12 j}=\beta_{13 j} \wedge g_{13} \wedge \mathcal{R}^{\prime}\left(s_{12}^{\prime}, s_{13}^{\prime}\right)\left\{\psi_{12} \uplus \psi_{13}\right\}\right)
\end{aligned}
$$

3. Lastly, we have to prove the satisfaction of the deadlock reduction condition, i.e., for all $\left(s_{12}, s_{13}\right) \in S_{12} \times S_{13}$

Let's start with the hypothesis of the theorem stating that $A_{2} \leqslant_{H} A_{3}$, thus we have for all $\left(s_{2}, s_{3}\right) \in S_{2} \times S_{3}$

By hypothesis the composition $A_{1}\left[A_{2} / k\right]$ is non-blocking, then according to the Definition 10 we have for all state $s_{12}$ :

$$
V_{12} \uplus \biguplus_{t_{1} \in \mathrm{OT}\left(s_{1}\right)} \operatorname{vars}\left(t_{1}\right) \vdash\left(\checkmark_{A_{12}\left(s_{12}\right)} \wedge \bigvee_{t_{1} \in \mathrm{OT}\left(s_{1}\right)} \operatorname{guard}\left(t_{1}\right)\right) \quad \Longrightarrow \quad \bigvee_{t_{12} \in \mathrm{OT}\left(s_{12}\right)} \operatorname{guard}\left(t_{12}\right)
$$

Which implies

$$
V_{12} \underset{t_{1} \in \mathrm{OT}\left(s_{1}\right)}{\uplus} \biguplus_{t_{12} \in \mathrm{OT}\left(s_{12}\right)} \operatorname{vars}\left(t_{1}\right) \vdash \underset{\bigvee_{12}}{ } \operatorname{guard}\left(t_{12}\right) \quad \Longrightarrow \quad\left(\neg \checkmark_{A_{12}\left(s_{12}\right)}^{\vee} \underset{t_{1} \in \mathrm{OT}\left(s_{1}\right)}{ } \operatorname{guard}\left(t_{1}\right)\right)
$$

Additionally, each transition $t_{13}$ of $\mathrm{OT}\left(s_{13}\right)$ is of the form $g_{1} \wedge g_{3} \wedge g$ with $g_{1}$ a guard of a transition $t_{1}$ of $\mathrm{OT}\left(s_{1}\right)$. Thus we have

$$
\neg \bigvee_{t_{1} \in \mathrm{OT}\left(s_{1}\right)} \operatorname{guard}\left(t_{1}\right) \Longrightarrow \neg\left(\bigvee_{t_{13} \in \mathrm{OT}\left(s_{13}\right)} \operatorname{guard}\left(t_{13}\right)\right)
$$

Thus we have, as $\mathcal{R}$ contains the reachability of state $s_{12}$ :

$$
\begin{aligned}
& V_{12} \uplus V_{13} \vdash \mathcal{R}^{\prime}\left(s_{12}, s_{13}\right) \wedge \neg\left(\bigvee_{t_{12} \in \mathrm{OT}\left(s_{12}\right)} \operatorname{guard}\left(t_{12}\right)\right) \Longrightarrow \\
& \\
& \left.\quad\left(\checkmark_{A_{12}\left(s_{12}\right)} \wedge\left(\neg \checkmark_{A_{12}\left(s_{12}\right)} \vee \neg\left(\bigvee_{t_{13} \in \mathrm{OT}\left(s_{13}\right)} \operatorname{guard}\left(t_{13}\right)\right)\right) \Longrightarrow \underset{t_{13} \in \mathrm{OT}\left(s_{13}\right)}{ } \operatorname{guard}\left(t_{13}\right)\right)\right)
\end{aligned}
$$
