1. Introduction

EDHOC [[I-D.ietf-lake-edhoc](#)] is a lightweight authenticated key exchange protocol designed for highly constrained settings. This document contains annotated traces of EDHOC sessions, with input, output, and intermediate processing results to simplify testing of implementations. The traces have been verified by two independent implementations.

1.1. Setup

EDHOC is run between an Initiator (I) and a Responder (R). The private/public key pairs and credentials of the Initiator and the Responder required to produce the protocol messages are shown in the traces when needed for the calculations.

EDHOC messages and intermediate results are encoded in CBOR [[RFC8949](#)] and can therefore be displayed in CBOR diagnostic notation using, e.g., the CBOR playground [[CborMe](#)], which makes them easy to parse for humans. Credentials can also be encoded in CBOR, e.g. CBOR Web Tokens (CWT) [[RFC8392](#)].

The document contains two traces:

*[Section 2](#) - Authentication with signature keys identified by the hash value of the X.509 certificates (provided in [Section 2.8](#)). The endpoints use EdDSA [[RFC8032](#)] for authentication and X25519 [[RFC7748](#)] for ephemeral-ephemeral Diffie-Hellman key exchange.

*[Section 3](#) - Authentication with static Diffie-Hellman keys identified by short key identifiers labelling CWT Claim Sets (CCSs) [[RFC8392](#)]. The endpoints use NIST P-256 [[SP-800-186](#)] for both ephemeral-ephemeral and static-ephemeral Diffie-Hellman key exchange. This trace also illustrates the cipher suite negotiation, and provides an example of low protocol overhead, with messages sizes of (39, 45, 19) bytes.

Examples of invalid EDHOC messages are found in [Section 4](#).

NOTE 1. The same name is used for hexadecimal byte strings and their CBOR encodings. The traces contain both the raw byte strings and the corresponding CBOR encoded data items.

NOTE 2. If not clear from the context, remember that CBOR sequences and CBOR arrays assume CBOR encoded data items as elements.

NOTE 3. When the protocol transporting EDHOC messages does not inherently provide correlation across all messages, like CoAP [[RFC7252](#)], then some messages typically are prepended with connection identifiers and potentially a message_1 indicator (see Sections [3.4.1](#) and [A.2](#) of [[I-D.ietf-lake-edhoc](#)]). Those bytes are not included in the traces in this document.

1.2. Terminology and Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in

BCP 14 [[RFC2119](#)] [[RFC8174](#)] when, and only when, they appear in all capitals, as shown here.

2. Authentication with Signatures, X.509 Certificates Identified by 'x5t'

In this example the Initiator (I) and Responder (R) are authenticated with digital signatures (METHOD = 0). Both the Initiator and the Responder support cipher suite 0, which determines the algorithms:

```
*EDHOC AEAD algorithm = AES-CCM-16-64-128
*EDHOC hash algorithm = SHA-256
*EDHOC MAC length in bytes (Static DH) = 8
*EDHOC key exchange algorithm (ECDH curve) = X25519
*EDHOC signature algorithm = EdDSA
*Application AEAD algorithm = AES-CCM-16-64-128
*Application hash algorithm = SHA-256
```

The public keys are represented with X.509 certificates identified by the COSE header parameter 'x5t'.

2.1. message_1

Both endpoints are authenticated with signatures, i.e., METHOD = 0:

```
METHOD (CBOR Data Item) (1 byte)
00
```

The Initiator selects cipher suite 0. A single cipher suite is encoded as an int:

```
SUITES_I (CBOR Data Item) (1 byte)
00
```

The Initiator creates an ephemeral key pair for use with the EDHOC key exchange algorithm:

```
Initiator's ephemeral private key
X (Raw Value) (32 bytes)
89 2e c2 8e 5c b6 66 91 08 47 05 39 50 0b 70 5e 60 d0 08 d3 47 c5 81

```

Initiator's ephemeral public key

```

```

63 2a 48 81 a1 c0 70 1e 23 7f 04
```

The Initiator selects its connection identifier C_I to be the byte string 0x2d, which since it is represented by the 1-byte CBOR int -14 is encoded as 0x2d:

Connection identifier chosen by Initiator

C_I (Raw Value) (1 byte)

```
2d
```

Connection identifier chosen by Initiator

C_I (CBOR Data Item) (1 byte)

```
2d
```

No external authorization data:

EAD_1 (CBOR Sequence) (0 bytes)

The Initiator constructs message_1:

message_1 =

```
(
  0,
  0,
  h'31f82c7b5b9cbbf0f194d913cc12ef1532d328ef32632a48

)
```

message_1 (CBOR Sequence) (37 bytes)

```

```

2.2. message_2

The Responder supports the most preferred and selected cipher suite 0, so SUITES_I is acceptable.

The Responder creates an ephemeral key pair for use with the EDHOC key exchange algorithm:

Responder's ephemeral private key

Y (Raw Value) (32 bytes)

e6 9c 23 fb f8 1b c4 35 94 24 46 83 7f e8 27 bf 20 6c 8f a1 0a 39 db

The Responder selects its connection identifier C_R to be the byte string 0x18, which since it is not represented as a 1-byte CBOR int is encoded as h'18' = 0x4118:

Connection identifier chosen by Responder

C_R (Raw Value) (1 byte)

The transcript hash TH_2 is calculated using the EDHOC hash algorithm:

The input to calculate TH_2 is the CBOR sequence:

PRK_2e is specified in [Section 4.1.1.1](#) of [[I-D.ietf-lake-edhoc](#)].

First, the ECDH shared secret G_XY is computed from G_X and Y, or G_Y and X:

G_XY (Raw Value) (ECDH shared secret) (32 bytes)

e5 cd f3 a9 86 cd ac 5b 7b f0 46 91 e2 b0 7c 08 e7 1f 53 99 8d 8f 84
2b 7c 3f b4 d8 39 cf 7b 28

Then, PRK_2e is calculated using EDHOC_Extract() determined by the EDHOC hash algorithm:

PRK_2e = EDHOC_Extract(salt, G_XY) =
= HMAC-SHA-256(salt, G_XY)

where salt is TH_2:

salt (Raw Value) (32 bytes)

Since METHOD = 0, the Responder authenticates using signatures.
Since the selected cipher suite is 0, the EDHOC signature algorithm is EdDSA.

The Responder's signature key pair using EdDSA:

Responder's private authentication key

SK_R (Raw Value) (32 bytes)

PRK_3e2m is specified in [Section 4.1.1.2](#) of [[I-D.ietf-lake-edhoc](#)].

Since the Responder authenticates with signatures PRK_3e2m = PRK_2e.

PRK_3e2m (Raw Value) (32 bytes)

bf 2c 24 0a fa 7b a8 04 da
```

The Responder constructs the remaining input needed to calculate MAC_2:

```
MAC_2 = EDHOC_KDF( PRK_3e2m, 2, context_2, mac_length_2 )
```

```
context_2 = << ID_CRED_R, TH_2, CRED_R, ? EAD_2 >>
```

CRED_R is identified by a 64-bit hash:

ID_CRED_R =

```
{
  34 : [-15, h'79f2a41b510c1f9b']
}
```

where the COSE header value 34 ('x5t') indicates a hash of an X.509 certificate, and the COSE algorithm -15 indicates the hash algorithm SHA-256 truncated to 64 bits.

ID_CRED_R (CBOR Data Item) (14 bytes)

```
a1 18 22 82 2e 48 79 f2 a4 1b 51 0c 1f 9b
```

CRED_R is a CBOR byte string of the DER encoding of the X.509 certificate in [Section 2.8.1](#):

MAC_2 is computed through EDHOC_Expand() using the EDHOC hash algorithm, see [Section 4.1.2](#) of [[I-D.ietf-lake-edhoc](#)]:

MAC_2 = HKDF-Expand(PRK_3e2m, info, mac_length_2), where

info = (2, context_2, mac_length_2)

Since METHOD = 0, mac_length_2 is given by the EDHOC hash algorithm.

2.3. message_3

Since METHOD = 0, the Initiator authenticates using signatures.
Since the selected cipher suite is 0, the EDHOC signature algorithm is EdDSA.

The Initiator's signature key pair using EdDSA:

PRK_4e3m is specified in [Section 4.1.1.3](#) of [\[I-D.ietf-lake-edhoc\]](#).

Since the Initiator authenticates with signatures PRK_4e3m = PRK_3e2m.

MAC_3 is computed through EDHOC_Expand() using the EDHOC hash algorithm, see [Section 4.1.2](#) of [[I-D.ietf-lake-edhoc](#)]:

MAC_3 = HKDF-Expand(PRK_4e3m, info, mac_length_3), where

info = (6, context_3, mac_length_3)

where context_3 = << ID_CRED_I, TH_3, CRED_I, ? EAD_3 >>

Since METHOD = 0, mac_length_3 is given by the EDHOC hash algorithm.

info for MAC_3 is:

2.6. OSCORE Parameters

The derivation of OSCORE parameters is specified in [Appendix A.1](#) of [\[I-D.ietf-lake-edhoc\]](#).

The AEAD and Hash algorithms to use in OSCORE are given by the selected cipher suite:

```
Application AEAD Algorithm (int)

```

```
Application Hash Algorithm (int)

```

The mapping from EDHOC connection identifiers to OSCORE Sender/Recipient IDs is defined in [Section 3.3.3](#) of [\[I-D.ietf-lake-edhoc\]](#).

C_R is mapped to the Recipient ID of the server, i.e., the Sender ID of the client. The byte string 0x18, which as C_R is encoded as the CBOR byte string 0x4118, is converted to the server Recipient ID 0x18.

Client's OSCORE Sender ID (Raw Value) (1 byte)
18

C_I is mapped to the Recipient ID of the client, i.e., the Sender ID of the server. The byte string 0x2d, which as C_I is encoded as the CBOR integer 0x2d is converted to the client Recipient ID 0x2d.

Server's OSCORE Sender ID (Raw Value) (1 byte)
2d

The OSCORE Master Secret is computed through EDHOC_Expand() using the Application hash algorithm, see [Appendix A.1](#) of [\[I-D.ietf-lake-edhoc\]](#):

```
OSCORE Master Secret = EDHOC_Exporter( 0, h'', oscore_key_length )  
= EDHOC_KDF( PRK_exporter, 0, h'', oscore_key_length )  
= HKDF-Expand( PRK_exporter, info, oscore_key_length )
```

where oscore_key_length is by default the key length in bytes for the Application AEAD algorithm, and info for the OSCORE Master Secret is:

```
info =  
(  
  0,  
  h'',

```

where `hash_length` is the length in bytes of the output of the EDHOC hash function, and `context` for `KeyUpdate` is

After key update, the `PRK_exporter` needs to be derived anew:

```
PRK_exporter = EDHOC_KDF( PRK_out, 10, h'', hash_length ) =  
= HKDF-Expand( PRK_out, info, hash_length )

3. Authentication with Static DH, CCS Identified by 'kid'

In this example the Initiator and the Responder are authenticated with ephemeral-static Diffie-Hellman (METHOD = 3). The Initiator supports cipher suites 6 and 2 (in order of preference) and the Responder only supports cipher suite 2. After an initial negotiation message exchange, cipher suite 2 is used, which determines the algorithms:

- *EDHOC AEAD algorithm = AES-CCM-16-64-128
- *EDHOC hash algorithm = SHA-256

The public keys are represented as raw public keys (RPK), encoded in a CWT Claims Set (CCS) and identified by the COSE header parameter 'kid'.

3.1. message_1 (first time)

Both endpoints are authenticated with static DH, i.e., METHOD = 3:

PRK_2e is specified in [Section 4.1.1.1](#) of [[I-D.ietf-lake-edhoc](#)].

First, the ECDH shared secret G_XY is computed from G_X and Y, or G_Y and X:

G_XY (Raw Value) (ECDH shared secret) (32 bytes)
2f 0c b7 e8 60 ba 53 8f bf 5c 8b de d0 09 f6 25 9b 4b 62 8f e1 eb 7d
be 93 78 e5 ec f7 a8 24 ba

Then, PRK_2e is calculated using EDHOC_Extract() determined by the EDHOC hash algorithm:

PRK_2e = EDHOC_Extract(salt, G_XY) =
= HMAC-SHA-256(salt, G_XY)

where salt is TH_2:

salt (Raw Value) (32 bytes)

c9 23 71 c9 82 56 31 70 b5

Since METHOD = 3, the Responder authenticates using static DH. The EDHOC key exchange algorithm is based on the same curve as for the ephemeral keys, which is P-256, since the selected cipher suite is 2.

The Responder's static Diffie-Hellman P-256 key pair:

Since the Responder authenticates with static DH (METHOD = 3),
PRK_3e2m is derived from SALT_3e2m and G_RX.

The input needed to calculate SALT_3e2m is defined in [Section 4.1.2](#)
of [[I-D.ietf-lake-edhoc](#)], using EDHOC_Expand() with the EDHOC hash
algorithm:

```
SALT_3e2m = EDHOC_KDF( PRK_2e, 1, TH_2, hash_length ) =
           = HKDF-Expand( PRK_2e, info, hash_length )
```

where hash_length is the length in bytes of the output of the EDHOC
hash algorithm, and info for SALT_3e2m is:

```
info =

```

PRK_3e2m is specified in [Section 4.1.1.2](#) of [[I-D.ietf-lake-edhoc](#)].

PRK_3e2m is derived from G_RX using EDHOC_Extract() with the EDHOC
hash algorithm:

```
PRK_3e2m = EDHOC_Extract( SALT_3e2m, G_RX ) =
           = HMAC-SHA-256( SALT_3e2m, G_RX )
```

where G_RX is the ECDH shared secret calculated from G_X and R, or G_R and X.

```

The Responder constructs the remaining input needed to calculate MAC_2:

```
MAC_2 = EDHOC_KDF( PRK_3e2m, 2, context_2, mac_length_2 )
```

```
context_2 = << ID_CRED_R, TH_2, CRED_R, ? EAD_2 >>
```

CRED_R is identified by a 'kid' with byte string value 0x32:

```

```

ID_CRED_R (CBOR Data Item) (4 bytes)

CRED_R is an RPK encoded as a CCS:

Since ID_CRED_R contains a single 'kid' parameter, only the byte string value is included in the plaintext, represented as described in [Section 3.3.2](#) of [\[I-D.ietf-lake-edhoc\]](#). The CBOR map { 4 : h'32' } is thus replaced, not by the CBOR byte string 0x4132, but by the

Since METHOD = 3, the Initiator authenticates using static DH. The EDHOC key exchange algorithm is based on the same curve as for the ephemeral keys, which is P-256, since the selected cipher suite is 2.

Since I authenticates with static DH (METHOD = 3), PRK_4e3m is derived from SALT_4e3m and G_IY.

The input needed to calculate SALT_4e3m is defined in [Section 4.1.2](#) of [[I-D.ietf-lake-edhoc](#)], using EDHOC_Expand() with the EDHOC hash algorithm:

```
SALT_4e3m = EDHOC_KDF( PRK_3e2m, 5, TH_3, hash_length ) =  
            = HKDF-Expand( PRK_3e2m, info, hash_length )
```

where hash_length is the length in bytes of the output of the EDHOC hash algorithm, and info for SALT_4e3m is:

```
info =

PRK_4e3m is specified in [Section 4.1.1.3](#) of [[I-D.ietf-lake-edhoc](#)].

Since I authenticates with static DH (METHOD = 3), PRK_4e3m is derived from G_IY using EDHOC_Extract() with the EDHOC hash algorithm:

```
PRK_4e3m = EDHOC_Extract(SALT_4e3m, G_IY) =  
            = HMAC-SHA-256(SALT_4e3m, G_IY)
```

where G_IY is the ECDH shared secret calculated from G_I and Y, or G_Y and I.

The Initiator constructs the remaining input needed to calculate MAC_3:

```

```

```
context_3 = << ID_CRED_I, TH_3, CRED_I, ? EAD_3 >>
```

CRED_I is identified by a 'kid' with byte string value 0x2b:

```

```

ID_CRED_I (CBOR Data Item) (4 bytes)

Since METHOD = 3, Signature_or_MAC_3 is MAC_3:

Signature_or_MAC_3 (CBOR Data Item) (9 bytes)

PLAINTEXT_3 =

```
(

Since ID_CRED_I contains a single 'kid' parameter, only the byte string value is included in the plaintext, represented as described in [Section 3.3.2](#) of [\[I-D.ietf-lake-edhoc\]](#). The CBOR map { 4 : h'2b' } is thus replaced, not by the CBOR byte string 0x412b, but by the CBOR int 0x2b, since that is a one byte encoding of a CBOR integer (-12).

The Responder constructs the input needed to derive the EDHOC message_4 nonce, see [Section 4.1.2](#) of [[I-D.ietf-lake-edhoc](#)], using the EDHOC hash algorithm:

```
IV_4 = EDHOC_KDF( PRK_4e3m, 9, TH_4, iv_length )
      = HKDF-Expand( PRK_4e3m, info, iv_length )
```

where iv_length is the nonce length in bytes for the EDHOC AEAD algorithm, and info for IV_4 is:

```
info =
(
  9,
  h'ba60adbc500fce789af25b108ada2275575056c52c1c203
  6a2da4a643891cb4',

```

where the last value is the nonce length in bytes for the EDHOC AEAD algorithm.

3.8. OSCORE Parameters

The derivation of OSCORE parameters is specified in [Appendix A.1](#) of [\[I-D.ietf-lake-edhoc\]](#).

The AEAD and Hash algorithms to use in OSCORE are given by the selected cipher suite:

Application AEAD Algorithm (int)
10

Application Hash Algorithm (int)
-16

The mapping from EDHOC connection identifiers to OSCORE Sender/Recipient IDs is defined in [Section 3.3.3](#) of [\[I-D.ietf-lake-edhoc\]](#).

C_R is mapped to the Recipient ID of the server, i.e., the Sender ID of the client. The byte string 0x27, which as C_R is encoded as the CBOR integer 0x27, is converted to the server Recipient ID 0x27.

Client's OSCORE Sender ID (Raw Value) (1 byte)
27

C_I is mapped to the Recipient ID of the client, i.e., the Sender ID of the server. The byte string 0x37, which as C_I is encoded as the CBOR integer 0x0e is converted to the client Recipient ID 0x37.

Server's OSCORE Sender ID (Raw Value) (1 byte)
37

The OSCORE Master Secret is computed through EDHOC_Expand() using the Application hash algorithm, see [Appendix A.1](#) of [\[I-D.ietf-lake-edhoc\]](#):

```
OSCORE Master Secret = EDHOC_Exporter( 0, h'', oscore_key_length )  
= EDHOC_KDF( PRK_exporter, 0, h'', oscore_key_length )  
= HKDF-Expand( PRK_exporter, info, oscore_key_length )
```

where `oscore_key_length` is by default the key length in bytes for the Application AEAD algorithm, and `info` for the OSCORE Master Secret is:

```
info =  
(  
  0,  
  h'',  
  16  
)
```

where the last value is the key length in bytes for the Application AEAD algorithm.

The OSCORE Master Salt is computed through `EDHOC_Expand()` using the Application hash algorithm, see [Section 4.2](#) of [\[I-D.ietf-lake-edhoc\]](#):

```
OSCORE Master Salt = EDHOC_Exporter( 1, h'', oscore_salt_length )  
= EDHOC_KDF( PRK_exporter, 1, h'', oscore_salt_length )  
= HKDF-Expand( PRK_4x3m, info, oscore_salt_length )
```

where `oscore_salt_length` is the length in bytes of the OSCORE Master Salt, and `info` for the OSCORE Master Salt is:

```

PRK_out = EDHOC_KDF( PRK_out, 11, context, hash_length )
           = HKDF-Expand( PRK_out, info, hash_length )
```

where hash_length is the length in bytes of the output of the EDHOC hash function, context for KeyUpdate is

```
context for KeyUpdate (Raw Value) (16 bytes)
a0 11 58 fd b8 20 89 0c d6 be 16 96 02 b8 bc ea
```

```
context for KeyUpdate (CBOR Data Item) (17 bytes)

```

and where info for key update is:

```
info =

```

After key update the PRK_exporter needs to be derived anew:

```
PRK_exporter = EDHOC_KDF( PRK_out, 10, h'', hash_length ) =
               = HKDF-Expand( PRK_out, info, hash_length )
```

where info and hash_length are unchanged as in [Section 3.7](#).

```

The OSCORE Master Secret is derived with the updated PRK_exporter:

```
OSCORE Master Secret =
= HKDF-Expand(PRK_exporter, info, oscore_key_length)
```

where info and key_length are unchanged as in [Section 2.6](#).

```

where info and salt_length are unchanged as in [Section 2.6](#).
