# USING FRICKE MODULAR POLYNOMIALS TO COMPUTE ISOGENIES 

FRANÇOIS MORAIN

#### Abstract

Let $\mathcal{E}$ be an elliptic curve over a field $\mathbf{K}$ and $\ell$ a prime. There exists an elliptic curve $\mathcal{E}^{*}$ related to $\mathcal{E}$ by an isogeny of degree $\ell$ only if $\Phi_{\ell}^{t}(X, j(\mathcal{E}))=0$, where $\Phi_{\ell}^{t}(X, Y)$ is the traditional modular polynomial. Moreover, $\Phi_{\ell}^{t}$ gives the coefficients of $\mathcal{E}^{*}$, together with parameters needed to build the isogeny explicitly. Since $\Phi_{\ell}^{t}$ has very large coefficients, many families with smaller coefficients can be used instead, as described by Elkies, Atkin and others. In this work, we concentrate on the computation of the family of modular polynomials introduced by Fricke and more recently used by Charlap, Coley and Robbins. In some cases, the resulting polynomials are small, which justifies the interest of this study. We review and adapt the known algorithms to perform the computations of these polynomials. After describing the use of series computations, we investigate fast algorithms using floating point numbers based on fast numerical evaluation of Eisenstein series. We also explain how to use isogeny volcanoes as an alternative. The last part is concerned with finding explicit formulas for computing the coefficients of $\mathcal{E}^{*}$. To this we add tables of numerical examples.

## 1. Introduction

Computing isogenies is the central ingredient of the Schoof-Elkies-Atkin (SEA) algorithm that computes the cardinality of elliptic curves over finite fields of large characteristic [40, 2, 20] and also [6]. More recently, it has found its way in post-quantum cryptography [14, 27, 11, 25] among others, as well as the cryptosystems [17, 39, 24].

Let $\mathbf{K}$ be a field of characteristic different from 2 and 3. A (separable) isogeny between two elliptic curves $\mathcal{E} / \mathbf{K}: Y^{2}=X^{3}+A X+B$ and $\mathcal{E}^{*} / \mathbf{K}: Y^{2}=X^{3}+A^{*} X+B^{*}$ is a group morphism that is a rational map of degree $N$ (the cardinality of its kernel assumed to be cyclic). There are two ways to handle these isogenies. When the degree $N$ is small, formulas for $A^{*}, B^{*}$ and the kernel polynomial can be precomputed. For large $N$, one of the key ingredients is modular polynomials, the second one finding rational expressions for $A^{*}$ and $B^{*}$ from $A, B$ and the modular polynomial. Note there is a purely algebraic approach using triangular sets [36, §7] (see also [35]).

There are many families of modular polynomials that can be used, with different properties. Very generally, a modular polynomial is some bivariate polynomial $\Phi(X, J)$ where $J$ corresponds to the $j$-invariant of the elliptic curve $\mathcal{E}$, and $X$ stands for some modular function on $\Gamma_{0}(N)$. The prototype is $j\left(\mathcal{E}^{*}\right)$ (see below for more precise statements) that yields traditional modular polynomials. Alternative choices for $X$ exist. They all lead to polynomials of (conjectured) height $O(\psi(N) \log N)$ but with small constants. Here $\psi(N)=N \prod_{p \mid N}(1+1 / p)$ is the cardinality of $\Gamma_{0}(N) \backslash \Gamma$.

In [26], Fricke computes a resolvant polynomial $U_{N}$ of degree $\psi(N)$ for $\wp(N z)$ where $\wp$ is the Weierstrass $\wp$-function of $\mathcal{E}$ and $N$ small. It turns out to be the same polynomial as used in Elkies's work and also by [12] (without notice). The latter authors complete this with two polynomials $V_{N}, W_{N}$ having the property (among others) that $A^{*}$ (resp. $B^{*}$ ) is a root of $V_{N}(X, A, B)$ (resp. $\left.W_{N}(X, A, B)\right)$. The polynomial $U_{N}$ is the modular polynomial associated with a form of weight 2
for $\Gamma_{0}(N)$ related to the Eisenstein series $E_{2} ; V_{N}\left(\right.$ resp. $\left.W_{N}\right)$ is the modular polynomial for $E_{4}(N \tau)$ (resp. $E_{6}(N \tau)$ ).

The aim of this work is to describe the properties of the polynomials $\left(U_{N}, V_{N}, W_{N}\right)$ and the relevant algorithms to compute them, extending methods already used in the traditional cases of bivariate modular polynomials based on modular functions. These methods apply to modular forms of even weight and yield trivariate polynomials in ( $E_{4}, E_{6}, \Delta$ ), see below for the rationale. Though our primary interest is in prime values $N=\ell$, the theory and practice for the general case of an integer $N$ follow the same paths. In Appendix B.2, we give some details on an example when $N=6$.

Section 2) recalls results on classical functions and modular forms, adding approaches to recognize a collection of modular forms as polynomials in the traditional quantities $E_{4}, E_{6}$ and $\Delta$. Section 3 addresses fast methods to evaluate these functions, including an approach to the simultaneous evaluation of several classical series. Section 4 gathers properties of Fricke polynomials; Section 5 is devoted to various algorithms for performing the computations developed for classical modular polynomials. This includes the computation of algebraic expressions for $A^{*}$ and $B^{*}$ as rational fractions (see [35]). Section 6 explains how to compute the isogenous curve using partial derivatives of the polynomial $U_{\ell}$, in the spirit of Atkin's work in the traditional case. We give numerical examples and height comparisons between modular polynomials in Section 7. An appendix contains numerical values for our polynomials, as well as a script for checking the results of Section 6.

Notations: Let $\tau$ be a complex number in the upper half plane. Put $q_{1}=\exp (i \pi \tau)$ and $q=q_{1}^{2}$. Depending on authors, formulas are expressed in either parameter, which sometimes is clumsy. We write indifferently $f(\tau)$ or $f(q)$ some series. We denote by $n^{\omega}$ the complexity of multiplying two $n \times n$ matrices over some field, that is used in the analysis of computer algebra algorithms, in our case solving linear systems.

## 2. Modular forms

For convenience, we follow [15] and the references given below are related to this.

### 2.1. Elements of theory.

### 2.1.1. Integer matrices. We note:

$$
\Gamma=\mathrm{Sl}_{2}(\mathbb{Z})=\left\{\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right), a d-b c=1\right\} .
$$

Let $n>0$ be an integer and $\mathcal{M}_{n}$ be the set of primitive integral $2 \times 2$ matrices of determinant $n$. The relation $R \sim_{\Gamma} R^{\prime}$ means $\Gamma R=\Gamma R^{\prime}$ for $R, R^{\prime}$ in $\mathcal{M}_{n}$.

Proposition 2.1 (Prop. 6.5.3). The matrices

$$
R_{i}=\left(\begin{array}{cc}
a_{i} & b_{i} \\
0 & d_{i}
\end{array}\right), 1 \leq i \leq \psi(n)
$$

with $a_{i}>0, a_{i} d_{i}=n, \operatorname{gcd}\left(a_{i}, b_{i}, d_{i}\right)=1$ and $0 \leq b_{i}<d_{i}$, form a set of representatives of $\mathcal{M}_{n}$ modulo $\sim_{\Gamma}$.
Proposition 2.2 (Prop. 6.5.3-cont'd). Let $M=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$ be of determinant $N$. Then

$$
M \sim_{\Gamma} R=\left(\begin{array}{cc}
A & B \\
0 & D
\end{array}\right)
$$

where $A=\operatorname{gcd}(a, c)$ and $D=N / A$.

Proof: We look for $V=\left(\begin{array}{cc}u & v \\ w & x\end{array}\right) \in \Gamma$ such that $V M=\left(\begin{array}{cc}A & B \\ 0 & D\end{array}\right)$ for $A D=N, \operatorname{gcd}(A, B, D)=$

1. This is equivalent to

$$
\begin{align*}
u a+v c & =A,  \tag{1}\\
w a+x c & =0,  \tag{2}\\
u b+v d & =B,  \tag{3}\\
w b+x d & =D . \tag{4}
\end{align*}
$$

A natural candidate for $A$ is $\operatorname{gcd}(a, c)=u a+v c$ in integers $u$ and $v$. Note that $A \mid N$ since $a d-b c=N$. Write $a=A a^{\prime}, c=A c^{\prime}$ with $\operatorname{gcd}\left(a^{\prime}, c^{\prime}\right)=1$. Equation (2) has solutions $w=-c^{\prime}$ and $x=a^{\prime}$, which is coherent with equation (4), with the choice of $D=N / A$. We are left with $B_{0}=u b+v d=B+q D$, with $0 \leq B<D$ so that

$$
\left(\begin{array}{cc}
1 & -q \\
0 & 1
\end{array}\right) \cdot V M=\left(\begin{array}{cc}
1 & -q \\
0 & 1
\end{array}\right)\left(\begin{array}{cc}
A & B+q D \\
0 & D
\end{array}\right)=\left(\begin{array}{cc}
A & B \\
0 & D
\end{array}\right) .
$$

We finish with

$$
U=V^{-1} \cdot\left(\begin{array}{cc}
1 & q \\
0 & 1
\end{array}\right)=\left(\begin{array}{cc}
a^{\prime} & a^{\prime} q-v \\
c^{\prime} & c^{\prime} q+u
\end{array}\right)
$$

and we are done.
We denote by

$$
\Gamma_{0}(N)=\left\{\left(\begin{array}{ll}
a & b \\
c & d
\end{array}\right) \in \Gamma, c \equiv 0 \bmod N\right\},
$$

and $\psi(N)=N \prod_{p \mid N}(1+1 / p)$ the cardinal of $\Gamma_{0}(N) \backslash \Gamma$.
The general case is treated in Corollary 6.2.11 but we need the prime case only.
Proposition 2.3 (Ex. 6.2.12). Let $N=\ell$ be a prime number. A system of representative of cosets for $\Gamma_{0}(\ell) \backslash \Gamma$ is formed of the matrices $R_{c}=\left(\begin{array}{cc}1 & 0 \\ c & 1\end{array}\right)$ for $0 \leq c<\ell$, and $R_{\ell}=\left(\begin{array}{cc}0 & -1 \\ 1 & \ell\end{array}\right)$.

The following result will prove useful for computing conjugate values of the functions that we study later on.

Lemma 2.4. For $0<c<\ell$ :

$$
\left(\begin{array}{ll}
\ell & 0 \\
c & 1
\end{array}\right)=\left(\begin{array}{cc}
\ell & -\bar{c} \\
c & u
\end{array}\right)\left(\begin{array}{cc}
1 & \bar{c} \\
0 & \ell
\end{array}\right)=T_{c} R_{c}^{\prime}
$$

with $u \ell+\bar{c} c=1$;

$$
\left(\begin{array}{cc}
0 & -\ell \\
1 & \ell
\end{array}\right)=\left(\begin{array}{cc}
0 & -1 \\
1 & 1
\end{array}\right)\left(\begin{array}{ll}
1 & 0 \\
0 & \ell
\end{array}\right)=T_{\ell} R_{\ell}^{\prime} .
$$

2.1.2. Modular forms. Let $f$ be a modular form for $\Gamma$ of integer weight $2 k$. By construction

$$
f(M \tau)=(c \tau+d)^{2 k} f(\tau)
$$

for any matrix $M=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$ in $\Gamma$.
If $M \in \mathrm{GL}_{2}(\mathbb{R})$, define

$$
\left.f\right|_{2 k} M(\tau)=\operatorname{det}(M)_{3}^{k}(c \tau+d)^{-2 k} f(M \tau) .
$$

2.2. Eisenstein series. The classical Eisenstein series ${ }^{1}$ we consider are

$$
\begin{aligned}
& E_{2}(q)=1-24 \sum_{n=1}^{\infty} \delta_{1}(n) q^{n}, \\
& E_{4}(q)=1+240 \sum_{n=1}^{\infty} \delta_{3}(n) q^{n}, \\
& E_{6}(q)=1-504 \sum_{n=1}^{\infty} \delta_{5}(n) q^{n},
\end{aligned}
$$

where $\delta_{r}(n)$ denotes the sum of the $r$-th powers of the divisors of $n$. Other series $E_{2 k}$ can be defined for even $k>3$. The series $E_{2 k}$ is a modular form of weight $2 k$ for $k>1$.

Also of interest is the discriminant $\Delta$ :

$$
\Delta(q)=\left(E_{4}(q)^{3}-E_{6}(q)^{2}\right) / 1728=\eta(q)^{24} .
$$

Dedekind's function is $\eta(q)=q^{1 / 24} \prod_{n=1}^{\infty}\left(1-q^{n}\right)$.
Finally, the modular invariant is

$$
j(q)=\frac{E_{4}(q)^{3}}{\Delta(q)}=\frac{1}{q}+744+\cdots
$$

The series $E_{2}$ is not a modular form since (see [38] or Corollary 5.2.17):
Theorem 2.5. For all matrices $\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$ in $\Gamma$, one has

$$
\begin{equation*}
E_{2}((a \tau+b) /(c \tau+d))=(c \tau+d)^{2} E_{2}(\tau)+\frac{6 c}{\pi i}(c \tau+d) \tag{5}
\end{equation*}
$$

We can build a modular form easily as follows. Let $N$ be an integer and let $F_{N}$ denote the multiplier $E_{2}(\tau)-N E_{2}(N \tau)$. From [37] and [3], we get
Proposition 2.6. The function $F_{N}$ is a modular form of weight 2 and trivial multiplier system for $\Gamma_{0}(N)$.

Proof: Write, for $a d-b c=1$ and $N \mid c$, the value

$$
E_{2}\left(N \frac{a \tau+b}{c \tau+d}\right)=E_{2}\left(\frac{a(N \tau)+N b}{(c / N)(N \tau)+d}\right)=((c / N) N \tau+d)^{2} E_{2}(N \tau)-\frac{6 c}{N \pi i}((c / N) N \tau+d)
$$

which leads to

$$
N E_{2}\left(N \frac{a \tau+b}{c \tau+d}\right)=N(c \tau+d)^{2} E_{2}(N \tau)-\frac{6 c}{\pi i}(c \tau+d) .
$$

Subtracting $E_{2}((a \tau+b) /(c \tau+d))$, we see that

$$
F_{N}((a \tau+b) /(c \tau+d))=(c \tau+d)^{2} F_{N}(\tau) .
$$

Some identities are known for small values of $N$, for instance [30] for $N \in\{2,4\} ;$ [3] for $N=3$ and $11 ;[7, \mathrm{Thm} 6.2],[4, \mathrm{Thm} 3.7]$ for $N \in\{5,7\}$. A very nice relation is [4, Thm 6.3]

$$
F_{7}(q)=6\left(\sum_{m, n=-\infty}^{\infty} q^{m^{2}+m n+2 n^{2}}\right)^{2}
$$

[^0]2.3. Formulas. Reference is Proposition 2.4.1. When $f(q)=\sum_{n \geq n_{0}} a_{n} q^{n}$, we introduce the operator
\[

$$
\begin{equation*}
f^{\prime}(q)=\frac{1}{2 i \pi} \frac{d f}{d \tau}=q \frac{d f}{d q}=\sum_{n \geq n_{0}} n a_{n} q^{n} . \tag{6}
\end{equation*}
$$

\]

Several identities are classical:

$$
\begin{gather*}
\Delta=\frac{E_{4}^{3}-E_{6}^{2}}{1728}, \quad j=\frac{E_{4}^{3}}{\Delta}, \quad j-1728=\frac{E_{6}^{2}}{\Delta}  \tag{7}\\
\frac{j^{\prime}}{j}=-\frac{E_{6}}{E_{4}}, \quad \frac{j^{\prime}}{j-1728}=-\frac{E_{4}^{2}}{E_{6}}, \quad j^{\prime}=-\frac{E_{4}^{2} E_{6}}{\Delta}, \quad \frac{\Delta^{\prime}}{\Delta}=E_{2}, \tag{8}
\end{gather*}
$$

to which we add the Ramanujan differential system:

$$
\begin{equation*}
3 E_{4}^{\prime}=E_{4} E_{2}-E_{6}, \quad 2 E_{6}^{\prime}=E_{6} E_{2}-E_{4}^{2}, \quad 12 E_{2}^{\prime}=E_{2}^{2}-E_{4} . \tag{9}
\end{equation*}
$$

2.4. Expressing modular forms as polynomials. We extend a remark already done in [12] that uses the following result from [41, §5.6.2].

Theorem 2.7. A modular form $f$ of weight $2 k$ with integer coefficients can be expressed as a polynomial with integer coefficients in $E_{4}, \Delta$ if $k$ is even and $E_{4}, \Delta, E_{6}$ otherwise. The number of coefficients in this polynomial is approximately $k / 6$.

We can apply this result to higher index Eisenstein series. For instance

$$
\begin{equation*}
E_{8}=E_{4}^{2}, E_{10}=E_{4} E_{6} . \tag{10}
\end{equation*}
$$

Lemma 2.8. Let $k>1$. Consider the equation

$$
\begin{equation*}
2 i_{4}+3 i_{6}+6 i_{12}=k \tag{11}
\end{equation*}
$$

where $i_{4}, i_{12}$ are positive integers and $i_{6} \in\{0,1\}$. Write $k=2 k_{0}+\epsilon$ for $\epsilon \in\{0,1\}$ and $m=k_{0}-\epsilon$. All solutions $\left(i_{6}, i_{4}, i_{12}\right)$ to equation (11) are

$$
(\epsilon, m-3 j, j) \text { for } 0 \leq j \leq j_{\max }:=\lfloor m / 3\rfloor .
$$

Proof: If $k$ is even, we write $k=2 m$, which forces $i_{6}=0$. We rewrite (11) as $i_{4}+3 i_{12}=m$ and the result follows. If $k=2 m+1$, we need $i_{6}=1$ and (11) becomes $i_{4}+3 i_{12}=m-1$, which concludes the proof.

Proof of the theorem: the expression we are looking for is

$$
f=\sum_{i_{4}, i_{6}, i_{12}} c_{i_{4}, i_{6}, i_{12}} E_{6}^{i_{6}} E_{4}^{i_{4}} \Delta^{i_{12}}
$$

for all positive indices satisfying $4 i_{4}+6 i_{6}+12 i_{12}=2 k$ and $i_{6} \in\{0,1\}$. which is in fact equivalent to (11) and we apply the Lemma.

For $w=2 k$, write

$$
P_{w, j}=E_{6}^{\epsilon} E_{4}^{m-3 j} \Delta^{j}=q^{j}+\sum_{n>j} g_{j, n} q^{n}
$$

where the coefficients $g_{j, n}$ are integers and do not depend on $f$. We may precompute all $P_{w, j}$ 's for $0 \leq j \leq j_{\max }=\lfloor m / 3\rfloor$ using Algorithm 1. The cost of this algorithm is $3 j_{\max }+2$ multiplications of series. We could improve on this using squarings in Step 1.2. If this is a one-time computation, Step 4 may not update and store the $P_{w, j}$ 's.

The next two results are crucial for our forthcoming computations.

```
Algorithm 1: Evaluating all \(P_{w, j}\) 's.
    Function EvaluateAllPwj \(\left(E_{4}, E_{6}^{\epsilon}, \Delta, w, j_{\text {max }}\right)\)
        Input : \(E_{4}, E_{6}, \Delta ; w=2 k, j_{\max }\)
        Output: \(\left(P_{w, j}\right)\) for \(0 \leq j \leq j_{\text {max }}\)
        0 . compute \(m\)
        1. \(\left[\right.\) compute \(P_{w, j}=E_{6}^{\epsilon} \cdot \Delta^{j}\) for all \(\left.j\right]\)
        1.1. \(P_{w, 0} \leftarrow E_{6}^{\epsilon}\)
        1.2. for \(j \leftarrow 1\) to \(j_{\text {max }}\) do
            \(P_{w, j} \leftarrow \Delta \cdot P_{w, j-1}\)
        2. \(Q[0] \leftarrow 1 ; Q[1] \leftarrow E_{4} ; Q[2] \leftarrow E_{4}^{2} ; Q[3] \leftarrow E_{4} \cdot Q[2]\)
        3. \(m^{\prime}=m-3 j_{\max } ; S \leftarrow Q\left[m^{\prime}\right]\)
        4. for \(j \leftarrow j_{\text {max }-1}\) to 0 do
                \(S \leftarrow Q[3] \cdot S\)
                // \(S=E_{4}^{m-3 j}\)
                \(P_{w, j} \leftarrow P_{w, j} \cdot S\)
        return \(\left\{P_{w, j}\right\}\)
```

Proposition 2.9. Let $f=\sum_{n \geq 0} f_{n} q^{n}$ be a modular form of weight $w=2 k$. With the notations of Lemma 2.8, there exist numbers $c_{j}$ such that

$$
f=\sum_{j=0}^{j_{\max }} c_{j} P_{w, j}
$$

where the $c_{j}$ 's are solution of a triangular linear system.
Proof: Write

$$
\sum_{n \geq 0} f_{n} q^{n}=\sum_{j=0}^{j_{\max }} c_{j}\left(q^{j}+\sum_{n>j} g_{j, n} q^{n}\right),
$$

the system giving the $c_{j}$ 's is triangular. Solving the system takes $O\left(j_{\max }^{2}\right)=O\left(w^{2}\right)$ operations with a very small constant.

From this, we deduce:
Corollary 2.10. When the $f_{n}$ 's are integers, so are the $c_{j}$ 's.
Corollary 2.11. To express $f$ as a polynomial, we need all series developped at order $j_{\max } \approx w / 12$.
To prepare for the computation of modular equations of Section 5 , we need to express a collection of modular forms of weight $2 k r$ for $1 \leq r \leq \psi(N)$ ( $\ell$ is an odd prime $>3$ ) as polynomials in $E_{4}$, $E_{6}$ and $\Delta$. The rationale is to share evaluations of products $P_{\epsilon, x, y}=E_{6}^{\epsilon} E_{4}^{x} \Delta^{y}$. It follows from Corollary 2.11 that the forms must be computed with order close to $w \psi(N) / 12=k \psi(N) / 6$.

Using notations from Lemma 2.8 for $1 \leq r \leq \psi(N)$, write $k r=2 k_{r}+\epsilon_{r}, m_{r}=k_{r}-\epsilon_{r}$. Each $m_{r}$ gives rise to a set of indices $\left(m_{r}-3 j_{r}, j_{r}\right)$ for $0 \leq j_{r} \leq m_{r} / 3$. We can gather all these points in the plane to give rise to interesting patterns, as indicated in Figure 1. We define two sets of indices $\mathcal{I}_{\epsilon}$ corresponding to pairs $\left(m_{r}-3 j_{r}, j_{r}\right)$ with $\epsilon_{r}=\epsilon \in\{0,1\}$. When $k$ is even, $\mathcal{I}_{1}$ is empty.

Lemma 2.12. The sets $\mathcal{I}_{\epsilon}$ satisfy the following properties.
i) $\mathcal{I}_{0}$ is included in the grid $(0,0) \times\left(m_{\max , 0}, j_{\max , 0}\right)$ with $m_{\max , 0}=\lfloor k \psi(N) / 2\rfloor, j_{\max , 0}=\lfloor k \psi(N) / 6\rfloor$;

$\ell=5, k=2$

$\ell=7, k=3, \epsilon=0$

$\ell=7, k=3, \epsilon=1$

Figure 1. Examples of grids and sets $\mathcal{I}_{\epsilon}$.
ii) the distance between two consecutive abscissas in $\mathcal{I}_{0}$ is $k / 2$ when $k$ is even and $k$ when $k$ is odd;
iii) for any abscissa $x$ of a point in $\mathcal{I}_{0}$, the maximal $y$ is $\left\lfloor\left(m_{\max , 0}-x\right) / 3\right\rfloor$.

For $k$ odd, $\mathcal{I}_{1}$ is such that
iv) $\mathcal{I}_{1} \subset(0,0) \times\left(m_{\max , 1}, j_{\max , 1}\right)$ with $m_{\max , 1}=k\left(r^{\prime}-3\right) / 2$ with $r^{\prime}$ the largest odd integer $\leq \psi(N)$ and $j_{\text {max }, 1}=\lfloor(k \ell-3) / 6\rfloor$;
v) the distance between two consecutive abscissas in $\mathcal{I}_{1}$ is $k$;
vi) for any abscissa $x$ in $\mathcal{I}_{1}$, the maximal $y$ is $\left\lfloor\left(m_{\max , 1}-x\right) / 3\right\rfloor$.

Proof: i) the maximal value of $y$ is always reached for $m_{\max , 0}=m_{\psi(N)}=\lfloor k \psi(N) / 2\rfloor$.
ii) When $k$ is even, all $\epsilon_{r}$ 's are $0, m_{r}=k_{r}$, the minimal value is $m_{1}=k / 2$. Two consecutive values have distance $m_{r+1}-m_{r}=k_{r+1}-k_{r}=k / 2$. When $k$ is odd, the smallest $m$ is $m_{2}=k$. Two consecutive values are such that $m_{2 r+2}-m_{2 r}=k$.
iii) A point $(x, y)$ is in $\mathcal{I}_{0}$ if and only if there exists $0 \leq m \leq m_{\max , 0}$ and $0 \leq j \leq j_{\max , 0}$ such that $(x, y)=(m-3 j, j)$. It follows that $j \leq(m-x) / 3 \leq\left(m_{\max , 0}-x\right) / 3$.
iv) In the remainder of the proof, $k$ is odd. When $\epsilon=1$ (which cannot happen unless both $k$ and $r$ are odd) we get $m_{r}=(k r-3) / 2$, and the maximal value is $m_{\text {max }, 1}=\left(k r^{\prime}-3\right) / 2$. Note that $r^{\prime}=\ell$ when $N=\ell$ is prime.
v) The minimal value is $m_{1}=\max (0,(k-3) / 2)$. Two consecutive values are such that $m_{2 r+3}-$ $m_{2 r+1}=k$.
vi) Proceed as in case iii.

We write algorithms in a generic manner, and it will work for series, floating point numbers, etc. The auxiliary routine performing operations is given in Algorithm 2. We need one multiplication for each point in $\mathcal{I}_{\epsilon}$. Each power of $E_{4}$ is computed incrementally. The main function is given in Algorithm 3. The simple algorithm expressing the coefficients of the representation of $f$ is give as Algorithm 4.

```
Algorithm 2: Compute all \(P_{\epsilon, x, y}\) 's.
    Function EvaluateAllPepsilon \(\left(\epsilon, E_{4}, E_{6}^{\epsilon}, \Delta, m_{\max }, x_{0}, d x\right)\)
        Input : \(E_{4}, E_{6}^{\epsilon}\) and \(\Delta, m_{\text {max }}, x_{0}, d x\)
        Output: \(\left(P_{\epsilon, x, y}\right)\) for all points in \(\mathcal{I}_{\epsilon}\)
        0. \(j_{\text {max }} \leftarrow\left\lfloor m_{\text {max }} / 3\right\rfloor\)
        1. compute \(P_{\epsilon, 0, j}\) for all \(0 \leq j \leq j_{\max }\)
        3. for \(x \leftarrow x_{0}\) to \(m_{\text {max }}\) by \(d x\) do
            compute \(P_{\epsilon, x, y}=E_{6}^{\epsilon} E_{4}^{x} \Delta^{y}\) for all \(0 \leq y \leq\left\lfloor\left(m_{\max }-x\right) / 3\right\rfloor\)
```

2.5. Modular polynomials from modular forms. Let us begin with modular forms $f$ for $\Gamma_{0}(N)$ of even weight $w$. In this section $\left(R_{i}\right)$ denote a list of representatives of cosets of $\Gamma_{0}(N) \backslash \Gamma$.

```
Algorithm 3: Evaluating all \(P_{\epsilon, x, y}\) 's.
    Function Evaluate \(\operatorname{AllP}\left(\psi, k, E_{4}, E_{6}^{\epsilon}, \Delta\right)\)
        Input : \(E_{4}, E_{6}^{\epsilon}\) and \(\Delta, \psi=\psi(N), k\)
        Output: \(\left(P_{\epsilon, x, y}\right)\) for all points in \(\mathcal{I}_{\epsilon}\) and all \(\epsilon\)
        1. if \(k\) is even then
            \(d x \leftarrow k / 2\)
        else
            \(d x \leftarrow k\)
        2. \(P_{0, x, y} \leftarrow\) EvaluateAllPepsilon \(\left(0, E_{4}, E_{6}, \Delta, k \psi / 2, d x, d x\right)\)
        3. if \(k\) is odd then
            \(P_{1, x, y} \leftarrow\) EvaluateAllPepsilon \(\left(1, E_{4}, E_{6}, \Delta, k\left(r^{\prime}-3\right) / 2,(k-3) / 2, k\right)\) where \(r^{\prime}\) is the
                largest odd integer \(\leq \psi\)
        4. return \(\left\{P_{0, x, y}\right\} \cup\left\{P_{1, x, y}\right\}\).
```

```
Algorithm 4: Express \(f\) as a polynomial in the \(P_{w, j}\) 's.
    Function ExpressForm ( \(f, P_{w, j}, j_{\text {max }}\) )
        Input : \(f\) a modular form of weight \(w\)
        Output: The coefficients of the representation of \(f\) as \(\sum_{j=0}^{j_{\max }} c_{j} P_{w, j}\)
        0. \(g \leftarrow f\)
        1. for \(j \leftarrow 0\) to \(j_{\text {max }}\) do
        // \(g=g_{j} q^{j}+\cdots\)
        \(1.1 c_{j} \leftarrow g_{j}\)
        \(1.2 g \leftarrow g-c_{j} P_{w, j}\)
    2. return \(c_{j}\) 's.
```

### 2.5.1. General results.

Theorem 2.13. Let $f$ be a modular form of weight $w$ for $\Gamma_{0}(N)$. The values $\left.f\right|_{w}\left(R_{i}\right)$ are conjugate over $\Gamma_{0}(N)$ and define a polynomial

$$
\Phi[f](X)=\prod_{R}\left(X-\left.f\right|_{w}\left(R_{i}\right)\right)=X^{\psi(N)}+C_{1}(f) X^{\psi(N)-1}+\cdots+C_{\psi(N)}(f) .
$$

a) The coefficient $C_{t}(f)$ is a modular form of weight wt for $\Gamma$.
b) The polynomial $\Phi[f]\left(X, E_{4}, E_{6}, \Delta\right)$ is homogeneous with weight $w(\ell+1)$.

Proof:
a) $C_{t}(f)$ is a symmetric function of the $\left.f\right|_{w}\left(R_{i}\right)$ 's. Having a matrix of $\Gamma$ operate on the $\left(R_{i}\right)$ 's leave them globally invariant, so that $C_{t}(f)$ is invariant under $\Gamma$.
b) is a consequence of a).

In practice, it is customary to compute the power sums of roots of $\Phi[f]$ :

$$
S_{t}(f)=\sum_{i=1}^{\psi(N)}\left(\left.f\right|_{w}\left(R_{i}\right)\right)^{t}
$$

for $1 \leq t \leq \psi(N)$. The sum $S_{t}(f)$ is also a modular form of weight $w t$ for $\Gamma$, hence is expressible as a polynomial in ( $E_{4}, E_{6}, \Delta$ ). The functions $S_{t}(f)$ are more easily computed and once recognized as
polynomials in $\left(E_{4}, E_{6}, \Delta\right)$, we can recover the coefficients of $\Phi[f]$ using Newton's formulas using $O(\mathrm{M}(\psi(N)))$ operations (in a field of characteristic 0 or larger than $\psi(N))$.

Let us turn towards a special case.
Proposition 2.14. If $f$ is a modular form of weight $w$ for $\Gamma$, then the function $g(\tau)=f(N \tau)$ is a modular form of weight $w$ for $\Gamma_{0}(N)$.

Proof: let $M=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right) \in \Gamma_{0}(N)$, in other words $c=N c^{\prime}$ for some integer $c^{\prime}$. Write

$$
g(M \tau)=f(N(M \tau))=f\left(\frac{(N a) \tau+(N b)}{\left(N c^{\prime}\right) \tau+d}\right) .
$$

Consider the matrix

$$
U=\left(\begin{array}{cc}
a & b N \\
c^{\prime} & d
\end{array}\right)
$$

which belongs to $\Gamma$ since $a d-b\left(N c^{\prime}\right)=1$. Using

$$
M=U \cdot\left(\begin{array}{cc}
N & 0 \\
0 & 1
\end{array}\right),
$$

we get

$$
g(M \tau)=f(U(N \tau))=\left(c^{\prime}(N \tau)+d\right)^{w} f(N \tau)=(c \tau+d)^{w} g(\tau),
$$

which proves invariance.
Inspired by [15, Example 6.2.15].
Theorem 2.15. Let $\left(R_{i}\right)$ be a system of cosets for $\Gamma_{0}(N) \backslash \Gamma$, the $\left(\left.g\right|_{w} R_{i}\right)$ are permuted by $\Gamma$ and we let $\Phi[g](X)$ denote the modular polynomial

$$
\Phi[g](X)=\prod_{i}\left(X-\left.g\right|_{w} R_{i}\right) .
$$

If $R=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$ is a representative of a coset, the matrix $\left(\begin{array}{cc}a N & b N \\ c & d\end{array}\right)$ is equivalent to a matrix $\left(\begin{array}{cc}A & B \\ 0 & D\end{array}\right)$ with $A=\operatorname{gcd}(a, c), A D=N$ and $0 \leq B<D$. Moreover

$$
\left.g\right|_{w} R(\tau)=D^{-w} f\left(\frac{A \tau+B}{D}\right)
$$

Proof: If a coset is $R=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right)$ with $d \mid N, d>0, c$ defined modulo $N / d$ :

$$
\begin{aligned}
\left.g\right|_{w} R(\tau) & =(c \tau+d)^{-w} g\left(\frac{a \tau+b}{c \tau+d}\right) \\
& =(c \tau+d)^{-w} f\left(\frac{a N \tau+b N}{c \tau+d}\right) \\
& =\left.N^{-w / 2} f\right|_{w}\left(\begin{array}{cc}
a N & b N \\
c & d
\end{array}\right)(\tau) .
\end{aligned}
$$

The last matrix is equivalent to some $R_{c}^{\prime}=\left(\begin{array}{cc}A & B \\ 0 & D\end{array}\right)$ with $A D=N$ and $0 \leq B<D$ given by Proposition 2.2, so that

$$
\begin{aligned}
\left.g\right|_{w} R(\tau) & =\left.N^{-w / 2} f\right|_{w}\left(\begin{array}{cc}
A & B \\
0 & D
\end{array}\right)(\tau) \\
& =N^{-w / 2}\left(N^{w / 2} D^{-w} f\left(\frac{A \tau+B}{D}\right)\right) \\
& =D^{-w} f\left(\frac{A \tau+B}{D}\right) .
\end{aligned}
$$

In order to handle series with integer coefficients, we scale all conjugates by multiplication by $N^{w}$. 2.5.2. Orders and heights. The traditional modular polynomial $\Phi_{N}^{t}$ has height $6 \psi(N) \log N$ approximately $[16,43]$. To get a general result for modular forms, we first estimate the order of the series needed.

For integer $t>0$, write

$$
f^{t}(q)=\sum_{n=0}^{\infty} \alpha(t, n) q^{n}
$$

Proposition 2.16. Let $D \mid N$. Then

$$
S_{D, t}(f)=\sum_{B=0}^{D-1} f^{t}\left(\frac{A \tau+B}{D}\right)=D \sum_{n=0}^{\infty} \alpha(t, D n) q^{A n}
$$

Proof: using $z=q^{A / D}$ :

$$
S_{D, t}(f)=\sum_{B=0}^{D-1} \sum_{n=0}^{\infty} \alpha(t, n) z^{n} \zeta_{D}^{B n}=\sum_{n=0}^{\infty} \alpha(t, n) z^{n} \sum_{B=0}^{D-1} \zeta_{D}^{B n}
$$

If $n$ is prime to $D$, the inner sum $\Sigma_{D}(n)$ is 0 using the properties of roots of unity. If $D \mid n$, the sum is $D$. Now, suppose that $g=\operatorname{gcd}(n, D) 1$ with $1<g<$, and $n^{\prime}=n / g$ which is prime to $D / g$. Write $B=B^{\prime}+x D^{\prime}, 0 \leq B^{\prime}<D^{\prime}$. We obtain

$$
\Sigma_{D}(n)=\sum_{x=0}^{g-1} \sum_{B^{\prime}=0}^{D^{\prime}-1} \zeta_{D^{\prime}}^{B^{\prime} n^{\prime}+x n^{\prime} D^{\prime}}=\sum_{x=0}^{g-1} \sum_{B^{\prime}=0}^{D^{\prime}-1} \zeta_{D^{\prime}}^{B^{\prime}}=0 .
$$

Finally:

$$
S_{D, t}(f)=D \sum_{n=0}^{\infty} \alpha(t, D n) q^{A n}
$$

Proposition 2.17. If $f$ is a modular form of weight $w$ for $\Gamma$. We need to develop $f$ up to order $w N \psi(N) / 12$ to compute $\Phi[f(N \tau)]$.

Proof: we need to compute the expansion of the sum

$$
S_{t}(f)=\sum_{D \mid N}(N / D)^{w t} S_{D, t}(f) .
$$

To get $\mathcal{O}$ terms in the sum, we need to develop the series up to order $N \mathcal{O}$. If we need $\mathcal{O}$ terms, we need to have $N n \geq \mathcal{O}$.

Since $S_{t}(f)$ is a modular form of weight $w t$, we need $(w t) / 12$ terms with a maximal $\mathcal{O}=$ $w \psi(N) / 12$, which yields the result.

Now, we turn our attention to estimating the height of $\Phi$. For this, we need general bounds on the coefficients of modular forms. This is [15, Theorem 9.2.1]:
Theorem 2.18. Let $f(q)=\sum_{n \geq 0} a_{n} q^{n}$ be a modular form of weight $w$ for $\Gamma$.
a) if $f$ is a cusp form, then $a(n)=O\left(n^{w / 2}\right)$.
b) if $f$ is not cuspidal (i.e., $a_{0} \neq 0$ ), then there are two positive constants $C_{1}, C_{2}$ s.t.

$$
C_{1} n^{w-1} \leq|a(n)| \leq C_{2} n^{w-1} .
$$

For instance, for Eisenstein series:

$$
n^{w-1} \leq \delta_{w-1}(n) \leq \zeta(n-1) n^{w-1} .
$$

We could use better estimates, see [15, Chapter 9].
We slightly generalize the computations in [12] to the case of an arbitrary form.
Proposition 2.19. Let $f$ be a modular form for $\Gamma$ of weight $w$ and $K>0$ an integer, $C>$ 0 two constants such that $|a(n)| \leq C n^{K-1}$. The size of the sum $S_{\psi(N)}(f)$ is approximately $K \psi(N) \log (N \psi(N))$.

Proof: Let us denote $\psi(N)$ by $\psi$ for short. With $u=|q|$, we get
$|f(q)| \leq \sum_{n=0}^{\infty} n^{K-1} u^{n} \leq C \sum_{n=0}^{\infty}(n+K-1)(n+K-2) \cdots(n+1) u^{n}=C(K-1)!(1-u)^{-K}:=C_{1}(1-u)^{-K}$,
from which $\left|f^{m}(q)\right| \leq C_{1}^{m}(1-u)^{-K m}$ for all $m$. By Proposition 2.17, we need to compute $f^{\psi}$ at order $d \approx w N \psi / 12$. The largest coefficient is therefore of the order of

$$
L=C_{1}^{\psi} \frac{(d+K \psi-1)!}{d!} .
$$

Using Stirling's formula, we get

$$
\log L \approx \psi \log C_{1}+d \log \left(\frac{d+K \psi}{d}\right)+K \psi \log (d+K \psi) .
$$

Replacing $d$, we get

$$
\log L \approx K \psi \log (N \psi)+C^{\prime} \psi,
$$

which yields the result.
This is the largest quantity used for computing power sums, before going back to the coefficients of the polynomial $\Phi[f(N \tau)]$, whose sizes have the same order. We infer
Corollary 2.20. The height of $\Phi[f(N \tau)]$ is approximately $K \psi(N) \log (N \psi(N))$.
2.5.3. The prime case. In this section, we keep the notations $f, w$, etc.

Proposition 2.21. When $N=\ell$ is prime, the roots of $\Phi[f(\ell \tau)]$ are

$$
f(\ell \tau) \text { and } \ell^{-w} f((\tau+h) / \ell) \text { for } 0 \leq h<\ell .
$$

Proof: In case $N=\ell$, the system of cosets is given in Proposition 2.3.
When $c>0$, let $\bar{c}=1 / c \bmod \ell$, so that $R_{c}^{\prime} \sim_{\Gamma}\left(\begin{array}{cc}1 & \bar{c} \\ 0 & \ell\end{array}\right)$ and

$$
\left.g\right|_{w} R_{c}^{\prime}(\tau)=\ell^{-w} f\left(\frac{\tau+\bar{c}}{\ell}\right) .
$$

When $c=0, R_{0}^{\prime}=\left(\begin{array}{ll}\ell & 0 \\ 0 & 1\end{array}\right)$ is already reduced and $\left.g\right|_{w} R_{0}^{\prime}(\tau)=f(\ell \tau)$. Finally, $R_{\ell}^{\prime} \sim_{\Gamma}\left(\begin{array}{ll}1 & 0 \\ 0 & \ell\end{array}\right)$, from which

$$
\left.g\right|_{w} R_{\ell}^{\prime}(\tau)=\ell^{-w} f\left(\frac{\tau}{\ell}\right)
$$

In practice, though, we prefer to scale all the conjugates by $\ell^{w}$, so that we have to deal with integer coefficients in the expansions. By Corollary 2.20, the corresponding modular polynomial has height close to $2 w(\ell+1) \log \ell$.
Proposition 2.22. For $t \geq 1$, the power sum $S_{t}(f)$ has a $q$-expansion.
Proof: with the notations of Proposition 2.16:

$$
S_{t}(f)=\ell^{w t} f^{t}(\ell \tau)+S_{\ell, t}(f)
$$

and both terms have a $q$-expansion.
2.5.4. The case of $F_{\ell}$. Remember that $F_{\ell}(\tau)=E_{2}(\tau)-\ell E_{2}(\ell \tau)$ is a modular form of weight 2 for $\Gamma_{0}(\ell)$. We simplify the presentation using $F=F_{\ell}$ and replace $\left.\right|_{2}$ by $\mid$. We need to compute all $F \mid(R \tau)$ for all $R$ 's from Proposition 2.3.
Proposition 2.23. We have $F \mid\left(R_{0} \tau\right)=F(\tau)$. With the notations of Lemma 2.4, for $0<c<\ell$ :

$$
F \left\lvert\,\left(R_{c} \tau\right)=-\frac{1}{\ell} F\left(\frac{\tau+\bar{c}}{\ell}\right) .\right.
$$

Also

$$
F \left\lvert\,\left(R_{\ell} \tau\right)=-\frac{1}{\ell} F\left(\frac{\tau}{\ell}\right) .\right.
$$

Proof: Let us suppose that $c>0$. Start with

$$
E_{2}\left(\left(\begin{array}{ll}
1 & 0 \\
c & 1
\end{array}\right)\right)(\tau)=(c \tau+1)^{2} E_{2}(\tau)+\frac{6 c}{\pi i}(c \tau+1) .
$$

Plugging $R_{c}^{\prime}$ in (5), we find

$$
E_{2}\left(\ell\left(R_{c} \tau\right)\right)=E_{2}\left(T_{c}\left(R_{c}^{\prime} \tau\right)\right)=\left(c\left(R_{c}^{\prime} \tau\right)+u\right)^{2} E_{2}\left(R_{c}^{\prime} \tau\right)+\frac{6 c}{\pi i}\left(c\left(R_{c}^{\prime} \tau\right)+u\right)
$$

We simplify

$$
c\left(R_{c}^{\prime} \tau\right)+u=\frac{c \tau+c \bar{c}+\ell u}{\ell}=\frac{c \tau+1}{\ell}
$$

which leads to

$$
E_{2}\left(\ell\left(R_{c} \tau\right)\right)=\left(\frac{c \tau+1}{\ell}\right)^{2} E_{2}\left(\frac{c \tau+1}{\ell}\right)+\frac{6 c}{\pi i} \frac{c \tau+1}{\ell} .
$$

We deduce that

$$
F\left(R_{c} \tau\right)=E_{2}\left(R_{c} \tau\right)-\ell E_{2}\left(\ell\left(R_{c} \tau\right)\right)=(c \tau+1)^{2}\left(E_{2}(\tau)-\frac{1}{\ell} E_{2}\left(R_{c}^{\prime} \tau\right)\right)
$$

Remark that

$$
F\left(R_{c}^{\prime} \tau\right)=E_{2}\left(R_{c}^{\prime} \tau\right)-\ell E_{2}(\tau+\bar{c})=E_{2}\left(R_{c}^{\prime} \tau\right)-\ell E_{2}(\tau)
$$

so that

$$
F\left(R_{c} \tau\right)=-\frac{1}{\ell}(c \tau+1)^{2} F\left(\frac{\tau+\bar{c}}{\ell}\right)
$$

or

$$
F \left\lvert\,\left(R_{c} \tau\right)=-\frac{1}{\ell} F\left(\frac{\tau+\bar{c}}{\ell}\right)\right.
$$

The last case is that of $R_{\ell}$, which needs

$$
E_{2}\left(\left(\begin{array}{cc}
0 & -1 \\
1 & \ell
\end{array}\right)\right)(\tau)=(\tau+\ell)^{2} E_{2}(\tau)+\frac{6}{\pi i}(\tau+\ell)
$$

Performing computations the way we treated $c>0$, we find

$$
F \left\lvert\,\left(R_{\ell} \tau\right)=-\frac{1}{\ell} F\left(\frac{\tau}{\ell}\right) .\right.
$$

Again, it is more convenient to scale all conjugates by $-\ell$, which gives us $-\ell F(\tau)$ and $F((\tau+h) / \ell)$ for all $0 \leq h<\ell$. Remark that Proposition 2.22 applies too, mutatis mutandis.

## 3. Fast numerical evaluation of Eisenstein series

Since one of the methods for computing modular polynomials uses floating point evaluations, we give some algorithms to compute our functions.
3.1. Jacobi $\theta$ functions. The classical $\theta$ functions are:

$$
\theta_{2}\left(q_{1}\right)=\sum_{n \in \mathbb{Z}} q_{1}^{(n+1 / 2)^{2}}, \theta_{3}\left(q_{1}\right)=\sum_{n \in \mathbb{Z}} q_{1}^{n^{2}}, \theta_{4}\left(q_{1}\right)=\sum_{n \in \mathbb{Z}}(-1)^{n} q_{1}^{n^{2}} .
$$

Among many properties, one has

$$
\theta_{3}^{4}\left(q_{1}\right)=\theta_{4}^{4}\left(q_{1}\right)+\theta_{2}^{4}\left(q_{1}\right)
$$

The latter formula enables to concentrate on the evaluation of $\theta_{3,4}\left(q_{1}\right)$ as is done in [18].
Note also the following [18, Prop. 4]
Proposition 3.1.

$$
\lim _{\operatorname{Im}(\tau) \rightarrow+\infty} \theta_{3}(\tau)=1, \lim _{\operatorname{Im}(\tau) \rightarrow+\infty} \theta_{4}(\tau)=1, \lim _{\operatorname{Im}(\tau) \rightarrow+\infty} \theta_{2}(\tau)=0
$$

The quantities (see [23, §13.20])

$$
a=\theta_{2}\left(q_{1}\right), \quad b=\theta_{3}\left(q_{1}\right), \quad c=\theta_{4}\left(q_{1}\right)
$$

satisfy the following identities (among others)

$$
\begin{equation*}
E_{4}=\left(a^{8}+b^{8}+c^{8}\right) / 2, E_{6}=(a+b)(b+c)(c-a) / 2, \Delta=(a b c / 2)^{8} . \tag{12}
\end{equation*}
$$

From which we deduce

$$
\lim _{\operatorname{Im}(\tau) \rightarrow+\infty} E_{4}(\tau)=1, \lim _{\operatorname{Im}(\tau) \rightarrow+\infty} E_{6}(\tau)=1 .
$$

3.2. Fast evaluation of $E_{2 k}(q)$ for $k \geq 1$. The $\theta$ functions that can be evaluated at precision $N$ in time $O(\mathrm{M}(N) \sqrt{N})$ with $q_{1}$-expansions (see [22]) or faster in $O(\mathrm{M}(N) \log N)$ using [18] and also [31]. It follows that the quantities $E_{2 k}$ (for $k \geq 2$ ) can be evaluated at precision $N$ in $O(\mathrm{M}(N) \log N)$ operations. As a consequence $j(q)$ can also be evaluated with the same complexity. This is also the case for $\eta$; in practice the lacunary properties of powers of $\eta$ can also be used (see [42] and [15, Remark 2.1.27 with the indications therein]).

Evaluating $E_{2}$ is less obvious. However, hidden in the proof of [29, Thm 4] (thanks to [30] for highlighting this), we find

$$
\frac{E_{2} E_{4}}{E_{6}}=\frac{{ }_{2} F_{1}\left(\frac{13}{12}, \frac{5}{12} ; 1 ; \frac{1728}{j}\right)}{{ }_{2} F_{1}\left(\frac{1}{12}, \frac{5}{12} ; 1 ; \frac{1728}{j}\right)}=1+\frac{720}{j}+\cdots
$$

where the Gauss hypergeometric function is defined by

$$
{ }_{2} F_{1}(a, b ; c ; x)=\sum_{k=0}^{\infty} \frac{(a)_{k}(b)_{k}}{(c)_{k} k!} x^{k},|x|<1
$$

where $(a)_{k}=a(a+1) \cdots(a+k-1)$. By [45, 46, 32] and also [9], this function can be computed at precision $N$ in $O\left(\mathrm{M}(N)(\log N)^{2}\right)$ operations. See also [28] for realistic computations. Other links with hypergeometric functions could be investigated (A. Bostan, personal communication).

Also, note that evaluating $F_{\ell}$ for small prime $\ell$ can be done using the special formulas we mentioned above.
3.3. A multi-value approach. In practice, a simpler approach yields the values $E_{2 k}$ of many $k$ 's with $k \geq 1$ in time $O(\mathrm{M}(N) \sqrt{N})$ based on [22]. The cost reduces to that of one series evaluation.

From [5], we take

$$
(q ; q)_{\infty}=\exp (-2 i \pi \tau / 24) \eta(q)
$$

and for $k \geq 0$ :

$$
T_{2 k}(q)=1+\sum_{n=1}^{\infty}(-1)^{n}\left\{(6 n-1)^{2 k} q^{n(3 n-1) / 2}+(6 n+1)^{2 k} q^{n(3 n+1) / 2}\right\}
$$

Note that $(q ; q)_{\infty}=T_{0}(q)$.
Theorem 3.2 (Section 6, general formulas for $T_{2 k}(q) / T_{0}(q)$ are also given).

$$
\frac{T_{2}(q)}{T_{0}(q)}=E_{2}, \frac{T_{4}(q)}{T_{0}(q)}=3 E_{2}^{2}-2 E_{4}, \frac{T_{6}(q)}{T_{0}(q)}=15 E_{2}^{3}-30 E_{2} E_{4}+16 E_{6} .
$$

If we need to compute $E_{2}, E_{4}$ and $E_{6}$, we see that it is enough to evaluate the series $T_{2 k}$ for $k \in\{0,1,2,3\}$ followed by a handful of multiplications and divisions as given in the preceding Theorem. Moreover, we can evaluate these series by sharing the common powers of $q$. These powers are evaluated at a reduced cost using [22, Algorithm2]. We give the modified procedure as algorithm 5. In Step 3.2.3, we have added the contribution $(6 n \pm 1)^{2 i}$ to each T[i]. We assume that the cost of multiplying by these small quantities is negligible. Were it not the case, we could use incremental computations of the polynomials $(6 n \pm 1)^{2 i}$. The cost of this algorithm reduces to that of one of the series, gaining a factor $k \max$.

Algorithm 5 uses the primitive in Algorithm 6. The reason of Step 4 is that $T[k]$ will be close to 1 when $q$ is small, so that we may not want to add 1 right at the beginning and perhaps not in this function.
3.4. The case of imaginary arguments. In practice, it is easier to consider $\tau=\rho i$ for real $\rho \geq 1$. In that case, $1>q_{0}=\exp (-2 \pi)=0.001867 \ldots \geq q=\exp (-2 \pi \rho)>0$. The functions $E_{2}$ and $E_{6}$ are increasing from $E_{2 k}\left(q_{0}\right)$ to 1 (note that $E_{6}\left(q_{0}\right)=0$ and $E_{2}\left(q_{0}\right)=3 / \pi$ from [19]); $E_{4}$ is decreasing from $E_{4}\left(q_{0}\right)$ to 1 . This is important to note for the computations not to explode. Remember also that $j(i)=1728$.

We turn to the precision needed for evaluating the functions $T_{2 k}$. Let $N$ denote an integer and $T_{2 k, N}$ the truncated sum up to $n=N-1$. Since the series is alternating, we can bound the error using

$$
\begin{aligned}
\left|T_{2 k}(q)-T_{2 k, N}(q)\right| & \leq\left\{(6 N-1)^{2 k} q^{N(3 N-1) / 2}+(6 N+1)^{2 k} q^{N(3 N+1) / 2}\right\} \\
& \leq\left((6 N-1)^{2 k}+(6 N+1)^{2 k}\right) q^{N(3 N-1) / 2} .
\end{aligned}
$$

Since $0<q<1$, this gives us a very fast quadratic convergent series.

```
Algorithm 5: Combined evaluation of \(T_{2 k}(q)\).
    Function EvaluateManyT(q, N, kmax)
        Input : \(q, N\), kmax
        Output: \(\left(T_{2 k}(q)\right)\) for \(0 \leq k \leq k \max\)
        1. for \(k:=0\) to \(k \max\) do

        5. return \(T\).
```

Algorithm 6: Finding $c$ as a combination of known values.
Function FindPowerInTable $(A, Q, c)$
Input : $A=\left\{a_{1}, \ldots, a_{z}\right\}, Q$ such that for all $i, Q\left[a_{i}\right]=q^{a_{i}}, c$
Output: $q^{c} ; A$ and $Q$ are updated
if $c=1$ then
$q^{\prime} \leftarrow Q[1]$
else if $c=2 a$ with $a \in A$ then
$q^{\prime} \leftarrow Q[a]^{2}$
else if $c=a+b$ with $a, b \in A$ then
$q^{\prime} \leftarrow Q[a] \cdot Q[b] ;$
else if $c=2 a+b$ with $a, b \in A$ then
$q^{\prime} \leftarrow Q[a]^{2} \cdot Q[b]$
$A \leftarrow A \cup\{c\}$
$Q[c] \leftarrow q^{\prime}$
return $q^{\prime}$.

## 4. The polynomials of Fricke and Charlap/Coley/Robbins

4.1. The work of Elkies. An isogeny is associated with its kernel, or its polynomial description (called kernel polynomial). Given some finite subgroup $F$ of $\mathcal{E}$, one can build an isogenous curve
$\mathcal{E}^{*}$ and the corresponding isogeny, using Vélu's formulas. In the context of point counting, we discover a curve $\mathcal{E}^{*}$ that is $\ell$-isogenous to $\mathcal{E}$ via its $j$-invariant as a root of the traditional modular polynomial, and we need to find the coefficients of $\mathcal{E}^{*}$, together with the isogeny. The idea of Elkies is to consider the same problems on the Tate curves associated to the elliptic curves $\mathcal{E}$ and $\mathcal{E}^{*}$.

To be brief, $\mathcal{E}$ has an equation in some parameter $q$, and the isogenous $\mathcal{E}^{*}$ is associated to parameter $q^{\ell}$, where $\ell$ is the degree of the isogeny, which in our case is associated with a finite subgroup $F$ of cardinality $\ell$. To be more precise, we consider $\mathcal{E}$ has having equation $y^{2}=x^{3}+A x+B$ with

$$
\begin{equation*}
A=-3 E_{4}(q), B=-2 E_{6}(q) \tag{13}
\end{equation*}
$$

With a compatible scaling, we get the equation for $\mathcal{E}^{*}: y^{2}=x^{3}+A^{*} x+B^{*}$ with

$$
\begin{equation*}
A^{*}=-3 \ell^{4} E_{4}\left(q^{\ell}\right), B^{*}=-2 \ell^{6} E_{6}\left(q^{\ell}\right) \tag{14}
\end{equation*}
$$

More importantly, writing $\kappa_{r}$ for the power sums of the roots of the kernel polynomial, we have

$$
\begin{equation*}
\kappa_{1}=\frac{\ell}{2}\left(\ell E_{2}\left(q^{\ell}\right)-E_{2}(q)\right)=-\frac{\ell}{2} F_{\ell}(q) \tag{15}
\end{equation*}
$$

Beyond this, Elkies proved [20, formulas (66) to (69)]

## Proposition 4.1.

$$
\begin{gathered}
A-A^{*}=5\left(6 \kappa_{2}+2 A \kappa_{0}\right) \\
B-B^{*}=7\left(10 \kappa_{3}+6 A \kappa_{1}+4 B \kappa_{0}\right)
\end{gathered}
$$

together with an induction relation satisfied by other $\kappa_{k}$ for $k>3$.
This can rephrased as $\left(\kappa_{1}, A^{*}, B^{*}\right)$ is enough to describe an isogeny. Also $A^{*}$ and $B^{*}$ belong to $\mathbb{Q}\left[\kappa_{1}, A, B\right]$ since $\kappa_{2}$ and $\kappa_{3}$ do. The minimal polynomial of $2 \kappa_{1}$ is the modular polynomial associated to $F_{\ell}$, and we can express $A^{*}$ and $B^{*}$ as elements in the field $\mathbb{Q}\left[\kappa_{1}, A, B\right]$, which we use below. Rephrased another times, $E_{4}\left(q^{\ell}\right)$ and $E_{6}\left(q^{\ell}\right)$ are modular forms we need to express as expressions in known modular forms. See [20] for more details on this subject.

Given these quantities, there are several algorithms to get the isogeny. We refer to [8] for this.

### 4.2. The Fricke polynomials.

4.2.1. Reinterpreting Elkies's results. One way of looking at the work of Elkies (taken from [12], but which originated in [26]) is to realize that we try to decompose the $\ell$-th division polynomial $f_{\ell}$ (say $\ell$ is odd) of degree $\left(\ell^{2}-1\right) / 2$ over a subfield of degree $\ell+1$. In Fricke's term, we compute a degree $\ell+1$ resolvent for the equation $f_{\ell}(X)=0$.

4.2.2. Theory. We start from an elliptic curve $\mathcal{E}: y^{2}=x^{3}+A x+B$ and we fix some odd prime $\ell$, putting $d=(\ell-1) / 2$. Our aim is to find the equation of an $\ell$-isogenous curve $\mathcal{E}^{*}: y^{2}=x^{3}+A^{*} x+B^{*}$. The results for $U_{\ell}$ are due to Fricke, and Charlap/Coley/Robbins for $V_{\ell}$ and $W_{\ell}$.

Theorem 4.2. There exist three polynomials $U_{\ell}, V_{\ell}, W_{\ell}$ in $\mathbb{Z}[X, Y, Z, 1 / \ell]$ of degree $\ell+1$ in $X$ such that $U_{\ell}\left(2 \kappa_{1}, A, B\right)=0$, respectively $V_{\ell}\left(A^{*}, A, B\right)=0, W_{\ell}\left(B^{*}, A, B\right)=0$.

Let us turn our attention to the properties of these polynomials. Note that $U_{\ell}$ (resp. $V_{\ell}$ and $W_{\ell}$ ) is the minimal polynomial of a weight 2 form (resp. 4 and 6 ). We note $\varpi$ the corresponding weight.

Theorem 4.3. When $\ell>3$, the polynomials $U_{\ell}, V_{\ell}, W_{\ell}$ live in $\mathbb{Z}[X, Y, Z]$.
As a consequence of Theorem 2.13 , we have
Proposition 4.4. The polynomials $U_{\ell}, V_{\ell}$ and $W_{\ell}$ are homogeneous with weight $\varpi(\ell+1)$.
Proposition 4.5. Put $z^{\ell}=q=\exp (2 i \pi \tau)$ and $\zeta_{\ell}$ a root of unity. Then

1) The roots of $U_{\ell}(X, A(q), B(q))$ are $F_{\ell}\left(z \zeta_{\ell}^{h}\right)$ for $0 \leq h<\ell$, and $-\ell F_{\ell}(q)$.
2) The roots of $V_{\ell}\left(X, E_{4}(q), E_{6}(q)\right)$ (resp. $W_{\ell}$ ) are $E_{4}\left(z \zeta_{\ell}^{h}\right)\left(\right.$ resp. $\left.E_{6}\left(z \zeta_{\ell}^{h}\right)\right)$ for $0 \leq h<\ell$, and $\ell^{4} E_{4}\left(q^{\ell}\right)\left(\right.$ resp. $\left.\ell^{6} E_{6}\left(q^{\ell}\right)\right)$.

Part 1 is proven in Proposition 2.23; part 2 is done in Proposition 2.21. We can also use Proposition 2.19 to get

Proposition 4.6. The height of $U_{\ell}\left(\right.$ resp. $\left.V_{\ell}, W_{\ell}\right)$ is approximately $\varpi(\ell+1) \log \ell$.
4.2.3. Representing $A^{*}$ and $B^{*}$ as rational fractions. Once we have computed $U_{\ell}$, we can either compute $V_{\ell}$ and $W_{\ell}$ or use another representation. From [35, Theorem 3.9], there exist polynomials $\mathcal{A}_{\ell}$ and $\mathcal{B}_{\ell}$ of degree less than $\ell+1$ such that

$$
\begin{equation*}
A^{*}=\frac{\mathcal{A}_{\ell}(X, A, B)}{U_{\ell}^{\prime}(X)}, B^{*}=\frac{\mathcal{B}_{\ell}(X, A, B)}{U_{\ell}^{\prime}(X)} \tag{16}
\end{equation*}
$$

(Only here: $U_{\ell}^{\prime}(X)=\frac{\partial U_{\ell}}{\partial X}$.) Moreover, $\mathcal{A}_{\ell}$ and $\mathcal{B}_{\ell}$ are polynomials with integer coefficients and of respected generalized weight $2 \ell+4$ and $2 \ell+6$. These formulas are of independent interest and may prove useful in other contexts. The authors of the reference use Groebner basis computations to find the two numerators. We propose another route later on.
4.2.4. Computing isogenous curves over finite fields. When using $\left(U_{\ell}, V_{\ell}, W_{\ell}\right)$, we need to find the roots of three polynomials of degree $\ell+1$ instead of a single one in the traditional case. In general, if $U_{\ell}$ has rational roots (it should be 1,2 or $\ell+1$ ), then this is the case for each of $V_{\ell}, W_{\ell}$. For each triplet of solutions $\left(2 \kappa_{1}, z_{1}, z_{2}\right)$ we need to test whether this leads to an isogeny or not. See techniques for this task in [8]. Using the rational fractions for $A^{*}$ and $B^{*}$ is faster, just needing evaluations of rational fractions. A method based on using $U_{\ell}$ only is described in Section 6.

## 5. Computing Fricke polynomials

The authors of [12] give two methods of computation using manipulations of $q$-expansions of series over $\mathbb{Q}$. Following Atkin [1], these can be replaced by computations modulo small primes (preferably with convenient FFT multiplication) followed by recovery using the Chinese remaindering theorem using the bounds in Proposition 4.6. To this, we add two evaluation-interpolation algorithms already used for classical modular polynomials: the first is based on floating point calculations, the second on isogeny volcanoes.

The polynomials $U_{\ell}, V_{\ell}$ and $W_{\ell}$ are modular polynomials of modular forms, so that they obey Theorem 2.13. Also

$$
\begin{aligned}
& \mathcal{A}_{\ell}(X, Y, Z)=\sum_{r=0}^{\ell} X^{r} \sum_{2 i_{2}+3 i_{3}=\ell+2-r} a_{r, i_{2}, i_{3}} Y^{i_{2}} Z^{i_{3}}, \\
& \mathcal{B}_{\ell}(X, Y, Z)=\sum_{r=0}^{\ell} X^{r} \sum_{2 i_{2}+3 i_{3}=\ell+3-r} b_{r, i_{2}, i_{3}} Y^{i_{2}} Z^{i_{3}} .
\end{aligned}
$$

All the methods to be described can be applied to $U_{\ell}, V_{\ell}, W_{\ell}$, and also to $\mathcal{A}_{\ell}, \mathcal{B}_{\ell}$. To simplify the presentation, we assume from now on (unless indicated) that $\ell>3$ and concentrate on $U_{\ell}$, indicating what has to be changed for the other polynomials; in particular we assume we are looking for the modular polynomial of a form of weight $w$.

We rewrite

$$
U_{\ell}(X)=X^{\ell+1}+C_{1}\left(E_{4}, E_{6}, \Delta\right) X^{\ell}+\cdots+C_{\ell+1}\left(E_{4}, E_{6}, \Delta\right) .
$$

By Theorem 2.13, $C_{t}$ is a modular form for $\Gamma$ of weight $w t=2 t$; this implies $C_{1}=0$. By (10), $C_{2}=c_{2} E_{4}, C_{3}=c_{3} E_{6}, C_{4}=c_{4} E_{4}^{2}, C_{5}=c_{5} E_{4} E_{6}, C_{6}=c_{6,1} E_{4}^{3}+c_{6,0} \Delta$. For instance, the following methods will give us

$$
U_{5}(X)=X^{6}-60 E_{4} X^{4}-320 E_{6} X^{3}-720 E_{4}^{2} X^{2}-768 E_{4} E_{6} X-320 E_{4}^{3}+552960 \Delta .
$$

5.1. Using $q$-expansions. Note that

$$
2 \kappa_{1}(q)=-\ell F_{\ell}(q)=\ell(\ell-1)+24 \ell \sum_{n=1}^{\infty} \delta_{1}^{\prime}(n) q^{n}
$$

where $\delta_{1}^{\prime}(n)$ is the sum of the divisors of $n$ prime to $\ell$.
Using Proposition 4.5, we denote by $\sigma_{t}(q)$ the corresponding power sums of roots of $U_{\ell}$ :

$$
\sigma_{t}(q)=\left(-\ell F_{\ell}(q)\right)^{t}+\sum_{h=0}^{\ell-1} F_{\ell}\left(z \zeta_{\ell}^{h}\right)^{t}
$$

for $z^{\ell}=q$ and $1 \leq t \leq \ell+1$. We compute them and recover the coefficients of $U_{\ell}$ using Newton's formulas as explained in Section 2.5.

The power sums $\sigma_{t}(q)$ are modular forms of weight $w t$ and can be represented as polynomials in $E_{4}, E_{6}, \Delta$

$$
\sigma_{t}(q)=\sum_{j} c_{t, j} P_{w t, j}
$$

using Proposition 2.9 and Algorithm 3. This leads to a triangular linear system $\mathcal{S}_{t}$ in the $c_{t, j}$ 's. The system has $\approx(w t / 6)$ rows and can be solved with $O\left((w t)^{2}\right)$ operations over $\mathbb{Z}$, for a total of $O\left(\sum_{t}(w t)^{2}\right)=O\left(\ell^{3}\right)$. Once solved for all $t$ 's, we use Newton's identities to recover the coefficients of $U_{\ell}$.

To start the process, one needs to evaluate the series $\sigma_{t}(q)$ using intermediate expressions in $z=q^{1 / \ell}$ having roots of unity $\zeta_{\ell}$ temporarily appearing and vanishing. See [21, $\left.\S 2.2\right]$ for more details and complexity analysis. In particular, if we denote by $\mathrm{M}_{q}(d)$ the number of arithmetic operations in $\mathbb{Z}$ required to multiply two dense $q$-expansions with $d$ terms, then the total complexity of the series computations is $O\left(\ell \mathrm{M}_{q}(\ell d)\right)$, which is $O\left(\ell \mathrm{M}_{q}\left(\ell^{2}\right)\right)$ in our case. If $H$ is a bound on the height of the polynomial, then the bit complexity is $O\left(\ell^{3}(\log \ell) \mathrm{M}(H)\right)$. Assuming $H \in O(\ell \log \ell)$ by Proposition 4.6, this is $O\left(\ell^{4} \log ^{3+\epsilon} \ell\right)$.

Example. Consider the case $\ell=5$. The systems $\mathcal{S}_{t}$ to be solved come from the equations:

$$
\begin{aligned}
\sigma_{2}(q) & =c_{2,0} E_{4}, \\
\sigma_{3}(q) & =c_{3,0} E_{6}, \\
\sigma_{4}(q) & =c_{4,0} E_{4}^{2}, \\
\sigma_{5}(q) & =c_{5,0} E_{6} E_{4}, \\
\sigma_{6}(q) & =c_{6,0} E_{4}^{3}+c_{6,1} \Delta .
\end{aligned}
$$

We compute

$$
\sigma_{6}(q)=1000320+186071040 q+\cdots
$$

and we remember that $E_{4}(q)=1+240 q+\cdots, \Delta(q)=q+\cdots$ so that the system $\mathcal{S}_{6}$ is

$$
\left\{\begin{aligned}
1000320 & =c_{6,0} \\
186071040 & =720 c_{6,0}+c_{6,1}
\end{aligned}\right.
$$

which is triangular indeed and therefore easy to solve. Its solutions are integers.
We can also work modulo small primes and use the Chinese Remainder Theorem to recover the polynomials.
5.2. Floating point methods. We adapt the methods proposed for ordinary modular equations to our polynomials $\left(U_{\ell}, V_{\ell}, W_{\ell}\right)$. We note $H$ for the logarithmic height of the polynomials, that we have estimated to $\varpi(\ell+1) \log \ell$ in Proposition 4.6. All the methods are heuristic.
5.2.1. Solving a linear system. We start from $U_{\ell}\left(2 \kappa_{1}(q), E_{4}(q), E_{6}(q), \Delta(q)\right)=0$ and we compute floating point values to get a linear system in the coefficients that should come out as integers for $\ell>3$. We evaluate $\kappa_{1}(q), E_{4}(q)$ and $E_{6}(q)$ (and therefore $\Delta(q)$ at high precision for chosen values of (imaginary) $\tau$ in $q=\exp (2 i \pi \tau)$. This would involve $O\left(\ell^{2 \omega}\right)$ floating point operations, and we can do better in the following section.
5.2.2. Using power sums. The case of the traditional modular polynomial is treated in [21]. We can use the same approach for our polynomials. First of all, we need to compute

$$
-\ell F_{\ell}(q), \quad\left\{F_{\ell}\left(z \zeta_{\ell}^{h}\right), 0 \leq h<\ell\right\},
$$

where $z^{\ell}=q$ and $\zeta_{\ell}$ is a primitive $\ell$-th root of unity. By definition

$$
F_{\ell}(q)=E_{2}(q)-\ell E_{2}\left(q^{\ell}\right)
$$

and

$$
F_{\ell}\left(z \zeta_{\ell}^{h}\right)=E_{2}\left(z \zeta_{\ell}^{h}\right)-\ell E_{2}(q),
$$

and the last term is a constant w.r.t. $h$. We first evaluate $E_{2}(q), E_{2}\left(q^{\ell}\right)$ and then the other roots, by sharing the computations: All terms we need are of the form $\left(z \zeta_{\ell}^{h}\right)^{e}=z^{e} \zeta_{\ell}^{(h e) \bmod \ell}$. When $\ell \mid e$, the computation is a little faster. We give the corresponding code as Algorithm 7. We also precompute $\xi_{h}=\zeta_{\ell}^{h}$. The complete code is in Algorithm 8. Multiple evaluations of $\eta(k \tau)$ can be shared as explained in [22].

The system $\mathcal{S}_{t}$ has size $O\left(t^{2}\right)$ and we need $O\left(t^{\omega}\right)$ operations to solve it, for a total of $O\left(\ell^{\omega+1}\right)$. Like in the series case, anticipate integer coefficients, which makes recognition of the coefficients easier.
Example. Take again $\ell=5$, for which the $\mathcal{S}_{t}$ were already given. Let us concentrate on the case of $\sigma_{6}(q)=u_{6,0} E_{4}^{3}+u_{6,1} \Delta$; we start with $\mathcal{L}_{6}=\emptyset$. Using $\rho=1.1$ leads to

$$
\mathcal{L}_{6}=\left\{1.912407642 u_{6,0}+0.0009726854527956 u_{6,1}=1393450.57337539139\right\}
$$

and the following iteration with $\rho=1.2$ adds

$$
\left\{1.435895343 u_{6,0}+0.0005247501300701 u_{6,1}=1156054.63606077432\right\}
$$

```
Algorithm 7: Combined evaluation of \(T_{2 k}\left(z \zeta_{\ell}^{h}\right)\).
    Function EvaluateConjugateValues \((\ell, z, N,(\xi)\), kmax \()\)
        Input : \(\ell, z,(\xi), N\)
        Output: \(\left(T_{2 k}\left(z \zeta_{\ell}^{h}\right)\right)\) for \(0 \leq k \leq k \max , 0 \leq h<\ell\)
        1. for \(k:=0\) to \(k \max\) do
            for \(h:=0\) to \(\ell-1\) do
                \(T[k, h] \leftarrow 0\)
    2. \(s \leftarrow 1 ; A \leftarrow\{1\} ; Z[1] \leftarrow\{z\} ; c \leftarrow 0\)
    3. for \(n:=1\) while \(n(3 n+1) / 2 \leq N\) do
        \(s \leftarrow-s\)
        // \(s=(-1)^{n}\)
        \(3.1 c \leftarrow c+2 n-1\)
        3.2 for \(r:=1\) to 2 do
                3.2.1 if \(r=2\) then
                    \(c \leftarrow c+n\)
                    \(/ / c=n(3 n+1) / 2\)
                3.2.2 \(z^{\prime} \leftarrow s\) •FindPowerInTable \((A, Z, c)\)
                \(3.2 .3 C \leftarrow\left(6 n+(-1)^{r}\right)^{2}\)
                3.2.4 for \(k:=0\) to \(k \max\) do
                \(T[k, 0] \leftarrow T[k, 0]+z^{\prime}\)
                for \(h:=1\) to \(\ell-1\) do
                        \(T[k, h] \leftarrow T[k, h]+\xi[(h c) \bmod \ell] z^{\prime}\)
                if \(k<k \max\) then
                    \(z^{\prime} \leftarrow C \cdot z^{\prime}\)
    4. for \(k:=0\) to \(k \max\) do
        for \(h:=0\) to \(\ell-1\) do
                \(T[k, h] \leftarrow T[k, h]+1\)
    5. return \(T\).
```

and the solution of $\mathcal{L}_{6}$ (rounded to integers) is

$$
u_{6,1}=-534159360, u_{6,0}=1000320 .
$$

5.3. Isogeny volcanoes. The method in [13] shares many common points with the method to be described next but with a worse complexity. It uses supersingular curves whose complete explicit $\ell$-torsion is required. The work of [10] is a building block in [43] where direct evaluation of $\Phi_{\ell}(X, j(E)) \bmod q$ is made possible using an explicit version of the Chinese remainder theorem modulo small primes. Our version is an adaptation to the computation of the Fricke polynomials.
5.3.1. Quick presentation. In a nutshell, the algorithm in [10] performs computations modulo special primes $p$ satisfying arithmetical conditions: $p \equiv 1 \bmod \ell$ and $4 p=t^{2}-\ell^{2} v^{2} D$ in integers $t$ and $v, D$ not a multiple of $\ell ; D<0$ is the (fundamental) discriminant of some auxiliary quadratic field. With these conditions, the so-called class polynomial $H_{D}(z)$ splits completely modulo $p$ and its roots are $j$-invariants of elliptic curves with complex multiplication by the maximal order $\mathcal{O}_{D}$. The isogeny volcanoes that we can build have only one level (see Figure 2) and the corresponding

```
Algorithm 8: Computing Fricke polynomial using floating point numbers.
    Function ComputeUVW ( \(\ell, w)\)
        Input : \(w \in\{2,4,6\}\) corresponding to \(U_{\ell}, V_{\ell}\) or \(W_{\ell}\) respectively, \(\ell\) an odd prime
        Output: the corresponding Fricke polynomial
        \(0.0 H \leftarrow w(\ell+1) \log \ell\); all computations are carried out at precision \(H\)
        0.1 compute \(\zeta_{\ell} \leftarrow \exp (2 i \pi / \ell)\)
        0.2 for \(h:=0\) to \(\ell-1\) do
        \(\xi_{h} \leftarrow \zeta_{\ell}^{h}\)
        0.3 Compute all systems \(\mathcal{S}_{t}\) for \(2 \leq t \leq \ell+1\)
        0.4 for \(t:=2\) to \(\ell+1\) do
            \(\mathcal{L}_{t} \leftarrow \emptyset\)
        \(0.5 \rho \leftarrow 1\)
        1. while there is a system \(\mathcal{L}_{t}\) that is not solved do
            \(1.0 \rho \leftarrow \rho+0.1\)
            \(1.1 z \leftarrow \exp (-2 \pi \rho / \ell) ; q_{\rho} \leftarrow z^{\ell}\)
            \(1.2 T \leftarrow\) EvaluateConjugateValues \(\left(\ell, z, N,\left(\xi_{h}\right), s\right)\)
            1.3. use Theorem 3.2 to evaluate \(E_{2 k}\) for all \(q_{i}\) 's from \(T\), yielding \(\left(\kappa\left(q_{i}\right)\right)\) for
            \(i=0, \ldots, \ell+1\); also deduce \(E_{4, \rho}=E_{4}\left(q_{\rho}\right), E_{6, \rho}=E_{6}\left(q_{\rho}\right), \Delta_{\rho}=\left(E_{4, \rho}^{3}-E_{6, \rho}^{2}\right) / 1728\)
            1.4 for \(r:=t\) to \(\ell+1\) do
                if \(\mathcal{L}_{t}\) is not solved then
                1.4.1 Instantiate \(\mathcal{S}_{t}\) with \(\sum_{i} \kappa_{1}\left(q_{i}\right)^{t}, E_{4, \rho}, E_{6, \rho}, \Delta_{\rho}\); add it to \(\mathcal{L}_{t}\)
                1.4.2 if \(\mathcal{L}_{t}\) has as many equations as unknowns then
                solve \(\mathcal{L}_{t}\) and store the values; declare \(\mathcal{L}_{t}\) solved
        2. Round the coefficients and use Newton's formulas.
```

$j$-invariants are the roots of $H_{\ell^{2} D}(X)$. Basically, the algorithm interpolates data using the isogenies attached to the volcanoes. We refer the reader to the original article for more properties related to elliptic curves. For our purpose, we just need to know that we have isogeny data available and that they can help us computing the polynomial $U_{\ell}\left(X, E_{4}, E_{6}, \Delta\right) \bmod p$ from these data. We refer to the article for the complexity under GRH, namely $O\left(\ell^{3}(\log \ell)^{3} \log \log \ell\right)$ using $O\left(\ell^{2} \log (\ell p)\right)$ space for suitably chosen $p$.

Figure 2. A typical set of volcanoes.
We adapt a slight modification of the simplified version Algorithm 2.1 of [10] to our needs to give Algorithm 9. All we describe is also valid in the full version in [10].
5.3.2. The algorithm for $U_{\ell}$. We denote by $\mathcal{P}_{r}$ the power sums of $U_{\ell}$. Such a $\mathcal{P}_{r}$ is a modular form of weight $w r$ for $\Gamma$. As explained in Section 2.4, we may write these power sums as

$$
\mathcal{P}_{r}\left(E_{4}, E_{6}, \Delta\right)=\sum_{j_{r}=0}^{m_{r}} c_{r, j_{r}} P_{w r, j}
$$

Algorithm 9: The core algorithm.
Function PartialVolcano( $\left(, D, H_{D}(X), p\right)$ Input : $\ell$ an odd prime, $D$ the discriminant of an imaginary quadratic order $\mathcal{O}$ with class number $h(D) \geq \ell+2 ; H_{D}$ the class polynomial associated to the order $\mathcal{O} ; p$ prime with $p \equiv 1 \bmod \ell$ and $4 p=t^{2}-\ell^{2} v^{2} D, v \not \equiv 0 \bmod \ell$ Output: A collection $\left(\mathcal{E}_{i},\left\{Q_{i k}, \mathcal{E}_{i k}^{\prime}\right\}_{1 \leq k \leq \ell+1}\right)_{1 \leq i \leq h}$ where $\mathcal{E}_{i k}^{\prime}=\mathcal{E}_{i} /\left\langle Q_{i k}\right\rangle$ 1. Build the list $\mathcal{J}_{D}$ containing the roots of $H_{D}(z)$ modulo $p$ 2. for $j_{i} \in \mathcal{J}_{D}$ do
2.1 find a curve $\mathcal{E}_{i}: y^{2}=x^{3}+A_{i} x+B_{i}$ having invariant $j_{i}$ and cardinality $m=p+1-t ;$
2.2 find all the neighbors $\mathcal{N}\left(\mathcal{E}_{i}\right)$ in the volcano of $\mathcal{E}_{i}$ : 2 horizontal isogenies and $\ell-1$ on the floor. Let $\mathcal{K}$ be a set to contain invariants and initialized to $\emptyset$.
while we do not have all isogenies of both kinds do
2.2.1 Select a random point $Q_{i k}$ of order $\ell$ on $\mathcal{E}_{i} / \mathbb{F}_{p}=\left[A_{i}, B_{i}\right]$.
2.2.2 Compute the rational isogeny $\mathcal{E}_{i} \rightarrow \mathcal{E}_{i k}^{\prime}=\mathcal{E}_{i} /\left\langle Q_{i k}\right\rangle$ using Vélu's formulas.

The result is a pair $\left(Q_{i k}, \mathcal{E}_{i k}^{\prime}\right)$.
2.2.3 if $j\left(\mathcal{E}_{i k}^{\prime}\right) \notin \mathcal{K}$ then
$\mathcal{K} \leftarrow \mathcal{K} \cup\left\{j\left(\mathcal{E}_{i k}^{\prime}\right)\right\}$
if $j\left(\mathcal{E}_{i k}^{\prime}\right)$ is a root of $H_{D}$, then $\mathcal{E}_{i k}^{\prime}$ is on the crater and is one of the two neighbours. If it does not belong to the crater, it belongs to the floor. Store the pair $\left(Q_{i k}, \mathcal{E}_{i k}^{\prime}\right)$.

Store $\mathcal{E}_{i},\left\{Q_{i k}, \mathcal{E}_{i k}^{\prime}\right\}_{1 \leq k \leq \ell+1}$ 3. return $\left(\mathcal{E}_{i},\left\{Q_{i k}, \mathcal{E}_{i k}^{\prime}\right\}_{1 \leq k \leq \ell+1}\right)_{1 \leq i \leq h}$.

The values of $P_{w r, j}$ and the sums will be reconstructed from values $\kappa_{1, i}$ associated to curves $\mathcal{E}_{i}$ : $y^{2}=x^{3}+A_{i} x+B_{i}$.

Note that for each $i$, the kernel polynomial of the isogeny from $\mathcal{E}_{i}$ to $\mathcal{E}_{i k}^{\prime}$ starts $X^{(\ell-1) / 2}-$ $\kappa_{1, i} X^{(\ell-3) / 2}+\cdots$, so that

$$
U_{\ell}\left(X, E_{4, i}, E_{6, i}, \Delta_{i}\right)=\prod_{i=1}^{\ell+1}\left(X-\kappa_{1, i}\right) .
$$

Given these roots, it is easy to compute the power sums, see Algorithm 10. Trading multiplications for additions, Step 2 costs $O\left(\ell^{2}\right)$ operations over $\mathbb{F}_{p}$.

For $V_{\ell}$ (resp. $W_{\ell}$ ), replace $\kappa_{1}$ by $A^{*}\left(\right.$ resp. $\left.B^{*}\right)$ in Step 4 as far as reconstruction is concerned.

A numerical example: Let us give one value for $\ell=5$. We select $D=-71$ for which $h(-71)=$ $7 \geq 5+2$. Consider $p=1811$. The roots of $H_{-71}(z)$ modulo $p$ are:

$$
\mathcal{J}_{D}=\{313,1073,1288,1312,1402,1767,1808\} .
$$

```
Algorithm 10: Computing \(U_{\ell}(X, Y, Z) \bmod p\).
```

    Function ComputeUMod \(\left(\ell, D, H_{D}(z), p\right)\) :
        Input : \(\ell\) an odd prime, \(D\) the discriminant of an imaginary quadratic order \(\mathcal{O}\) of
                discriminant \(D\) with class number \(h(D) \geq \ell+2 ; H_{D}\) is the class polynomial
                    associated to order \(\mathcal{O} ; p\) prime with \(p \equiv 1 \bmod \ell\) and \(4 p=t^{2}-\ell^{2} v^{2} D\),
                    \(v \not \equiv 0 \bmod \ell\)
        Output: \(U_{\ell}(X, Y, Z) \bmod p\)
        1. \(\left(\mathcal{E}_{i},\left\{Q_{i k}, \mathcal{E}_{i k}^{\prime}\right\}_{1 \leq k \leq \ell+1}\right)_{1 \leq i \leq h} \leftarrow\) PartialVolcano \(\left(\ell, D, H_{D}(X), p\right)\)
        2. Evaluate the quantities \(P_{w t, j}\) in the \(\left\{\mathcal{E}_{i k}^{\prime}\right\}\) using Algorithm 3
        3. for \(i \leftarrow 1\) to \(\ell+1\) do
            for \(t \leftarrow 1\) to \(\ell+1\) do
                \(\sigma_{t, i} \leftarrow(1 / 2) \sum_{k=1}^{\ell-1} x\left(Q_{i k}\right)^{t}\)
        4. for \(t \leftarrow 1\) to \(\ell+1\) do
            solve the linear system
    $$
\sigma_{t, i}=\sum_{j=0}^{m_{t}} c_{t, j} P_{t, j} .
$$

5. return $U_{\ell}$ recovered from $c_{t, j_{t}}$ 's using Newton's formulas.

Associated are curves and neighbors for each $j$ value. These can be found in Table 1. The power sums $\mathcal{P}_{r}$ corresponding to the values are:

| $\mathcal{E}_{i} \backslash r$ | 1 | 2 | 3 | 4 | 5 | 6 |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| $[1582,902]$ | 0 | 105 | 1680 | 1379 | 756 | 772 |
| $[1662,405]$ | 0 | 527 | 1188 | 90 | 748 | 888 |
| $[1451,1331]$ | 0 | 1723 | 403 | 350 | 293 | 583 |
| $[1013,747]$ | 0 | 1133 | 18 | 1594 | 1738 | 105 |
| $[224,753]$ | 0 | 95 | 760 | 1790 | 1603 | 27 |
| $[1128,1504]$ | 0 | 155 | 669 | 1424 | 1130 | 522 |
| $[91,725]$ | 0 | 1793 | 1523 | 589 | 1233 | 134 |

For instance, $\sigma_{6}=c_{6,0} E_{4}^{3}+c_{6,1} \Delta$, we need to solve

$$
\left\{\begin{aligned}
& 772=c_{6,0} 680^{3}+c_{6,1} 1067 \bmod 1811, \\
& 888= \\
& c_{6,0} 1257^{3}+c_{6,1} 874 \bmod 1811, \\
& 583= \\
& c_{6,0} 120^{3}+c_{6,1} 363 \bmod 1811, \\
& \cdots \cdots
\end{aligned}\right.
$$

that is $648 E_{4}^{3}+523 \Delta$. The coefficients are:

$$
\begin{aligned}
\sigma_{2} & =120 E_{4} \\
\sigma_{3} & =960 E_{6} \\
\sigma_{4} & =1025 E_{4}^{2} \\
\sigma_{5} & =235 E_{6} E_{4} \\
\sigma_{6} & =648 E_{4}^{3}+523 \Delta
\end{aligned}
$$

5.3.3. Computing $\mathcal{A}_{\ell}$ and $\mathcal{B}_{\ell}$. In this section, we use $A$ and $B$ instead of $\left(E_{4}, E_{6}, \Delta\right)$ for ease of presentation. Once $U_{\ell}$ is available, we can use equation (16) in which we plug the series to get

$$
\begin{equation*}
-3 \ell^{4} E_{4}\left(q^{\ell}\right) \cdot U_{\ell}^{\prime}\left(\sigma_{1}(q), A(q), B(q)\right)=\mathcal{A}_{\ell}\left(\sigma_{1}(q), A(q), B(q)\right) \tag{17}
\end{equation*}
$$

Similarly, we would use

$$
-2 \ell^{6} E_{6}\left(q^{\ell}\right) \cdot U_{\ell}^{\prime}\left(\sigma_{1}(q), A(q), B(q)\right)=\mathcal{B}_{\ell}\left(\sigma_{1}(q), A(q), B(q)\right)
$$

to compute $\mathcal{B}_{\ell}$.
We find the coefficients by solving a linear system (over $\mathbb{Q}$ or using small primes as already described). We can precompute the powers of the series for $\sigma_{1}, A$ and $B$ and remark that $U_{\ell}$ and $\mathcal{A}_{\ell}$ share a lot of them. Also, the series $E_{4}\left(q^{\ell}\right)$ is rather sparse, so that the product with this quantity is fast. There is an advantage to compute $\mathcal{A}_{\ell}$ and $\mathcal{B}_{\ell}$ at the same time, sharing as many powers as possible.

Let us turn our attention towards the computations of $\mathcal{A}_{\ell}$ (resp. $\mathcal{B}_{\ell}$ ) using evaluation/interpolation methods. There is nothing special about using floating point numbers, except that the system we have to solve has size $O\left(\ell^{2} \times \ell^{2}\right)$ leading to a $O\left(\ell^{2 \omega}\right)$ time algorithm.

Some care must be taken when using the isogeny approach. To exemplify the problem, consider the case $\ell=11$ (similar problems do not occur for smaller $\ell$ 's). The polynomial $\mathcal{A}_{11}$ reads:

$$
\mathcal{A}_{11}=a_{1,1,0}\left(X^{11} A\right)++\cdots+X\left(a_{11,6,0} A^{6}+a_{11,3,2} A^{3} B^{2}+a_{11,0,4} B^{4}\right)+\left(a_{12,5,1} A^{5} B+a_{12,2,3} A^{2} B^{3}\right) .
$$

To find them, we use a $20 \times 20$ system whose rightmost columns are

$$
M=\left(\begin{array}{cccccc}
\cdots & \kappa_{1,1} A_{1}^{6} & \kappa_{1,1} A_{1}^{3} B_{1}^{2} & \kappa_{1,1} B_{1}^{4} & A_{1}^{5} B_{1} & A_{1}^{2} B_{1}^{3} \\
\cdots & \kappa_{1,12} A_{1}^{6} & \kappa_{1,12} A_{1}^{3} B_{1}^{2} & \kappa_{1,12} B_{1}^{4} & A_{1}^{5} B_{1} & A_{1}^{2} B_{1}^{3} \\
\cdots & \kappa_{1,13} A_{2}^{6} & \kappa_{1,13} A_{2}^{3} B_{2}^{2} & \kappa_{1,13} B_{2}^{4} & A_{2}^{5} B_{2} & A_{2}^{2} B_{2}^{3} \\
\cdots & \kappa_{1,20} A_{2}^{6} & \kappa_{1,20} A_{2}^{3} B_{2}^{2} & \kappa_{1,20} B_{2}^{4} & A_{2}^{5} B_{2} & A_{2}^{2} B_{2}^{3}
\end{array}\right)
$$

The first 12 rows $(12=\ell+1)$ are the $\ell+1$ curves isogenous to $\left[A_{1}, B_{1}\right]$. The remaining 8 are taken from the $\ell+1$ curves isogenous to $\left[A_{2}, B_{2}\right]$. Consider the product

$$
M \times\left(\begin{array}{c}
0 \\
0 \\
\cdots \\
0 \\
1 \\
u \\
v \\
0 \\
0
\end{array}\right)=\left(\begin{array}{c}
\kappa_{1,1}\left(A_{1}^{6}+u A_{1}^{3} B_{1}^{2}+v B_{1}^{4}\right) \\
\cdots \\
\kappa_{1,12}\left(A_{1}^{6}+u A_{1}^{3} B_{1}^{2}+v B_{1}^{4}\right) \\
\kappa_{1,13}\left(A_{2}^{6}+u A_{2}^{3} B_{2}^{2}+v B_{2}^{4}\right) \\
\cdots \\
\kappa_{1,20}\left(A_{2}^{6}+u A_{2}^{3} B_{2}^{2}+v B_{2}^{4}\right)
\end{array}\right) .
$$

Given the $A_{i}$ 's and $B_{i}$ 's, we can solve for $u$ and $v$, yielding a non-zero vector in the kernel of $M$, showing the system is under-determined.

Fortunately, we can circumvent this problem using the dual equations

$$
\begin{equation*}
U_{\ell}^{\prime}\left(-\ell \kappa_{1}, A^{*}, B^{*}\right)\left(\ell^{4} A\right)=\mathcal{A}_{\ell}\left(-\ell \kappa_{1}, A^{*}, B^{*}\right), \quad U_{\ell}^{\prime}\left(-\ell \kappa_{1}, A^{*}, B^{*}\right)\left(\ell^{6} B\right)=\mathcal{B}_{\ell}\left(-\ell \kappa_{1}, A^{*}, B^{*}\right) \tag{18}
\end{equation*}
$$

in Algorithm 11.
Note that the system is $O\left(\ell^{2}\right) \times O\left(\ell^{2}\right)$, leading to a $O\left(\ell^{2 \omega}\right)$ time complexity. Adapting this to the case of $\mathcal{B}_{\ell}$ is straightforward.

```
Algorithm 11: Computing \(\mathcal{A}_{\ell}(X, Y, Z) \bmod p\).
    Function ComputeAMod \(\left(\ell, D, H_{D}(z), p\right)\) :
        Input : \(\ell\) an odd prime, \(D\) the discriminant of an imaginary quadratic order \(\mathcal{O}\) of
                        discriminant \(D\) with class number \(h(D) \geq \ell+2 ; H_{D}\) is the class polynomial
                    associated to order \(\mathcal{O} ; p\) prime with \(p \equiv 1 \bmod \ell\) and \(4 p=t^{2}-\ell^{2} v^{2} D\),
                        \(v \not \equiv 0 \bmod \ell\)
        Output: \(\mathcal{A}_{\ell}(X, Y, Z) \bmod p\)
        1. \(\left(\mathcal{E}_{i},\left\{P_{i k}, \mathcal{E}_{i k}^{\prime}\right\}_{1 \leq k \leq \ell+1}\right)_{1 \leq i \leq h} \leftarrow\) PartialVolcano \(\left(\ell, D, H_{D}(X), p\right)\)
        2. Inject the values ( \(\kappa_{1, i}, A_{i k}^{\prime}, B_{i k}^{\prime}\) ) in equation (18) to get a linear system with enough
        rows
        3. Solve the relevant linear system
        4. return \(\mathcal{A}_{\ell}\).
```

## 6. Computing the isogenous curve à la Atkin

The idea is to generalize the approach in [1, 2, 33], that is exploit $q$-series identities to get the parameters $\left(\kappa, A^{*}, B^{*}\right)$, where we write $\kappa$ for $\kappa_{1}$ from now on. As a matter of fact, we need relations involving $\tilde{E}_{2 k}=E_{2 k}\left(q^{\ell}\right)$, from which all other quantities follows: $A^{*}=-3 \ell^{4} \tilde{E}_{4}, B^{*}=-2 \ell^{6} \tilde{E}_{6}$.
6.1. Properties of $U_{\ell}$. We write for readability $U\left(\kappa, E_{4}, E_{6}\right)=U_{\ell}\left(X, E_{4}, E_{6}, \Delta\right)$ after replacing $\Delta$ by its expression and

$$
\partial_{\kappa}=\frac{\partial U}{\partial \kappa}, \partial_{4}=\frac{\partial U}{\partial E_{4}}, \partial_{6}=\frac{\partial U}{\partial E_{6}} .
$$

and propagate the notation to double derivatives.
The polynomial $U$ is homogeneous with weights, so that

$$
\begin{equation*}
(\ell+1) U=\kappa \partial_{\kappa}+2 E_{4} \partial_{4}+3 E_{6} \partial_{6} . \tag{19}
\end{equation*}
$$

Note that partial derivatives of $U$ are also homogeneous polynomials and we find

$$
\begin{align*}
\ell \partial_{\kappa} & =\kappa \partial_{\kappa \kappa}+2 E_{4} \partial_{\kappa 4}+3 E_{6} \partial_{\kappa 6},  \tag{20}\\
(\ell-1) \partial_{4} & =\kappa \partial_{\kappa 4}+2 E_{4} \partial_{44}+3 E_{6} \partial_{46},  \tag{21}\\
(\ell-2) \partial_{6} & =\kappa \partial_{\kappa 6}+2 E_{4} \partial_{46}+3 E_{6} \partial_{66} . \tag{22}
\end{align*}
$$

### 6.2. Getting the isogenous curve from $U_{\ell}$.

### 6.2.1. Finding $\tilde{E}_{4}$.

Proposition 6.1. The value of $\tilde{E}_{4}$ is given by

$$
-\frac{4 \ell\left(3 E_{4}^{2} \partial_{6}+2 E_{6} \partial_{4}\right)-\partial_{\kappa}\left(\ell^{2} E_{4}+4 \kappa^{2}\right)}{\ell^{4} \partial_{\kappa}} .
$$

Proof: We differentiate (using (6)) $U\left(\kappa, E_{4}, E_{6}\right)=0$ to get

$$
\begin{equation*}
\kappa^{\prime} \partial_{\kappa}+E_{4}^{\prime} \partial_{4}+E_{6}^{\prime} \partial_{6}=0 \tag{23}
\end{equation*}
$$

We differentiate (15) leading to

$$
\kappa^{\prime}=\frac{\ell}{2}\left(\ell^{2} \tilde{E}_{2}^{\prime}-E_{2}^{\prime}\right)=\frac{\ell}{24}\left(\ell^{2}\left(\tilde{E}_{2}^{2}-\tilde{E}_{4}\right)-\left(E_{2}^{2}-E_{4}\right)\right) .
$$

Use (15) to replace $\ell \tilde{E}_{2}$ by $2 \kappa / \ell+E_{2}$ to get

$$
\kappa^{\prime}=\frac{\ell}{24}\left(\frac{4 \kappa^{2}}{\ell^{2}}+\frac{4 \kappa}{\ell} E_{2}-\left(\ell^{2} \tilde{E}_{4}-E_{4}\right)\right)
$$

that we plug in (23) together with the expressions for $E_{4}{ }^{\prime}$ and $E_{6}{ }^{\prime}$ from equation (9) to get a polynomial of degree 1 in $E_{2}$ whose coefficient of $E_{2}$ is

$$
\kappa \partial_{\kappa}+2 E_{4} \partial_{4}+3 E_{6} \partial_{6}
$$

which we recognize in (19). Therefore, we get

$$
\begin{equation*}
(\ell+1) U E_{2}+\frac{\ell \partial_{\kappa}}{4}\left(\frac{4 \kappa^{2}}{\ell^{2}}-\left(\ell^{2} \tilde{E}_{4}-E_{4}\right)\right)-2 E_{6} \partial_{4}-3 E_{4}^{2} \partial_{6}=0 \tag{24}
\end{equation*}
$$

from which we deduce $\tilde{E}_{4}$ since $U\left(\kappa, E_{4}, E_{6}\right)=0$.

### 6.2.2. Finding $\tilde{E}_{6}$.

Proposition 6.2. The value of $\tilde{E}_{6}$ may be written

$$
\tilde{E}_{6}=-\frac{N}{\ell^{6} \partial_{\kappa}^{3}}
$$

where $N$ is some polynomial of degree 3 in $\ell$ and given at the end of the proof.
Proof: We differentiate (23).

$$
\begin{align*}
& \kappa^{\prime \prime} \partial_{\kappa}+\kappa^{\prime}\left(\kappa^{\prime} \partial_{\kappa \kappa}+E_{4}^{\prime} \partial_{\kappa 4}+E_{6}^{\prime} \partial_{\kappa 6}\right)  \tag{25}\\
+ & E_{4}^{\prime \prime} \partial_{4}+E_{4}^{\prime}\left(\kappa^{\prime} \partial_{4 \kappa}+E_{4}^{\prime} \partial_{44}+E_{6}^{\prime} \partial_{46}\right)  \tag{26}\\
+ & E_{6}^{\prime \prime} \partial_{6}+E_{6}^{\prime}\left(\kappa^{\prime} \partial_{6 \kappa}+E_{4}^{\prime} \partial_{64}+E_{6}^{\prime} \partial_{66}\right)=0 \tag{27}
\end{align*}
$$

We compute in sequence

$$
\begin{aligned}
& 12 E_{2}^{\prime \prime}=2 E_{2} E_{2}^{\prime}-E_{4}^{\prime}=E_{2}\left(E_{2}^{2}-E_{4}\right) / 6-\left(E_{2} E_{4}-E_{6}\right) / 3, \\
& 12 \tilde{E}_{2}^{\prime \prime}=2 \tilde{E}_{2} \tilde{E}_{2}^{\prime}-\tilde{E}_{4}^{\prime}=\tilde{E}_{2}\left(\tilde{E}_{2}^{2}-\tilde{E}_{4}\right) / 6-\left(\tilde{E}_{2} \tilde{E}_{4}-\tilde{E}_{6}\right) / 3,
\end{aligned}
$$

which give us the value

$$
\kappa^{\prime \prime}=\frac{\ell}{2}\left(\ell^{3} \tilde{E}_{2}^{\prime \prime}-E_{2}^{\prime \prime}\right)
$$

to be used in (25). Differentiating relations of (9), we get

$$
E_{4}^{\prime \prime}=\frac{1}{3}\left(E_{2}^{\prime} E_{4}+E_{2} E_{4}^{\prime}-E_{6}^{\prime}\right), \quad E_{6}^{\prime \prime}=\frac{1}{2}\left(E_{2}^{\prime} E_{6}+E_{2} E_{6}^{\prime}-2 E_{4} E_{4}^{\prime}\right),
$$

to be used in lines (26) and (27) respectively. We replace $\tilde{E}_{4}$ by its value from (24), and $\tilde{E}_{2}$ using $\kappa=(\ell / 2)\left(\ell \tilde{E}_{2}-E_{2}\right)$. This finally yields an expression as polynomial in $E_{2}$ :

$$
C_{2} E_{2}^{2}+C_{1} E_{2}+C_{0}=0
$$

The unknown $\tilde{E}_{6}$ is to be found in $C_{0}$ only.
By luck(?)
Proposition 6.3. The coefficients $C_{1}$ and $C_{2}$ vanish for a triplet such that $U_{\ell}\left(\kappa, E_{4}, E_{6}\right)=0$.
Sketch of the proof: The strategy to prove this is the same in both cases. Replace $\partial_{\kappa \kappa}, \partial_{44}$ and $\partial_{66}$ by their values from (20). Factoring the resulting expressions yields the same factor $\kappa \partial_{\kappa}+2 E_{4} \partial_{4}+$ $3 E_{6} \partial_{6}$, which cancels $C_{1}$ and $C_{2}$. We add a SageMath script for the convenience of the reader as an appendix to this work.

We are left with

$$
\tilde{E}_{6}=-\frac{N}{\ell^{6} \partial_{\kappa}^{3}}
$$

where $N$ is a polynomial in degree 3 in $\ell$

$$
N=-E_{6} \partial_{\kappa}^{3} \ell^{3}+c_{2} \ell^{2}+\underset{26}{12 \partial_{\kappa}^{2} \kappa\left(3 E_{4}^{2} \partial_{6}+2 E_{6} \partial_{4}\right) \ell-\partial_{\kappa}^{3} \kappa^{3} . . . . ~}
$$

The coefficient $c_{2}$ is heavy looking and we give slightly factored as a polynomial in $E_{4}$ :

$$
\begin{aligned}
& c_{2}= 18\left(\partial_{6}^{2} \partial_{\kappa \kappa}-2 \partial_{6} \partial_{\kappa} \partial_{\kappa 6}+\partial_{66} \partial_{\kappa}^{2}\right) E_{4}^{4} \\
&+\left(24 E_{6} \partial_{4}\left(\partial_{6} \partial_{\kappa \kappa}-\partial_{\kappa} \partial_{\kappa 6}\right)+24 E_{6} \partial_{\kappa}\left(\partial_{46} \partial_{\kappa}-\partial_{6} \partial_{\kappa 4}\right)+10 \partial_{4} \partial_{\kappa}^{2}\right) E_{4}^{2} \\
&+3 \partial_{\kappa}^{2}\left(7 E_{6} \partial_{6}-\kappa \partial_{\kappa}\right) E_{4}+8 E_{6}^{2}\left(\partial_{4}^{2} \partial_{\kappa \kappa}-2 \partial_{4} \partial_{\kappa} \partial_{\kappa 4}+\partial_{44} \partial_{\kappa}^{2}\right) . \\
& \square
\end{aligned}
$$

6.2.3. Numerical example. Consider $E: Y^{2}=X^{3}+X+3$ over $\mathbb{F}_{1009}$ and $\ell=5$. Using

$$
U_{5}(X)=X^{6}+20 X^{4} A+160 X^{3} B-80 X^{2} A^{2}-128 X A B-80 B^{2},
$$

we select $\kappa=584$ and compute

$$
\partial_{\kappa}=905, \partial_{4}=779, \partial_{6}=140
$$

from which $\tilde{E}_{4}=497, A^{*}=441$. After tedious computations, we find $B^{*}=997$.

## 7. Implementation and numerical results

A lot of trials were done using Maple programs, some of which were then rewritten in Magma (version 2.26-10), for speed. See the author's web page. Computing the polynomials for $\ell \leq 100$ takes a few minutes on a classical laptop. Checking them is done using SEA, as mentioned in [35].

We give some examples of the relative height $\tilde{H}$ for some of our polynomials. Here $\tilde{H}(P)=$ $H(P) /((\ell+1) \log \ell)$. Note that these quantities seem to stabilize when $\ell$ increases and are in accordance with Proposition 4.6.

|  |  |  |  |  |
| ---: | ---: | ---: | ---: | :---: |

Data are computed using the polynomials available in MAGMA: $\Phi_{\ell}^{c}$ is called canonical polynomial and $\Phi_{\ell}^{*}$ is called Atkin polynomial. In the case of $\Phi_{\ell}^{c}$, the height depends on $\ell \bmod 12$. Still, Atkin's minimal functions remain the best choice for large $\ell$ 's.

## 8. Conclusions

We have given several methods for computing the Fricke and Charlap-Coley-Robbins polynomials, and manage to adapt known algorithms for this task. We also included representations as fractions in polynomials. In some cases, $U_{\ell}$ has smaller height, at long as $\ell$ is small.

In isogeny cryptography they are useful for relatively small $\ell$ 's, if we store ( $U_{\ell}, \mathcal{A}_{\ell}, \mathcal{B}_{\ell}$ ). If one wants to compute an isogeny, it is enough to compute a root of $U_{\ell}$ followed by instantiations of three polynomials.

Also, we insisted on families of modular forms. Some of the techniques can be used for ad hoc forms.

In a follow up work [34], we look at modular polynomials for cuspidal $\eta$-products, as already described by Fricke, one of which was recommanded by Atkin to replace the $U_{\ell}$ polynomial when $\ell \equiv 11 \bmod 12$.

Acknowledgments. The author wishes to thank A. Bostan and F. Chyzak for helpful discussions around some aspects of this work; special thanks to the former for his impressive list of references for the fast evaluation of hypergeometric functions. Thanks also to L. De Feo for his updates on cryptographic applications of isogenies.

## Appendix B. Some values of Fricke/CCR polynomials

B.1. Prime indices. Note there is a sign flip compared to [35]: They use $B=3 E_{6}$, whereas we use $B=-3 E_{6}$ which is coherent with Atkin's work, say.

For $\ell=2, U_{2}(X)=X^{3}+A X+B$ itself, which is the minimal polynomial of any of the 2-torsion points. For $\ell=3$, we compute

$$
\begin{aligned}
W_{3}\left(X, E_{4}, E_{6}, \Delta\right)= & X^{4}+1464 E_{6} X^{3}+\left(8760 E_{4}^{3}-1185643008 \Delta\right) X^{2}+\left(17504 E_{4}^{3}-152195991552 \Delta\right) E_{6} X \\
& +11664 E_{4}^{6}-1790914074624 \Delta E_{4}^{3}-20889728069861376 \Delta^{2}
\end{aligned}
$$

Remark that $U_{3}=\psi_{3} / 3$. Also

$$
\begin{gathered}
\mathcal{A}_{3}\left(X, E_{4}, E_{6}, \Delta\right)=-252 E_{4} X^{3}-720 E_{6} X^{2}-684 E_{4}^{2} X-216 E_{4} E_{6} \\
\mathcal{B}_{3}\left(X, E_{4}, E_{6}, \Delta\right)=-1464 E_{6} X^{3}-4368 E_{4}^{2} X^{2}-4344 E_{4} E_{6} X-1440 E_{4}^{3}+746496 \Delta
\end{gathered}
$$

For $\ell=5$ :

$$
\begin{gathered}
\mathcal{A}_{5}=-1890 E_{4} X^{5}-18720 E_{6} X^{4}-74160 E_{4}^{2} X^{3}-146880 E_{4} E_{6} X^{2}+\left(-145440 E_{4}^{3}+199065600 \Delta\right) X-57600 E_{4}^{2} E_{6}, \\
\mathcal{B}_{5}=-31260 E_{6} X^{5}-312480 E_{4}^{2} X^{4}-1249440 E_{4} E_{6} X^{3}+\left(-2497920 E_{4}^{3}+763084800 \Delta\right) X^{2}-2496960 E_{4}^{2} E_{6} X \\
-998400 E_{4}^{4}+1725235200 \Delta E_{4} . \\
31
\end{gathered}
$$

B.2. An example with $N=6$. Let $f=E_{4}$. We give some details for the computation of the modular polynomial for $E_{4}\left(q^{6}\right)$. For each representative $R=[a, b ; c, d]$ of a coset, we compute the matrices $[N a, N b ; c, d]=U R^{\prime}$ with $U \in \Gamma$ and $R^{\prime}=[A, B ; 0, D]$ to which corresponds the conjugate $f\left(R^{\prime} \tau\right)$. Following Proposition 2.16, we group the conjugates matrices $R^{\prime}$ w.r.t. $D$. We find

| $R$ | $U$ | $R^{\prime}$ | $f\left(R^{\prime} \tau\right)$ |
| :--- | :--- | :--- | :--- |
| $[1,0 ; 0,1]$ | $[1,0 ; 0,1]$ | $[6,0 ; 0,1]$ | $1296+O\left(z^{36}\right)$ |

| $[1,0 ; 1,1]$ | $[0,1 ;-1,6]$ | $[1,1 ; 0,6]$ | $1+240 \zeta_{6} z+2160 \zeta_{6}^{2} z^{2}+6720 \zeta_{6}^{3} z^{3}+17520 \zeta_{6}^{4} z^{4}+O\left(z^{5}\right)$ |
| $[1,1 ; 1,2]$ | $[0,1 ;-1,6]$ | $[1,2 ; 0,6]$ | $1+240 \zeta_{6}^{2} z+2160 \zeta_{6}^{4} z^{2}+6720 \zeta_{6}^{6} z^{3}+17520 \zeta_{6}^{8} z^{4}+O\left(z^{5}\right)$ |
| $[1,2 ; 1,3]$ | $[0,1 ;-1,6]$ | $[1,3 ; 0,6]$ | $1+240 \zeta_{6}^{3} z+2160 \zeta_{6}^{6} z^{2}+6720 \zeta_{6}^{9} z^{3}+17520 \zeta_{6}^{12} z^{4}+O\left(z^{5}\right)$ |
| $[3,1 ; 5,2]$ | $[-3,11 ;-5,18]$ | $[1,4 ; 0,6]$ | $1+240 \zeta_{6}^{4} z+2160 \zeta_{6}^{8} z^{2}+6720 \zeta_{6}^{12} z^{3}+17520 \zeta_{6}^{16} z^{4}+O\left(z^{5}\right)$ |
| $[1,0 ; 5,1]$ | $[-4,5 ;-5,6]$ | $[1,5 ; 0,6]$ | $1+240 \zeta_{6}^{5} z+2160 \zeta_{6}^{10} z^{2}+6720 \zeta_{6}^{15} z^{3}+17520 \zeta_{6}^{20} z^{4}+O\left(z^{5}\right)$ |

The corresponding power sums $S_{D, t}(f)$ have $q$-expansion in $q^{A}$ (with $A=N / D$ ) and rational integer coefficients. For instance

| $D$ | $A$ | $S_{1}(D)$ |
| :--- | :--- | :--- |
| 1 | 6 | $1296+311040 q^{6}+O\left(q^{12}\right)$ |
| 2 | 3 | $162+349920 q^{3}+2838240 q^{6}+O\left(q^{9}\right)$ |
| 3 | 2 | $48+322560 q^{2}+2903040 q^{4}+8720640 q^{6}+O\left(q^{8}\right)$ |
| 6 | 1 | $6+362880 q+2943360 q^{2}+9810720 q^{3}+O\left(q^{4}\right)$ |

Summing all these, we get

$$
S_{1}=1512+362880 q+3265920 q^{2}+10160640 q^{3}+O\left(q^{4}\right)
$$

in which we recognize $1512 E_{4}$. Finally

$$
\begin{aligned}
& \Phi\left[E_{4}(6 \tau)\right]=X^{12}-1512 E_{4} X^{11}+296316 E_{4}^{2} X^{10}+120\left(-181381 E_{4}^{3}+3782160000 \Delta\right) X^{9} \\
& -270 E_{4}\left(-2610581 E_{4}^{3}+45664128000 \Delta\right) X^{8}-72 E_{4}^{2}\left(155634011 E_{4}^{3}+97714341360000 \Delta\right) X^{7} \\
& \quad+12\left(7370195077 E_{4}^{6}+29670256575360000 \Delta E_{4}^{3}+32018727707136000000 \Delta^{2}\right) X^{6} \\
& \quad-1944 E_{4}\left(170853343 E_{4}^{6}-4897879320240000 \Delta E_{4}^{3}+23743887602688000000 \Delta^{2}\right) X^{5} \\
& +45 E_{4}^{2}\left(15102174661 E_{4}^{6}-9546408010149120000 \Delta E_{4}^{3}+47160528043659264000000 \Delta^{2}\right) X^{4}
\end{aligned}
$$

```
            +3547348992E E4
    +34828517376(-E E4}+54000\Delta)(-\mp@subsup{E}{4}{9}+151013228706000\Delta\mp@subsup{E}{4}{6}-224179462188000000\Delta\mp@subsup{\Delta}{}{2}\mp@subsup{E}{4}{3}+1879994705688000000000\Delta\mp@subsup{\Delta}{}{3})
```
