## Tralics, a L<sup>A</sup>T<sub>E</sub>X to XML translator Part II

José Grimm\*

Thème NUM — Systèmes numériques  
Projet Apics

Rapport technique n° 310 — version 2 — initial version September 2005 — revised version  
January 2007 — 390 pages

**Abstract:** In this document we describe Tralics, a L<sup>A</sup>T<sub>E</sub>X to XML translator, and its application to the Raweb. There are two parts: the first part describes the translator, the second part the tools required for the Raweb.

This document has different chapters; we shall describe first how T<sub>E</sub>X can read an XML file and convert it to Pdf; in effect, we shall describe the xmltex, fotex and mathml packages, written by D. Carlisle et S. Rahtz, with some minor bug corrections and additions. We show how style sheets can be used to convert the XML source into XSL/FO or HTML, or even XML. Finally, we shall explain the Raweb DTD.

The second version of this report contains an additional chapter that explains how to convert a Research Report or a PhD thesis in HTML using Tralics and an XML processor.

**Key-words:** Latex, XML, HTML, MathML, XSLT, PostScript, Pdf, stylesheet, formatting

# **Tralics, un traducteur de L<sup>A</sup>T<sub>E</sub>X vers XML**

## **Partie II**

**Résumé :** Dans cet rapport nous décrivons le logiciel Tralics, un traducteur de L<sup>A</sup>T<sub>E</sub>X vers XML, et son application au Raweb. La première partie de ce document décrit le traducteur lui-même, et la deuxième partie explique tous les outils nécessaires pour exploiter les fichiers XML.

Ce document contient plusieurs chapitres: on expliquera d'abord comment T<sub>E</sub>X peut interpréter du XML et produire du Pdf; il s'agit des packages xmltex, fotex, mathml2, écrits par D. Carlisle et S. Rahtz, avec quelques corrections et ajouts. On expliquera comment des feuilles de style permettent de convertir le XML en XSL/FO ou HTML, ou même en XML. Finalement, on expliquera la DTD Raweb.

La version 2 de ce rapport contient un chapitre supplémentaire qui explique comment convertit un document de type rapport de recherche ou thèse en HTML grâce à Tralics et un processeur XML.

**Mots-clés :** Latex, XML, HTML, MathML, XSLT, PostScript, Pdf, feuilles de style, formatage

# Chapter 1

## Introduction

This document is the second part of a report that explains Tralics and how it can be used for the Raweb. You will find a sequence of commented source files, most of them publicly available on the Web, followed by a large index (over twenty pages).

The index is sorted alphabetically; in the case of `<a>`, or `$c` or `\z@`, the first character is not used for sorting; the object `\@car` can be found with the character ‘c’; some private T<sub>E</sub>X commands have an at-sign in their name, sometimes in the middle, and sometimes at the start.

If you look at the letter Y, you can see five occurrences of the word ‘year’. The first item uses a normal font; we use such a font for an attribute value (for instance, in the Raweb DTD, line 292, you can see that the `<citation>` element has an attribute from whose value can be ‘year’). The second item uses a sans-serif font, this is the name of an attribute (for instance of the main Raweb element has a `year` attribute). Other items in the index use a type-writer font, and additional characters. For instance `<year>` is the name of a HTML or XML element, `$year` is the name of a xsl variable, and `\year` is the name of a T<sub>E</sub>X command (this one is not used here).

If you look at the letter I, you will find `id`, `id`, and `ID` and `ID`. The case of `ID` is a bit special since it is the name of an attribute set (and only one such data structure is used); and `ID` is an attribute type. We use `id` for the name of an attribute, and `id` for an xsl template (whose purpose is to set the attribute). The index contains also entity names like `%list;`, such entities appear only in the DTD.

We do not index everything! Consider a source line, of the form

`\XMLNSAX{fo}{break-before}{\FObreakbefore}{auto}`

The number in the left margin has nothing to do with the line number of the source document; it will be referenced to in some cases. This line is to be interpreted by T<sub>E</sub>X, it has 28 tokens. However, for a human reader, it contains five tokens, that could be indexed. The first token is the name of a T<sub>E</sub>X command that appears more than a hundred times (with and without the trailing X); it will not be indexed, as well as other common T<sub>E</sub>X commands like `\def`, `\gdef`, `\XMLElement`, or `<xsl:template>` in the part concerning style sheets, and `<!ELEMENT>` and `<!ATTLIST>` in the last chapter. The ‘fo’ in this example is a prefix that appears almost always after `\XMLNSA` or `\XMLNSAX`, thus it does not appear in the index. On the other hand, the attribute name, the associated T<sub>E</sub>X command and the default value will be found in the index. Consider a second example

`<xsl:variable name="Directory" select="concat($LeProjet,$year)" />`

Here, the line contains seven tokens. There is an element and two attributes. These will not be found in the index (the attribute name `name` will only be indexed if it appears in the HTML or XML document, not in the style sheet as xsl keyword). Xsl functions like ‘concat’ will not be indexed.

On the other hand you will find the three variables `$Directory`, `$LeProjet` and `$year` (in the line above, one variable is set, the other two variables are used).

The first chapter describes `xmltex.tex`. This is a `TEX` file whose purpose is to read and evaluate an `XML` file. The interpretation depends on some user commands, to be put in a `.xmt` file (the “user” here being the guy who designs the DTD of the `XML` file, as opposed to the author of the document, or the author of `xmltex`). The file contains a lot of commands of the form `\expandafter`, `\csname`, `\edef`, and the like, that are not described in standard `LATEX` books. If you understand this file, you can be called a `TEX` Master (according to the `TEXbook`, a Master is somebody who understand tables, a Grandmaster is somebody who can design output routines; the whole `XML` stuff described in this report is somewhere between these two levels). It is however a challenge for a software like `Tralics` to be able to read the `xmltex.tex` file.

Using `xmltex` is easy. For instance, Chapter 3 explains how maths can be interpreted (this is an extension of the work of Carlisle, the author of `xmltex`). We have added commands that interpret the `picture` environment, and some extensions; the only difficulty here is that the commands have an irregular syntax, so that the standard mode of evaluation cannot be used (for instance, if you say

```
<oval x='1.2' y='3.4' specs='lt'> Text</oval>
```

we must call the associated `TEX` command like this

```
\oval(1.2,3.4)[lt]{Text}
```

rather than

```
\oval{1.2}{3.4}[lt]{Text}
```

Perhaps, the easiest way would be to write an intermediate command. The code is only given as an example of what can be done; it is not completely tested, and not used for the Raweb at all, because we do not know how to convert it into `HTML`.

Chapter 8 is an addition to version 2 of this document. It explains how to convert a document (like a PhD thesis, or a technical report) into a `HTML` document, after conversion into `XML`. We show how to solve a non-trivial problem: there are objects, similar to `<oval>` above, that cannot be rendered in `HTML`, and have to be replaced by images: these are obtained by creating an auxiliary `XML` file, evaluating it by `LATEX`, converting the `dvi` into a sequence of images.

A similar idea is used in the Kraken software by Nader Salman: in this case, the `XML` file contains `<math>` and `<cite>` elements, containing `LATEX` code; a script extracts this code, calls `Tralics`, and reinserts the math formulas; the `<cite>` elements are replaced by pointers to the bibliography, generated as a by-product by `Tralics`; this is a rather original way to produce an activity report, see <http://www-sop.inria.fr/odyssee/>.

## Chapter 2

# Interpreting XML in T<sub>E</sub>X

We shall describe here the `xmltex.tex` file. This is a piece of code written by David Carlisle as described in [1], it is a follow-up to `typehtml`, a package for typesetting HTML. The idea was to write a T<sub>E</sub>X file that interprets some XML code and typesets it, using rules defined in some other files (the so-called `.xmt` files), that depend on the DTD or namespaces. Some of these files are described in following chapters. This interpreter is used for the production of the Raweb (on figure 1 of the first part of this document, the arrows from ‘xmlfo’ to ‘PDF’ or ‘PS’ use this file). The XML file contains a lot of Unicode characters, that can be coded using iso-latin1 or UTF-8 encoding. Interpreting them in T<sub>E</sub>X is a real challenge. Here is an example:

```
<m:math overflow="scroll">
  <mrow xmlns="http://www.w3.org/1998/Math/MathML">
    <msup><mi>L</mi> <mn>2</mn> </msup><mo>#x2192;</mo>
    <msup><mi>L</mi> <mi>#x221E;</mi> </msup></mrow></m:math>
```

In this example, only ASCII characters are used, complicated things are written in the form `&#x221E;`, this is the same as `&#8734;`. The `<mrow>` element has an `xmlns` attribute, it is hence the same as `<m:mrow>`. The action associated to this element is stored in some command, so one question is: what’s the name of this command? every Unicode character is allowed, i.e., much more than the 256 internal characters of T<sub>E</sub>X. We have another problem, it is that an element name could be entered as `<José>` (iso-latin1 encoding). A good encoding is UTF-8, since it allows encoding of all Unicode characters on 8 bits. For instance, the representation of a character looks like this: `\8:Ã©`, and that of the element is `\E:0:JosÃ©`. Here between the two colons we have the value of the namespace, a sequence of digits, where 0 represents the empty namespace, 3, the MathML namespace, etc. (namespaces are defined in [11]). All commands that are dynamically created start with a prefix. This is ‘8:’ for a UTF-8 character, ‘A:’ for the global attribute list, ‘E:’ for the start of an element, ‘E/:’ for the end of an element, ‘Q:’ for a processing instruction like `<?xml?>`, ‘XML:’ for a namespace. An example of such a namespace command is `\XML:http://www.w3.org/1998/Math/MathML`. Usual L<sup>A</sup>T<sub>E</sub>X commands contain only letters, reserved names may contain @; using a prefix with a character other than these reduces the risk of conflict with existing commands. We must use `\csname` for producing these commands. The math formula above is  $L^2 \rightarrow L^\infty$ .

In order to make the code easier to understand, we have invented some commands that are inlined in the real code (for efficiency reasons). The command `\XML:http.../MathML` (full name shown above) contains the unique identifier for the MathML namespace; this is in fact the number 3. It can be constructed via `\jg@NSuri`. In the case of `<m:math>`, the value of the ‘m’ prefix is the same number, it will be obtained via `\jg@namespace{m}`. In fact, when we parse an element, the prefix is in a global variable, so that we can use the parameterless command `\jg@this@namespace`.

---

```
\def\jg@NSuri#1{\csname XML:#1\endcsname}
\def\jg@namespace#1{\csname XMLNS@#1\endcsname}
\def\jg@this@namespace#1{\jg@namespace{\XML@this@prefix}}
```

In some cases, we need a canonical version of a string. We shall use the `\catxii` command for this: if `\val` is a command that expands to ‘`some/val`’ then the expansion of ‘`\meaning\val`’ is ‘`macro:->some/val`’, this is a list of character tokens with category code 12 (except for spaces). The `\strip@prefix` command removes everything up to ‘`>`’, it yields ‘`some/val`’. We need an `\expandafter` for changing the order of expansion.

```
\def\catxii#1{\expandafter\strip@prefix\meaning#1}
```

See the *TEXbook* [6] for details about `\expandafter`, category codes, the result of `\meaning`, what happens if `\meaning` produces no greater-than sign, etc. See the *LATEX* source code for `\strip@prefix`. See the *Unicode book* [8], paragraph 2.5, for the definition of encodings like UTF-8, UTF-16 and UTF-32, and the whole book for the significance of characters U+221E.

UTF-8 encoding is defined as follows. A character X will be represented using a variable number of bytes, say A, AB, ABC or ABCD. Let  $x$  be the integer value of X, and  $a, b, c$  and  $d$  the values of A, B, C, and D. The first byte indicates the length of the sequence: if  $a < 128$ , the sequence is of length one, and  $x = a$ . Otherwise,  $a$  starts with  $k$  bits 1 followed by a 0 bit, the sequence is of length  $k$ , the  $k - 1$  characters that follow start with a 1 and a 0 (and have 6 significant bits). These are the relations we shall use:

$$\begin{aligned} \text{If } 0 \leq x < 2^7 & \quad k = 1 \quad x = x_1 \quad a = x \\ \text{If } 2^7 \leq x < 2^{11} & \quad k = 2 \quad x = x_1 2^6 + x_2 \\ & \quad a = 128 + 64 + x_1, b = 128 + x_2 \\ \text{If } 2^{11} \leq x < 2^{16} & \quad k = 3 \quad x = x_1 2^{12} + x_2 2^6 + x_3 \\ & \quad a = 128 + 64 + 32 + x_1, b = 128 + x_2, c = 128 + x_3 \\ \text{If } 2^{16} \leq x < 2^{21} & \quad k = 4 \quad x = x_1 2^{18} + x_2 2^{12} + x_3 2^6 + x_4 \\ & \quad a = 128 + 64 + 32 + 16 + x_1, b = 128 + x_2, c = 128 + x_3, d = 128 + x_4 \end{aligned}$$

In all cases  $0 \leq x_i < 64$ . The case  $x \geq 2^{21}$  is not handled. As an example, the character with code 233 is coded as  $\text{Ã©}$ . Note: assume that X is an iso-latin1 character, if it fits on seven bits it is represented by itself. Otherwise, if  $128 \leq x < 128 + 64$ , the first character is  $\text{Ã}$ , the second is X, and if  $x \geq 128 + 64$  the first character is  $\text{Ã}$ , the second has value  $x - 64$  (note that most useful latin1 characters are in the range 192-255).

The file we consider starts like this:

```
1 %% Copyright 2000 David Carlisle, NAG Ltd.
2 %% re-released by Sebastian Rahtz June 2002
3 %% This file is distributed under the LaTeX Project Public License
4 %% (LPPL) as found at http://www.latex-project.org/lppl.txt
5 %% Either version 1.0, or at your option, any later version.
```

Unless told otherwise, newline characters are ignored in the `xmltex` file (in particular, on line 6, the space after the opening brace). More generally, lots of characters have category codes that depend on the context. We have not shown all these category changes; since definitions are in local groups, they are generally global (hence the `\gdef` here).

## 2.1 Constructing characters

Let's consider the following task: We have a character X, with code  $x$ , and  $x$  is in `\count@`. We want to find the bytes ABCD, with codes  $a, b, c$  and  $d$ . These quantities are obtained by writing  $x$  in base 64, with digits  $x_i$ , and we add 128 to everything. The first byte is a bit more complicated to compute. This piece of code uses two temporary registers `\@tempcnta` and `\@tempcntb` for the division. It replaces  $x$  by its quotient, and puts in the `\uccode` of '#1 the next byte (this assumes that the argument of the command is a character).

```

6 \gdef\XML@utfeight@a#1{
7   \@tempcnta\count@
8   \divide\count@64
9   \@tempcntb\count@
10  \multiply\count@64
11  \advance\@tempcnta-\count@
12  \advance\@tempcnta"80
13  \uccode'#1\@tempcnta
14  \count@\@tempcntb}

```

This is the caller of the preceding command:

```

15 \gdef\XML@charref#1#2;{
16   \begingroup
17   \uppercase{\count@\if x\noexpand#1"\else#1\fi#2}\relax
18   \ifnum\count@<"80\relax
19     \uccode'~\count@
20     \uppercase{
21     \ifnum\catcode\count@=\active
22       \gdef\XML@tempa{\utfeightay~}
23     \else
24       \gdef\XML@tempa{~}
25     \fi}
26   \else\ifnum\count@<"800\relax
27     \XML@utfeight@a,
28     \XML@utfeight@b C\utfeightb.,
29   \else\ifnum\count@<"10000\relax
30     \XML@utfeight@a;
31     \XML@utfeight@a,
32     \XML@utfeight@b E\utfightc.{,;}
33   \else
34     \XML@utfeight@a;
35     \XML@utfeight@a,
36     \XML@utfeight@a!
37     \XML@utfeight@b F\utfightd.{!,;}
38   \fi
39   \fi
40 \fi
41 \endgroup}

```

There is a similar command, except that the test on lines 21-25 is assumed to be true, and code on line 22 is executed. It seems to be used only for reading auxiliary files in XML format; however, the .aux files contain currently no XML code.

```

42 \gdef\XML@charref@tex#1#2;{
43   ...

```

We shall see in the sequel some instances of ‘black magic’. The result of ‘\uppercase{xe9}’ is ‘XE9’. However, if you say ‘\uppercase{\foo~}’ the result is ‘\foo W’, where W is the character found in the uc table of the tilde character, and the category code of this character is the same as the tilde character (in general active). The substitution is done before \foo is evaluated<sup>1</sup>. In some cases, \foo is \endgroup. In our case, the group ends at line 41. The \uppercase on line 17 is not black magic. The idea is the following: imagine that we want to read something like ‘&#233;’ or ‘&#xe9;’, and that the ampersand and sharp characters have been read. Then \XML@charref reads all characters up to the semi colon. Arguments are 2, 33 in one case, x, e9 in the other case. A construction like \count@="E9 puts 233 into \count@, upper case letters are needed. What \uppercase produces in our example is ‘\count@if X\noexpand X"\else X\fi E9’; there is a \relax in the code whose purpose is to mark the end of the number (we do not want the \ifnum to be expanded before assignment is done); this \relax command could have been in the uppercase list. I don’t know if \noexpand is needed here<sup>2</sup>. The effect of the conditional is just to replace the X by a ” (you cannot do this using black magic, because the double quote has to be of category 12, so that the argument of the command must be of category code 12). What our code does is to put the number (say 233) into \count@. It chooses one of four alternatives on line 18, 26, 29 and 33; it corresponds to the number of bytes used to represent the Unicode character in UTF-8 format. In any case, the result is a definition of \XML@tempa as a command that start with \UTF8? (this is a shorthand for one of \UTF8ax, \UTF8ay, \UTF8az, \UTF8b, \UTF8c, or \UTF8d, the real name of the command is \utfheightax, etc.) followed by some characters (1, 1, 1, 2, 3, and 4 respectively).

Let’s start with the case of one byte, lines 19-25. We have a special case here, because the UTF-8 character can be represented by a single TeX character; we use it, in the case where it is not expandable (i.e., is non active); the code on lines 41-42 does not use this simplification. As an example, if the number  $x$  is 65, then \XML@tempa will contain A; if it is 60, it will contain ‘\utfheightay’ (we assume that the less-than sign is of category code 12 when the code is read, this is needed on line 18, and of category 13 when the code is executed).

In the case where more than one byte is used, the idea is the following. We have to compute some integers  $a$ ,  $b$ ,  $c$  and  $d$  (two three or four values are required). These integers are in the range 1–255. If we store them in the uc-slot of A, B, C or D, then \uppercase{ABCD} will give a sequence of four characters, whose codes are the numbers  $a$ ,  $b$ ,  $c$  and  $d$ . Instead of these letters, point, exclamation point, comma and semi colon are used, in a random order. This is completely irrelevant since modifications are local (the group ends on line 41), and the \uppercase on line 47 sees only these character tokens, together with non-character tokens that are not affected. The code could be slightly optimized if, on one hand, we notice that  $a$  is always stored in ‘.’ (point) and, on the other hand, that  $b$  could always be stored in ‘!’ (exclamation point). On lines 26 to 37 we compute  $b$ ,  $c$  and  $d$ , and call \XML@utfheight@b with four arguments. Argument #3 is the character that will hold  $a$ , argument #4 is the list of characters that are already set, argument #2 is the command name, one of the \UTF8? commands mentioned above. The first argument is a C, E, or F. Remember that  $a = x_1 + s$ , where  $x_1$  is in \count@,  $s$  depends on the number of bytes. It is sixteen times 12, 14 or 15 (in base 16, it is C0, E0 or F0). What the next function does is then obvious:

```

44 \gdef\XML@utfheight@b#1#2#3#4{
45   \advance\count@"#10\relax
46   \uccode`#3\count@
47   \uppercase{\gdef\XML@tempa{#2#3#4}}}
```

Assume that our number is 233 (or E9, in base 16). We have  $x_1 = 3$  and  $x_2 = 41$ . This gives  $b = 128 + 41$ , stored in the \uccode of #4. This is the character ©. Here #1 is C, "#10 is 192.

---

<sup>1</sup>The \uppercase command cannot be expanded; however its evaluation is a sequence of tokens that will be read again, expanded, and evaluated.

<sup>2</sup>The first character should be X or a digit, otherwise, the XML source is invalid. If you replace xe9 by xy9 or ye9, strange errors may be signaled; the case of a non-ASCII character is worse

Thus we store 195 (this is the code of Ä) in the \uccode of #3. Thus, the effect of the uppercase is to define the command \XML@tempa (this is a temporary command name that any command may redefine), it takes no argument, expands to \utfeightbÄ. The important point to remember: \XML@charref puts in \XML@tempa a list of tokens, this list is independent of the context, but the commands in the list have a meaning that depends on the context (redefined by the commands defined in the next paragraph).

## 2.2 Using UTF-8 characters

The piece of code that follows defines the six commands \UTF8? (there are other versions of the same commands). These definitions are useful in a context where we evaluate a piece of text.

```

48 \def\unprotect@utfeight{
49   \let<\XML@lt@markup
50   \let&\XML@amp@markup
51   \def\utfightax##1{
52     \csname 8:\string##1\endcsname}
53   \let\utfightay\utfightax
54   \let\utfightaz\utfightax
55   \def\utfightb##1##2{
56     \csname 8:##1\string##2\endcsname}
57   \def\utfightc##1##2##3{
58     \csname 8:##1\string##2\string##3\endcsname}
59   \def\utfightd##1##2##3##4{
60     \csname 8:##1\string##2\string##3\string##4\endcsname}}

```

For instance, \utfightbÄ expands to \csname8:Ä\string @\endcsname. We shall see in a minute why all characters have to be protected, except the first one. If we expand this, we get the command with this strange name \8:Ä. This command is assumed to typeset the Unicode character 233. Its definition could be, for instance, ‘\ifmmode \acute{e}\else '\{e}\fi’. Such a definition is valid only in a context where we typeset the object. Inside an \edef, the expansion of the conditional may give random results, inside a \csname, some tokens are illegal. Note that, in this command, less-than and ampersand are active, they scan something in the XML file; they should be input as ‘&lt;’ or ‘&amp;’ if you want a typeset < or &.

The next command looks funny:

```

61 \gdef\UnicodeCharacter#1#2{
62   \begingroup
63   \def\active{\catcode\count@}
64   \XML@charref#1;
65   \expandafter\expandafter\expandafter
66   \expandafter\expandafter\expandafter
67   \expandafter
68   \gdef\XML@tempa{#2}
69 \endgroup

```

There are seven \expandafter in a row. Write \E instead, in order to gain space. Assume that we have a command \A that expands to \B that expands to \C that expands to \D. The expansion of ‘\E\E\E\E\E\gdef\A’ is ‘\E\E\E\gdef\B’. This expands to ‘\E\gdef\C’. This expands to ‘\gdef\D’. Suppose that we say \UnicodeCharacter{233}{\e}. In this case \XML@charref will define \XML@tempa as shown above. This is our \A. The expansion \B is \utfightbÄ. Its expansion \C is \csname..., its expansion \D is \8:Ä. Hence, the code is \def\8:Ä{\e}. Thus, we know how to define every Unicode character. There is a little hack here (on line 63, you

see why?). Characters like A, B, C, typeset to themselves. But some other characters have to be defined. We say for instance

```
70 \UnicodeCharacter{94}{\textasciicircum}
71 \UnicodeCharacter{x5C}{\textbackslash}
72 \UnicodeCharacter{x5F}{\textunderscore}
73 \UnicodeCharacter{13}{\ignorespaces}
74 \UnicodeCharacter{32}{\ignorespaces}
75 \UnicodeCharacter{9}{\ignorespaces}
```

These definitions come from the `xmltex.tex` file, and the Raweb redefines the character U+5C, so as to allow it in math mode also. The definition of characters 9, 13 and 32 (spaces) is a bit strange: the `\ignorespaces` command expands the next token, and removes it, if it is a space; hence spaces given in the form `&#32;` are not removed. Worse: ‘`\parindent = 12 cm`’ becomes illegal if what follows the equals sign comes from an XML file. The `xmltex.tex` file also has these definitions<sup>3</sup>.

```
76 \expandafter\def\csname8:\string<\endcsname{\ifmmode\langle\else\textless\fi}
77 \expandafter\def\csname8:\string>\endcsname{\ifmmode\rangle\else\textgreater\fi}
78 \expandafter\def\csname8:\string{\endcsname{\{}}
79 \expandafter\def\csname8:\string}\endcsname{\}}}
```

What does the test on line 21 do? it compares the category code of `\count@` with `\active`; this is 13, and the test is false in the cases shown above (well, the backslash may be active while reading the XML file, it is surely not while processing line 71). Redefining `\active` has as side effect that it will expand to ‘`\catcode\count@`’ and this is the same as `\catcode\count@`. As a consequence ‘`\XML@tempa`’ expands to ‘`\utfeightay^`’ that expands to `\csname...` that expands to `\8:^`. Hence, line 70 defines the command `\8:^`. This is what is desired. Note: when the XML file is read, all characters with code  $\geq 128$  are active, those with code  $\leq 31$  have category 12 (in fact, they are invalid in XML1.0).

The `xmltex.tex` file starts like this (before category codes of usual characters have been changed).

```
80 \count@0
81 \catcode0=13
82 \gdef\XML@tempa{
83   \begingroup
84     \uccode0\count@
85     \uppercase{\endgroup
86       \edef^^@{
87         \ifnum\catcode\count@=11 %
88           \noexpand\utfeightay\else\noexpand\utfeightax\fi
89         \noexpand^^@}
90       \expandafter\edef\csname 8:\string^^@\endcsname{\string^^@}}
91     \ifnum\count@<127\advance\count@1 \expandafter\XML@tempa\fi}
92 \XML@tempa
93 \catcode0=9
```

Here we have real magic. There is a loop over all numbers  $x$  between 0 and 127. The number  $x$  is in `\count@`. For each  $x$ , code on lines 83–90 are executed. The null character (number zero) is active, and its uc value is  $x$ . In lines 86–90, it will be replaced by the character  $x$ . Note that this character is input as `^^@`. Assume for instance that  $x = 65$ , so that it represents the letter A, or that  $x = 61$  (character ‘=’). The second `\edef` defines `\8:A` or `\8:=` to be A or = (note: the purpose of the `\edef` is to expand the `\string` in the body, so that the character in the body is a non-active character). Hence the effect is the same as `\UnicodeCharacter{65}{A}`.<sup>4</sup> The purpose

---

<sup>3</sup>These definitions of less-than and greater-than are wrong; they will be redefined later.

<sup>4</sup>The code on lines 70–79 overrides some of these settings

of the \edef on line 86 is the expansion of the conditional: we define A to be ‘\utf eightay A’, and = to be ‘\utf eightax’. The character after the command is active. Consider this:

```
94 \def\use@utf eightay{...}
95 \use@utf eightay ^^M ^_~%$#{}
```

We have simplified a bit the code. The idea is that, for the characters listed here, \utf eightay is used instead of \utf eightax. We shall see later that \utf eightaz is used for ampersand and less than in a case like & and <.

The following piece of code defines the commands \UTF8? (version two).

```
96 \def\utf eight@protect@internal{
97   \let\utf eightax\noexpand
98   \let\utf eightay\noexpand
99   \def\utf eightaz{
100     \noexpand\utf eightaz\noexpand}
101   \let<\relax\let&\relax
102   \def\utf eightb##1##2{
103     \noexpand\utf eightb##1\string##2}
104   \def\utf eightc##1##2##3{
105     \noexpand\utf eightc##1\string##2\string##3}
106   \def\utf eightd##1##2##3##4{
107     \noexpand\utf eightd##1\string##2\string##3\string##4}}
```

What happens if a UTF8 character appears in an \edef? For instance, the character ‘é’, represented as ‘\utf eightb é’ expands to the expansion of ‘\noexpand\utf eightb é\string’, namely ‘\utf eightbé’. The only thing that might have changed is the category code of é. If it was active, it is now 12 (remember, the first character is never active). In the case \utf eightay A, the expansion is A, because \utf eightay is \noexpand. In the case of \utf eightaz W, the expansion is itself! Note that ‘<’ and ‘&’ are not modified.

This is version three:

```
108 \def\utf eight@protect@external{
109   \def\utf eightax{
110     \noexpand\noexpand\noexpand}
111   \let\utf eightay\utf eighta@ref
112   \let\utf eightaz\utf eighta@ref
113   \edef<{\string<}
114   \edef&{\string&}
115   \def\utf eightb##1##2{
116     ##1\string##2}
117   \def\utf eightc##1##2##3{
118     ##1\string##2\string##3}
119   \def\utf eightd##1##2##3##4{
120     ##1\string##2\string##3\string##4}}
```

In such a case, the expansion of ‘\utf eightb é’ is ‘é’ where both characters are of category code 12. This is very interesting in the case of \write that expands everything. The string é is the UTF-8 representation of é, and can be read again without trouble.<sup>5</sup> The expansion of ‘\utf eightax’ is ‘\noexpand’. It will become ~ after another expansion. In the case of ‘\utf eightay A’, the expansion is ‘&#65;’ because of the following lines:

```
121 \def\utf eighta@ref#1{
122   \string&\string##\number\expandafter‘\string#1\string;’
```

---

<sup>5</sup>The trouble is that, when the aux file contains \newlabel, its argument uses \csname, this expands to é, and this does not match the UTF-8 character.

Version four: this is the easy version: everything is converted into characters, of category code 12; in this case Unicode characters can be used inside a \csname.

```

123 \def\utfeight@protect@chars{
124   \let\utfeightax\string
125   \let\utfeightay\string
126   \let\utfeightaz\string
127   \def\utfeightb##1##2{
128     ##1\string##2}
129   \def\utfeightc##1##2##3{
130     ##1\string##2\string##3}
131   \def\utfeightd##1##2##3##4{
132     ##1\string##2\string##3\string##4}

```

## 2.3 Warnings

This piece of code is used in cases where we want to print something. It is the last definition of the \UTF8? series.

```

133 \def\utfeight@protect@typeout{
134   \utfeight@protect@chars
135   \let<\relax
136   \let&\relax}

```

This is the piece of code that removes the traces.

```

137 \def\xmltraceoff{
138   \global\let\xml@trace@warn\gobble
139   \global\let\xml@trace@warnNI\gobble
140   \global\let\xml@trace@warnE\gobble
141   \global\let\xml@attrib@trace\relax}

```

These are the commands that print a warning. We simplified a bit the code by removing (here) the body of some commands, and (elsewhere) calls to trace.

```

142 \def\xml@warnNI#1{
143   {\let\protect\string\utfeight@protect@typeout\message{^^J#1}}
144 \def\xml@warn#1{
145   {\let\protect\string\utfeight@protect@typeout\message{^^J\xml@w@#1}}
146 \def\xml@attrib@trace{...}
147 \def\xml@doattribute@warn#1#2#3{...}
148 \let\xml@trace@warn\xml@warn
149 \let\xml@trace@warnNI\xml@warnNI
150 \let\xml@trace@warnE\message

```

## 2.4 Reading the text

The next lines of code define a command \nfss@catcodes, such that, when executed, all characters have standard category codes. The @ character is a letter, quotes, less-than greater-than and equals-to are of category other.

```

151 \def\nfss@catcodes{
152   \catcode`\\0
153   % Idem for {}%`@#`'<=>
154 }

```

This changes even more category codes. Dollar, ampersand, hat, underscore, space have standard category codes, others have category 12.

```

155 \def\XML@reset{
156   \nfss@catcodes
157   % reset $&_ space
158   % reset :!=|
159   \catcode`~\active\def{\nobreakspace{}}
160   \let\XML@ns@a@\XML@ns@a@tex
161   \let\XML@ns\XML@ns@tex}
```

The next lines of code define a command `\XML@catcodes`, such that, when executed, all characters have category codes useful for reading an XML file.

```

162 \def\XML@catcodes{
163   \catcode`\ \active
164   % same for: ^^M ^^I <>:[]%&"'
165   % same for: /!?-${}#_\~
166   \def{\utf eightay~}
167   \let\XML@ns@a@\XML@ns@a@xml
168   \let\XML@ns\XML@ns@xml
169 }
```

The following two commands are inlined for efficiency reasons. We have introduced them in order to gain space.

```

170 \def\Normalspace{\catcode`^^I=10 \catcode`^^M=10 \catcode`_=10 }
171 \def\Activespace{\catcode`^^I=13 \catcode`^^M=13 \catcode`_=13 }
```

This piece of code does a loop, starting with `\count@`, up to `\@tempcnta` (excluded). The loop puts the current number in the uc-code of tilde, and uppercasifies the value of `\XML@tempa`, to be defined later, in the form `\def\XML@tempa{{...}}`, double braces are needed because `\uppercase` want a brace-delimited list of tokens.

```

172 \gdef\utf eightloop{
173   \uccode`~\count@
174   \expandafter\uppercase\XML@tempa
175   \advance\count@\@ne
176   \ifnum\count@<\@tempcnta
177   \expandafter\utf eightloop
178   \fi}
```

We leave it as an exercise to the reader to define a command `\XML@utf eight` whose expansion is ‘utf-8’, all characters being of category code 12. This piece of code does nothing if the current encoding is ‘utf-8’, otherwise it sets the current encoding to ‘utf-8’, and does some action.

```

179 \gdef\XML@setutf eight{
180   \ifx\XML@utf eight\XML@thisencoding
181   \else
182     \let\XML@thisencoding\XML@utf eight
183     ...% see below
184   \fi}
```

This is the action: for every character that is the first in a sequence of 2, 3 or 4 characters, it defines the character (for instance Ä) to take 1, 2 or 3 arguments. For instance Ä is defined as `\utf eightb Ä#1`. The first argument to `\utf eightb`, `\utf eightc`, or `\utf eightd` is not active! This works, because `\string~` is expanded to ~ of category code 12, where ~ is replaced by the `\uppercase` on line 174 by the character (for instance Ä), the `\utf eightb` command is not expanded since preceded by a `\noexpand`. The definition is in a double group (`\begingroup` on

line 185, braces on lines 188, 192, 194). The definition is visible outside the group because it is global: we use `\xdef`. We could replace `\gdef` by `\def` here, whether the temporary is restored or not after the loop is irrelevant.

```

185 \begingroup
186 \count@"C2
187 \tempcnta"E0
188 \gdef\XML@tempa{{\xdef~####1{\noexpand\utfeightb\string~####1}}}
189 \utfeightloop
190 \count@"E0
191 \tempcnta"F0
192 \gdef\XML@tempa{{\xdef~####1####2{\noexpand\utfeightc\string~####1####2}}}
193 \utfeightloop
194 \tempcnta"F4 \gdef\XML@tempa{{\xdef~####1####2####3{%
195 \noexpand\utfeightd\string~####1####2####3}}}
196 \utfeightloop
197 \endgroup

```

This defines a command named `\Q:xml`. It calls `\XML@xmldecl` after having changed the category code of white space.

```

198 \expandafter\gdef \csname Q:xml\endcsname{
199   \Normalspace
200   \XML@xmldecl}

```

This resets some category codes and calls `\XML@encoding`. The argument is something strange. The idea is that we parse `<?xml foo='bar'?>`. We read everything up to the end of the element, and provide a default encoding attribute. A `\relax` marker is put at the end.

```

201 \gdef\XML@xmldecl#1?{
202   \Activespace
203   \XML@encoding#1 e="utf-8"\relax}

```

The XML norm (see for instance [9, 10, 3]) says (rules 23, 24, 32, 80) that in `<?xml?>` only the `encoding` attribute can start with the letter ‘e’. This makes the loop easy. Note: other attributes are `version`, currently ignored (there are two versions of the XML standard, and the difference between them is tiny), and `standalone` (completely ignored).

```

204 \gdef\XML@encoding#1 #2{
205   \if\noexpand#2e
206     \expandafter\XML@encoding@aux
207   \else
208     \expandafter\XML@encoding
209   \fi}

```

We shall see later that `\XML@quoted\foo` reads ‘bar’ or “bar”, and calls `\foo` with the value ‘bar’. The following piece of code grabs the attribute name, the equals sign, reads the attribute value and calls another command.

```

210 \gdef\XML@encoding@aux#1={
211   \XML@quoted\XML@setenc}

```

Here the `\lowercase` is no magic: the XML norm says (rule 80) that all characters should be ASCII characters (letters, digits, dot, underscore, dash), and case independent. In the case where the encoding is not UTF-8, some file is read; for instance `iso-8859-1.xmt`. On page 6, we have seen how to find the UTF-8 representation of a latin1 character. It depends on whether the character is smaller or larger than 192. Two easy loops suffice to define all characters like é as `\utfeightb@`.

```

212 \def\XML@setenc#1#2\relax{
213   \lowercase{\gdef\XML@tempa{#1}}

```

```

214  \xdef\XML@tempa{\catxii\XML@tempa}
215  \ifx\XML@tempa\XML@thisencoding
216  \else
217  \ifx\XML@utfeight\XML@tempa
218  \XML@setutfeight
219  \else...% code not shown here
220  \fi
221 \fi}
```

## 2.5 Namespaces

You say `\XML@ns@alloc{foo}` in order to declare ‘foo’ as a namespace name; after that the value can be found by `\jg@NSuri {foo}`. In the case this command is defined, there is nothing to do. Otherwise, we allocate a number using the counter `\XML@ns@count`, say 3, and put this in the command. We define two other commands: `\jg@namespace{3}` will be 3, and `\A:3` will be empty (we shall see that this is the global attribute list of the namespace). Note: we use here the pseudo commands `\jg@NSuri`, so that a double indirection is needed; as a consequence `\expandafter3` should be replaced by a sequence of three `\expandafter` tokens.

```

224 \def\XML@ns@alloc#1{
225   \expandafter3\ifx\jg@NSuri{#1}\relax
226   \global\advance\XML@ns@count@ne
227   \expandafter3\xdef\jg@NSuri{#1}{\the\XML@ns@count}
228   \global\expandafter3\let\csname A:\the\XML@ns@count\endcsname\empty
229   \expandafter3\xdef\jg@namespace{\the\XML@ns@count} {\the\XML@ns@count}
230 \fi}
```

The namespace stuff is initialized like this; number 0 corresponds to the empty namespace. Note that the recommendations say: The prefix ‘xml’ is by definition bound to the namespace name: `http://www.w3.org/XML/1998/namespace`.

```

231 \XML@ns@count-1
232 \XML@ns@alloc{}
233 \XML@ns@alloc{http://www.w3.org/1998/xml}
234 \def\XMLNS@xml{1}
235 \XML@ns@alloc{http://www.dcarlisle.demon.co.uk/xmltex}
```

The next piece of code is standard trick to convert ‘`foo:bar`’ into `{foo}{bar}` and ‘`foo`’ into `{}``{foo}`. The auxiliary command sees ‘`bar`’ or ‘`\@`’ as second argument, argument 3 is junk. This works only if `\@` does not appear in the argument, moreover, it is recommended that at most one colon appears, and no `\@`, otherwise, two many tokens are considered as junk.

```

236 \gdef\XML@ns@xml#1{\expandafter\XML@ns@a@xml#1:\@:\\"}
237 \gdef\XML@ns@a@xml#1:#2:#3\\{
238   \ifx\@#2 \XML@ns@b{}{#1}
239   \else    \XML@ns@b{#1}{#2}
240 \fi}
```

The function above depends on the category code of the colon character. We define an alternative version of the command and its helper, and install `\XML@ns@a@` to be the T<sub>E</sub>X variant, but it may be redefined (see lines 160 and 167).

```

241 \def\XML@ns@tex#1{...}
242 \def\XML@ns@a@tex#1:#2:#3\\{...}
243 \let\XML@ns@a@\XML@ns@a@tex
244 \let\XML@ns\XML@ns@tex
```

What this code does is just to expand everything (in order to get a canonical form). Thus `\XML@ns`, as well as all its variants, take a sequence like ‘`foo:bar`’, puts it in a canonical form, and puts ‘`foo`’ in `\XML@this@prefix`, ‘`bar`’ in `\XML@this@local`.

```
245 \def\XML@ns@b#1#2{
246   \begingroup
247   \utfeight@protect@chars
248   \xdef\XML@tempa{#1}
249   \xdef\XML@tempb{#2}
250   \endgroup
251   \let\XML@this@prefix\XML@tempa
252   \let\XML@this@local\XML@tempb
253 }
```

## 2.6 Redefining `\protect`

In order to prevent premature expansion, you can insert `\protect` before a command; this makes it “robust”; the `\protect` command is defined in L<sup>A</sup>T<sub>E</sub>X, its value depends on the context. It may be `\@unexpandable@protect`, that is `\noexpand\protect\noexpand`. Hence `\protect\foo` expands to itself in an `\edef`. On line 96, we define a command so that `\utfeightb` (the internal representation of é) also expands to itself. In this section, we modify all context switch commands in order to make all UTF-8 characters naturally robust.

We start with a modified `\xdef` in which `\protect` and UTF-8 characters are left unchanged. This works well in a group because the end of the group restores the old value.

```
254 \def\unrestored@protected@xdef{
255   \utfeight@protect@internal
256   \let\protect\@unexpandable@protect
257   \xdef
258 }
```

Another extension to L<sup>A</sup>T<sub>E</sub>X: Here everything is done in a group, the definition is global, the modifications to `\protect` and `\UTF8?` are local; the group is terminated after the `\xdef` because of the `\afterassignment`.

```
259 \def\protected@xdef{
260   \begingroup
261   \utfeight@protect@internal
262   \let\protect\@unexpandable@protect
263   \afterassignment\endgroup
264   \xdef}
```

Yet another one: No group is used here, and `\afterassignment` gets another token as argument. This is useful if we do not want an `\xdef` (for instance, `\refstepcounter` uses this to define the current label). The meaning of UTF-8 characters is not restored, but reset to XML mode.

```
265 \def\protected@edef{
266   \let\@protect\protect
267   \let\protect\@unexpandable@protect
268   \utfeight@protect@internal
269   \afterassignment\restore@protect
270   \edef
271 }
```

We have to restore `\protect` and some other commands.

```
272 \def\restore@protect{\let\protect\@@protect
273   \unprotect@utfeight}
```

We have to redefine `\protected@write`. This is a command that takes 3 arguments. It writes the last argument on the file defined by the first argument. Protection works as follows: there is an `\edef` that will expand all tokens but the protected ones, the current page reference (i.e., `\thepage`), including side-effects that come from evaluating the second argument. For instance, in Chapter 4, line 2445, there is an example where `\jgF0label` is set to `\relax`; the `\addtocontents` command defines `\label`, `\index` and `\glossary` to gobble their arguments.

```
274 \long\def \protected@write#1#2#3{
275   \begingroup
276     \let\thepage\relax
277     #2
278     \utfeight@protect@external
279     \let\protect\@unexpandable@protect
280     \edef\reserved@a{\write#1{#3}}
281     \reserved@a
282   \endgroup
283   \if@nobreak\ifvmode\nobreak\fi\fi
284 }
```

We must also redefine this (it is used by `\typeout`).

```
285 \def\set@display@protect{
286   \let\protect\string
287   \utfeight@protect@typeout}
```

## 2.7 The catalogue

The catalogue is an association list, a sequence of the form `\key{val1}{val2}`. We have mentioned elsewhere that adding something at the end of a token list is not obvious. Here we proceed as follows. Consider

```
\edef\val{\noexpand\the\list\noexpand\key{\catxii\val}}
```

If we assume that `\list` is a command that cannot be expanded and `\val` expands to ‘`some/val`’, the code above puts `\the\list\key{some/val}` into `\val`. Assume now that `\list` is a reference to a token list, and that we say

```
\list\expandafter\expandafter\expandafter{\val{aux}}
```

Since `\list` is a reference to a token list, the code above is an assignment, after `\list` we have a token list, and the first token is expanded to see if it is a left brace. Because of the `\expandafter` the code is equivalent to

```
\list\expandafter{\the\list\key{some/val}{aux}}
```

Now, the token that follows `\list` can be expanded; hence the result is the same as

```
\list{<value of the list>\key{some/val}{aux}}
```

We can also say something like

```
\list\expandafter{\the\expandafter\list\expandafter\key\val{aux}}
```

Here the effect of `\expandafter` is to expand `\the`; this expands the token that follows, namely the `\expandafter`, so that `\val` is expanded. This the result is the same as

```
\list{<value of the list>\key some/val{aux}}
```

The catalogue is a token list defined by sequence of assignments like this:

```
\SYSTEM {http://www.oucs.ox.ac.uk/dtds/tei-oucs.dtd} {tei.xmt}
\NAMESPACE{http://www.w3.org/1998/Math/MathML} {mathml2.xmt}
\NAMESPACE{http://www.dcarlisle.demon.co.uk/sec} {sec.xmt}
\NAME{langtest} {langtest.xmt}
\NAME{TEI.2} {tei.xmt}
\NAME{html} {html.xmt}
\NAMESPACE{http://www.w3.org/1999/XSL/Format} {fotex.xmt}
```

Here the last item on each line is the name of a TeX file to load in some cases. There are five different items in the catalogue, thus five commands that put things in it, and five other commands that extract something. The action of `\FOO{A}{B}` is essentially to add `\XML@@FOO{A}{B}` at the end of the token list.

Let's start with the `\PUBLIC` command. It takes two arguments, an URI and a file name.

```
288 \def\PUBLIC#1#2{
289   \xdef\XML@tempa{#1}
290   \xdef\XML@tempa{\noexpand\the\XML@catalogue\noexpand\XML@@PUBLIC
291     {\catxii\XML@tempa}}
292   \global\XML@catalogue\expandafter\expandafter\expandafter{
293     \XML@tempa{#2}}}

Same idea here.

294 \def\SYSTEM#1#2{
295   \xdef\XML@tempa{#1}
296   \xdef\XML@tempa{\noexpand\the\XML@catalogue\noexpand\XML@@SYSTEM
297     {\catxii\XML@tempa}}
298   \global\XML@catalogue\expandafter\expandafter\expandafter{
299     \XML@tempa{#2}}}
```

In the case of a namespace, for instance MathML, we compute the namespace number of it, and the catalogue associates to this number the file in which everything is defined.

```
300 \def\NAMESPACE#1#2{
301   \utfeight@protect@chars
302   \XML@ns@alloc{#1}
303   \edef@\tempa{\jg@NSuri{#1}}
304   \global\XML@catalogue\expandafter{\the\expandafter\XML@catalogue
305     \expandafter\XML@@NAMESPACE@\tempa{#2}}
306   \unprotect@utfeight}
```

This is the easiest of all commands, since we do not have to do anything with the arguments.

```
307 \def\NAME#1#2{
308   \global\XML@catalogue\expandafter{\the\XML@catalogue\XML@@NAME{#1}{#2}}}
```

You run the catalogue by evaluating it. For instance, if you put ‘foo’ into `\XML@PUBLIC`, then the value associated to `foo` by the `\PUBLIC` command will be put in `\XML@use`.

```
309 \def\XML@PUBLIC#1#2{
310   \gdef\XML@tempa{#1}
311   \ifx\XML@tempa\XML@PUBLIC \def\XML@use{#2}\fi}
```

Same action for `SYSTEM`. The temporary variable has a different name.

```
312 \def\XML@SYSTEM#1#2{
313   \def@\tempa{#1}
314   \ifx@\tempa\XML@SYSTEM \def\XML@use{#2}\fi}
```

Same action for `NAMESPACE`.

```

315 \def\XML@NAMESPACE#1#2{
316   \def\@tempa{#1}
317   \ifx\@tempa\XML@NAMESPACE \def\XML@use{#2}\fi}
      Same action for NAME.
318 \def\XML@NAME#1#2{
319   \def\@tempa{#1}
320   \ifx\@tempa\XML@NAME \def\XML@use{#2}\fi}

```

You say `\XMLNS{html}{http://www.w3.org/1999/xhtml}`. The effect is to associate to the name `html` the namespace value of the second argument, for instance 17.

```

321 \def\XMLNS#1#2{
322   \utfeight@protect@chars
323   \XML@ns@alloc{#2}
324   \edef\@tempa{{#1}{\jg@NSuri{#2}}}
325   \global\XML@catalogue\expandafter{\the\expandafter\XML@catalogue
326     \expandafter\XML@XMLNS\@tempa}
327   \unprotect@utfeight}

```

This piece of code is a bit strange; it might produce unexpected results. The idea is the following. The command `\XML@checkknown` will run the catalogue in case of unknown elements. In the case of `<TEI.2>` or `<html>`, where no namespace prefix is given, the command `\XML@NAME` is set, and `\XML@NAME` may define `\XML@use`. However, if `\XMLNS` has been defined as above, this piece of code is also executed: it defines a default namespace, in particular it could replace `<0:html>` by `<17:html>`. The last action is to define `\XML@NAMESPACE`, and we are ready to run the catalogue again.

```

328 \def\XML@XMLNS#1#2{
329   \def\@tempa{#1}
330   \ifx\@tempa\XML@NAME
331     \edef\XMLNS@{#2}
332     \edef\XML@this@element{\XMLNS@\noexpand:\XML@this@local}
333     \let\XML@NAMESPACE\XMLNS@
334   \fi}

```

## 2.8 Reading elements

Let's start slowly. This piece of code is executed whenever we see a less-than sign, that is the start of an element. We have to distinguish between `</foo>`, `<?foo>`, `<!foo>` and `<foo>`. The procedure reads one character. What makes everything interesting is that `\fi` tokens are missing. On the other hand, we have inserted a `\@` marker, whose purpose is to skip easily over all useless tokens.

```

335 \def\XML@lt@markup#1{
336   \Normalspace
337   \ifx/#1\XML@getend
338   \else\ifx!#1\XML@getdecl
339   \else\ifx?#1\XML@getpi
340   \else\XML@getname#1\@}

```

The function that follows is defined in an environment where space, newline, and tabulation are active characters (remember that `\endlinechar` is  $-1$ , so that newline characters are produced only via `^M`). The code makes these characters active, and defines them; this action is local to a group (the groups ends on line 352). When we typeset some text, it is wise to activate these characters; on the other hand, spaces have normal category code when scanning attributes. In any case, space characters disappear at end of line, this explains the need of the `%` signs here. This

piece of code is called when the XML file contains <foo>; we have read the less than sign, and the letter that follows; the letter is in #1 (if you look at line 340, you see that #1 is nothing else than the first argument of \XML@lt@markup, because this cannot be \@. It could be Ä, i.e., the first byte of a Unicode character). We know that this is not slash, not an exclamation point, not a question mark, and we close these conditionals. The reader should take some time, in order to understand how \XML@tempa is defined.

```

341 \gdef\XML@getname#1@{
342   \fi\fi\fi
343   \begingroup
344   \Activespace
345   \def {\iffalse{\fi}\XML@getname@}
346   \let^{\M} %
347   \let^{\I} %
348   \def/{\iffalse{\fi}\XML@getname@}
349   \def>{\iffalse{\fi}\XML@getname@>}
350   \unrestored@protected\xdef\XML@tempa{\iffalse}\fi#1}

```

The last line contains \unrestored@protected\xdef; this is a command that modifies the behavior of some UTF-8 characters; it assumes to be in a group (thus the ‘unrestored’); it evaluates to \xdef (see line 257). After T<sub>E</sub>X has seen the opening brace, all tokens are expanded; as a result the ‘\iffalse}\fi’ is ignored; note that the ‘\iffalse{\fi’ that appears in the definition of space, tabulation, newline, slash, greater-than sign disappears also; the full expansion of these commands is: a closing brace, \XML@getname@, and maybe one character. It is this closing brace that terminates the \xdef; said otherwise, \XML@tempa will contain everything up to these characters. In the case <foo>, <foo/>, <foo a='b'>, it will contain ‘foo’. In the case of <José>, in a document with latin1 encoding, it will contain ‘JosÃ©’, where the Ä is an active character.

The \XML@getname@ command is defined below. It closes the group in which space and other characters have a funny definition. The \XML@begingroup is a hack that saves some stack space. It has the same features as \begingroup. The \XML@w@ command contains N spaces (where N is the current level). It is used for debugging, and argument grabbing. What the code does is: Put in \begintag the name of the element, in \XML@parent the current element (the parent of this one), initialize the current attribute list \XML@attribute@toks to the empty list, and parse the attributes.

```

351 \def\XML@getname@{
352   \endgroup
353   \XML@begingroup
354   \edef\XML@w@{ \XML@w@}
355   \let\begintag\XML@tempa
356   \let\XML@parent\XML@this@element
357   \XML@attribute@toks{}
358   \XML@getattrib}

```

All these \expandafter in the code have as purpose to pop the conditional stack (said otherwise, if the command takes an argument, the argument will be what follows the \fi, not the \fi itself)<sup>6</sup>. There are two cases to consider: there is an attribute, or there is none. In the case where there is no attribute, there are two subcases: the element can be empty or not. If you say <foo bar='gee'>, the first space was active, and read by the magic above; the second one has category code 10, and is discarded because the argument to this command is not a delimited argument.

```

359 \def\XML@getattrib#1{
360   \ifx#1/
361     \expandafter\XML@endempty

```

---

<sup>6</sup>Guess: why is there no \expandafter after the second \else?

```

362   \else
363     \ifx#1>
364       \expandafter\expandafter\expandafter\XML@startelement
365     \else
366       \XML@getattrib@a#1
367     \fi
368   \fi}
369 \let\XML@@getattrib\XML@getattrib

```

In the case of <foo bar='1'>, when the slash is seen, the greater sign is read, and </foo> is pushed back in the input stream. After that, we proceed as if there were no slash. This means that <foo/> is the same as <foo></foo>.

```

370 \def\XML@endempty#1>{
371   \expandafter\XML@startelement
372   \expandafter<\expandafter/\begintag>}

```

Here is a little trick: in the case where we are reading <foo bar='1'>, line 366 contains the command \XML@getattrib@a, followed by the letter b, followed by \fi\fi, followed by ar='1' (still unread). What we do is a trick to read an optional space before the equals sign (the space after the equals sign disappears because \XML@quoted uses an undelimited argument; a space in the attribute value will not disappear, because \XML@qq uses a delimited argument). We save the attribute name in a variable, and read the value.

```

373 \gdef\XML@getattrib@a#1\fi\fi#2={
374   \fi\fi
375   \XML@set@this@attribute#1#2 \@
376   \XML@quoted\XML@attribval
377
378 \def\XML@set@this@attribute#1 #2\@{
379   \def\XML@this@attribute{#1}}

```

You say \XML@quoted\foo'bar' or \XML@quoted\foo"bar". In both cases, \foo is called with bar as argument. In general, error handling is very poor. The purpose of \ERROR here is not to report an error in the case of wrong syntax. It will be used on line 550.

```

380 \def\XML@quoted#1#2{
381   \ifx#2"\expandafter\XML@qq
382   \else\ifx#2'\expandafter\expandafter\expandafter\expandafter\XML@q
383   \else
384     \ERROR#2
385   \fi \fi #1}
386 \def\XML@qq#1#2"#{#1{#2}}
387 \def\XML@q#1#2'#{#1{#2}}

```

In order to make things easier to understand, write \Att instead of \XML@this@attribute, this is the attribute to analyze. Write \AL instead of \XML@attribute@toks, this is the resulting list to which tokens will be added. Before we forget it: this command terminates on line 407, with \XML@getattrib, hence continues parsing the attribute list. The normalized attribute value is compared to \XML@ns@decl, a command that contains 'xmlns' with category codes 12. If the attribute name is 'xmlns', this defines the default namespace, if the attribute is 'xmlns:foo', this defines the namespace prefix 'foo' for this element and its content. In both cases, we call \XML@ns@uri. Otherwise if the attribute is foo:bar='gee' we add \XML@doattribute{foo}{bar}{gee} to the token list.

```

388 \def\XML@attribval#1{
389   \xdef\XML@tempa{\catxii\XML@this@attribute}
390   \ifx\XML@tempa\XML@ns@decl

```

```

391     \XML@ns@uri{}{\#1}
392 \else
393     \XML@ns\XML@this@attribute
394     \edef\XML@this@prefix{\catxii\XML@this@prefix}
395     \ifx\XML@this@prefix\XML@ns@decl
396         \XML@ns@uri\XML@this@local{\#1}
397     \else
398         \begingroup
399         \utfeight@protect@internal
400         \xdef\XML@tempa{
401             \the\XML@attribute@toks
402             \noexpand\XML@doattribute{\XML@this@prefix}{\XML@this@local}{\#1}}
403         \endgroup
404         \XML@attribute@toks\expandafter{\XML@tempa}
405     \fi
406 \fi
407 \XML@getattrib

```

Assume that we have `xmlns:foo='http://www.w3.org/1998/Math/MathML'`. This piece of code allocates a number for the URI if not already done. Let's assume that this number is 3. It then defines `\XMLNS@foo` to be 3. In the case `xmlns='...'` it defines `\XMLNS@`, the default namespace.

```

408 \def\XML@ns@uri#1#2{
409     \utfeight@protect@chars
410     \XML@ns@alloc{\#2}
411     \expandafter3\edef\jg@namespace{\#1}{\jg@NSuri{\#2}}
412     \unprotect@utfeight}

```

The next macro is called when we see the greater-than sign that closes the opening tag of an element. We first do something with default attributes, this will be explained later. After that, we split the element name into 'foo:bar'. Assume that the namespace number of 'foo' is 4, we put in '`\XML@this@element`' the tokens '4:bar'. We execute a piece of code that can possibly load a file in which the element's behavior is defined, and then, we execute the associated code. We shall see later that there is a command `\xmlgrab` that reads everything (including subelements) up to some end tag. This command redefines `\XML@doelement`. This explains why `\XML@doelement` is not inlined.

```

413 \gdef\XML@startelement{
414     \XML@default@attributes
415     \Activespace
416     \XML@ns\begin{tag}
417     \edef\XML@this@element{
418         \jg@namespace{\XML@this@prefix\expandafter}\noexpand:\XML@this@local}
419     \XML@checkknown
420     \XML@doelement}

```

The action associated to `<m:math>` is just to call `\E:3:math`. We shall see later how this command can be defined.

```

421 \def\XML@doelement{
422     \csname E:\XML@this@element \endcsname}

```

Assume that we want to evaluate `\E:3:math`. This routine does nothing if the command exists. Otherwise, it "runs the catalogue", and does a check: a warning is printed in case where the command does not exist. Assume first that the prefix is empty (has number 0). In this case, the catalogue can have an entry for the name (defined via the `\NAME` command), defining a file to load. Otherwise, the catalogue should have an entry for the namespace (here 3) defined via

\NAMESPACE. In any case, the catalogue should define \XML@use the name of a file to be loaded. We simplified a bit the code by introducing the \jg@this@namespace command; note that we could use \XML@this@element. Important note: on line 353, there is a command \XML@begingroup, so that all definitions from the included file are local to this group. If the current element is not the root element, and if you want the definitions to apply to all elements (and not only the descendants of this one), the definitions should better be \global.

```

423 \def\XML@checkknown{
424   \expandafter\ifx
425     \csname E:\jg@this@namespace:\XML@this@local\endcsname
426     \relax
427     \let\XML@use\@empty
428     \ifnum0=\jg@this@namespace
429       \let\XML@NAME\XML@this@local
430       \the\XML@catalogue
431     \else
432       \edef\XML@NAME{\jg@this@namespace}
433     \fi
434     \let\XML@NAME\relax
435     \the\XML@catalogue
436     \inputonce\XML@use
437     \expandafter\ifx\csname E:\jg@this@namespace\csname
438       :\XML@this@local\endcsname\relax
439       \XML@trace@warnE{Undefined}
440     \fi
441   \fi
442 }
```

## 2.9 End of element

Look at lines 337-340. When we are reading </foo >, the \XML@getend command is called after the slash has been read. This little piece of code grabs all tokens, until the end of the command (argument #1, unused), and everything up to the greater-than sign (argument #2). It closes the conditional, and calls another command (the purpose of the call is to get rid of the final space). Why this changes the category code of space and not tabulation is beyond me.

```

442 \def\XML@getend#1\@#2|{
443   \fi
444   \catcode`\ \active
445   \XML@getend@a#2 \@}
```

We have now read </foo >, and \endtag contains ‘foo’. We extract the namespace part, and call a command (that may be redefined in case of grab).

```

446 \gdef\XML@getend@a#1 #2\@{
447   \Activespace
448   \def\endtag{\#1}
449   \XML@ns\endtag
450   \XML@doend}
```

The action associated to </m:math> is to call the command named \E/:3:math. After that, we have to close a group (opened on line 353).

```

451 \gdef\XML@doend{
452   \csname E:\jg@this@namespace:\XML@this@local\endcsname
```

```
453   \XML@endgroup
454   \Activespace}
```

## 2.10 Using attributes

Consider `<X:elt foo:bar='gee' color='red' xmlns:X='myX' />`. We have already seen that the effect of the `xmlns:X` attribute is to define X as a namespace for this element and its children. In the case `foo:bar`, the definition of ‘foo’ could come later. For this reason, when we parse the attribute list, we construct a list of the form `\do{a}{b}{c}`<sup>7</sup>, in our case it contains `\do{foo}{bar}{gee}` and `\do{}{color}{red}`. This list is in `\XML@attribute@toks`. There is another list that contains terms of the form `\Att name\relax\cmd{val}action`<sup>8</sup>, it depends on the behavior of the element `<X:elt>`. Imagine that any element in the X namespace has an attribute `some:background`, with a default value of black, and `<X:elt>` has an attribute `color`, with some default value, and that some action is associated to it. This second list is the argument of the macro whose definition follows. It is constructed by `\XMLElement`; this construction can occur because of autoloading of some package, and this depends on the current namespace, i.e., `myX`. What follows `\Att` is the name with its namespace, for instance `25:background` or `0:color`; it is followed by `\relax` and the name of the command in which the element can get the value; it is followed by the default value (in braces) and an action (a sequence of commands, generally empty). Let’s assume that there is no action for the background, but `\checkcolor` for the color.

This piece of code evaluates both lists, with a double `\relax` at the end. We have to evaluate all namespaces, but there is no default namespace for attributes. For this reason we set `\XMLNS@` to 0.

```
455 \def\XML@setattributes#1{
456   \let\XMLNS@@\XMLNS@
457   \def\XMLNS@#0{
458     \the\expandafter\XML@attribute@toks#1\relax\relax
459     \let\XMLNS@\XMLNS@@}
```

Let’s assume that our big list is the following `\do{foo}{bar}{gee} \do{}{color}{red} \Att 25:background\relax \setbg{black} \Att 0:color\relax \setcol{blue} \checkcolor \relax \relax`. We give here the definition of the command that evaluates the `\do`. It reads the three token lists that follow and defines a command that will be used twice. If this command is `\T`, then `\T\foo` applies `\foo` to some argument, namely `\Att name\relax`, where the character string between the two commands is the full name, for instance `17:bar` or `0:color`.

```
460 \def\XML@doattribute#1#2#3{
461   \xdef\XML@tempa##1{\noexpand##1
462   \noexpand\XML@attrib{jg@namespace{#1}:#2\relax}}
463   \XML@tempa\XML@attrib{x{#3}}
464   \XML@tempa\XML@attrib{y}}
```

The command that follows is called twice in our example, with arguments ‘`\Att17:bar\relax`’ and ‘`gee`’, then ‘`\Att0:color\relax`’ and ‘`red`’. The action is to define a command `\XML@tempb`, whose action is to read some tokens, and define some command to be ‘`gee`’ or ‘`red`’. We shall see in a moment how this command is used. Putting a `\def` in a `\def` in a `\def` is unusual. There is a priori no reason why the second one should be global. The inner one has to be local.

```
465 \def\XML@attrib{x#1#2{
466   \gdef\XML@tempb##1##2##3##4\relax\relax{
```

<sup>7</sup>Here `\do` is short for `\XML@doattribute`

<sup>8</sup>Here `\Att` is short for `\XML@attrib`

```
467 \def##2{#2}
468 ##1##4\relax\relax}
```

The command that follows is simple (its body has one line) but a bit subtle. Remember the long list of tokens shown above. It is of the form `\do... \do... \Att... \Att... \relax\relax`. We have read the `\do...`, and constructed a `\Att...`, which is in #1. Everything else is in #2. We apply `\XML@tempb` to the list, where the first `\do...` is removed and a new `\Att...` is added. Remember that `\Att` is followed by a name, then `\relax`, a command, a value, and maybe action. In #1 we have only the name and `\relax`; we provide here `\XML@temp@1` as command name, and 6 as value. We show the code, then the explanations.

```
469 \def\XML@attrib@y#1#2\relax\relax{
470   \XML@tempb#2#1\XML@temp@1{6}\relax\relax}
```

Consider first the case where #1 is ‘`\Att17:bar\relax`’. The command `\XML@tempb` takes four arguments, the first argument is delimited by #1, and the last by a double `\relax`. Our element `<X:elt>` knows nothing about ‘foo:bar’, so that the #1 is the one provided on line 470. Thus, the first argument is #2, the second argument is `\XML@temp@1`, the third argument is ‘6’, the last is empty. The effect of line 467 is to define `\XML@temp@1`, this is a dummy command, its definition is irrelevant. The effect of line 468 is to evaluate the long list again.

Consider now the case where #1 is ‘`\Att0:color\relax`’. This is found in the long list because the element accepts the `color` attribute. Hence the arguments of `\XML@tempb` are the following: The first argument is ‘`\Att 5:background\relax \setbg {black}`’ (in general, it starts with all the unhandled `\do...` commands), the second argument is ‘`\setcol`’, the third is ‘blue’, the last is ‘`\checkcolor \Att 0:color\relax \XML@temp@1 {6}`’. The concatenation of arguments 1 and 4 is the long list, with the `\Att...` of color removed, and re-inserted at the end, with `\XML@temp@1` as command and 6 as value. The action is to define `\setcol` to ‘red’. The definition is local to the group started on line 353, ended on line 453. The action associated to `<X:elt>`, `</X:elt>` and descendants can see this value.

After all these `\do...` have been evaluated, our long list reduces to ‘`\Att 25:background\relax \setbg {black} \checkcolor \Att 0:color\relax \XML@temp@1 {6} \relax \relax`’. This is the list constructed by `\XMLElement`, possibly re-ordered, where the command name associated to attributes that have a value is replaced by a dummy name. Note the placement of `\checkcolor` in this list: when it is evaluated, `\setcol` is defined, either to the value of the XML file or the default value. The definition of `\Att` is given here: it sets `\setbg` to black, and `\XML@temp@1` to 6. The only subtlety is that, if the default value is `\inherit` nothing happens. Note: the initial value should always be defined; however, the code checks this, replacing undefined by `\relax`.

```
471 \def\XML@attrib#1\relax#2#3{
472   \ifx\inherit#3\relax% #3 might be empty
473     \ifx#2\@undefined
474       \def#2{\relax}
475     \fi
476   \else
477     \def#2{#3}
478   \fi%
479 %
480 \let\inherit\XML@attrib % just some random name
```

## 2.11 Processing instructions

We consider here parsing `<?xml?>`. The layout here is awful, for the same reason as `\XML@getname`. We use however a different trick: we use `\csname` and define the delimiters (space, question mark), to evaluate to `\endcsname` (no namespace hacking needed here).

```

481 \gdef\XML@getpi#1@{
482   \fi\fi\fi
483   \begingroup
484   \utfeight@protect@chars
485   \Activespace
486   \def?{\endcsname?}
487   \let \endcsname
488   \let^~M\endcsname
489   \let^~I\endcsname
490   \expandafter\XML@getpi@\csname
491   Q:\}
```

Hence, in the case `<?xml something?>`, the `\XML@getpi@` command is called, with as argument the token `\Q:xml`. What we do is close the current group, activate spaces, evaluate the command. If the command is not defined, we put a `\XML@getpi@x` before it. Note that, if a command is constructed by `\csname`, its value is `\relax` instead of undefined; this is a local assignment, after `\endgroup`, the undefined value is restored. Note that the action associated to `<?xml?>` is defined on line 198.

```

492 \def\XML@getpi@#1{
493   \endgroup
494   \Activespace
495   \ifx#1\undefined
496     \expandafter\XML@getpi@x
497   \fi
498   #1}
```

In the case where `<?foo something?>` is seen, and the command `\Q:foo` is undefined, we read everything, and call `\XML@dopi` with innocent arguments.

```

499 \def\XML@getpi@x#1#2?>{
500   \XML@dopi{Undefined}{}}
```

In the case `<?xmltex something?>` we use an auxiliary command that grabs the content with the right category codes. This allows TeX commands, with TeX syntax.

```

501 \expandafter\def \csname Q:xmltex\endcsname{
502   \begingroup
503   \XML@reset
504   \catcode`>\active
505   \XML@xmltexpi}
```

The code of the command is trivial. We call `\XML@dopi`.

```

506 \gdef\XML@xmltexpi#1?>{
507   \endgroup
508   \XML@dopi{xmltex}{#1}}
```

The default action is trivial also. Not inlined because of grabbing.

```

509 \def\XML@dopi#1#2{
510   #2}
```

## 2.12 Declarations

In this paragraph, we consider declarations, things that start with <!. Here the \@ has as purpose to read in #1 all tokens up to the end of \XML@lt@markup. We read the first two characters after the <! and decide what to do. The @ at the end makes reading of arguments easy.

```

511 \def\XML@getdecl#1@#2#3{
512   \fi\fi
513   \if-\noexpand#2\XML@comment    % -- 
514   \else\if N\noexpand#3\XML@entity% EN TITY
515   \else\if L\noexpand#3\XML@dec@e% ELEMNT
516   \else\if A\noexpand#2\XML@dec@a% AT TLIST
517   \else\if D\noexpand#2\XML@doctype% DO CTYPE
518   \else\if C\noexpand#3\XML@cdata% [C DATA
519   \else      \XML@dec@n%          NOTATION
520 }

```

Easy part: Element declarations are ignored. In fact, elements can only be defined via an xmt file.

```

521 \def\XML@dec@e#1@#2{
522   \fi\fi\fi
523   \XML@checkend@subset}

```

In the case of <!ATTLIST...> declarations, we will do something. We start with closing all conditionals. After that, we read the element name and save it somewhere. Then we parse the list.

```

524 \def\XML@dec@a#1 #2 {
525   \fi\fi\fi\fi
526   \protected@xdef\XML@tempa{#2}
527   \XML@dec@a@x}

```

The XML production number 52 says that we should have ‘AttDef\*’, optional space and close tag; thus the code fails if no attribute is declared. Let’s hope that the list is not empty. Production 53 says that ‘AttDef’ is space, name, space, ‘AttType’, space, ‘DefaultDecl’. We read the name and store it in \XML@tempb. After that we look at the character that follows. It could be an open parenthesis, or something else. The type of the attribute is ignored.

```

528 \gdef\XML@dec@a@x#1 #2{
529   \protected@xdef\XML@tempb{#1}
530   \if(\noexpand#2
531     \begingroup
532       \catcode`\\active
533       \expandafter\XML@dec@a@brack
534     \else
535       \expandafter\XML@dec@a@type
536     \fi}

```

Rule 59 says that the type can be a list enclosed by parentheses.

```

537 \gdef\XML@dec@a@brack#1{
538   \endgroup
539   \XML@dec@a@hash}

```

According to rules 54, 55, and 56, the type can be CDATA, ID, IDREF, IDREFS, ENTITY, ENTITIES, NMTOKEN or NMTOKENS. It could also be NOTATION followed by a list. Here we skip over the word, and continue parsing.

```
540 \def\XML@dec@a@type#1 {
541   \XML@dec@a@hash}
```

Rule 60 says that we should have #REQUIRED, #IMPLIED, or a default value, optionally preceded by #FIXED. We consider three cases: If we see a #, we read it via \XML@dec@a@type; this will call this function. Said otherwise, when we are here, we might have read the #FIXED, and are ready for the value, or we might have read #REQUIRED, and a > sign is OK, as well as another attribute declaration; for this reason, we redefine \ERROR: this command is called when the character that follows is neither a single quote nor a double quote.

```
542 \gdef\XML@dec@a@hash$1{
543   \if\noexpand$1#
544     \expandafter\XML@dec@a@type
545   \else
546     \ifx$1>
547       \let\ERROR\undefined
548       \expandafter\expandafter\expandafter\XML@checkend@subset
549     \else
550       \let\ERROR\XML@dec@a@nodef
551       \XML@dec@a@def$1
552     \fi
553   \fi}
```

When we come here, we have finished our ‘AttDef’ and we are ready for the next one.

```
554 \gdef\XML@dec@a@nodef#1\fi\fi#2{
555   \fi\fi
556   \XML@dec@a@x#1}
```

When we come here, we have a default value for the attribute.

```
557 \def\XML@dec@a@def#1\fi\fi{
558   \fi\fi
559   \XML@quoted\XML@dec@a@default#1}
```

This code adds \XML@add@attrib{name}{att}{val} to a global list, where ‘name’ is the name of the element, ‘att’ the name of the attribute and ‘val’ the default value of the attribute. It continues parsing the declaration.

```
560 \def\XML@dec@a@default#1#2{
561   \ifx\XML@default@attributes\relax
562     \let\XML@default@attributes\@empty
563   \fi
564   \toks@\expandafter{\XML@default@attributes}
565   \protected@xdef\XML@default@attributes{
566     \the\toks@\noexpand\XML@add@attrib{\XML@tempa}{\XML@tempb}{#1}}
567   \XML@dec@a@hash#2}
```

Remember line 414: there was \XML@default@attributes. This list was constructed by the code above. It consists of a sequence of \XML@add@attrib ABC. What we do here is to evaluate in a context where \begintag is the element to be evaluated. If it matches, we call \XML@attribval. The effect is as if the user gave B = ‘C’; in the case B = ‘something’ is on the attribute list, this is evaluated first, and the B = ‘C’ is useless.

```
568 \def\XML@add@attrib#1#2#3{
569   \gdef\XML@tempa{#1}
570   \ifx\XML@tempa\begintag
571     \def\XML@this@attribute{#2}
572     \let\XML@getattrib\relax
```

```

573     \XML@attribval{#3}
574     \let\XML@getattrib\XML@getattrib
575     \fi}

```

This reads a comment. The code is trivial. An intermediary command is needed for the case where we want to grab something.

```

576 \def\XML@comment#1@#2--{
577   \fi
578   \Activespace
579   \XML@comment@}

This is the intermediary command.

580 \def\XML@comment@{\XML@checkend@subset}

```

## 2.13 Entities

We have to distinguish between `<!ENTITY foo ...>` and `<!ENTITY % foo ...>`. If a percent character is present, this is a parameter entity, and it can be used only in a DTD. Moreover, it is always a parsed entity (no NDATA allowed in the declaration). The command defined here takes as argument some junk, and what follows, the percent sign or a name. Here in the code, we have two versions of `\XML@input`. This command will be explained later. We continue parsing with `\XML@p@ent` or `\XML@ent`.

```

581 \gdef\XML@entity#1 #2 {
582   \fi\fi
583   \ifx%#2
584     \def\XML@input{
585       \ifx\XML@use\XML@SYSTEM\expandafter\@gobble\else
586         \noexpand\inputonce\fi}
587     \expandafter\XML@p@ent
588   \else
589     \def\XML@input{\noexpand\xmlinput}
590     {\utfeight@protect@chars\xdef\XML@ename{##2}}
591     \expandafter\XML@ent
592     \fi}

```

We have to distinguish between `<!ENTITY % foo "val">`, `<!ENTITY % foo2 SYSTEM "val">`, and `<!ENTITY % foo3 PUBLIC "file" "val">`. Here we put in `\XML@ename` the entity name '%foo1' and look at the first character of what follows.

```

593 \gdef\XML@p@ent#1 #2{
594   {\utfeight@protect@chars\xdef\XML@ename{##1}}
595   \if\noexpand#2P\XML@E@public
596   \else\if\noexpand#2S\XML@E@system
597   \else\XML@E@internal#2}

```

We have to make the same distinctions in the case `<!ENTITY foo1 ...>`. Here we have put the entity name '&foo1' in `\XML@ename` and look at the first character of what follows. This looks like above, but NDATA is allowed here.

```

598 \def\XML@ent#1{
599   \if\noexpand#1P\XML@E@public
600   \else\if\noexpand#1S\XML@E@system
601   \else\XML@E@internal#1}

```

This handles the case `<!ENTITY % foo1 "val">` or `<!ENTITY foo2 'val'>`. In `\XML@ename` we have '`%foo1`' or '`&foo2`'. We have read the opening quote. What we do on line 607 is to redefine it to be `</`, so that the parser will see `val</>`. We will read the argument via `\xmlgrab`. This command will be explained later; the important point is that it will read everything up to the end of the current element (i.e. up to the `</>`), and call the command associated to the current element, defined on line 608. The effect is to call `\XML@E@internal@x` after the assignment, which is the `\gdef` that defines `\+%foo1` or `\+&foo2` with as body all the grabbed text. The whole difficulty is that the declaration could be something like `<!ENTITY ier "<hi rend='sup'>er</hi>"`, so that the attribute list has to be parsed, but it is too early for namespace processing. For this reason, some commands have to be redefined.

```

602 \gdef\XML@E@internal#1{
603   \fi\fi
604   \begingroup
605   \let\XML@endgroup\endgroup % use real groups instead of faked ones.
606   \let\XML@begingroup\begingroup
607   \def#1{</}
608   \expandafter\def\csname E\string/: \endcsname{
609     \afterassignment\XML@E@internal@x
610     \expandafter\gdef\csname+\XML@ename\endcsname}
611   \begingroup
612   \let\XML@ns@decl\relax% stop xmlns 'attribute' being recognised
613   \let\XML@this@local\empty
614   \def\XML@this@prefix{} % set up special prefix to gobble colon
615   \let\XML@checkknown\relax % disable these
616   \def\XML@ns##1% hobble namespace code to put all name in local part.
617     \protected@edef\XML@this@local{##1}
618   \def\XML@this@prefix{}
619   \xmlgrab}
```

This closes the group started line 611. After that, we execute three tokens after the current group, namely `\XML@trace@warn` (for debug), `\+&foo2` (argument of previous) and `\fihack`. The group ends because of the token at line 812 (the `\XML@endgroup` redefined above).

```

620 \def\XML@E@internal@x{
621   \endgroup
622   \aftergroup\XML@trace@warn
623   \expandafter\aftergroup\csname+\XML@ename\endcsname
624   \aftergroup\fihack
625 }
```

The `\fi` comes from line 813. This piece of code just ignores the conditional. It continues parsing of the element.

```
626 \def\fihack#1\fi{\expandafter\XML@checkend@subset}
```

When we see `<!ENTITY foo PUBLIC 'pub-part' 'system-part'>`, this piece of code finishes reading the `PUBLIC` token, then reads `pub-part`, and calls `\XML@E@pubid`.

```

627 \def\XML@E@public#1 {
628   \fi
629   \XML@quoted\XML@E@pubid}
```

After that, all characters in `pub-part` are converted to category 12, using a classical method, the result is stored in `\XML@E@pubid`, and `system-part` is read.

```

630 \def\XML@E@pubid#1{
631   \def\XML@PUBLIC{#1}
```

```

632 \edef\XML@PUBLIC{\catxii\XML@PUBLIC}
633 \XML@quoted\XML@E@systemid}

The case <!ENTITY foo SYSTEM 'system-part'> is similar, but there is no public part.

634 \def\XML@E@system#1 {
635   \fi\fi
636   \def\XML@PUBLIC{}
637   \XML@quoted\XML@E@systemid}

```

Now we run the catalogue. This sets `\XML@use` to either the value associated to the ‘pub-part’ in a PUBLIC item of the catalogue, or the value associated to the ‘system-part’ in a SYSTEM item, or `\XML@SYSTEM` if nothing is found. Assume that this is X; we call `\XML@E@internal@` with `\XML@input{X}` as first argument, the second argument being the unread character, that should be a greater-than sign (but junk is silently ignored). An unparsed entity contains NDATA Y for some Y. In this case, the command is called with `{Y}{X}` instead, and `\XML@E@ndata` is used to read Y.

```

638 \def\XML@E@systemid#1#2{
639   \def\XML@SYSTEM{#1}
640   \let\XML@use\XML@SYSTEM
641   \the\XML@catalogue
642   \if\noexpand#2N
643     \expandafter\XML@E@ndata
644   \else
645     \afterfi
646     \XML@E@internal@\{\XML@input{\XML@use}\}#2
647   \fi}

```

In the case of NDATA, we hack a bit. All characters up to the greater-than sign are read, this gives three lists: the unread part of ‘NDATA’, the value that follows, optional junk.

```

648 \def\XML@E@ndata#1 #2>\{\XML@ndata@#2 >
649 \def\XML@ndata@#1 #2>{
650   \XML@E@internal@\{\#1\}\{\XML@use\}}>}

```

The command takes two arguments: some action, and everything that remains on the current element. Assume that we consider <!ENTITY % foo SYSTEM "bar">. In this case (parameter entity), we define `\+%foo`; its body will be the expansion of #1. This is `\XML@input{\XML@use}`, where the argument is what is found in the catalogue, and the command is defined on lines 584 or 589. In the case of `foo`, without percent sign (general entity), the command `\XML@input` is the same as `\xmlinput`. Otherwise, it is `\inputonce` (except: it ignores the argument if not found in the catalogue).

```

651 \def\XML@E@internal@#1#2>{
652   \expandafter\protected\csname+\XML@ename\endcsname{#1}
653   \XML@checkend@subset}}

```

This is done at the end of an <!ENTITY...> declaration.

```

654 \gdef\XML@checkend@subset{
655   \Normalspace
656   \XML@checkend@subset@}

```

This is a bit strange: why does the command take these four arguments? The definition of the percent character is to make it a normal Unicode character (end of local DTD).

```

657 \gdef\XML@checkend@subset@#1#2#3#4{
658   \ifx]#1
659   \let\XML@w@\empty
660   \gdef%\{\utf eightay\}

```

```

661   \let\XML@checkend@subset\relax
662   \expandafter\XML@loaddoctype
663   \fi
664   #1#2#3#4}

```

In the case where the <!DOCTYPE> element specifies a DTD, we load the file.

```

665 \def\XML@loaddoctype#1#2{
666   \Activespace
667   \ifx\XML@D@dtd\relax\else
668     \inputonce\XML@D@dtd
669   \fi}

```

## 2.14 Interpreting the Doctype element

Consider now that case of <!DOCTYPE TEI.2 SYSTEM "teilite.dtd">. This piece of code finishes reading the DOCTYPE name, then the name of the document element, it puts it in \documentelement. It then checks if what follows is PUBLIC, SYSTEM, an internal subset, or the end of the element. The command closes all \fi that are open. There is an @ here that makes it easy to skip over the conditionals defined here.

```

670 \gdef\XML@doctype#1 #2 #3{
671   \fi\fi\fi\fi\fi
672   \def\documentelement{#2}
673   \let\XML@D@dtd\relax
674   \if\noexpand#3P\XML@D@public
675   \else\if\noexpand#3S\XML@D@system
676   \else\ifx#3[\XML@D@internal
677   \else%must be > the end
678     \XML@D@empty
679   @}

```

If nothing is given, we have nothing to do.

```

680 \gdef\XML@D@empty @{
681   \fi\fi\fi}

```

In the case of PUBLIC, we parse the public value, and do something with it.

```

682 \gdef\XML@D@public#1 {
683   \fi
684   \XML@quoted\XML@pubid}

```

In the case of <!DOCTYPE foo PUBLIC "aaa" "bbb">, we put the aaa part in \XML@PUBLIC, change all category codes to 12, and read the 'bbb' part.

```

685 \gdef\XML@pubid#1{
686   \def\XML@PUBLIC{#1}
687   \edef\XML@PUBLIC{\catxii\XML@PUBLIC}
688   \XML@quoted\XML@systemid}

```

In the case of <!DOCTYPE foo SYSTEM "bbb">, it is as above, but the public part is empty.

```

689 \gdef\XML@D@system#1 {
690   \fi\fi
691   \def\XML@PUBLIC{}
692   \XML@quoted\XML@systemid}

```

We put the bbb part in \XML@SYSTEM, change all category codes to 12, run the catalogue, and put the result in \XML@D@dtd for later use by \XML@loaddoctype.

```

693 \gdef\XML@systemid#1{
694   \protected@edef\XML@SYSTEM{#1}
695   \edef\XML@SYSTEM{\catxii\XML@SYSTEM}
696   \let\XML@use\@empty
697   \the\XML@catalogue
698   \let\XML@D@dtd\XML@use
699   \XML@D@internal@}

```

When we have no PUBLIC and no SYSTEM part, but only a local DTD, we call this: it pops the conditional stack, and pushes back the open bracket. The action is the same as if a PUBLIC or SYSTEM part had been given.

```

700 \gdef\XML@D@internal#1@{
701   \fi\fi\fi
702   \XML@D@internal@[]

```

We parse the internal DTD in the same fashion as everything else. However %foo; evaluates to something, so that the percent sign must be activated. The vertical bar is used for comments.

```

703 \gdef\XML@D@internal@#1{
704   \ifx[#1
705     \let%\XML@pcnt
706     \edef\XML@w@{\XML@w@}
707     \expandafter\XML@checkend@subset
708   \else
709     | it had better be the closing >
710   \fi}

```

Inside a local DTD, the parameter entity '%foo;' evaluates to \+%foo.

```

711 \gdef\XML@pcnt#1;{
712   \csname+\#1\endcsname
713   \XML@checkend@subset}

```

When you say &#foo; the \XML@charref command is called to parse the entity; the result is in \XML@tempa. It will in general be evaluated right now. On the other hand '&foo;' evaluates to \+&foo, there is no intermediate command.

```

714 \let&\XML@amp@markup
715 \gdef\XML@amp@markup$1$2;{
716   \ifx#$1\@empty
717     \XML@charref$2;
718     \XML@tempa
719   \else
720     \begingroup\utfeight@protect@chars
721     \expandafter\aftergroup
722     \csname+\string&$1$2\expandafter\endcsname
723     \endgroup
724   \fi}

```

In the case of <! [CDATA xxx ]]>, this reads up to the first space.

```

725 \gdef\XML@cdata #1[{
726   \fi\fi\fi\fi\fi
727   \Activespace
728   \XML@cdata@a}

```

And this reads everything up to the special end marker ]]>. Less-than sign and ampersand are not active.

```

729 \gdef\XML@cdata@a#1]{{
730   \begingroup
731   \edef<{\noexpand\utfeightaz\string<}
732   \edef&{\noexpand\utfeightaz\string&}
733   \XML@docdata{#1}}

```

The action here is trivial. We need an intermediary command, in the case of grab.

```

734 \def\XML@docdata#1{#1\endgroup}

```

The only thing done here is to skip over everything, until the end.

```

735 \def\XML@dec@n#1N #2 #3 {
736   \fi\fi\fi\fi\fi
737   \XML@quoted\XML@notation
738 }

```

```

739
740 \def\XML@notation#1#2{
741   \ifx>#2
742     \expandafter\XML@checkend@subset
743   \else
744     \afterfi
745     \XML@quoted\XML@notation#2
746   \fi}

```

## 2.15 Grabbing content

The normal behavior of `<foo>text</foo>` is like `\begin{foo}text\end{foo}`. This method is the most efficient concerning memory space. In some cases, we prefer the equivalent of `\def \arg {text}, \foo {\arg}`. The interesting point is that, assuming that `<foo>` takes two children, and that we do not care about cases with incorrect syntax, we can manage everything so that the user function sees these two children, for instance in the form `\split\arg\first\second` followed by `\foo\first\second`. In fact, instead of calling a single command, we call two commands, as `\foofirst\first, \foosecond`.

The following piece of code is the definition of the `<m:msup>` element in the MathML namespace. We shall explain the syntax of `\XMLElement` later. Line 10002 says: we do not care about attributes, line 10003 says that we want to grab the content of the element. Line 10004 says: there are two children, and we want to apply some commands to them.

```

10000 \XMLElement{m:msup}
10001   {}
10002   {\xmlgrab}
10003   {\xmltexttwochildren@\firstofone\sp#1}

```

We shall define `\xmlgrab` below. It will read the content of the element, and use `\empty` as element separator (see code line 819); remember that `\empty` expands to nothing, hence is harmless. This marker allows easy splitting. In the case of the example of the start of the chapter, the tokens are

```

\xmltexttwochildren@\firstofone\sp
+<3:mi^^I>L</3:mi>\empty <3:mn^^I>2</3:mn>\empty +

```

The second line is printed by TeX, when we ask for the value of `+#1+`, we have inserted the plus signs, this being the easiest way to see that each `\empty` is followed by a space (they are in the input file), and for each opening tag, a tabulation between the tag name and the attribute list (which is empty in this case). With the definition below, the arguments of `\xmltexttwochildren` will be

```
#1=\@firstofone
#2=\sp
#3=<3:mi>L</3:mi>
#4=<3:mn>2</3:mn>
```

(we did not show the tabulations, nor the spaces). Tabulations are read again by the parser when looking for attributes, spaces are ignored, as usual, in math mode. The effect of the command is to apply the first argument to the third, the second to the fourth. If the arguments are, say, \A, \B, CC and DD, the result is \A{CC}\B{DD}. In our case, we want CC<sup>DD</sup>, so that \A is just a command that removes useless braces, and \B is the T<sub>E</sub>X primitive for superscripts.

```
747 \def\xmltexttwochildren#1#2#3\@empty#4\@empty{
748   #1{#3}#2{#4}}
749 \def\xmltextthreechildren#1#2#3#4\@empty#5\@empty#6\@empty{
750   #1{#4}#2{#5}#3{#6}}
```

This is a small function that returns everything before the \@empty. You have to use \@ to mark the end of the child list (only first child is used here).

```
751 \def\xmltexfirstchild#1\@empty#2\@{
752   #1}
```

If you say \xmltexforall\cmd{list}, where the second argument is a list of tokens with \@empty between tokens, this applies \cmd to each item. Moreover, the quantity \xml@name contains the name of the element. The end of the loop relies on the fact that no element name starts with a space.

```
753 \def\xmltexforall#1#2{
754   \xmltexf@rall#1#2< >\@empty}
755
756 \def\xmltexf@rall#1#2<#3 #4>#5\@empty{
757   \ifx\relax#3\relax
758   \else
759   \def\xml@name{#3}#1{<#3 #4>#5}
760   \expandafter\xmltexf@rall\expandafter#1
761   \fi}
```

The action associated to <foo> consists in two parts: first all attributes are scanned, and some commands are instantiated (see section 2.10), and then the start code is executed (in the example, line 10002). When we see </foo>, we execute the end code (line 10003, in the example). In the special case where the initial action is \xmlgrab, the command gets an argument. This argument is computed on line 811 as the value of the token list \XMLgrabtoks. Thus, the \xmlgrab command must read all tokens, up to the end tag; it must handle namespaces properly (as the example shows, all namespaces, even the default ones, are replaced by integers).

The idea is to redefine temporarily all commands \XML@do..., for the case <foo>, <?foo>, <!foo>, and </foo>, and ask them to put the result in the list. We store in \XML@next@level the value of \XML@w@ at the next level. It is thus possible to check, for a given element, if it is a child (and not merely a descendant) of the current element, so that we know where to insert the \@empty markers. The main routine here is \grab@.

```
762 \def\xmlgrab{
763   \begingroup
764   \global\XMLgrabtoks={}
765   \let\XML@this@level\XML@w@
766   \edef\XML@next@level{\XML@w@}
767   \let\XML@doelement\XML@grabelement
768   \let\XML@doend\XML@grabend
769   \let\XML@docdata\XML@grabcdata
```

```

770   \let\XML@comment@\XML@grabcomment@
771   \let\XML@dopi\XML@grabpi
772   \XMLgrab@}

```

This uses the same magic as `\XML@getname`. The idea is to read everything until the next less-than sign, putting all tokens in the command `\XML@tempa`.

```

773 \def\XMLgrab@{
774   \utfeight@protect@internal
775   \def<{\iffalse{\fi}\XMLgrab@@}
776   \xdef\XML@tempa{\iffalse}\fi}

```

When `\XMLgrab@` has read everything between tags, it puts the grabbed tokens in the token register `\XMLgrabtoks`, and then evaluates the less-than sign.

```

777 \def\XMLgrab@@{
778   \global\XMLgrabtoks\expandafter{\the\expandafter\XMLgrabtoks\XML@tempa}
779   \XML@lt@markup}

```

This command is called when we grab the content of an element. Assume that we have seen `<mi>L</mi>`. When we are here, we have seen the first less-than sign. And we know that `\XML@this@element` is '3:mi'. We add to the token list `<3:mi attrs>`. There is a tabulation after the element name, this is obtained by uppercasing the tilde. Attributes are added by a call to `\the\XML@attribute@toks`, with a temporary redefinition of `\XML@doattribute`, and the default namespace is neutralized.

```

780 \uppercase{
781 \gdef\XML@grabelement{
782   \Activespace
783   \global\XMLgrabtoks\expandafter{
784     \the\expandafter\XMLgrabtoks
785     \expandafter<\XML@this@element~}
786   \begingroup
787   \let\XML@doattribute\XML@grabattribute
788   \def\XMLNS@{0}
789   \expandafter\let\csname XMLNS@0\endcsname\XMLNS@
790   \the\XML@attribute@toks
791   \endgroup
792   \Activespace
793   \global\XMLgrabtoks\expandafter{
794     \the\XMLgrabtoks
795     >}
796   \XMLgrab@}
797 }

```

Assume that `foo:bar = 'gee'` is in the attribute list of the current element, and assume that `foo` has namespace number 4. We add `4:bar="gee"` and a space to the token list.

```

798 \gdef\XML@grabattribute#1#2#3{
799   \protected\xdef\XML@tempa{\jg@namespace{#1}:#2}
800   \global\XMLgrabtoks\expandafter{
801     \the\expandafter\XMLgrabtoks
802     \XML@tempa="#3" }

```

Let's assuming that we are grabbing something and we see `</foo>`. There are two cases to consider. If this element is the one we are looking for, we close the group open by `\xmlgrab`, and we execute the command `\E/:3:msup` (there are some hacks here; the `\uppercase` command replaces dot and star by slash and colon with the right category code). We pass the grabbed token list as argument. This is achieved by putting an `\expandafter` just before the `\endcsname`, it will

expand `\the`, i.e., replace `\XMLgrabtoks` by its value (since we want braces around this token list, another `\expandafter` is needed). After execution of the command, we have to close our XML group and hack with category codes. On the other hand, in the case where the element does not end grabbing, we add `</4:foo>` to the end of the `\XMLgrabtoks` token list. If this is a direct child, we add also a `\empty` marker. We continue grabbing via a call to `\XMLgrab@`.

```

803 \uppercase{
804 \gdef\XML@grabend{
805   \ifx\XML@this@level\XML@w@
806     \endgroup
807     \csname
808       E.*\jg@this@namespace
809       *\XML@this@local
810     \expandafter\endcsname\expandafter{
811       \the\XMLgrabtoks}
812     \XML@endgroup
813     \ifnum\catcode`^=10 \Activespace \fi
814   \else
815     \xdef\XML@tempa{\noexpand<\noexpand/
816       \jg@this@namespace\noexpand: %%% \expandafter omitted [jg]
817       \XML@this@local
818     \noexpand>
819     \ifx\XML@next@level\XML@w@\noexpand\empty\fi}
820     \global\XMLgrabtoks\expandafter{
821       \the\expandafter\XMLgrabtoks
822       \XML@tempa}
823     \XML@endgroup
824   \expandafter
825     \XMLgrab@
826   \fi}}

```

When we want to grab something and see `<?PI etc?>`, we add all these tokens to our list.

```

827 \gdef\XML@grabpi#1#2{
828   \global\XMLgrabtoks\expandafter{
829     \the\XMLgrabtoks<?#1^^I#2?>}
830   \XMLgrab@}

```

If you say `\NDAEntity\att\A\B`, if the expansion of `\att` is something like `foo`, and `\&+foo` expands to `\bar` and `\gee`, this piece of code applies `\A` to `\bar` and `\B` to `\gee`<sup>9</sup>.

```

831 \gdef\NDAEntity#1{
832   \expandafter\expandafter\expandafter
833   \XML@ndataentity\csname+\#1\endcsname}

834 \gdef\XML@ndataentity#1#2#3#4{
835   #3{#1}#4{#2}}

```

Grabbing CDATA is easy: what we do is re-insert the content of the element, and continue grabbing. Ampersands and less-than signs are replaced by the equivalent of `&` and `<`, said otherwise, inactive characters.

```

837 \def\XML@grabcdata#1{
838   \utfeight@protect@internal
839   \edef<{\noexpand\utfeightaz\string<}
840   \edef&{\noexpand\utfeightaz\string&}

```

---

<sup>9</sup>This is unclear to me

```

841 \xdef\XML@tempa{#1}
842 \endgroup
843 \expandafter\XMLgrab@\XML@tempa}
When we grab a comment, the only thing we need to do is continue grabbing.
844 \def\XML@grabcomment@{
845   \XMLgrab@}

```

## 2.16 Defining actions

This is for use in a .xmt file, the file that defines actions for each element. After `\XMLentity{foo}{bar}`, the XML entity `&foo;` evaluates to `bar`.

```

846 \gdef\XMLentity#1#2{
847   \expandafter\gdef\csname+\endcsname{#2}}

```

These are the predefined entities:

```

848 \XMLentity{amp}{\utf eightaz&}
849 \XMLentity{quot}{\utf eightax"}
850 \XMLentity{apos}{\utf eightax'}
851 \XMLentity{lt}{\utf eightaz<}
852 \XMLentity{gt}{\utf eightax>}

```

The `\XMLElement` command appears in a .xmt file. It takes four arguments: the first one is the name of an element. We have seen an example above. Assume that the name is `m:msup`. Assume that the ‘m’ prefix stands for MathML and this corresponds to the number 3. We define two commands `\E:3:msup` and `\E:/3:msup`. The body of these commands is argument #3 and #4. In the case where #3 is `\xmlgrab` then the `\E:/3:msup` command takes an argument (see previous section). Argument #2 explains what to do with attributes. It should contain a sequence of `\XMLattribute` commands. Note: all attributes declared for the current namespace (found in `\A:3`) are added to the list. A call to evaluation of the attribute list is inserted in the body of `\E:3:msup` before the user code. On line 860, 861, the purpose of all these `\expandafter` is to expand the `\the`, so as to insert the token list (and not a reference to it) in the body of the definition.

```

853 \long\def\XMLElement#1#2#3#4{
854   \XML@ns{#1}
855   \xdef\XML@tempc{:}\jg@this@namespace
856   :\XML@this@local}
857   \toks@\expandafter{\csname A:\jg@this@namespace
858   \endcsname}
859   #2
860   \expandafter\gdef\csname E\XML@tempc\expandafter\endcsname
861   \expandafter{\expandafter\XML@setattributes\expandafter{\the\toks@}#3}
862   \gdef\XML@tempa{#3}
863   \ifx\XML@tempa\XML@xmlgrab
864     \expandafter\gdef\csname E\string/\XML@tempc\endcsname##1
865     {#4}
866   \else
867     \expandafter\gdef\csname E\string/\XML@tempc\endcsname
868     {#4}
869   \fi}
870 \def\XML@xmlgrab{\xmlgrab}

```

When you say `\XMLattribute {form} {\mycmd} {inline}` this puts in `\XML@tempa` the quantity `\XML@attrib 0:form\relax \mycmd {inline}`. If ‘form’ is replaced by ‘m:form’ and the namespace value of ‘m’ is 3, then ‘3:form’ will be used instead of ‘0:form’. This works by redefining locally the default namespace to be the empty namespace. The value of `\XML@tempa` will be added to the end of `\toks@`, the token list used in `\XMLElement` or `\XMLnamespaceattribute`. For some strange reason the second argument is put in `\XML@tempa`, but not the last one (this implies that the third argument is not expanded; the single token of the second argument is not expanded, because of the `\noexpand`; if the second argument has more than one token, you lose).

```
871 \long\def\XMLattribute#1#2#3{
872   {\def\XMLNS@{0}
873    \XML@ns{#1}
874    \xdef\XML@tempa{\noexpand\XML@attrib
875      \jg@this@namespace
876      :\XML@this@local\relax\noexpand#2}
877    \toks@\expandafter{\the\expandafter\toks@\XML@tempa{#3}}}
```

Like above, with a little hack. Assume that the attribute has to be stored in `\foo`. Then `\utfeight@chardef\foo` is executed (some time after a value has been stored).

```
878 \long\def\XMLattributeX#1#2#3{
879   {\def\XMLNS@{0}
880    \XML@ns{#1}
881    \xdef\XML@tempa{\noexpand\XML@attrib
882      \jg@this@namespace
883      :\XML@this@local\relax\noexpand#2}
884    \toks@\expandafter{\the\expandafter\toks@\XML@tempa{#3}\utfeight@chardef#2}}
```

This is the action associated to the special setting used above. The command is fully expanded, in a group where this is harmless, globally put in a temporary, and then, outside the group, the temporary is put again in the command. There seems to be a problem here: what if the argument contains ampersands and less-than signs?

```
885 \def\utfeight@chardef#1{
886   \begingroup
887   \utfeight@protect@chars
888   \xdef\x@temp{#1}
889   \endgroup
890   \let#1\x@temp
```

In case `\XMLnamespaceattribute{foo}{bar}{gee}{etc}`, if the namespace number of `foo` is 4, this code will define the action associated to the attribute defined by bar, gee, etc, and put it in `\A:4`. This command should be used at toplevel, not inside `\XMLElement`.

```
891 \long\def\XMLnamespaceattribute#1#2#3#4{
892   \toks@\expandafter\expandafter\expandafter{\csname A:%
893     \jg@namespace{#1}\endcsname}
894   \XMLattribute{#2}{#3}{#4}
895   \expandafter\xdef\csname A:\jg@namespace{#1}\endcsname{\the\toks@}}
```

Idem, expanded.

```
896 \long\def\XMLnamespaceattributeX#1#2#3#4{
897   \toks@\expandafter\expandafter\expandafter{\csname A:%
898     \jg@namespace{#1}\endcsname}
899   \XMLattributeX{#2}{#3}{#4}
900   \expandafter\xdef\csname A:\jg@namespace{#1}\endcsname{\the\toks@}}
```

If you say `\XMLname{foo:bar}{\gee}` this puts in `\gee` something like 4:bar.

```

901 \long\gdef\XMLname#1#2{{
902   \XML@ns{#1}
903   \xdef#2{\jg@this@namespace\noexpand:\XML@this@local}}}
904
905 If you say \XMLstring\foo<>bar</> this piece of code reads the <>, then calls \xmlgrab, which
906 reads everything until the </>, and executes the code associated to the end tag: this defines \foo,
907 and closes the group.
908
909 \gdef\XMLstring#1#2<>{
910   \begingroup
911   \let\XML@endgroup\endgroup
912   \let\XML@this@local\empty
913   \let\XML@this@prefix\empty
914   \expandafter\def\csname E:/:\XMLNS@\endcsname{\gdef#1}
915   \XML@catcodes
916   \xmlgrab}
917
918   Same code, expanded.
919
920 \gdef\XMLstringX#1#2<>{
921   \begingroup
922   \let\XML@endgroup\endgroup
923   \let\XML@this@local\empty
924   \let\XML@this@prefix\empty
925   \expandafter\def\csname E:/:\XMLNS@\endcsname{\xdef#1}
926   \XML@catcodes
927   \utfeight@protect@chars
928   \xmlgrab}
```

## 2.17 Other commands

Public version of \XML@setenc.

```

921 \let\DeclareNamespace\XML@ns@uri % version for xmt files
922 \def\FileEncoding#1{\XML@setenc{#1}\relax}
923 \newtoks\XML@attribute@toks
924 \newcount\XML@ns@count
925 \newtoks\XMLgrabtoks
```

The next function reads an XML file. The idea is to restore the current encoding. We have not shown the source of \XML@xmlinput.

```

926 \def\xmlinput#1{
927   \IfFileExists{#1}
928   {\expandafter\XML@xmlinput\expandafter
929    \XML@setenc\expandafter{\XML@thisencoding}\relax
930   }{\XML@warn{No file: #1}}}

931
932 \def\XML@xmlinput{...}

933 This reads a TeX file only once.

934 \def\inputonce#1{
935   \expandafter\ifx\csname xmt:#1\endcsname\relax
936   \global\expandafter\let\csname xmt:#1\endcsname\one
937   \begingroup
938   \XML@reset
939   \def\XMLNS@{0}
```

```

939   \input{#1}
940   \endgroup
941   \fi}
      In case you want some characters to be active.

942 \gdef\ActivateASCII#1{
943   \uppercase{\count@"0\if x\noexpand#1\relax\else\count@#1\fi\relax}
944   \toks@\expandafter{\nfss@catcodes}
945   \xdef\nfss@catcodes{
946     \catcode\the\count@=\the\catcode\the\count@\relax\the\toks@}
947   \toks@\expandafter{\XML@catcodes}
948   \xdef\XML@catcodes{
949     \catcode\the\count@\active\the\toks@}
950   \expandafter\ifx\csname8:"\endcsname\relax
951     \expandafter\gdef\csname8:"\endcsname{"}
952   \fi}

953 \ActivateASCII{94}%
954 \ActivateASCII{x5C}%
955 \ActivateASCII{x5F}%
956 \ActivateASCII{123}%
957 \ActivateASCII{125}%

```

We redefine `\obeyspaces` and `\obeylines`. The idea is to redefine the action associated to space and newline character.

```

958 \expandafter\def\expandafter\obeylines\expandafter{
959 \expandafter\def\csname 8:\string^~M\endcsname{\leavevmode\hfil \break\null}}
960
961 \expandafter\def\expandafter\obeyspaces\expandafter{
962 \expandafter\def\csname 8: \endcsname{\nobreakspace}}

```

This line is a bit strange:

```

963 \expandafter\def\csname 8:\string^~I\expandafter\endcsname
964   \expandafter{\csname 8: \endcsname}

```

The end of the `xmltex.tex` file is like this (we simplified a bit the code, by assuming that we do not want to dump a format, and that `\xmlfile` is defined). Essentially, we reset the end-of-line character to its normal meaning, we set the category codes, and we load the XML file.

```

965 \def\XML@tempa{\catcode`-12\relax\input\xmlfile\relax}
966 \endlinechar`^~M \expandafter\XML@catcodes\XML@tempa

```

## 2.18 Example

Assume that we have a file `thesis.tex` containing the following lines.

```

\def\xmlfile{these.xml}
\def\LastDeclaredEncoding{T1}
\input{xmltex.tex}
\end{document}

```

When T<sub>E</sub>X processes this file, it loads `xmltex.tex`, the file described in this chapter, because of line 1003. This defines a lot of commands; however the last line (line 966) contains some action, consisting essentially into setting some variables (end-of-line character, category codes) to values useful for typesetting. There are two hooks, not shown here. First, if the file `xmltex.cfg` is found, it will be loaded. The default file contains some Unicode character definitions, and the catalogue

shown earlier. Second, if `thesis.cfg` is found, it will be loaded. After that the XML file is loaded, this is defined on line 1001. Let's assume that the root element of the XML file is `<fo:root>`, and that the name space associated to 'fo' is declared in the catalogue, and loads `fotex.xmt`. This file is described in Chapter 4, and the action associated to `</fo:root>` is `\end{document}`, so that line 1004 is not really needed. Line 1002 is required in some cases (but it is not clear which ones).

## Chapter 3

# Interpreting MathML and related stuff in T<sub>E</sub>X

In the previous chapter, we have seen that T<sub>E</sub>X is able to read and evaluate an XML file. The Raweb is not typeset directly: there is a stylesheet that converts it into XSL/Format, see Chapter 7. The purpose of the next chapter is to explain how XSL/Format has to be interpreted by T<sub>E</sub>X; in this chapter we explain everything else, the big part being MathML, described in [2].

We describe here the file raweb-cfg.sty. It starts with the following lines

```
\makeatletter
\immediate\write20{Loading mathml support and raweb extensions
$ Revision: 2.14 $}
```

It is not a real style file, so that the category code of the '@' character is not known, and we do not want to use the \ProvidesPackage command for the identification. The revision number given above is computed by RCS, it is likely that the Tralics distribution comes with another version of this file.

This file was obtained by some additions to a file named mathml2.xmt, and it starts with the following copyright notice.

```
1 % patch to xmltex.tex plus mathml2.xmt plus other stuff
2 %% Copyright 2000 David Carlisle, for the original mathml part
3 %% Copyright 2004, 2006 Jos\'e Grimm
4
5 %% This file is distributed under the LaTeX Project Public License
6 %% (LPPL) as found at http://www.latex-project.org/lppl.txt
7 %% Either version 1.0, or at your option, any later version.
```

We have seen in the previous chapter that, if `xmltex.tex` is loaded and L<sup>A</sup>T<sub>E</sub>X reads an XML file, then the first occurrence of an element in a name space 'xx' provokes loading of file `yy.xmt`, assuming that 'xx' and 'yy' are associated in the catalogue. In our case, the root element is in the 'fo' namespace, some file is loaded, and the interpretation of the root element provokes loading of all required packages, as well as `\begin{document}`. After that, it is not possible to load other packages, so that the `yy.xmt` file cannot be a real L<sup>A</sup>T<sub>E</sub>X package.

For some unknown reason, in some cases, this autoloading mechanism did not work with the file `mathml2.xmt`, so that we decided to load it systematically, using a hook. At the end of the previous chapter we have explained that, if your file is called `foo.tex`, then `foo.cfg` is loaded. Thus this file is loaded if it has `foo.cfg` as alternate name (in Chapter 8, we give an example where a Perl

script makes a symbolic link from `foo.cfg` to `raweb-cfg.sty`). As a consequence, the file is loaded before anything else (in particular before the class file), but we can use the begin-document hook.

### 3.1 Local patches to `xmltex.tex`

Redefinition of `\utfeight@protect@chars`. Compare this with the definition on page 12, line 123. The idea is that using `\let` rather than `\def` should be more efficient. Some tests show that the speedup factor is nearly 10 percent.

```
8 \def\utfeight@protect@chars{%
9   \let\utfightax\string
10  \let\utfightay\string
11  \let\utfightaz\string
12  \let\utfightb\utfightb@jg@
13  \let\utfightc\utfightc@jg@
14  \let\utfightd\utfightd@jg@}
```

Three auxiliary definitions used above.

```
15 \def\utfightb@jg@#1#2{#1\string#2}
16 \def\utfightc@jg@#1#2#3{#1\string#2\string#3}
17 \def\utfightd@jg@#1#2#3#4{#1\string#2\string#3\string#4}
```

We redefine this also (original definition on page 11, line 96).

```
18 \begingroup
19 \catcode`<\active
20 \catcode`&\active
21 \gdef\utfight@protect@internal{%
22   \let\utfightax\noexpand
23   \let\utfightay\noexpand
24   \let\utfightaz\utfightaz@jg@int
25   \let<\relax\let&\relax
26   \let\utfightb\utfightb@jg@int
27   \let\utfightc\utfightc@jg@int
28   \let\utfightd\utfightd@jg@int}
```

These are the auxiliary commands.

```
29 \def\utfightaz@jg@int{\noexpand\utfightaz\noexpand}
30 \def\utfightb@jg@int#1#2{\noexpand\utfightb#1\string#2}
31 \def\utfightc@jg@int#1#2#3{\noexpand\utfightc#1\string#2\string#3}
32 \def\utfightd@jg@int#1#2#3#4{\noexpand\utfightd#1\string#2\string#3\string#4}
```

This is redefined (original on page 39, line 885); we locally change the meaning of the ampersand character, using the command `\XML@amp@markup` shown below.

```
33 \gdef\utfight@chardef#1{%
34   \begingroup
35   \utfight@protect@chars
36   \let&\XML@amp@markup@jg      % <- modified
37   \xdef\x@temp{#1}%
38   \endgroup
39   \let#1\x@temp
40 }
```

The `fotex.xmt` file contains a declaration of the form  
`'\XMLnamespaceattributeX {fo} {external-destination} {FOexternaldestination} {}'`

The ‘X’ after the command name means that the argument is evaluated in an `\xdef`. In the case where we want a & in an URL, this does not work. Thus we redefine the meaning of &: in the case of `&#amp;`; the expansion is &, otherwise the standard behavior is used.

```
41 \def\XML&#amp;@markup@jg#1;{%
42   \XML&#amp;@markup@jgw#1;amp;\@nil}
43 \def\XML&#amp;@markup@jgw#1amp;#2\@nil{%
44   \ifx b#2b\XML&#amp;@markup#1;\else\string&\fi}
```

## 3.2 Support for MathML

We pretend here that `mathml2.xmt` has been loaded (we do not want the original file to be loaded later).

```
45 \global\expandafter\let\csname xmt:mathml2.xmt\endcsname\@ne
     We declare the namespaces.
46 \DeclareNamespace{m}{http://www.w3.org/1998/Math/MathML}
47 \DeclareNamespace{fotex}{http://www.tug.org/fotex}
48 \DeclareNamespace{fo}{http://www.w3.org/1999/XSL/Format}
```

Let’s start with simple things: `<m:mrow>text</m:mrow>` translates to `\bgroup text \egroup`. This differs from the original coding, allowing constructions like `$(x^2)^3$`.

```
49 \XMLElement{m:mrow}
50 {}
51 {\bgroup}
52 {\egroup}
```

Processing of `<m:msub> base subscript </m:msub>`. The translation is `base_{subscript}`. The MathML standard says that there is a `subscriptshift` attribute that specifies the minimum amount to shift the baseline of subscript down. This is not implemented.

```
53 \XMLElement{m:msub}
54 {}
55 {\xmlgrab}
56 {\xmltexttwochildren\@firstofone\sb#1}
```

Processing of `<m:msup> base superscript </m:msup>`. The translation is `base^{supscript}`. The attribute `superscriptshift` defined by the standard is ignored.

```
57 \XMLElement{m:msup}
58 {}
59 {\xmlgrab}
60 {\xmltexttwochildren\@firstofone\sp#1}
```

Processing of `<m:msubsup> base subscript superscript </m:msubsup>`: the translation is `base_{subscript}^{supscript}`. The attributes `subscriptshift` and `superscriptshift` defined by the standard are ignored.

```
61 \XMLElement{m:msubsup}
62 {}
63 {\xmlgrab}
64 {\xmltextthreechildren\@firstofone\sb\sp#1}
```

Processing of `<m:mstyle attrs> text </m:mstyle>`. The translation is `text`. However, the attributes of the element influence typesetting of it. The attributes `veryverythinmathspace`, `verythinmathspace`, `thinmathspace`, `mediummathspace`, `thickmathspace`, `verythickmathspace`, and `veryverythickmathspace` can be modified (default value  $k/18em$ , for  $k=1$  to 7). TeX provides only three values: thin, medium and thick. The attribute `scriptsizemultiplier` gives the quotient of the

font size at level  $N$  and  $N+1$  and `scriptminsize` indicates the minimum size (TeX has three levels of math fonts: text, script, and scriptscript; there is no such limit in MathML, however there is a limit on the size). The default value of the multiplier is 0.71. If the main font is a 10pt, then the script size will be 7pt, and scriptscript size will be 5pt (these are the default values or TeX; however the default `scriptminsize` is 8pt). We ignore the `background` attribute.

In this piece of code, we consider the value of the `displaystyle` attribute. If it is true, we evaluate `\displaystyle`. If it is neither true nor false, nothing happens. If it is false, we look at the `scriptlevel` attribute. We execute `\textstyle`, or `\scriptstyle`, or `\scriptscriptstyle`, if it is 0, 1 or 2. If the attribute is not provided, we use 0 as default value; if the value is out of range, we use 2.

```

65 \XMLElement{m:mstyle}
66   {\XMLattribute{displaystyle}{\XML@att@displaystyle}{foo} %
67    \XMLattribute{scriptlevel}{\XML@scriptlevel}{0}%
68  }
69 {\xmlgrab}
70 {{\ifx\XML@att@displaystyle\att@true\displaystyle
71   \else{\ifx\XML@att@displaystyle\att@false
72     \ifx\XML@scriptlevel\att@dzero\textstyle
73     \else{\ifx\XML@scriptlevel\att@done\scriptstyle
74       \else \scriptscriptstyle\fi\fi
75     \fi %do nothing if neither true nor false
76     \fi#1}}

```

Processing of `<m:mroot> base index </m:mroot>`. We call `\mathmlroot` with `base` and `index` as arguments (note that the empty group {} disappears when this calls the intermediate command). The MathML norm says that the scriptlevel of `index` should be increased by two (thus, it will be as small as the TeX version).

```

77 \XMLElement{m:mroot}
78   {}
79   {\xmlgrab}
80   {\xmltexttwochildren\mathmlroot{}#1}
81
82 \def\mathmlroot#1#2{\root#2\of{#1}}

```

Processing of `<m:msqrt> base </m:msqrt>`. We just call `\sqrt`.

```

83 \XMLElement{m:msqrt}
84   {}
85   {\xmlgrab}
86   {\sqrt{#1}}

```

Processing of `<m:mtext>...</m:mtext>`. That's easy, we use `\text`.

```

87 \XMLElement{m:mtext}
88   {}
89   {\xmlgrab}
90   {\text{#1}}

```

Processing of `<m:ms>...</m:ms>`. Not yet implemented. The MathML doc says: The `<m:ms>` element is used to represent “string literals” in expressions meant to be interpreted by computer algebra systems.

```

91 % \XMLElement{m:ms} {} {"} {"}

```

Processing of `<m:mn>...</m:mn>`. The MathML doc says: Unlike `<mi>`, `<mn>` elements are (typically) rendered in an unslanted font by default, regardless of their content.

```

92  \XMLElement{m:mn}
93  {}
94  {\xmlgrab}
95  {\mathrm{\#1}}

```

Processing of  $\langle m:mi\mathvariant=xx\rangle\dots\langle/m:mi\rangle$ . The MathML doc says that the `fontstyle` attribute is deprecated, and the `mathvariant` attribute can take one of the following values: normal, bold, italic, bold-italic, double-struck, bold-fraktur, script, bold-script, fraktur, sans-serif, bold-sans-serif, sans-serif-italic, sans-serif-bold-italic, monospace.

```

96  \XMLElement{m:mi}
97  {\XMLAttribute{mathvariant}{\XML@mathmlvariant}{normal}}
98  {\xmlgrab}
99  {\mi@test#1\relax}

```

As you can see, not all variants are implemented here. On the other hand, the test done on line 107 is false in the case where the content of the element is a letter plus some space. (The MathML norm does not say how to get a single letter using an upright variant).

```

100 \gdef\mi@test#1\#2\relax{
101   \ifx\XML@mathmlvariant\att@mathml@bold
102     \mathbf{\#1\#2}\else
103   \ifx\XML@mathmlvariant\att@mathml@sansserif
104     \mathsf{\#1\#2}\else
105   \ifx\XML@mathmlvariant\att@mathml@tt
106     \texttt{\#1\#2}\else
107     \ifx\mi@test#2\mi@test
108       \expandafter#1
109     \else
110       \mathrm{\#1\#2}
111     \fi\fi\fi\fi\fi

```

These are used in the code above.

```

112 \XMLstring\att@mathml@bold<>bold</>
113 \XMLstring\att@mathml@sansserif<>sans-serif</>
114 \XMLstring\att@mathml@tt<>monospace</>

```

Processing of  $\langle m:mspace\atts\rangle\langle/m:mspace\rangle$ . The MathML doc says that attributes `width`, `height`, `depth`, `linebreak` are allowed. Here we consider only the `width`. The `\@defaultunits` command is called for the case where a dimension is given without a unit.

```

115 \XMLElement{m:mspace}
116   {\XMLAttribute{width}{\XML@mspacewidth}{0}}
117   {}
118   {\@defaultunits\dimen@\XML@mspacewidth pt\relax\@nnil
119     \ifnum\dimen@=\z@\else\kern\dimen@\fi}

```

### 3.2.1 Fences

Processing of  $\langle m:mfenced\open=A\close=B\separators=...\rangle content\langle/m:mfenced\rangle$ . We ignore the separators. The translation is `\left A content \right B`. However, what `\left` and `\right` want are numbers (to be precise, slots into math fonts that indicate how large delimiters can be made from smaller pieces); what L<sup>A</sup>T<sub>E</sub>X wants is a character with a `\delcode`, what the XML file contains is a character. We hack a bit, because we cannot expand all these Unicode characters.

```

120 \XMLElement{m:mfenced}
121   { \XMLAttribute{open}{\XML@fenceopen}{()}

```

```

122     \XMLattribute{close}{\XML@fenceclose}{}
123 }
124 {\jg@hacko\left\{\XML@fenceopen}
125 {\jg@hackc\right\}\XML@fenceclose}
```

This code is easy: for instance, if the character is U+2329, we replace it by \langle.

```

126 \def\jg@hacko{%
127   \ifx\XML@fenceopen\jg@lt\let\XML@fenceopen\langle\fi
128   \ifx\XML@fenceopen\jg@lbra\let\XML@fenceopen\langle\fi
129   \ifx\XML@fenceopen\jg@xlbra\let\XML@fenceopen\langle\fi
130   \ifx\XML@fenceopen\jg@gt\let\XML@fenceopen\rangle\fi
131   \ifx\XML@fenceopen\jg@rbra\let\XML@fenceopen\rangle\fi
132   \ifx\XML@fenceopen\jg@xrbra\let\XML@fenceopen\rangle\fi
133   \ifx\XML@fenceopen\jg@verbar\let\XML@fenceopen\|\fi
134   \ifx\XML@fenceopen\jg@Verbar\let\XML@fenceopen\|\fi
135   \ifx\XML@fenceopen\jg@lfloor\let\XML@fenceopen\lfloor\fi
136   \ifx\XML@fenceopen\jg@rfloor\let\XML@fenceopen\rfloor\fi
137   \ifx\XML@fenceopen\jg@lceil\let\XML@fenceopen\lceil\fi
138   \ifx\XML@fenceopen\jg@rceil\let\XML@fenceopen\rceil\fi
139   \ifx\XML@fenceopen\jg@lmoustache\let\XML@fenceopen\lmoustache\fi
140   \ifx\XML@fenceopen\jg@rmoustache\let\XML@fenceopen\rmoustache\fi
141   \ifx\XML@fenceopen\jg@lgroup\let\XML@fenceopen\lgroup\fi
142   \ifx\XML@fenceopen\jg@rgroup\let\XML@fenceopen\rgroup\fi
143   \ifx\XML@fenceopen\jg@uparrow\let\XML@fenceopen\uparrow\fi
144   \ifx\XML@fenceopen\jg@downarrow\let\XML@fenceopen\downarrow\fi
145   \ifx\XML@fenceopen\jg@Uparrow\let\XML@fenceopen\Uparrow\fi
146   \ifx\XML@fenceopen\jg@Downarrow\let\XML@fenceopen\Downarrow\fi
147   \ifx\XML@fenceopen\jg@updownarrow\let\XML@fenceopen\updownarrow\fi
148   \ifx\XML@fenceopen\jg@Updownarrow\let\XML@fenceopen\Updownarrow\fi
149 }
```

Same code for closing delimiters.

```

150 \def\jg@hackc{%
151   \ifx\XML@fenceclose\jg@gt\let\XML@fenceclose\rangle\fi
152   \ifx\XML@fenceclose\jg@rbra\let\XML@fenceclose\rangle\fi
153   \ifx\XML@fenceclose\jg@xrbra\let\XML@fenceclose\rangle\fi
154   \ifx\XML@fenceclose\jg@lt\let\XML@fenceclose\langle\fi
155   \ifx\XML@fenceclose\jg@lbra\let\XML@fenceclose\langle\fi

157   \ifx\XML@fenceclose\jg@verbar\let\XML@fenceclose\|\fi
158   \ifx\XML@fenceclose\jg@Verbar\let\XML@fenceclose\|\fi
159   \ifx\XML@fenceclose\jg@lfloor\let\XML@fenceclose\lfloor\fi
160   \ifx\XML@fenceclose\jg@rfloor\let\XML@fenceclose\rfloor\fi
161   \ifx\XML@fenceclose\jg@lceil\let\XML@fenceclose\lceil\fi
162   \ifx\XML@fenceclose\jg@rceil\let\XML@fenceclose\rceil\fi
163   \ifx\XML@fenceclose\jg@lmoustache\let\XML@fenceclose\lmoustache\fi
164   \ifx\XML@fenceclose\jg@rmoustache\let\XML@fenceclose\rmoustache\fi
165   \ifx\XML@fenceclose\jg@lgroup\let\XML@fenceclose\lgroup\fi
166   \ifx\XML@fenceclose\jg@rgroup\let\XML@fenceclose\rgroup\fi
167   \ifx\XML@fenceclose\jg@uparrow\let\XML@fenceclose\uparrow\fi
168   \ifx\XML@fenceclose\jg@downarrow\let\XML@fenceclose\downarrow\fi
169   \ifx\XML@fenceclose\jg@Uparrow\let\XML@fenceclose\Uparrow\fi
170   \ifx\XML@fenceclose\jg@Downarrow\let\XML@fenceclose\Downarrow\fi
```

```

171   \ifx\XML@fenceclose\jg@updownarrow\let\XML@fenceclose\updownarrow\fi
172   \ifx\XML@fenceclose\jg@Updownarrow\let\XML@fenceclose\Updownarrow\fi
173 }

```

Here we put each delimiter in a string command.

```

174 \XMLstring\jg@verbar<>#x2016;</>
175 \XMLstring\jg@Verbar<>#8214;</>
176 \XMLstring\jg@lfloor<>#x230A;</>
177 \XMLstring\jg@rfloor<>#x230B;</>
178 \XMLstring\jg@lceil<>#x2308;</>
179 \XMLstring\jg@rceil<>#x2309;</>
180 \XMLstring\jg@lmoustache<>#x23B0;</>
181 \XMLstring\jg@rmoustache<>#x23B1;</>
182 \XMLstring\jg@lgroup<>#x3014;</>
183 \XMLstring\jg@rgroup<>#x3015;</>
184 \XMLstring\jg@uparrow<>#x2191;</>
185 \XMLstring\jg@Uparrow<>#x21D1;</>
186 \XMLstring\jg@downarrow<>#x2193;</>
187 \XMLstring\jg@Downarrow<>#x21D3;</>
188 \XMLstring\jg@updownarrow<>#x2195;</>
189 \XMLstring\jg@Updownarrow<>#x21D5;</>

```

The Unicode standard says that U+2329 and U+232A should not be used for math. For this reason, we add U+27E8 and U+27E9 in this list.

```

190 \XMLstring\jg@lbra<>#x2329;</>
191 \XMLstring\jg@rbra<>#x232A;</>
192 \XMLstring\jg@xlbra<>#x27E8;</>
193 \XMLstring\jg@xrbra<>#x27E9;</>

```

### 3.2.2 Accents

The translation by Tralics of \$\\vec x\$ is `<mover accent='true'> <mi>x</mi> <mo>&rightarrow; </mo> </mover>`. A non obvious point is how to translate this back. This idea is that we evaluate the accent in a context (defined by `\notinover`), this will set the two commands `\cur@mo@content` and `\jg@cur@acc`. Let's declare them here.

```

194 \let\notinover\relax
195 \def\cur@mo@content{TOTO}
196 \let\jg@cur@acc\relax
    Processing of <m:munderover accent=bool accentunder=bool> base underscript overscript</m:munderover>. This is wrong. Moreover, attributes are ignored.
197 \XMLElement{m:munderover}
198 {
199 {\xmlgrab
200 {\xmltextthreechildren@\firstofone\sb\sp#1}}

```

Processing of `<m:mover accent=bool> base overscript</m:mover>`. We use an intermediate command. If no accent, we use `\stackrel`. Otherwise, we call a command, say `\jg@bindings`, evaluate the accent in an environment where `\notinover` is `\over`, then execute two commands `\cur@mo@content` and `\jg@cur@acc` (`\X` and `\Y` for simplicity). Evaluating the overscript should define `\X`, and evaluating `\X` should define `\Y`, in such a way that `\Y` applied to the base should put an accent on it.

```

201 \XMLElement{m:mover}
202   {\XMLattribute{accent}{\XML@overaccent}{none}}
203   {\xmlgrab}
204   {\xmltexttwochildren\xml@implement@over{}#1}
      The auxiliary function.

205 \def\xml@implement@over#1#2{%
206   \ifx\XML@overaccent\att@true {%
207     \jg@bindings
208     \let\notinover\over #2\let\notinover\relax \cur@mo@content\jg@cur@acc{#1}%
209   }\else\stackrel{#2}{#1}\fi

```

Processing of  $\langle m:munder accentunder="bool"> base underscript \rangle$ . We use an intermediate command: same idea as above. If no accent, we use `\underset`.

```

210 \XMLElement{m:munder}
211   {\XMLattribute{accentunder}{\XML@underaccent}{none}}
212   {\xmlgrab}
213   {\xmltexttwochildren\xml@implement@under{}#1}

214 \def\xml@implement@under#1#2{%
215   \ifx\XML@underaccent\att@true {%
216     \jg@ubindings
217     \let\notinover\over #2\let\notinover\relax \cur@mo@content\jg@cur@acc{#1}%
218   }\else \underset{#2}{#1}\fi

```

Processing of  $\langle m:mo atts \dots \rangle$ . The MathML norm says that the following attributes are recognized: form, fence, separator, lspace, rspace, stretchy, symmetric, maxsize, minsize, largeop, movablelimits, and accent. We implement only two attributes. We assume that, if `form = 'prefix'` is given, that our operator is like `log` or `sin`, and never used as an accent. Thus, we generate a `\mathop` with an operator font. We set `\limits` or `\nolimits`, depending on the value of the `movablelimits` attribute. Otherwise, some command is called.

```

219 \XMLElement{m:mo}
220   {\XMLattribute{form}{\XML@mathmlform}{inline}%
221    \XMLattribute{movablelimits}{\XML@movablelimits}{false}}
222   {\xmlgrab}
223   {\ifx\XML@mathmlform\att@PREFIX
224     \ifx\XML@movablelimits\att@true
225       \mathop{\operator@font #1}\limits
226     \else
227       \mathop{\operator@font #1}\nolimits
228     \fi
229   }\else\special@mo{#1}\fi

```

For some strange reason, the default code does not produce a less than sign. Hence we hack a bit. In the case of accent, we have two commands, let's call them `\X` and `\Y`. We define `\X`, so that it will define `\Y`. The definition is global (it must be seen by the caller of the `<mo>` element). In the case of grave accent, what we have here is a 7bit character, and we have to set `\Y` directly. In the case of 3 or 4 dots, we have to set this command.

```

230 \def\special@mo#1{%
231   \def\jg@tck{#1}\% save the argument
232   \ifx\notinover\over\% we cannot typeset here
233     \ifx\jg@tck\jg@accgrave \% strange
234       \global\let\jg@cur@acc\jg@grave@acc
235       \global\let\cur@mo@content\relax

```

```

236      \else \ifx\jg@tck\jg@accdddot % strange
237          \global\let\jg@cur@acc\dddot
238          \global\let\cur@mo@content\relax
239      \else \ifx\jg@tck\jg@accddddot % strange
240          \global\let\jg@cur@acc\ddddd
241          \global\let\cur@mo@content\relax
242      \else\gdef\cur@mo@content{\#1}\fi\fi\fi
243      \else % typeset the argument, handle < and > in the correct way
244          \ifx\jg@tck\jg@gt\string>\else
245              \ifx\jg@tck\jg@lt\string<\else
246                  #1\fi\fi\fi}

```

Some declarations, needed above.

```

247 \XMLstring\jg@lt<>&lt;</>
248 \XMLstring\jg@gt<>&gt;</>
249 \XMLstring\jg@accgrave<>'</>
250 \XMLstring\jg@accdddot<>&#x20DB;</>
251 \XMLstring\jg@accdddot<>&#x20DC;</>

```

This is the big hack. Remember that, in the case of \vec, the accent is an arrow, in fact, a Unicode character, that typesets as an arrow. What we do is to redefine \rightarrow, in order to put in \Y (in fact in \jg@cur@acc) a command that behaves like \vec. In the case of a breve accent, the character 2D8 is defined to be \ifmmode \u\else \textasciibreve \fi, so that we have to redefine \u. In the case of the character 302, the definition is \ifmmode \hat{}\else \^{}\fi, so that we have to redefine \hat in such a way that it reads an argument, and evaluates to something that looks like \hat.

```

252 \def\jg@bindings{%
253     \def\texttildelow {\global\let\jg@cur@acc\jg@tilde@acc}%

Note that when \jg@overRarrow@acc is called, \rightarrow does something strange. We must redefine it here, because \rightarrowfill@ uses it.

```

300 \def\jg@overRarrow@acc{\let\rightarrow\JGG@orig@rarrow
301   \mathpalette{\overarrow@\rightarrowfill@}}
302 \def\jg@overLarrow@acc{\let\leftarrow\JGG@orig@larrow
303   \mathpalette{\overarrow@\leftarrowfill@}}
304 \def\jg@underRarrow@acc{\let\rightarrow\JGG@orig@rarrow
305   \mathpalette{\underarrow@\rightarrowfill@}}
306 \def\jg@underLarrow@acc{\let\leftarrow\JGG@orig@larrow
307   \mathpalette{\underarrow@\leftarrowfill@}}

```

### 3.2.3 More math

This is the main math element. Only the display attribute is taken into account. It can be ‘inline’ or ‘block’. If it is block, we use brackets, otherwise parentheses. The original code defined a command \GATHER.

```

308 \XMLElement{m:math}
309   {\XMLattribute{display}{\XML@mathmlmode}{inline}}
310   {
311     \ifx\XML@mathmlmode\att@BLOCK\[\else\(\fi
312   }
313   {
314     \ifx\XML@mathmlmode\att@BLOCK\]\else\)\fi
315   }

```

Processing of `<m:mfrac linethickness=A numalign=B denomalign=C bevelled=D>num denom</m:mfrac>`. We ignore the bevelled attribute. In the current version, we also ignore the horizontal alignment attributes.

```

316 \XMLElement{m:mfrac}
317   {\XMLAttribute{linethickness}{\XML@linethickness}{true}%
318   \XMLAttribute{numalign}{\XML@numalign}{center}%
319   \XMLAttribute{denomalign}{\XML@denomalign}{center}%
320 }
321 {\xmlgrab}
322 {\xmltexttwochildren\xml@implement@frac{}#1}

The auxiliary command.

323 \def\xml@implement@frac#1#2{%
324   \ifx\XML@linethickness\att@true\frac{#1}{#2}%
325   \else \genfrac{}{}{\XML@linethickness}{#1}{#2}\fi

```

### 3.2.4 Tables

Processing of `<m:mtable atts>body</m:mtable>`. The MathML specification says that the following attributes are allowed: align, rowalign, columnalign, groupalign, alignmentscope, columnwidth, width, rowspacing, columnspacing, rowlines, columnlines, frame, framespacing, equalrows, equalcolumns, displaystyle, side, and minlabelspacing. They are currently all ignored. New implementation, dated January 2005.

```

326 \XMLElement{m:mtable}
327 {}
328 {\xmlgrab }
329 {\jg@start@mtable#1\jg@end@mtable }

```

Processing of `<m:mtr atts>body</m:mtr>`. The attributes are: rowalign, columnalign, and groupalign.

```

330 \XMLElement{m:mtr}
331 {}
332 {\xmlgrab }
333 {\jg@start@mtr#1}

```

Processing of `<m:mtd atts>body</m:mtd>`. The attributes are: rowspan, colspan, rowalign, columnalign, and groupalign.

```

334 \XMLElement{m:mtd}
335   {\XMLAttribute{columnalign}{\XML@mtdalign}{center}}
336   \XMLAttribute{colspan}{\XML@mtddspan}{1}}
337 {\xmlgrab}
338 {\jg@start@mtd{#1}}

```

The current implementation of math tables uses two token lists, one holds the table, the other one holds the current row. The same holds for normal tables, but since normal tables can contain math tables, we need four lists.

```

339 \newtoks\jg@table@toks
340 \newtoks\jg@mrow@toks
341 \newtoks\jg@table@toks
342 \newtoks\jg@row@toks

```

There is a command `\addto@hook` that inserts some tokens at the end of a token list; it is similar to `\gaddto@hook` without the `\global`. The command `\merge@toks` appends the current row to the table (action has to be global, because it is executed from the group that defines the

row). We also need a command that adds the content of a command to the back of the token list, this is used by normal table when constructing the optional argument of `\\".`

```
343 \newcommand\merge@toks[2]{%
344   \expandafter\gaddto@hook\expandafter#1\expandafter{\the#2}%
345 \long\def\gaddto@hook#1#2{\global#1\expandafter{\the#1#2}}%
346 \newcommand\merge@cmd[2]{%
347   \expandafter\gaddto@hook\expandafter#1\expandafter{#2}}
```

When we see the start of a table, we initialize the token list. What we will finally evaluate is an array, declared as `*{99}{c}`. In the current implementation, it is possible to count the number of columns, and replace 99 by a better value, but this would cost more than constructing a preamble of length 99. We shall see later that, for normal tables, we count the number of columns. Note that, in amsmath, matrices are declared in this way, using the counter `MaxMatrixCols`, with initial value 10, instead of the constant 99. We initialize the row token list to be empty, and `\ifStartTable` to true (this means that the next row is the first one).

```
348 \newif\ifStartTable\newif\ifStartRow
349 \newif\ifStartRowx\newif\ifStartTablex
350 \newcommand\jg@start@mtab{\%
351   \jg@mtab@toks{\begin{array}{*{99}{c}}}\%
352   \jg@mrow@toks{}\%
353   \StartTabletrue}
```

When the end of the array is seen, we insert the last row and the `\end{array}` in the token list, then evaluate it.

```
354 \newcommand\jg@end@mtab{\%
355   \merge@toks\jg@mtab@toks\jg@mrow@toks
356   \addto@hook\jg@mtab@toks{\end{array}}\%
357   \the\jg@mtab@toks}
```

When we see the start of a row, we insert the previous row into the table; we reset it; we define the command `\ifStartRow` to true (this means that the next cell is the first in the row). In the case where `\ifStartTable` is true, we set it to false, otherwise we add a `\\"`, the row separator, in the array.

```
358 \newcommand\jg@start@mtr{\%
359   \merge@toks\jg@mtab@toks\jg@mrow@toks
360   \ifStartTable
361     \glbal\StartTablefalse
362   \else \gaddto@hook\jg@mtab@toks{\}\\}\fi
363   \jg@mrow@toks{}\%
364   \StartRowtrue}
```

The main action associated to a cell consists in putting the content in the `\jg@row@toks` token list; in the case where `\ifStartRow` is true, we set it to false, otherwise we add a `\&`, the cell separator, in the token list. In `\temp`, we put the content of our cell, plus some `\hfill` in the case where alignment is left or right; if alignment is ‘left’, we insert an empty group after the `\hfill` (the preamble of the array for our cell is `\hfil\ignorespaces#\unskip\hfil`). In the general case, there is no need to use a temporary command: we could add the tokens directly into the token list; however, in the case where the span is greater than one, the action is a bit more complicated, in this case, we use a temporary token register.

```
365 \newcommand\jg@start@mtd[1]{%
366   \ifStartRow
367     \global\StartRowfalse
368   \else\gaddto@hook\jg@mrow@toks{\tabcellsep}\fi
369   \ifx\xML@mtdalign\att@mtd@left
```

```

370      \def\temp{\#1\hfill{}}
371      \else\ifx\XML@mtdalign\att@mtd@right
372          \def\temp{\hfill#1}
373          \else \def\temp{\#1}\fi\fi%
374      \ifnum\XML@mtdspan=1\else
375          \toks0=\expandafter{\temp}%
376          \edef\temp{\noexpand\multicolumn{\XML@mtdspan}{c}{\the\toks0}}%
377          \fi
378      \expandafter\gaddto@hook\expandafter\jg@mrow@toks\expandafter{\temp}}

```

### 3.3 Other commands

#### 3.3.1 Pictures

In this section, we define some elements that Tralics constructs when evaluating a command from the epic package. These elements are in the default namespace with ‘pic-’ prefix; in a future version, we will move them in another namespace.

Processing of `<picture width=A height=B xpos=C ypos=D>...</picture>`. This defines the picture environment. Translation is `\begin{picture} (A,B)(C,D) ... \end{picture}`.

```

379 \XMLElement{picture}
380   {\XMLattribute{width}{\XML@width}{1}
381    \XMLattribute{height}{\XML@height}{1}
382    \XMLattribute{xpos}{\XML@xpos}{0}
383    \XMLattribute{ypos}{\XML@ypos}{0}
384  }
385  {\begin{picture}(\XML@width,\XML@height)(\XML@xpos,\XML@ypos)}
386  \end{picture}

```

Processing of `<pic-put xpos=A ypos=B>C</pic-put>`. We translate this into `\put(A,B){C}`.

```

387 \XMLElement{pic-put}
388   {\XMLattribute{xpos}{\XML@xpos}{0}
389    \XMLattribute{ypos}{\XML@ypos}{0}}
390   {\xmlgrab}
391   {\put(\XML@xpos,\XML@ypos){#1}}

```

Processing of `<pic-arc xpos=A ypos=B angle=C></pic-arc>`. We translate this in an obvious manner into `\arc(A,B){C}`.

```

392 \XMLElement{pic-arc}
393   {\XMLattribute{xpos}{\XML@xpos}{0}
394    \XMLattribute{angle}{\XML@angle}{0}
395    \XMLattribute{ypos}{\XML@ypos}{0}}
396   {\xmlgrab}
397   {\arc(\XML@xpos,\XML@ypos){\XML@angle}}

```

Processing of `<pic-scaleput xpos=A ypos=B xscale=xsyscale=ys xscaley=xsy>C</pic-scaleput>`. We translate this into `\scaleput(A,B){C}`. Other attributes are put in variables named `\xscale`, `\yscale`, `\xscaley`, and `\yscalex`.

```

398 \XMLElement{pic-scaleput}
399   {\XMLattribute{xscale}{\xscale}{1.0}
400    \XMLattribute{yscale}{\yscale}{1.0}
401    \XMLattribute{xscaley}{\xscaley}{0.0}
402    \XMLattribute{yscalex}{\yscalex}{0.0}}

```

```

403     \XMLattribute{xpos}{\XML@xpos}{0}
404     \XMLattribute{ypos}{\XML@ypos}{0}
405     {\xmlgrab}
406     {\scaleput(\XML@xpos,\XML@ypos){#1}}

```

Processing of `<pic-thicklines/>` and `<pic-thinlines/>`. We call a command, that is executed just after the group. In the case of `<pic-linethickness size=V/>`, the command takes an argument; we have to expand the value of the attribute, put this in a global variable, and ask for that variable to be expanded after the group. In a first version, we redefined the three commands `\thinlines`, `\thicklines` and `\linethickness`. The current code is simpler.

```

407 \XMLElement{pic-thicklines}
408   {}{}{\aftergroup\thicklines}

```

Case of thin lines.

```

409 \XMLElement{pic-thinlines}
410   {}{}{\aftergroup\thinlines}

```

Case of line thickness.

```

411 \XMLElement{pic-linethickness}
412   {\XMLattribute{size}{\XML@size}{1pt}}
413   {}
414   {\xdef\temp{\noexpand\linethickness{\XML@size}}\aftergroup\temp}

```

Processing of `<pic-multiput xpos=A ypos=B repeat=C dx=D dy=E>obj</pic-multiput>`. We translate this as `\multiput(A,B)(D,E){C}{obj}`.

```

415 \XMLElement{pic-multiput}
416   {\XMLattribute{xpos}{\XML@xpos}{0}
417    \XMLattribute{ypos}{\XML@ypos}{0}
418    \XMLattribute{repeat}{\XML@repeat}{1}
419    \XMLattribute{dx}{\XML@dx}{1}
420    \XMLattribute{dy}{\XML@dy}{1}
421    {\xmlgrab}
422    {\multiput(\XML@xpos,\XML@ypos)(\XML@dx,\XML@dy){\XML@repeat}{#1}}

```

Processing of `<pic-bezier a1=A1 a2=A2 b1=B1 b2=B2 c1=C1 c2=C2 repeat=D/>`. Translation is `\qbezier[D](A1,A2)(B1,B2),(C1,C2)`.

```

423 \XMLElement{pic-bezier}
424   {\XMLattribute{a1}{\XML@ai}{0}
425    \XMLattribute{a2}{\XML@aii}{0}
426    \XMLattribute{b1}{\XML@bi}{0}
427    \XMLattribute{b2}{\XML@bii}{0}
428    \XMLattribute{c1}{\XML@ci}{0}
429    \XMLattribute{c2}{\XML@cii}{0}
430    \XMLattribute{repeat}{\XML@repeat}{0}}
431   {}
432   {
433     \qbezier[\XML@repeat](\XML@ai,\XML@aii)(\XML@bi,\XML@bii)(\XML@ci,\XML@cii)
434   }

```

Processing of `<pic-line xdir=A ydir=B width=C/>`. The translation is `\line(A,B){C}`.

```

435 \XMLElement{pic-line}
436   {\XMLattribute{xdir}{\XML@xdir}{0}
437    \XMLattribute{ydir}{\XML@ydir}{0}
438    \XMLattribute{width}{\XML@width}{0}}

```

```

439     {}
440     {\line(\XML@xdir,\XML@ydir){\XML@width}}
Processing of <pic-vector xdir=A ydir=B width=C>. The translation is \vector(A,B){C}.
441 \XMLelement{pic-vector}
442   {\XMLattribute{xdir}{\XML@xdir}{0}
443   \XMLattribute{ydir}{\XML@ydir}{0}
444   \XMLattribute{width}{\XML@width}{0}}
445   {}
446   {\vector(\XML@xdir,\XML@ydir){\XML@width}}

```

Processing of <pic-curve unit-length=A>B</pic-curve>. The translation is \curve(B). There are two hacks here: one is that \curve modifies \unitlength globally, so that we have to reset it. The other hack is that \ignorespaces must be ignored: the argument of \curve is a sequence of numbers, converted to dimensions by using \unitlength. Between a sequence of digits and a unit of measure, spaces are allowed (but here, spaces are active, there expansion is: space plus \ignorespaces).

```

447 \newdimen\jgunitlength
448 \newcommand\withulength[1]{%
449   {\def\ignorespaces{}%
450   \jgunitlength=\unitlength \setlength\unitlength{\XML@ulength pt}%
451   #1\global\unitlength\jgunitlength}}
452
453 \XMLelement{pic-curve}
454   {\XMLattribute{unit-length}{\XML@ulength}{1}}
455   {\xmlgrab}
456   {\withulength{\curve(#1)}}

```

Processing of <pic-closecurve unit-length=A>B</pic-closecurve>. With the same hack as above, the translation is \closecurve(B).

```

457 \XMLelement{pic-closecurve}
458   {\XMLattribute{unit-length}{\XML@ulength}{1}}
459   {\xmlgrab}
460   {\withulength{\closecurve(#1)}}

```

Processing of <pic-tagcurve unit-length=A>B</pic-tagcurve>. With the same hack as above, the translation is \tagcurve(B).

```

461 \XMLelement{pic-tagcurve}
462   {\XMLattribute{unit-length}{\XML@ulength}{1}}
463   {\xmlgrab}
464   {\withulength{\tagcurve(#1)}}

```

Processing of <pic-frame>X</pic-frame>. Translation is \frame{X}.

```

465 \XMLelement{pic-frame}
466   {}
467   {\xmlgrab}
468   {\frame{#1}}

```

Processing of <pic-circle size=A full=B>. Translation is \circle{A} or \circle\*[A]. A star is used B is given and not ‘false’.

```

469 \XMLelement{pic-circle}
470   {\XMLattribute{size}{\XML@size}{1}
471   \XMLattribute{full}{\XML@full}{false}}
472   {}
473   {\ifx\XML@full\att@false\circle{\XML@size}\else \circle*{\XML@size}\fi}

```

Processing of `<pic-circle size=A unit-length=B/>`. Translation is `\bigcircle{A}`. We locally change `\unitlength`.

```
474 \XMLelement{pic-bigcircle}
475   {\XMLattribute{size}{\XML@size}{1}
476     \XMLattribute{unit-length}{\XML@ulength}{1}}
477   {}
478   {\withulength{\bigcircle{\XML@size}}}
```

The strings defined here are needed in the next command.

```
479 \XMLstring\att@l<>l</>
480 \XMLstring\att@r<>r</>
481 \XMLstring\att@t<>t</>
482 \XMLstring\att@b<>b</>
483 \XMLstring\att@lt<>lt</>
484 \XMLstring\att@lb<>lb</>
485 \XMLstring\att@rt<>rt</>
486 \XMLstring\att@rb<>rb</>
487 \XMLstring\att@tl<>tl</>
488 \XMLstring\att@bl<>bl</>
489 \XMLstring\att@tr<>tr</>
490 \XMLstring\att@br<>br</>
```

Given a string A, in `\XML@pos`, we construct a string B, that has the same characters (order is irrelevant), with category code 11. Moreover, if we have a command `\bar` and an argument `gee`, we evaluate `\bar[B]{gee}` (in fact, we construct a command that does this; this command will be evaluated after all conditionals have been closed.)

```
491 \def\@att@to@rtb#1#2{%
492   \ifx\XML@pos\att@l \def\jg@tmp{\#1[1]{#2}}%
493   \else\ifx\XML@pos\att@r \def\jg@tmp{\#1[r]{#2}}%
494   \else\ifx\XML@pos\att@t \def\jg@tmp{\#1[t]{#2}}%
495   \else\ifx\XML@pos\att@b \def\jg@tmp{\#1[b]{#2}}%
496   \else\ifx\XML@pos\att@lt \def\jg@tmp{\#1[lt]{#2}}%
497   \else\ifx\XML@pos\att@lb \def\jg@tmp{\#1[lb]{#2}}%
498   \else\ifx\XML@pos\att@rt \def\jg@tmp{\#1[rt]{#2}}%
499   \else\ifx\XML@pos\att@rb \def\jg@tmp{\#1[rb]{#2}}%
500   \else\ifx\XML@pos\att@tl \def\jg@tmp{\#1[lt]{#2}}%
501   \else\ifx\XML@pos\att@bl \def\jg@tmp{\#1[lb]{#2}}%
502   \else\ifx\XML@pos\att@tr \def\jg@tmp{\#1[rt]{#2}}%
503   \else\ifx\XML@pos\att@br \def\jg@tmp{\#1[rb]{#2}}%
504   \else \def\jg@tmp{\#1{#2}}%
505   \fi\fi\fi\fi\fi\fi\fi
506   \jg@tmp
507 }
```

Processing `<pic-framebox width=A height=B position=C framed=D>obj</pic-framebox>`. The translation is `\framebox(A,B)[CC]{obj}` (it could be `\makebox` if the attribute framed is false). Here CC is the value of C, processed as indicated above.

```
508 \XMLelement{pic-framebox}
509   {\XMLattribute{width}{\XML@width}{0}
510     \XMLattribute{height}{\XML@height}{0}
511     \XMLattribute{position}{\XML@pos}{}
512     \XMLattribute{framed}{\XML@framed}{false}
513 }
```

```

514  {\xmlgrab}
515  {\let\cmd\framebox\ifx\XML@framed\att@false\let\cmd\makebox\fi
516  \att@to@rtb{\cmd(\XML@width,\XML@height)\{#1\}}
517  Processing <pic-dashbox width=A height=B position=C dashdim=D> obj </pic-dashbox>.
518  The translation is \dashbox{D}{(A,B)}[CC]{obj}, where CC is as above.
519  \XMLElement{pic-dashbox}
520  {\XMLattribute{width}{\XML@width}\{0\}
521  \XMLattribute{height}{\XML@height}\{0\}
522  \XMLattribute{position}{\XML@pos}\{w\}
523  \XMLattribute{dashdim}{\XML@dashdim}\{1pt\}
524  }
525  {\xmlgrab}
526  {\att@to@rtb{\dashbox{\XML@dashdim}{(\XML@width,\XML@height)\{#1\}}}
527  Processing of <pic-oval xpos=A ypos=B specs=C>obj</pic-oval>.
528  The translation is \oval(A,B)[CC]{obj}, where CC is as above.
529  \XMLElement{pic-oval}
530  {\XMLattribute{xpos}{\XML@xpos}\{0\}
531  \XMLattribute{specs}{\XML@pos}\{}
532  \XMLattribute{ypos}{\XML@ypos}\{0\}
533  {\xmlgrab}
534  {\att@to@rtb{\oval(\XML@xpos,\XML@ypos)\{#1\}}}

```

### 3.3.2 Titlepage

We found no easy way to describe the title page of the Raweb using XSL/Format; thus additional elements were invented and described here. The \ra@atxy command adds a box (that occupies no space) at a give position in the page (the position is absolute).

```

531  \newbox\ra@atxybox
532  \def\ra@atxy(#1,#2){\global\setbox\ra@atxybox=\hbox
533  {\unhbox\ra@atxybox
534  \vtop to 0pt{\kern #2\hbox to 0pt{\kern #1\relax #3\hss}\vss}}}

```

We use \texttop (a command that does nothing)<sup>1</sup> for insertion of our box. After that, we kill our command. We have to shift horizontally by 1in plus \hoffset and the current margin, vertically by 1in, plus \voffset plus \headheight plus \headsep plus \topmargin.

```

535  \def\ra@useatxy{%
536  \let\@themargin\oddsidemargin
537  \vtop to 0pt{\kern-\headsep \kern-\topmargin \kern-\headheight
538  \kern-1in \kern-\voffset
539  \hbox to 0pt{\kern-\@themargin \kern-1in \kern-\hoffset
540  \unhbox\ra@atxybox \hss}\vss}}%
541  \global\let\@texttop\relax}

```

The command \firstchar is nowadays useless. In the times when Inria themes were 1A, 1B, 2A, 2B etc, we used it to remove the letter. Nowadays themes are NUM, COG, etc, and we hope people give only the theme.<sup>2</sup> We insert the logo, and, above it, something that looks like

THEME NUM

<sup>1</sup>This is redefined by \raggedbottom to be empty; you have to find a different trick if you want to insert something at a given position using this code as a model.

<sup>2</sup>and not the subtheme; we could use a command that picks up the first three characters.

```

542 \def\foratheme#1{\vskip8cm \vfil
543   \ra@atxy(74mm,175mm) {\hbox to 70mm{%
544     \hrulefill\hspace{8mm}
545     \def\firstchar##1##2\relax{##1##2} % ducon
546     \href{http://www.inria.fr/recherche/equipes/listes/theme%}
547       _\firstchar#1\relax.en.html}{THEME \uppercase{#1}}%
548     \hspace{8mm}\hrulefill}}
549   Start of the title page.
550 \def\foinria{%
551   \ra@atxy(7.8cm,2.5cm){\includegraphics[width=5.7cm]{Logo-INRIA-couleur}}%
552   \ra@atxy(55mm,173mm){\includegraphics{LogoRA\ra@year}}%
553   \setbox0\hbox to 14cm{%
554     \noindent\hskip3cm\hfill
555     {\fontencoding{T1}\fontfamily{ptm}\fontseries{m}%
556      \fontshape{n}\fontsize{10pt}{12pt}\selectfont
557      \href{http://www.inria.fr}{INSTITUT NATIONAL DE RECHERCHE EN %
558        INFORMATIQUE ET EN AUTOMATIQUE}}%
559     \hskip-5cm\hfill}%
560   \null\vskip0.7cm \leavevmode\hskip-3.5cm\box0\null\vskip2cm\vfil}
561   This is a hack: we just want \cleardoublepage. This is not used anymore.
562 \XMLElement{cleardoublepage}
563 {} {\cleardoublepage} {}
564   This is a hack: we want a rule below the page headings. We found no other way. This is not
565   used anymore.
566 \XMLElement{pagestylehrule}
567 {} {\hbox to0pt{\rule[-1ex]{.03cm}{\textwidth}\hss}} {}

```

### 3.3.3 Images

For the **HTML** version of the Raweb, we convert all math formulas into images. The idea is to construct an **XML** file that contains a **<formula>** for each object to convert. This file is translated by **T<sub>E</sub>X** into a **dvi** file, containing one formula per page; after that the **dvi** is converted to PostScript then **png**, or some other image format recognized by **HTML**.

A non trivial problem is the size of the image. When **T<sub>E</sub>X** translates the formula, it creates a box, and prints the dimension of the box on the transcript file. We want the baseline of the image to be aligned with the baseline of the text, but **HTML** provides only ‘center’ or ‘bottom’ as alignment options; for this reason, if the alignment cannot be ‘bottom’, said otherwise, if the depth of the box is non-zero, we add some blank space so that the height and depth will be the same. If two much space is added, this is not a good thing to do.

Assume that  $x$  is (a bit more than) the maximum of the height and depth of **\sizebox**. We modify the height and depth to be  $x$ ; we insert a vertical invisible rule of height  $x$  and depth  $x$ . This code is not used any more.

```

\def\@centerinlinemath{%
  \dimen1=\ifdim\ht\sizebox<\dp\sizebox \dp\sizebox\else\ht\sizebox\fi
  \advance\dimen1by.5pt \vrule width0pt height\dimen1 depth\dimen1
  \dp\sizebox=\dimen1\ht\sizebox=\dimen1\relax}

```

We noticed that if the images contains a single table, it is not vertically centered. In fact, the following code

```
$\vcenter{\vrule height 0pt depth5pt width2pt}$
```

produces a box of height 5pt, and depth 0pt (for details, see TeXbook, appendix G, rule 8: the distance between the center of the box and the baseline is parameter  $\sigma_{22}$  of the current math font). In fact, the `\vcenter` command is designed for math mode only, and the the distance between the center of the box and the math axis is zero.

In a first version, we used the ‘E’ option of dvips; this produces a set of PostScript files, one for each formula, with the correct bounding box. This bounding box is computed by dvips, according to characters and rules of the dvi file. If the TeX file contains a `\special` command that asks a PostScript interpreter to draw a circle of radius R, and an empty box that has the size of the circle, followed by some text, then you will see the circle followed by the text when viewing the PostScript file; but dvips is not a PostScript interpreter and has no idea of the size of the circle.

We solve this problem by adding two rules, one at the left of the image and one below. If everything works correctly, conversion from PostScript to png will remove them, but this is not always the case. The code is taken from `latex2html1`, it has a strange feature. In the case of overflow, only the vertical rule is added. This is the code that adds rules to the box in `\sizebox`.

```
\hbox{\vrule width1pt\kern-.5pt\vtop{\vbox{%
  \kern1pt\kern0.6 pt\hbox{\hglue1.7pt\copy\sizebox\hglue0.6 pt}}\kern.3pt%
  \ifdim\dp\sizebox>0pt\kern1pt\fi \kern0.6 pt%
  \ifdim\hsize>\wd\sizebox \hrule depth1pt\fi}%
  \ifdim\ht\sizebox<\vsize
    \ifdim\wd\sizebox<\hsize\hfill\fi
    \vfill
  \else\vss\fi
}
```

Assume that (x,y) is the position of the upper left corner of the image, (X,Y) are the dimensions of the image. If  $\epsilon$  is the width of the rule plus the distance to the image, then the bounding box of the page will be  $x - \epsilon, x + X, y, y + Y + \epsilon$ . These quantities can be computed by dvips; it is then obvious to remove the two rules.

We now use a different method. The bounding box is not computed anymore by dvips; we call an external program with the parameters x, y, X and Y. This program has a comment that says: *should (x,y) be (78,72) or (72,72) ?* but it uses (62,41); if `pstoimg` is unavailable, then `convert` is used with (64, 44). Remember that TeX puts its origin at 1in (this is 72pt) from the upper left corner, but we have no idea what the current margins could be. If we ask TeX what it puts on the dvi, we see that the main vertical box contains 16pt of glue, and a box shifted by 62pt, this one starts with a header, then 25pt of glue. After that we see a vbox containing some kerns: -25pt, -16pt, -12pt, and two kerns with sum 0, and absolute value 72.27pt. We also noticed that the message *Underfull \hbox (badness 10000) has occurred while \output is active* // printed on each page is a consequence of loading the `hyperref` package, that tries to put something in the header (which is empty, of course); as a consequence, we have patched the file, so that the `hyperref` package is not loaded in the case were we just want to convert a piece of XML into an image.

The result is cropped. This means: if Y is too big, a smaller value will be used; in particular this will remove the additional blank space added (as explained above for vertical centering). We simplified a bit the algorithm: no rules are printed, the size is no more adjusted.

There are two elements `<formula>` and `<tree>` that produce images. A formula contains a `<math>` element, and a tree contains a table (that defines the nodes and their layout) together with the connections. When we see a formula in a table, we simply ignore it (we typeset the math). Nothing special has to be done for math formulas, because they contain no tables, no trees (only MathML stuff).

Here we translate `<formula id=A>math</formula>`; the id attribute is the number of the image.

```
5 \XMLelement{formula}
6   {\XMLattribute{id}{\XML@formid}{none}}
```

```

7  {\formula@start}
8  {\formula@end}

9 \def\formula@start{@inlinemathA{\XML@formid}}
10 \let\formula@end@inlinemathZ

```

The two commands `\@inlinemathA` and `\@inlinemathZ` are used to start and finish a math image; originally, they were used directly in the code of `<formula>`. When we evaluate a `<tree>`, we must change these two commands.

```

11 \XMLElement{tree}
12  {\XMLAttribute{hpos}{\XML@hpos}{0pt}
13   \XMLAttribute{vpos}{\XML@vpos}{0pt}
14 }
15 {
16 \stepcounter{treecounter}
17 \let\formula@start\relax
18 \let\formula@end\relax
19 \startdimen=\XML@hpos
20 \enddimen=\XML@vpos
21 \@inlinemathA{\thetreecounter}
22 {\@inlinemathZ}

```

It may happen that space must be added around the object. Currently, we need space on the left and bottom, thus we declare these two variables. Since assignment is local, there is no need to reset them.

```

23 \newdimen\startdimen
24 \newdimen\enddimen

```

For some strange reasons, the `fotex.sty` file says that `eps` files should be included by converting them into `pdf`; this works for `pdftEX`, but not for `LATEX`. We make sure here that this rule is never applied.

```

25 \newbox\sizebox
26 \AtBeginDocument{
27 \@namedef{Gin@rule@.eps}#1{{\eps}{.eps}{#1}}

```

We redefine `\normalsize`, in the same way as `latex2html`. This is really, really, strange.

```

28 \let\realnormalsize=\relax
29 \def\adjustnormalsize{%
30   \def\normalsize{\mathsurround=0pt \realnormalsize
31   \parindent=0pt\abovedisplayskip=0pt\belowdisplayskip=0pt}%
32   \def\phantompar{\csname par\endcsname}%
33   \normalsize}

```

The action at the start of a formula is the following: we remember the id somewhere, we start a new page, and we construct a box; this box will start with a strut and some space.

```

34 \def\@inlinemathA#1{%
35   \xdef\@mathenv{#1}%
36   \adjustnormalsize \newpage\clearpage
37   \setbox\sizebox=\hbox\bgroup

```

```

38   \vrule height1.5ex width0pt
39   \kern\startdimen }

```

This is done at the end. The action is the following: we terminate the box, we modify the depth of the box in the case additional vertical space is needed, and print the dimensions on the log file. We insert the box on the current page and start a new one.

```

40 \def\@inlinemathZ{%
41   \egroup
42   \ifdim\enddimen>0pt
43     \dimen1=\dp\sizebox\advance\dimen1by \enddimen\dp\sizebox=\dimen1
44   \fi
45   \typeout{l2hSize %
46   :@\mathenv:\the\ht\sizebox::\the\dp\sizebox::\the\wd\sizebox.}
47   \box\sizebox
48   \clearpage
49 }

```

### 3.3.4 Trees

A tree is defined by a set of nodes, together with connections. The elements here are handled by the tree-dvips package, using commands described in part I of this report. All elements, except <node> have an empty content. Translation of element <foo> is in general \foo, with arguments depending on the attributes.

The content of a <node> is typeset normally, it has an a `name` attribute, that identifies it uniquely (On each page in the PostScript file, there is a unique node with a given name).

```

50 \XMLElement{node}
51 { \XMLAttribute{name}{\XML@name}{somenode} }
52 { \xmlgrab }
53 { \node{\XML@name}{#1} }

      A <nodepoint> element has a name, and two optional attributes xpos, ypos.
54 \XMLElement{nodepoint}
55 { \XMLAttribute{name}{\XML@name}{somenode} }
56   \XMLAttribute{xpos}{\XML@xpos}{0pt}
57   \XMLAttribute{ypos}{\XML@ypos}{0pt}
58 { \xmlgrab }
59 { \nodepoint{\XML@name}[\XML@xpos] [\XML@ypos] }

```

A <nodebox> element has a `nameA` attribute. The effect is to add a frame around the node defined by the name.

```

60 \XMLElement{nodebox}
61 { \XMLAttribute{nameA}{\XML@nameA}{somenode} }
62 }
63 { \xmlgrab }
64 { \nodebox{\XML@nameA} }

```

A <nodeoval> element has a `nameA` attribute. The effect is to put an oval around the node defined by the name.

```

65 \XMLElement{nodeoval}
66 { \XMLAttribute{nameA}{\XML@nameA}{somenode} }
67 }
68 { \xmlgrab }
69 { \nodeoval{\XML@nameA} }

```

A `<nodecircle>` element has a `nameA` attribute. The effect is to put an circle around the node defined by the name. There is another attribute `depth` that specifies a parameter of the circle.

```

70 \XMLElement{nodecircle}
71   {\XMLattribute{nameA}{\XML@nameA}{somenode}
72     \XMLattribute{depth}{\XML@depth}{0pt}
73   }
74   {\xmlgrab}
75   {\nodecircle[\XML@depth]{\XML@nameA}}

```

A `<nodetriangle>` element has two names, `nameA` and `nameB`. The effect is to insert a triangle between the nodes defined by the names.

```

76 \XMLElement{nodetriangle}
77   {\XMLattribute{nameA}{\XML@nameA}{nodeA}
78     \XMLattribute{nameB}{\XML@nameB}{nodeB}
79   }
80   {\xmlgrab}
81   {\nodetriangle{\XML@nameA}{\XML@nameB}}

```

Both elements `<nodeconnect>` and `<anodeconnect>` have a `nameA` and `nameB` attributes; the effect is to connect the nodes defined by the names; if the first letter of the element is a, there will be an arrow. The attributes `posA` and `posB` explain the positions of the connection, it can be one of top, bottom, left, right, or a combination. For instance ‘br’ stands for bottom right. This is the reverse order of that chosen for pictures in section 3.3.1, but we check nothing here.

```

82 \XMLElement{nodeconnect}
83   {\XMLattribute{nameA}{\XML@nameA}{nodeA}
84     \XMLattribute{nameB}{\XML@nameB}{nodeB}
85     \XMLattribute{posA}{\XML@posA}{b}
86     \XMLattribute{posB}{\XML@posB}{t}
87   }
88   {\xmlgrab}
89   {\nodeconnect[\XML@posA]{\XML@nameA}[\XML@posB]{\XML@nameB}}
90
91 \XMLElement{anodeconnect}
92   {\XMLattribute{nameA}{\XML@nameA}{nodeA}
93     \XMLattribute{nameB}{\XML@nameB}{nodeB}
94     \XMLattribute{posA}{\XML@posA}{b}
95     \XMLattribute{posB}{\XML@posB}{t}
96   }
97   {\xmlgrab}
98   {\anodeconnect[\XML@posA]{\XML@nameA}[\XML@posB]{\XML@nameB}}

```

Both elements `<barnodeconnect>` and `<abarnodeconnect>` have a `nameA` and `nameB` attributes; the effect is to connect the nodes defined by the names; if the first letter of the element is a, there will be an arrow. The attribute `depth` is optional.

```

99 \XMLElement{barnodeconnect}
100  {\XMLattribute{nameA}{\XML@nameA}{nodeA}
101    \XMLattribute{nameB}{\XML@nameB}{nodeB}
102    \XMLattribute{depth}{\XML@depth}{5pt}
103  }
104  {\xmlgrab}
105  {\barnodeconnect[\XML@depth]{\XML@nameA}{\XML@nameB}}
106
107 \XMLElement{abarnodeconnect}

```

```

108  {\XMLattribute{nameA}{\XML@nameA}{nodeA}
109    \XMLattribute{nameB}{\XML@nameB}{nodeB}
110    \XMLattribute{depth}{\XML@depth}{5pt}
111  }
112  {\xmlgrab}
113  {\abarnodeconnect[\XML@depth]{\XML@nameA}{\XML@nameB}}

```

Both elements <nodecurve> and <anodecurve> have a nameA and nameB attributes; the effect is to connect the nodes defined by the names; if the first letter of the element is a, there will be an arrow. The attributes depthA and depthB are optional.

```

114  \XMLElement{nodecurve}
115  {\XMLattribute{nameA}{\XML@nameA}{nodeA}
116    \XMLattribute{nameB}{\XML@nameB}{nodeB}
117    \XMLattribute{posA}{\XML@posA}{b}
118    \XMLattribute{posB}{\XML@posB}{t}
119    \XMLattribute{depthA}{\XML@depthA}{5pt}
120    \XMLattribute{depthB}{\XML@depthB}{5pt}
121  }
122  {\xmlgrab}
123  {\nodecurve[\XML@posA]{\XML@nameA}[\XML@posB]{\XML@nameB}{\XML@depthA}[\XML@depthB]}
124
125 \XMLElement{anodecurve}
126  {\XMLattribute{nameA}{\XML@nameA}{nodeA}
127    \XMLattribute{nameB}{\XML@nameB}{nodeB}
128    \XMLattribute{posA}{\XML@posA}{b}
129    \XMLattribute{posB}{\XML@posB}{t}
130    \XMLattribute{depthA}{\XML@depthA}{5pt}
131    \XMLattribute{depthB}{\XML@depthB}{5pt}
132  }
133  {\xmlgrab}
134  {\anodecurve[\XML@posA]{\XML@nameA}[\XML@posB]{\XML@nameB}{\XML@depthA}[\XML@depthB]}

```

### 3.3.5 Tables

We use the same method for normal tables as for math table, said otherwise, we read everything, construct the code, and finally evaluate it. This piece of code is only used for trees, so that we assume that cells have no borders. We could handle all attributes.

A <table> has a unique attribute vpos, currently unused.

```

135 \XMLElement{table}
136  {\XMLattribute{vpos}{\XML@vpos}{b}}
137  {\xmlgrab}
138  {\jg@start@table#1\jg@end@table}

```

A <row> can have lots of attributes, but we consider only one; it defines the vertical space after the current row.

```

139 \XMLElement{row}
140  {\XMLattribute{spaceafter}{\XML@spaceafter}{0pt}}
141  {\xmlgrab}
142  {\jg@start@tr#1}

```

Attributes right-border, left-border, halign and rows are declared for a <cell>, but only cols is used (this is the number of effective columns spanned by the cell).

```

143 \XMLElement{cell}
144 { \XMLattribute{cols}{\XML@cols}{1}
145   \XMLattribute{rows}{\XML@rows}{1}
146   \XMLattribute{halign}{\XML@halign}{center}
147   \XMLattribute{right-border}{\XML@rightborder}{false}
148   \XMLattribute{left-border}{\XML@leftborder}{false}
149 }
150 {\xmlgrab}
151 {\jg@start@td{\#1}}

```

Action when we start a table. We kill the two token lists, and say that we are at the start of the table. For our application, we need a lot of space between rows, so that `\arraystretch` is redefined to some value; an intermediate macro is used, it can be redefined, for instance at begin-document, by a config file. The redefinition is local.

```

152 \def\@myarraystretch{1.7}%
153 \newcounter{localcolcounter}
154 \newcounter{globalcolcounter}
155
156 \newcommand\jg@start@table{%
157   \let\arraystretch\@myarraystretch
158   \jg@table@toks{}%
159   \jg@row@toks{}%
160   \setcounter{globalcolcounter}{1}%
161   \StartTabletrue}

```

Action when we see the end of a table. Since we are at the end of the table, we know the number of columns of the last row, so that we can compute the number of columns of the table. After that, we insert the last row to the table. We insert the `\begin` and `\end` commands, then evaluate everything.

```

162 \newcommand\jg@end@table{%
163   \ifnum\value{localcolcounter}>\value{globalcolcounter}%
164     \setcounter{globalcolcounter}{\value{localcolcounter}}\fi
165   \merge@toks\jg@table@toks\jg@row@toks
166   \addto@hook\jg@table@toks{\end{tabular}}%
167   \edef\foo{\noexpand\begin{tabular}{*\{\theglobalcolcounter\}c}}%
168   \the\jg@table@toks}%
169 \foo

```

Action when we see the start of a row. We insert the content of the row token list to the table, and clear it. If this is not the first row of the table, we insert a double backslash, plus its optional argument; the current column counter is the number of columns of this row, and from this we deduce the current number of columns of the table. In any case, we compute the optional argument to be inserted at the end of the row, we say that the number of columns of this row is zero, and we are at the start of the row.

```

170 \newcommand\jg@start@tr{%
171   \merge@toks\jg@table@toks\jg@row@toks
172   \ifStartTablex
173     \global\StartTablexfalse
174   \else
175     \gaddto@hook\jg@table@toks{\\"}%
176     \merge@cmd\jg@table@toks\Rowsep
177     \ifnum\value{localcolcounter}>\value{globalcolcounter}%
178       \setcounter{globalcolcounter}{\value{localcolcounter}}\fi

```

```

179   \fi
180   \jg@row@toks{}%
181   \ifdim\XML@spaceafter=0pt \gdef\Rowsep{} \else
182   \xdef\Rowsep{[\XML@spaceafter]}\fi
183   \setcounter{localcolcounter}{0}%
184   \global\StartRowxtrue}

```

Action when we see a cell (in the argument of the command). If this not the first cell of the row, we insert an ampersand character (in `\tabcellsep`). We increment the current column number by N, the span; if this is not one, we must use `\multicolumn`.

```

185 \newcommand{\jg@start@td}[1]{%
186   \ifStartRowx\global\StartRowxfalse
187   \else \gaddto@hook{\jg@row@toks{\tabcellsep}}\fi
188   \addtocounter{localcolcounter}{\XML@cols}%
189   \ifx\XML@mtdalign\att@mtd@cleft
190     \def\temp{\#1\hfill}%
191   \else\ifx\XML@mtdalign\att@mtd@right
192     \def\temp{\hfill\#1}%
193   \else \def\temp{\#1}\fi\fi%
194   \ifnum\XML@cols=1 \else
195     \toks0=\expandafter{\temp}%
196     \edef\temp{\noexpand\multicolumn{\XML@cols}{c}{\the\toks0}}%
197   \fi
198   \expandafter\gaddto@hook\expandafter{\jg@row@toks\expandafter{\temp}}}

```

### 3.3.6 Other commands

The `<hi>` element has a `rend` attribute that indicates how to typeset the content; we use `\csname` for dispatching.

```

199 \XMLElement{hi}
200   {\XMLAttribute{rend}{\XML@rend}{rm}}
201   {\xmlgrab}
202   {\csname rend@\XML@rend\endcsname{\#1}}

```

In order to be complete, we should implement all font commands.

```

203 \let\rend@it\textit
204 \let\rend@bf\textbf
205 \let\rend@rm\textrm
206 \def\rend@small#1{{\small #1}}
207 \def\rend@sub#1{\textsubscript{#1}}
208 \let\rend@sup\textsuperscript

```

We want L<sup>A</sup>T<sub>E</sub>X and I<sup>A</sup>T<sub>E</sub>X to typeset properly.

```

209 \XMLElement{TeX}
210   {}{\TeX{}}
211
212 \XMLElement{LaTeX}
213   {}{\LaTeX{}}

```

We use this for producing little images.

```

214 \XMLElement{preview}
215   {}

```

```

216  {\begin{preview}}
217  {\end{preview}}
218  Some attribute definitions.
219  \XMLstring\att@true<>true</>
220  \XMLstring\att@false<>false</>
221  \XMLstring\jg@OverBrace<>&#xFE37;</>
222  \XMLstring\jg@UnderBrace<>&#xFE38;</>
223  \XMLstring\jg@OverBar<>&#xAF;</>
224  \XMLstring\jg@UnderBar<>&#x332;</>
225  \XMLstring\att@mtd@left<>left</>
226  \XMLstring\att@mtd@right<>right</>
227  \XMLstring\att@mtd@center<>center</>
228  \XMLstring\att@none<>none</>
229  \XMLstring\att@dzero<>0</>
230  \XMLstring\att@done<>1</>
231  \XMLstring\att@dtwo<>2</>
232  \XMLstring\att@mathml@rm<>rm</>
233  \XMLstring\att@BLOCK<>block</>
234  \XMLstring\att@PREFIX<>prefix</>
235  \XMLstring\att@EQUATION<>equation</>
236  \XMLstring\att@sub<>sub</>

```

Some commands must be redefined at start of document. Note: the Unicode character 3F5 is ‘greek unate epsilon symbol’, we translate it as  $\epsilon$ , the character 3B5 ‘greek small letter epsilon’ is translated as  $\varepsilon$ .

```

236  \AtBeginDocument{
237  \UnicodeCharacter{x332}{\jgunderline}
238  \UnicodeCharacter{x3F5}{\epsilon}
239  \UnicodeCharacter{x3B5}{\varepsilon}
240  \let\downslopeellipsis\ddots
241  \mathchardef\Rightarrow="3229
242  \let@\texttop\ra@useatxy
243  \let\xURL\relax
244  \selectlanguage{english}
245  \let@\item\jg@item
246  }

```

### 3.4 The fotex.cfg file

The fotex.cfg file contains the definitions of some elements. Two of them are used by the Raweb. The action associated to these elements is shown above.

```

247  \XMLElement{fo:RATHHEME}
248  {}
249  {\xmlgrab}
250  {\foratheme{\#1}}
251
252  \XMLElement{fo:INRIA}
253  {\XMLattribute{year}{\ra@@year}{2001}}
254  {}
255  {\xdef\ra@year{\ra@@year}\foinria}

```

## Chapter 4

# Interpreting XSL/Format in T<sub>E</sub>X

In general, an XML file describing a document like the Raweb contains instructions like: insert the table of contents here, or emphasize this word, but gives no details. In the next chapter we shall explain how these details can be added (using something like XSL/Transformations); here we explain how T<sub>E</sub>X can interpret these formatting commands. We assume that our document conforms to XSL (Extensible Style Sheet), which is a W3C recommendation of 15 October 2001. The important part of the recommendation is chapter 6 (Formatting objects) that describes all XML elements; they are in some namespace, conventionally abbreviated to ‘fo’.

We start with an example; it contains one line of the table of contents, associated to some section, here it is named “National Actions” and has a unique identifier, number 120. The style sheet that creates this piece of code added the section number 8.2, but the page number is still unknown: T<sub>E</sub>X must compute it. Some other information is added, for instance the color of the link, the font of the text, various dimensions, the type of the leaders.

Normally, such details do not appear in a T<sub>E</sub>X file, but are defined by a class. Since everything is explicit, any class could be used, and we shall see later that the article class is used; however your document can have a front matter, main matter, etc., as in the book class; they are associated to page sequences and page masters, which are rather complicated concepts.

```
<fo:block font-weight="bold" text-indent="0.25in">8.2. &#x2003;
  <fo:inline space-start="20pt">
    <fo:inline>National Actions</fo:inline>
  </fo:inline>
  <fo:leader rule-style="dotted" rule-thickness="0pt"/>
  <fo:inline color="red">
    <fo:basic-link internal-destination="uid120">
      <fo:page-number-citation ref-id="uid120"/>
    </fo:basic-link>
  </fo:inline>
</fo:block>
```

### 4.1 Generalities

We describe here the content of two files: `fotex.xmt` and `fotex.sty`. The `fotex.xmt` file contains definitions of elements, while the `fotex.sty` file contains some commands. Both files start like this

```
1 % Copyright 2003 Sebastian Rahtz/Oxford University
2 %       <sebastian.rahtz@oucs.ox.ac.uk>
```

```

3 %
4 % Permission is hereby granted, free of charge, to any person obtaining
5 % a copy of this software and any associated documentation files (the
6 % "Software"), to deal in the Software without restriction, including
7 % without limitation the rights to use, copy, modify, merge, publish,
8 % distribute, sublicense, and/or sell copies of the Software, and to
9 % permit persons to whom the Software is furnished to do so, subject to
10 % the following conditions:
11 % The above copyright notice and this permission notice shall be included
12 % in all copies or substantial portions of the Software.

```

Lots of people are working on these files:

```

13 % Includes fixes from Tomas Bures <ghort@pauline.vellum.cz>
14 % Yura Zотов <yznews@hotmail.ru>
15 % Anton V. Boyarshinov <boyarsh@ru.echo.fr>
16 % Dirk Roorda <dirk.roorda@planet.nl>

```

In the first version of this document, we discussed version 1.17, here it is version 1.25 (distributed by TeTeX3.0). Newer versions might exist. In what follows, version V1 refers to the first version of the document, hence to version 1.17 of the *fotex* package, and V2 refers to 1.25.

```

17 \ProvidesPackage{fotex}[2003/03/10: version 1.25.
18   support for XSL formatting, S Rahtz]

```

This file was modified by José Grimm in some places, we shall see why later on, this line gives the local revision number (this corresponds to the version dated 2006/11/23).

```

19 \immediate\write20{fotex.sty version 1.25. S Rahtz
20   (JG patches: $ Revision: 1.13 $)}

```

We shall indicate the differences between these two versions whenever appropriate. In some cases, local assignments were replaced by global ones; as a general rule, if *<a>* and *<b>* are children of *<c>*, then typesetting of *<b>* is independent of typesetting of *<a>*, and a group is created for every element; hence, if side effects are needed while typesetting *<a>* they should be local, unless required by *<b>*, case where global assignments are needed; if moreover the scope is restricted to *<c>*, a local copy is needed. In some other cases, *\relax* tokens were added at the end of assignments. Remember that, if *TEX* sees *\foo=0*, it expands the following token, in order to see if additional digits are found. Since *\relax* is a non-expandable token that produces no text, it can be put after the zero. In most of the cases, the space inserted at the end of the line is enough.

The first difference is the following.

```

21 \gdef\XML@attrib@x#1#2{
22   \gdef\XML@tempb##1##2##3##4\relax\relax{
23     \global\let\inheritexplicit\relax
24     {\set@display@protect
25       \expandafter\ifx\csname#2\endcsname\inherit
26         \global\let\inheritexplicit\noexpand
27         \fi}%
28       \ifx\inheritexplicit\relax
29         \def##2{#2}%
30         \fi
31       ##1##4\relax\relax}

```

As explained in Chapter 2, putting a *\def* in a *\def* in a *\def* is not usual. In our case, the inner definition is conditional, so that it is unclear what happens. The outer command takes two arguments, say A and B, and defines another command, say C. The command C takes as argument a long list, and extracts expression A, followed by two expressions D and E; the remaining part

of the list is evaluated again. Quantity E is ignored, and D is defined to be B. Assume that we evaluate an element, defined by `\XMLElement`, and the first argument says that attribute X should be put in command Y with default value Z. Then D is Y, A is related to X, and B is the value of the attribute or a default value. The original code sets D. The modified code sets it conditionally, if the first `\ifx` is false. In fact, the test is done in a group, and if the test is true, a variable is globally changed, and the second `\ifx` looks at this change. The test is true in case B is ‘`inherit`’, but instead of comparing token lists, the code converts B in a command via `\csname` and compares command names. This can produce a lot of commands and might overflow the hash table. Commands produced by `\csname` are never undefined, but outside the group, the old value is restored.

Second addition:

```
32 \gdef\explicitattribute#1{  
33 { \expandafter\def\csname#1-test\endcsname{\global\def\isexplicit{1}}  
34 \global\let\isexplicit\relax  
35 \def\XML@doattribute##1##2##3{\csname##2-test\endcsname}  
36 \the\XML@attribute@toks}}
```

Write `\do` instead of `\XML@doattribute` and `\L` instead of `\XML@attribute@toks`. The quantity `\L` is a token list containing all items of the form of a `\do` followed by a namespace A, a local name B and a value C. This code takes an argument, say ‘foo’, and sets `\isexplicit` to true (i.e., `\non-relax`) if one B is ‘foo’. The idea is simple: the `\do` command is redefined in such a way as to modify `\isexplicit` if B is ‘foo’. Implementation is horrible: the package defines `\foo-test` to change the flag, and evaluates the command named B-test for every B.

In Chapter 2, we gave the example of an element with two attributes, ‘`foo:bar`’ and ‘`color`’, with values ‘`gee`’ and ‘`red`’. The first modification creates commands `\gee` and `\red`, and compares them to `\inherit`. The second modification creates commands `\bar-test` and `\color-test`, and evaluates them; the assumption is that these commands are not defined (made `\relax` by `\csname`), hence provoke no undesired result.

In one of our examples the code fails because the attribute is something like ‘`&#2016;`’, corresponding to the math construct `\left\Vert`. The second command always gives a negative result because applied in the case of an empty attribute list. One way to patch the first command is to redefine the ampersand; but the code shown here is safer.

```
37 \def\inheritname{inherit}  
38 \def\jgXML@attrib@x#1#{  
39   \gdef\XML@tempb##1##2##3##4\relax\relax{  
40     \def\tmp{#2}%  
41     \ifx\tmp\inheritname\else\def##2{#2}%  
42     \fi  
43   ##1##4\relax\relax}}
```

Patch of the second command. We put ‘`foo`’ in `\tmp`, B in `\atmp`. In case of equality, we globally set `\isexplicit` to `\empty` (this should be different from `relax`).

```
44 \def\explicitattribute#1{{%  
45   \def\tmp{#1}  
46   \global\let\isexplicit\relax  
47   \def\XML@doattribute##1##2##3{  
48     \def\atmp{##2}\ifx\tmp\atmp\global\let\isexplicit\empty\fi  
49   \the\XML@attribute@toks}}
```

The `fotex-add.sty` file loads the following packages: `graphics`, `multicol`, `rotating`, `curves`, `soul`, `array`, `amsmath`, `longtable`, `url`, `ulem`, `color`, `times`, `mlnames`, `unicode`, `marvosym`, `ipa`, `ifsym`, `ucharacters`, `nameref`, `hyperref`, and `rawweb-uni`. This last package defines (or redefines) some Unicode characters. Some packages, like `ifsym`, were not in the original style file, they were added because

providing access to some fonts. Setting the boolean `hyperref` to false via `\hyperreffalse` inhibits loading of the `hyperref` package.

The `fotex-add.sty` loads `fotex-supp.tex` if such a file exists. This file can load some additional packages; it can also inhibit loading of the package `hyperref` (in fact, it is the only place where you can use `\hyperreffalse`). This mechanism is a bit complicated, because all packages must be loaded before the start of the document, and you cannot unload a package. Both files `fotex.xmt` and `fotex.sty` had to be adapted for the Raweb.

50    \RequirePackage{fotex-add}

The `fotex.xmt` file starts with these two lines, it is followed by declarations of attributes, strings and elements. The namespace number of `fo` is 5 (see below), that of `fotex` is 6.

51    \DeclareNamespace{fotex}{http://www.tug.org/fotex}  
 52    \DeclareNamespace{fo}{http://www.w3.org/1999/XSL/Format}

## 4.2 The root

Handling the `<fo:root>` element is trivial, but some magic is implied. Let's describe it. The main `TEX` file should define the `\xmlfile` command to be the name of the XML file to process, and input the `xmltex.tex` file. The last action of this file is to input `xmltex.cfg`, `\jobname.cfg` and the XML file. The file `xmltex.cfg` typically defines a catalog similar to the one shown in section 2.7. It defines the XSL/Format namespace (it assigns the number 5 to it) and says that the definitions are to be found in the `fotex.xmt` file. It may define other things. The `\jobname.cfg` file can also define some commands.

The `\xmlfile` file is read using XML syntax. It typically starts with a `<?xml?>` declaration (that defines the encoding, say UTF-8). In the case of the Raweb, it is followed by a `<fo:root>` element. This one contains a `<fo:layout-master-set>`, followed by some `<fo:static-content>` elements and some `<fo:page-sequence>` elements. The root element has three attributes, of the form `xmlns:XX = 'YY'`. For each attribute, the code line 388 (page 21) is executed. One of the attributes has the name `xmlns:fo` and its value is the XSL/Format URI. This URI is the same as the declaration above (on line 51 above, in this chapter), so that the 'fo' in `<fo:root>` is the same namespace in the XML file and the xmt file. After all attributes have been read, the code on line 413 is executed. In particular, the 'fo' in `<fo:root>` is evaluated now (line 416, command `\XML@ns`, the value is 5). The command `\XML@checkknown` has as side effect to call `\inputonce` with, as argument, the file `fotex.xmt`, as explained in the catalogue. This has as effect to load the `fotex.xmt` file. After that, we know how to handle the root element. The first action is to evaluate the attributes. Almost all attributes are global. The norm<sup>1</sup> says: there is one attribute `media-usage`, in what follows, we shall assume that its value is 'paginate'. The action is as follows: we define the `documentclass` to something non-trivial but not too complicated, and load the `fotex` package.

53    \XMLElement{fo:root}  
 54     {\XMLNSAX{fo}{fotex:spacing-style}{\FoTeXSpacingStyle}{normal}}  
 55     {\documentclass{article}}  
 56     \usepackage{fotex}

We are now ready to evaluate everything. We start with `\begin{document}` plus some action (empty pagestyle, default language). When we see `</fo:root>` we evaluate `\end{document}`: this will stop everything.

57    \begin{document}  
 58     \pagestyle{empty}  
 59     \FOSetHyphenation

---

<sup>1</sup> URL is <http://www.w3.org/TR/xsl/slice6.html>, see also slices 1 to 7.

```

60   \FoTeXSetSpacingStyle
61   }
62 {\end{document}}
```

Bootstrap code: We use here `\XMLNSA` as a short name for `\XMLnamespaceattribute` (and the same for `\XMLNSAX`). Remember that this takes four arguments. In the line that follows, the effect is the following: for every element in the ‘fo’ namespace, the value of the `language` trait is stored in `\FOlanguage`; the default value is ‘`inherit`’, this means that it is the same as the value of the father. The initial value is ‘`none`’. In the case of the `hyphenate` trait, the initial value is ‘`false`’, the default value is ‘`inherit`’. Note: the mechanism works only if attributes are declared before elements; the `fotex.xmt` file starts with the list of all attributes, in alphabetic order; we prefer give the definition after first use.

```

63 \XMLNSAX{fo}{language}{\FOlanguage}{\inherit}
64 \XMLNSAX{fo}{hyphenate}{\FOhyphenate}{\inherit}
65 \gdef\FOlanguage{none}
66 \gdef\FOhyphenate{false}
67 \def\LastLanguage{(undefined)}
68 \selectlanguage{english}
```

This is an addition of V2. If `fotex:spacing-style` is ‘`french`’ then `\frenchspacing` will be executed.

```

69 \def\FoTeXSetSpacingStyle{%
70   \ifx\FoTeXSpacingStyle\att@french \frenchspacing \fi
71 }
72 \XMLstringX\att@french<>french</>
```

In the case where hyphenation is desired, this piece of code is assumed to switch to the right language, it sets `\hyphenpenalty` to some value (typically 50), otherwise to infinity.

```

73 \def\FOSetHyphenation{%
74   \ifx\FOhyphenate\att@true
75     \LoadLanguage{\FOlanguage}%
76     \hyphenpenalty=\exhyphenpenalty
77   \else
78     \hyphenpenalty=10000
79   \fi}
```

We put in `\newL` a canonical version of the language, say ‘`FR`’, then evaluate `\L@FR`, unless the language is the same. We remember in `\LastLanguage` the language. The file `mlnames.sty` defines a lot of languages<sup>2</sup>.

```

80 \def\LoadLanguage#1{%
81   \begingroup\utfeight@protect@chars\xdef\newL{#1}\endgroup
82   \ifx\newL\LastLanguage
83   \else
84     \csname L@\newL\endcsname
85   \fi
86   \edef\LastLanguage{\newL}}
```

### 4.3 Mathematics

The elements defined in this paragraph are not defined by XSL/Format. In fact, they are not used by the Raweb.

---

<sup>2</sup>The English language is selected by: `GB`, `US`, `gb`, `us`, `en`, and `none`. But not `EN`. New in V2: `en_GB` and `en_US`.

```

Typesetting of <fotex:inlinemath>math</fotex:inlinemath>. We evaluate \(math\).
87 \XMLElement{fotex:inlinemath}
88   {} {\{} {\}}
Typesetting of <fotex:equation>math</fotex:equation>. The evaluation of the math is in
an equation environment.
89 \XMLElement{fotex:equation}
90   {}
91   {\begin{equation}}
92   {\end{equation}}
Typesetting of <fotex:displaymath> math </fotex:displaymath>. The evaluation of the
math is a displaymath environment.
93 \XMLElement{fotex:displaymath}
94   {}
95   {\begin{displaymath}}
96   {\end{displaymath}}
Typesetting of <fotex:eqnarray>math</fotex:eqnarray>. The evaluation of the math is a
gather* environment. This is an amsmath environment, that requires an explicit \end tag, so
that we need to grab it.
97 \XMLElement{fotex:eqnarray}
98   {}
99   {\xmlgrab}
100  {\begin{gather*}#1\end{gather*}}
Handling of <fotex:subeqn>math</fotex:subeqn>. There is some action, that consists of
evaluating the math, and a double backslash; this end-of-row marker must be executed outside
the group defined by \xmlgrab, thus the \aftergroup. If there is a label (i.e. an id attribute in
\FOid), we execute the \label command3, otherwise, the equation will have no number.
101 \XMLElement{fotex:subeqn}
102   {}
103   {\xmlgrab}
104   {%\ifx\FOid\@empty
105     \gdef\w@t{\#1\nonumber\\}
106   \%else
107     \% \gdef\w@t{\#1\label{\temp}\\}
108   \%fi
109   \aftergroup\w@t}

```

## 4.4 Multiple columns

The passive tex package provides the nomulticol.sty file. It contains the following comments:

```

110 %% This is file 'nomulticol.sty',
111 %% a tweak in package multicol.sty [2000/07/10 v1.5z
112 %%     multicol column formatting (FMi)]
113 %% Tweaked by Dirk Roorda 2003/01/09

```

The purpose is to have the \begin{multicols} ... \end{multicols} functionality without putting
the material inside a group. This is needed because in PassiveTeX a <fo:flow> is embedded in a
multicols environment. But the <fo:block> with attribute span='all' must be able to interrupt
this. However, saying \end{multicols} just before and \begin{multicols}{N} just after does

---

<sup>3</sup>I don't understand this \temp stuff. Moreover, as we shall see, we never use the \label command

not work, because it makes the attributes, set between the start of the flow and the beginning of the block, invisible. That's why a grouping-transparent multicol setup is needed. The package provides two macros `\nobeginmulticols` and `\noendmulticols` that do essentially the same but do not create a group.

Initial version of the `fotex` package did not implement the `span` feature, hence loaded the `multicol` package like this.

```
114 \IfFileExists{multicol.sty}{\RequirePackage{multicol}[1997/12/16]}{\newenvironment{multicols}[1]{\typeout{Warning, at line \the\inputlineno,}{\multicol package not available}}{}}
115
116
117
118
119 }
```

The current version tries to load this new package if possible, the old one otherwise.

```
120 \IfFileExists{nomulticol.sty}{\confirmnomulticols}{\IfFileExists{multicol.sty}{\warnnomulticols}{\warnmulticols}}
121
122
123
124
125 }
```

If the `nomulticol` package is not available, we define the five commands provided by the package.

```
126 \def\fakenomulticols{
127   \def\nobeginmulticols##1{\begin{multicols}{##1}}
128   \def\noendmulticols{\end{multicols}}
129   \def\interbeginmulticols##1{}
130   \let\interendmulticols\relax
131   \let\refreshmulticols\relax
132 }
```

This is the action in case where the new package exists, or the old one exists, or none is found.

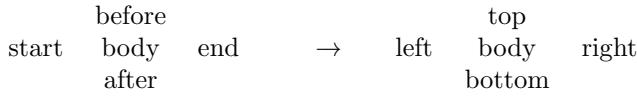

```
133 \def\confirmnomulticols{
134   \RequirePackage{nomulticol}[2003/01/09]
135   \typeout{INFO (nomulticol.sty: fo:block span="all" works)}
136 }
137 \def\warnnomulticols{
138   \RequirePackage{multicol}[1997/12/16]
139   \typeout{WARNING (multicol.sty: fo:block span="all" does not work)}
140   \fakenomulticols
141 }
142 \def\warnmulticols{
143   \typeout{WARNING (no multicol.sty: multiple columns not available)}
144   \newenvironment{multicols}[1]{\typeout{Warning, at line}{\the\inputlineno, multicol package not available}}{}}
145   \fakenomulticols
146 }
147 }
```

## 4.5 Page masters

The children of `<fo:root>` are: a `<fo:layout-master-set>`, an optional `<fo:declarations>`, and some `<fo:page-sequence>`. The `<fo:declarations>` has a sequence of `<fo:color-profile>` elements as children, that define color profiles. These are currently unimplemented.

```
148 \XMLElement{fo:color-profile}{}{}{}
149 \XMLElement{fo:declarations}{}{}{}
```

The children of `<fo:layout-master-set>` are either `<fo:simple-page-master>` (that define the layout of a page) or `<fo:page-sequence-master>` (that define which simple page masters are to be used). We define in this section how simple-page-masters are handled. Each such object has a name, which is in the `master-name` trait. For the Raweb, we define eight such masters, named: simple1, left1, right1, first1, simple2, left2, right2, first2. Here the digit at the end indicates the number of columns of text on the page. The names left and right stand for even or odd pages (odd pages are on the right, even pages on the left). We have a special case for simple ('blank' pages) and first pages. Each master has a `reference-orientation`. This will be ignored; it has also a `writing-mode`, that will be ignored. We assume that it is 'lr-tb', meaning: inline components and text within a line are written left-to-right; lines and blocks are placed top-to-bottom. With this convention, we have `before=top`, `after=bottom`, `start=left` and `end=right`. Schematically this can be represented like this:

The page is divided into five rectangular regions, four of them are called region-before, region-after, region-start and region-end (they correspond to the header, the footer, left margin, right margin). The content of these is 'static', said otherwise, it is the same for each page, except that it can contain the current page number. These regions have an extent (vertically, or horizontally). Whether the upper-left corner is part of the region-before or region-start depend on the precedence of the region-before. The four regions mentioned above surround the region-body. Both the page and the region-body have margins. How these margins and extents define the size of the body is unclear to me. For instance, the Raweb defines one page master with the following attributes: `master-name='left1'`, `page-width='210mm'`, `page-height='297mm'`, `margin-top='75pt'`, `margin-bottom='100pt'`, `margin-left='80pt'`, `margin-right='80pt'`. With these values the text width is near 15cm, and the text height is 21cm (in fact, after the text, we have some space, an empty footer, and the margin, i.e. 24pt, 12pt and 100pt, a total of nearly 5cm).

We declare here some attributes (margins are declared later).

```
150 \XMLNSA{fo}{page-width}{\FOpagewidth}{auto}
151 \XMLNSA{fo}{page-height}{\FOpageheight}{auto}
152 \XMLNSAX{fo}{master-name}{\FOmastername}{}
153 \XMLNSAX{fo}{extent}{\FOextent}{0.0pt}
```

Action is trivial: we just evaluate the content.

```
154 \XMLElement{fo:layout-master-set}
155   {} {} {}
```

This will be used twice. The idea is that typesetting a page uses "traits", that are computed from attributes; all four margins define a single trait, that can be defined by a single attribute (`margin`) or a sequence of four attributes (for instance `margin-right`), or can be inherited. We shall see later that the equivalent of TeX glue is a complicated trait.

```
156 \def\jg@expandmargins{%
157   \ifx\FOmargin\empty\relax\else
158     \let\FOmarginright\FOmargin
159     \let\FOmarginleft\FOmargin
160     \let\FOmargintop\FOmargin
161     \let\FOmarginbottom\FOmargin
162   \fi}
```

The code for <fo:simple-page-master> has a comment that says *tests removed see above*. In V1, there were four lines of code shown here. These lines of code are now removed, so that our remark has to be commented out too: *As mentioned above, the sum of the vertical margins are used, so that it is unclear why one variable is replaced by the maximum. In our cases, outer margins are larger than inner margins, so that the tests are false, and no variable is changed.*

```
\ifdim\InnerTopMargin>\F0margintop\def\F0margintop{\InnerTopMargin}\fi
\ifdim\InnerBottomMargin>\F0marginbottom\def\F0marginbottom{\InnerBottomMargin}\fi
\ifdim\InnerRightMargin>\F0marginright\def\F0marginright{\InnerRightMargin}\fi
\ifdim\InnerLeftMargin>\F0marginleft\def\F0marginleft{\InnerLeftMargin}\fi
```

This defines \Atomic:left1 (assuming that the master name is ‘left1’), it contains the size of the page and the max values of the margins of the page and body. This is the old version.

```
\def\jg@define@atomic{
  \expandafter\xdef\csname Atomic:\F0Master\endcsname{
    \MasterTopMargin\F0margintop
    \MasterBottomMargin\F0marginbottom
    \MasterRightMargin\F0marginright
    \MasterLeftMargin\F0marginleft
    \paperwidth\F0pagewidth
    \paperheight\F0pageheight}}
```

Assume that the master name is ‘left1’, this defines \Atomic:left1; when executed, this defines some commands to contain the sum of outer and inner values; the outer value is the value of the attribute (for instance margin-top) of the current element (the simple-page-master), the inner value is the value of the same attribute of the region-body child of the master. Quantities used in this code are defined later; the body of the macro contains ten lines of the form AXYR, where A is an optional \advance, R is an optional \relax, X is a dimension register, and Y a macro (definitions will be given later). The effect of the code is to store Y in X, or increment X by Y. Since the command is defined by \xdef, all possible tokens are expanded. Only these Y tokens can be expanded.

```
163 \def\jg@define@atomic{
164   \expandafter\xdef\csname Atomic:\F0Master\endcsname{
165     \MasterTopMargin\F0margintop
166     \advance\MasterTopMargin\InnerTopMargin\relax
167     \MasterBottomMargin\F0marginbottom
168     \advance\MasterBottomMargin\InnerBottomMargin\relax
169     \MasterRightMargin\F0marginright
170     \advance\MasterRightMargin\InnerRightMargin\relax
171     \MasterLeftMargin\F0marginleft
172     \advance\MasterLeftMargin\InnerLeftMargin\relax
173     \paperwidth\F0pagewidth
174     \paperheight\F0pageheight}}
```

In the example of the Raweb, \Atomic:left1 contains the following.

```
\MasterTopMargin 75pt\advance \MasterTopMargin 24pt\relax
\MasterBottomMargin 100pt\advance \MasterBottomMargin 24pt\relax
\MasterRightMargin 80pt\advance \MasterRightMargin 0pt\relax
\MasterLeftMargin 80pt\advance \MasterLeftMargin 0pt\relax
\paperwidth 210mm
\paperheight 297mm.
```

The content of a <fo:simple-page-master> is a definition of each of the five regions mentioned above. In this version, we ignore the start and end regions: we assume that they are blank and have zero extent. Only region-body is mandatory, so that we provide a default for region-before

and region-after. After this element has been completely evaluated, six commands are defined: assume that the master name is ‘left1’; we define `\left1:before`, `\left1:after`, to be names of regions, `\left1:before-extent`, `\left1:after-extent`, their extents; there is also `\left1:B` (instead of ‘B’, the name of the body region should be used, it is ‘xsl-region-body’, see below), and `\Atomic:left1`.

```

175 \XMLElement{fo:simple-page-master}
176   {}

191     \endgroup
192   }

```

These lines are from `fotex.sty`. The quantities `\hoffset` and `\voffset` are the opposite of the TeX offsets. The default paper width is strange.

```

193 \paperwidth211mm
194 \paperheight297mm
195 \hoffset-1in
196 \voffset-1in

```

The `<fo:region-before>` element is empty, it has some traits. We only consider `region-name` and `extent`. In the example given above, attributes are `region-name = ‘xsl-region-before-left’` and `extent = ‘12pt’`. Each region has a default name, it is not used here. The code defines two global commands. For instance, this could define `\left1:before` to the name shown above (in the case where the master name is ‘simple1’ or ‘simple2’, the default name is used).

```

197 \XMLElement{fo:region-before}
198   {}
199   {\ifx\FOregionname\empty\def\FOregionname{xsl-region-before}\fi
200     \begingroup

213     \expandafter\xdef\csname\FOMaster:after-extent\endcsname{\FOextent}
214     \endgroup
215   }
216 {}
```

These are not implemented.

```

217 \XMLElement{fo:region-start}{}{}
218 \XMLElement{fo:region-end}{}{}
```

The <fo:region-body> is empty; it has traits as the region-before. In the example of ‘left1’ they are the following: margin-bottom = ‘24pt’, margin-top = ‘24pt’ (the default value for the two other margins is zero; no extent can be given here). The default value of the region-name is used, because all pages have the same layout.

There are possibly other attributes, but most of them are not implemented. As explained above, we store somewhere the margins so that the page-master can use them. We also store in \left1:B (where ‘left1’ is the name of the master, and B the name of the region), the four following quantities: top margin, bottom margin, column-count and column-gap: this is because the page can contain more than one column of text, and we have to specify this number and the distance between the columns.

```

219 \XMLElement{fo:region-body}
220   {}
221   {
222     \jg@expandmargins
223     \xdef\InnerBottomMargin{\FOmarginbottom}
224     \xdef\InnerTopMargin{\FOmarginbottom}
225     \xdef\InnerLeftMargin{\FOmarginleft}
226     \xdef\InnerRightMargin{\FOmarginright}
227     \ifx\FOregionname\empty\def\FOregionname{xsl-region-body}\fi
228     \begingroup
229       \utfeight@protect@chars
230       \expandafter\xdef\csname\FOMaster:\FOregionname\endcsname
231         {\FOcolumngap|\FOcolumncount|\FOmarginbottom|\FOmargintop|}
232     \endgroup
233   }
234 }
```

This will be used later. It grabs the four values saved by the procedure above.

```

```

## 4.6 Page sequences

A `<fo:page-sequence-master>` is an element that has a single trait `master-name`; its content defines the page sequence with that name, according to its single child, that can be one of three possibilities. The Raweb defines the following: `twoside1nofirst`, `twoside1`, `oneside1`, `twoside2`, `one-side2`, but uses only the second one. The meaning is the following: all even pages are the same, as well as all odd pages; the first page is special. If you look very closely, there are three pages numbered 2. At least one of them is empty; but this is a kludge. In fact, the initial page (the title page) has no headings, it is of type `First`; is it followed by an empty page, generated by `<cleardoublepage/>`. This page is followed by a second page sequence that contains the table of contents; this page sequence is followed by the text; this is a page sequence that starts on a right page, numbered one. The first two page sequences should define `force-page-count` to be `end-on-even`, rather than using this kludge. The behavior will change in 2005.<sup>4</sup>

In all examples that follow, we shall assume that the master name is ‘`twoside1`’; this quantity is saved in a variable that can be used by the children. The master can define a single page, in this case the child defines this page; it can define a sequence of pages that look all the same, in this case, the child gives a model for these pages; finally, it can define a sequence of pages, whose aspect depend on parameters, case where the child contains a list of definitions; for each of this definitions, the master is the grand-father, this explains why the name is stored in a variable named `\Granpa`.

We shall see later that the V2 implementation allows the use of more than one simple page, numbered one, two, three, etc. The counter `\SimplePMRefs` holds the index of the next simple page master.

```
248 \XMLElement{fo:page-sequence-master}
249   {}
250   {\global\SimplePMRefs0\relax
251     \let\Granpa\F0mastername
252   }
253   {\global\SimplePMRefs0\relax}
```

We have an implementation problem: the FO specifications are too complex to match those of TeX, so that we use only 4 types of pages, named Even, Odd, First, Blank. The original `fotex.sty` did define but not use Blank. We changed this. In version V1, children of a page sequence master, say ‘`twoside1`’, were assumed to define the four commands `\First:twoside1`, `\Blank:twoside1`, `\Odd:twoside1`, `\Even:twoside1`, to be the name of a page master. In the case of a single, or repeatable page master reference, these four quantities were defined to be the `master-reference` attribute. In V2, we define only `\Odd:twoside1` in the case of a repeatable page master reference, and we define `\Lead:3:twoside1` if this is the third single page master reference in the list.

We define here `<fo:single-page-master-reference>`; this defines a single page. The non-trivial part here is that any Unicode character is allowed in the attribute value, and some protection is needed.

```
254 \XMLElement{fo:single-page-master-reference}
255   {}
256   {
257     \global\advance\SimplePMRefs1\relax
258     \begingroup
259       \utfeight@protect@chars
260       \expandafter\xdef\csname Lead:\the\SimplePMRefs:\Granpa\endcsname
261         {\F0masterreference}
262     \endgroup
```

---

<sup>4</sup>The kludge is still active in 2006; let’s hope it will be removed in 2007.

```
263 }
264 {}
```

We define here <fo:repeatable-page-master-reference>; this defines a sequence (of some length) of pages. The length is ignored. The action is as described above.

```
265 \XMLElement{fo:repeatable-page-master-reference}
266   {}
267   {
268     \begingroup
269       \utfeight@protect@chars
270       \expandafter\xdef\csname Odd:\Granpa\endcsname{\FOmasterreference}
271     \endgroup
272   }
273 {}
```

The content of <fo:repeatable-page-master-alternatives> is a sequence of conditional page master references. The recommendations specify how to chose them, but we use another algorithm.

```
274 \XMLElement{fo:repeatable-page-master-alternatives}
275   {} {} {}
```

The <fo:conditional-page-master-reference> may define one of \First:twoside1, etc., to the value of the master-reference-trait trait. This is the name of a page-master, for instance ‘left1’. The conditions are defined by the following traits: page-position which can be ‘first’, ‘last’<sup>5</sup>, ‘rest’, or ‘any’ (here ‘rest’ means any page that is neither the first nor the last in a sequence); blank-or-not-blank can be ‘blank’, ‘not-blank’, or ‘any’ (a blank page is a forced page that contains no text); odd-or-even can be ‘odd’, ‘even’ or ‘any’. The parity of the page number is considered (if there are two consecutive pages numbered one, they are both odd; thus, this is not the same as left-or-right). What we do here is to define one and only one command. For instance, we could define \Even:twoside1 to be ‘right1’.

```
276 \XMLElement{fo:conditional-page-master-reference}
277   {}
278   {
279     \begingroup
280       \utfeight@protect@chars
281       \ifx\FOoddoreven\att@even
282         \expandafter\xdef\csname Even:\Granpa\endcsname{\FOmasterreference}
283       \else\ifx\FOoddoreven\att@odd
284         \expandafter\xdef\csname Odd:\Granpa\endcsname{\FOmasterreference}

289       \else
290         \expandafter\xdef\csname Odd:\Granpa\endcsname{\FOmasterreference}
291       \fi\fi\fi\fi
292     \endgroup
293   {}
294 }
```

---

<sup>5</sup>Is it possible to know, in TeX, if a given page is the last in a sequence? Maybe, we could modify the \output routine, so that the \clearpage on line 372 will output some pages, the last one being special. The situation is complicated by the fact that lines 377 and 380 may output empty pages in the sequence. The \clearpage on line 389, together with the \BlankPage on lines 393 and 396 are also candidates for producing the last page in the sequence.

Declarations of attributes used here.

```

301 \XMLNSAX{fo}{page-position}{\FOpageposition}{any}
302 \XMLNSAX{fo}{odd-or-even}{\FOoddoreven}{any}

304 \XMLstringX\att@even><even/>
305 \XMLstringX\att@odd><odd/>
306 \newcount\SimplePMRefs

```

A `<fo:page-sequence>` is linked via its `master-reference` trait to a page master or a page sequence master. Its children are some `<fo:static-content>` elements (they define the content of the regions defined by the page master, except for the region-body) and a `<fo:flow>` that defines the content of the pages. Some important attributes are: `initial-page-number` that indicates the number of the first page (it can be ‘auto-even’ or ‘auto-odd’, this means that the first page number should be even or odd; it may imply the use of a blank page). The value of `force-page-count` can be ‘end-on-odd’ or ‘end-on-even’ (this may insert a final blank page). The `language` can be defined for a page sequence, a block or a character. The action is to evaluate the language trait via `\FOSetHyphenation` and to put the others in variables. Some traits are unused: `country`, `letter-value`, `grouping-separator`, `grouping-size`, `format`<sup>6</sup>. In the case of the Raweb, the attributes of the main page sequence are `format = ‘1’`, `text-align = ‘justify’`, `hyphenate = ‘true’`, `language = ‘en’`, `initial-page-number = ‘1’`, `master-name = ‘twoside1’`.

```

307 \XMLelement{fo:page-sequence}
308   {}
309   {\let\CurrentPageMaster\FOmasterreference

314     \LoadLanguage{\FOlanguage}
315   }
316 {}
```

Attributes.

```

317 \XMLNSAX{fo}{initial-page-number}{\FOinitialpagenumber}{auto}
318 \XMLNSAX{fo}{force-page-count}{\FOforcepagecount}{auto}
319 \XMLstringX\att@autoodd><auto-odd/>
320 \XMLstringX\att@autoeven><auto-even/>
321 \XMLstringX\att@endonodd><end-on-odd/>
322 \XMLstringX\att@endoneven><end-on-even/>
```

You can say `<fo:static-content>`, with an attribute `flow-name` whose value is something like `xsl-region-before-right`. This is the `region-name` of some page master (used by the current page sequence). Logically, given the name, it should define the header of odd pages. The content is a sequence of blocks, that will be typeset later (on one or more pages). The action is to call a command defined below. A priori, the result should be used only by the flow that is a sibling of this element, but this is hard to do in TeX.

```

323 \XMLelement{fo:static-content}
324   {}
325   {\xmlgrab
326     {\protectCS\FOflowname
327       \FOSetStatic{\#1}{\FOflowname}}
```

---

<sup>6</sup>This last one explains how page numbers are typeset; see later.

We show here a function `\FOSetStatic` that takes two arguments, the body of the static content, and its flow-name attribute. This code is wrong. Instead of `\noexpand#1`, there should be something that inserts the first argument, without expansion (this could be achieved by putting the argument in a token list, and using `\the`). The actual code uses `\gdef` instead of `\xdef` and `\expandafter` for each token that must be expanded.

```
\def\FOSetStatic#1#2{%
  \expandafter\xdef\csname Static:\FOflowname\endcsname
  {{{
    \def\noexpand\XML@parent{}
    \global\noexpand\FOinOutputtrue
      \def\noexpand\FOwhitespacecollapse{true}%
      \def\noexpand\FOwrapoption{wrap}%
      \def\noexpand\FOtextalign{start}%
      \def\noexpand\FOfontfamily{\FOfontfamily}%

      \def\noexpand\FOfontstretch{\FOfontstretch}%
      \def\noexpand\FOfontvariant{\FOfontvariant}%
      \def\noexpand\FOfontweight{\FOfontweight}%
      \%ignore{\FOtextindent}
      \def\noexpand\FOfontstyle{\FOfontstyle}
      \noexpand#
    \global\noexpand\FOinOutputfalse
  }}}%
  \jg@hack@foot}
```

The action associated to `<fo:static-content>` is to grab some parameters. We have a sequence of commands, each of them reads and expands a quantity, and passes it to the next one. Assume that `\foo` expands to `bar`. Then `bar\`` is added to the input stream. This is re-read, and converted to `{bar}`. This could be done directly, and left in stream until used by the final function. Said otherwise, the line shown here has the same effect and is more efficient.

```
\def\@SetStatic{\expandafter\@SetStatic\expandafter{\FOfontweight}}
```

That's the real code.

```
328 \def\FOSetStatic{\expandafter\@SetStatic\FOtextindent\\}
329 \def\@SetStatic#1\\{\expandafter\@SetStatic\FOfontsize\\{#1}}
330 \def\@SetStatic#1\\#2{\expandafter\@SetStatic\FOfontweight\\{#1}{#2}}
331 \def\@SetStatic#1\\#2#3{\expandafter
  \@SetStatic\FOfontvariant\\{#1}{#2}{#3}}
332 \def\@SetStatic#1\\#2#3#4{\expandafter
  \@SetStatic\FOfontstyle\\{#1}{#2}{#3}{#4}}
333 \def\@SetStatic#1\\#2#3#4#5{\expandafter
  \@SetStatic\FOfontstretch\\{#1}{#2}{#3}{#4}{#5}}
334 \def\@SetStatic#1\\#2#3#4#5#6{\expandafter
  \@SetStatic\FOfontfamily\\{#1}{#2}{#3}{#4}{#5}{#6}}
```

This code globally defines `\Static:xsl-region-before-right` (or a command like this) whose effect is to execute the content of the `<fo:static-content>` in a TeX group, where some parameters are defined. These parameters are: font family, font stretch, font style, font variant, font weight, font size, textindent (unused, but explicitly set to zero in the main block of the static content), (arguments #1 to #7). Argument #8 is the content, argument #9 is the name. The switch `\ifFOinOutput` is set to true while evaluating the content. The `\XML@parent` command is locally set to empty. See explanations later.

```

339 \def\@#####SetStatic#1\\#2#3#4#5#6#7#8#9{%
340   \expandafter\gdef\csname Static:#9\endcsname{%
341     {%
342       {\def\xml@parent{} \global\f0inOutputtrue
343         \def\f0whitespacecollapse{true}%
344         \def\f0wrapoption{wrap}%
345         \def\f0textalign{start}%
346         \def\f0fontfamily{\#1}%

349         \def\f0fontvariant{\#4}%
350         \def\f0fontweight{\#5}%
351         \def\f0fontstyle{\#3}\#8\global\f0inOutputfalse}}}}%
352   \jg@hack@foot{\#9}
353 }

```

Assume that `\Static:xsl-footnote-separator` was just defined. Said otherwise, we have defined a static region for the footnote separator. We store in `\footnoterulepre` the name of this command, and execute it. This should produce the footnote rule. The dimension of the resulting box is remembered in `\skip\footins`, a quantity that defaults to `\bigskipamount`. We set `\footnotesep` to zero. This quantity is defined by the class file (to 6.6pt for a ten point article). Finally, we define `\footnoterule` to use this funny command in a vbox of height zero. The `\vfill` is strange.

```

354 \def\jg@hack@foot#1{
355   \ifx\f0flowname\att@xsl@footnote@separator\relax
356     \xdef\footnoterulepre{\Static:\#1}%
357     \global\footnotesep\z@
358     \setbox\@tempboxa\vbox{\csname\footnoterulepre\endcsname}%
359     \tempdima=\z@
360     \advance\tempdima\ht\@tempboxa
361     \advance\tempdima\dp\@tempboxa
362     \global\skip\footins\tempdima\relax
363     \gdef\footnoterule{\vfill\vbox to\z@{%
364       \vss\csname\footnoterulepre\endcsname}}%
365   \fi
366 }

```

We define here the action associated to `DummyRegion`, it is empty.

```

367 \expandafter\def\csname Static:DummyRegion\endcsname{}%
368 \XMLNSAX{fo}{flow-name}{\f0flowname}{}

```

## 4.7 Flows

Changes in V2: the command `\setaccordingtomaster` was added; it contains a very long (one hundred lines) and complicated piece of code, moved from `fotex.xmt` to `fotex.sty`. We have split this code into smaller pieces, this is the only way to understand what happens. Another change: a great number of assignments are made global, replacing `\def` by `\gdef`, `\edef` by `\xdef`, or adding a `\global` prefix. The command `\BlankPage` not only creates a blank page, but also ships it out. Finally, handling of multiple columns per page has changed.

The content of the `<fo:flow>` formatting object is a sequence of blocks that defines a sequence of pages. The action associated is a bit complicated; for this reason, we shall define some pseudo functions instead of the original big code. Let's recall that the `<fo:page-sequence>` element

remembers in `\pendingID` the current id and in `\PageNumber` the value of the initial page number. What we do here is to evaluate these instructions. We start with `\clearpage`, this makes sure that all pages are shipped out; this is not needed in the case where there are more than one column per page, see below. In the case where the desired page number is ‘auto’ we are done; if it is ‘auto-odd’ or ‘auto-even’, we emit an empty page, if needed, so as to make sure that the page number has the given parity. Finally, the page number can be an integer, in this case, we set the page counter. From now one, the page number is correct, so that we can insert the label of the parent. It is however too early to typeset something, for instance, `\textwidth` is still random. Changes in V2: `\BlankPage` used instead of `\hbox{} \newpage`.

```

369 \def\jg@flowI{%
370   \ifnum\PrevNColumns>1\relax
371   \else
372     \clearpage
373   \fi
374   \ifx\PageNumber\att@auto
375   \else
376     \ifx\PageNumber\att@autoeven
377       \ifodd\c@page\BlankPage\fi
378     \else
379       \ifx\PageNumber\att@autoodd
380         \ifodd\c@page\else\BlankPage\fi
381       \else
382         \setcounter{page}{\PageNumber}%
383       \fi
384     \fi
385   \fi
386   \let\F0id\pendingID \F0label\global\let\pendingID\empty % hacked jg
387 }

```

After evaluation of the children of the flow, we terminate with a `\clearpage`. We look at the `force-page-count` trait. If this imposes that the last page be even or odd, we may emit a blank page (note that the page counter holds one more than the last page number).

```

388 \def\jg@flowV{%
389   \clearpage
390   \ifx\ForcePage\att@auto
391   \else
392     \ifx\ForcePage\att@endoneven
393       \ifodd\c@page\else\BlankPage\fi
394     \else
395       \ifx\ForcePage\att@endonodd
396         \ifodd\c@page\BlankPage\fi
397       \fi
398     \fi
399   \fi
400 }

```

We define now four quantities `\PEven`, `\POdd`, `\PBlank` and `\PFirst` according to the `master-reference`; this can be the name of a page-sequence-master or a page-master. In the second case, we put this name into all four commands<sup>7</sup>. Otherwise, the reference is something like ‘twoside1’ and the command `\Odd:twoside1` is a pagemaster. We put this value in `\POdd`. We do the same for the other commands. However, if `\PEven` is undefined, we use the value of `\POdd` instead.

---

<sup>7</sup>code shown here as ‘...’, it is a bit more complicated in V2

The case of `\PFirst` is a bit more complicated: in fact, if it is undefined, we look at the parity of the current page number. The code shown here is much simpler than the initial one, but has the same effects. Note: the code shown in the first version of the document was wrong; we have replaced it by a call to `\ifnotdefined`, that is a conditional macro that should evaluate to true if the argument comes from an undefined `\csname`. We shall give the real code below.

```
\@ifundefined{Atomic:\CurrentPageMaster}
{
  \edef\PFirst{\csname First:\CurrentPageMaster\endcsname}
  \edef\PBlank{\csname Blank:\CurrentPageMaster\endcsname}
  \edef\PEven{\csname Even:\CurrentPageMaster\endcsname}
  \edef\POdd{\csname Odd:\CurrentPageMaster\endcsname}
  \ifnotdefined\PBlank\let\PBlank\POdd\fi
  \ifnotdefined\PEven\let\PEven\POdd\fi
  \ifnotdefined\PFirst
    \ifodd\c@page\let\PFirst\POdd \else\let\PFirst\PEven\fi\fi
}
{...}
```

In order to make the code easy to understand, we introduce the command `\Fdef`, and we can say `\Fdef{\POdd}{Odd}`. This defines `\POdd` as above. The next function computes `\PFirst`; we cannot say: if the page master does not define `First`, than use `\POdd` or `\PEven` because these commands are not yet defined. If the first page is even, the value of `\PFirst` depends on whether the page master defines `Even`; if undefined, we use the value for odd pages. We use `\Cdef` for such a conditional definition. There is a further complication. The value of the first page is defined by `\FOinitialpagenumber`. In the code shown above, we assumed that the page counter has already been set according to this value. In the code below, this is not necessarily true. Thus, we introduce `\Pdef` that sets its first argument depending on the parity of the second.

```
401 \def\Fdef#1#2{\xdef#1{\csname #2:\CurrentPageMaster\endcsname}}
402 \def\Cdef#1#2#3{%
403   \@ifundefined{#2:\CurrentPageMaster}
404     {\Fdef{#1}{#3}}{\Fdef{#1}{#2}}%
405 }
406 \def\Pdef#1#2{%
407   \ifodd#2 \Fdef{#1}{Odd}
408   \else \Cdef{#1}{Even}{Odd}\fi
409 }
410
411 \def\jg@compute@Pfirst{%
412   \@ifundefined{First:\CurrentPageMaster}
413   {
414     \ifx\FOinitialpagenumber\att@auto
415       \Pdef\PFirst\c@page
416     \else \ifx\FOinitialpagenumber\att@autoeven
417       \Cdef{\PFirst}{Even}{Odd}
418     \else \ifx\FOinitialpagenumber\att@autoodd
419       \Fdef{\Pfirst}{Odd}
420     \else
421       \Pdef\Pfirst\FOinitialpagenumber
422     \fi\fi\fi\fi
423   }
424   {\Fdef{\Pfirst}{First} }
425 }
```

This is the complete code, in the case of a page sequence master like ‘twoside1’. A non trivial question is when to use `\PFirst`. The answer is when the boolean `@specialpage` is true. This is initially set to true, then to false after first use. A special case is when `\Lead:17:twoside1` is not defined, but could be used. In this case, the page is special if the number is one, non-special otherwise.

```
426 \def\jg@flowII@conditional{
427   \ifnum\SimplePMRefs>1\relax\global\@specialpagefalse\fi
428   \jg@compute@Pfirst
429   \Cdef{\PBlank}{Blank}{Odd}
430   \Cdef{\PEven}{Even}{Odd}
431   \Fdef{\POdd}{Odd}
432 }
```

This is the code in case the reference is a page-master sequence. In the case `\Lead:17:twoside1` is defined, this is the name of the page to be used, whatever the value of the page number.

```
433 \def\jg@flowII{
434   \@ifundefined{Lead:\the\SimplePMRefs:\CurrentPageMaster}
435   { \jg@flowII@conditional }
436   {
437     \xdef\PFirst{\csname Lead:\the\SimplePMRefs:\CurrentPageMaster\endcsname}
438     \global\let\POdd\PFirst
439     \global\let\PEven\PFirst
440     \global\let\PBlank\PFirst
441   }
442 }
```

This is now the whole function. There are two cases to consider. The `master-reference` can be the name a page-master, for instance ‘left1’, case where `\Atomic:left1` is defined and we set `\First`, as well as all other quantities to ‘left1’. It can be a page-sequence-master, case handled above. Action associated to `\jg@flowIII` is described later.

```
443 \def\setaccordingtomaster{%
444   \global\@specialpagetrue
445   \@ifundefined{Atomic:\CurrentPageMaster}
446   { \jg@flowII }
447   {
448     \global\let\PFirst\CurrentPageMaster
449     \global\let\PBlank\CurrentPageMaster
450     \global\let\POdd\CurrentPageMaster
451     \global\let\PEven\CurrentPageMaster
452   }
453   \jg@flowIII
454 }
```

We use the `\PEven` command to define four commands, that contain the name of the header, footer, and their extent. The same is done for the other type of pages.

```
455 \def\jg@set@headings{
456   \xdef\EvenHeadExtent{\csname\PEven:before-extent\endcsname}
457   \xdef\EvenHead{Static:\csname\PEven:before\endcsname}
458   \xdef\EvenTailExtent{\csname\PEven:after-extent\endcsname}
459   \xdef\EvenTail{Static:\csname\PEven:after\endcsname}
460   \xdef\FirstHeadExtent{\csname\PFirst:before-extent\endcsname}
461   \xdef\FirstHead{Static:\csname\PFirst:before\endcsname}
462   \xdef\FirstTailExtent{\csname\PFirst:after-extent\endcsname}
```

```

463   \xdef\FirstTail{Static:\csname\PFfirst:after\endcsname}
464   \xdef\OddHeadExtent{\csname\POdd:before-extent\endcsname}
465   \xdef\OddHead{Static:\csname\POdd:before\endcsname}
466   \xdef\OddTailExtent{\csname\POdd:after-extent\endcsname}
467   \xdef\OddTail{Static:\csname\POdd:after\endcsname}
468   \xdef\BlankHeadExtent{\csname\PBlank:before-extent\endcsname}
469   \xdef\BlankHead{Static:\csname\PBlank:before\endcsname}
470   \xdef\BlankTailExtent{\csname\PBlank:after-extent\endcsname}
471   \xdef\BlankTail{Static:\csname\PBlank:after\endcsname}
472 }

```

We define here a function that fetches some of these parameters. The value stored in `\themargin` will be defined later. It depends on the parity of the page number. This was not in the original `fotex.sty`.

```

473 \def\jg@use@blankpage{%
474   \def\@thehead{\csname\BlankHead\endcsname}%
475   \def\@thefoot{\csname\BlankTail\endcsname}%

496   \def\headheight{\OddHeadExtent}%
497   \def\tailheight{\OddTailExtent}}%

```

This is how we select one of these four commands.

```

498 \newif\ifBlankPage
499 \def\jg@usepagestyle{%
500   \ifBlankPage
501     \jg@use@blankpage
502   \else \if@specialpage
503     \jg@use@specialpage

```

```

504 \else \ifodd\count\z@          % if odd page
505   \jg@use@oddpage\else \jg@use@evenpage
506 \fi\fi\fi
507 \global\@specialpagefalse
508 \global\BlankPagefalse
509 }

```

This defines a blank page. The original code was wrong. This was corrected in V2. Originally there was a `\mark{}`, it has disappeared. Is this OK?

```

510 \def\nocontentbox{\vbox to \z@{}}
511 \def\BlankPage{%
512   \global\BlankPagetrue
513   \nocontentbox
514   \newpage
515 }

```

The original output routine contained: `\hb@xt@ \textwidth {\@thehead}`. In the code that follows, we removed the line that decreases the text width by `\F0headindent`, because this value is always zero. We also replace `\vfil` by `\vss`, in the case of a border.

```

516 \def\jg@headings#1#2{%
517   \tempdima\textwidth
518   \%advance\tempdima by -\F0headindent
519   \setbox\tempboxa\vbox to #1{%
520     \color@hbox
521     \normalcolor
522     \hb@xt@\textwidth{\hfill\llap{\hb@xt@\tempdima{#2}}}\%
523     \color@endbox
524     \vss% \vfil
525   }%
526   \dp\tempboxa \z@
527   \box\tempboxa}%

```

The boolean quantity `\ifForcePageSetup` is sometimes true. We shall see later that it is true inside a flow, said otherwise, almost always. The command is called at the end of the output routine; we increment the `\SimplePMRefs` counter, and recompute the new page master. This is done for every page; in V1, it was done once per `<fo:flow>`; this make the code a little bit slower.

```

528 \def\jg@check@setup{%
529   \ifForcePageSetup
530     \global\advance\SimplePMRefs1\relax
531     \setaccordingtomaster
532     \ifnum\NColumns>1\relax
533       \refreshmulticols
534     \fi\fi
535 }

```

This is the modified output routine. Changes in V2 use `\offinterlineskip` instead of the code commented out below. The result is not exactly the same. Added lines marked V2.

```

536 \def\@outputpage{%
537   \begingroup % the \endgroup is put in by \aftergroup
538   \let \protect \noexpand

582 \gdef\EvenHeadExtent{\z@}
583 \gdef\FirstTailExtent{\z@}
584 \gdef\FirstHeadExtent{\z@}

```

We simplified the code by removing all references to a quantity `SpecialOffset` that was always zero. We have already explained what the `\Pass` command does: it fetches some parameters from the region-body (note the fixed name here); they are `\columnsep`, `\NColumns`, `\Marginbottom` and `\Margintop`. We also evaluate `\Atomic:XXX`. The result is to define `\MasterXXXMargins`, as well as `\paperwidth` and `\paperheight`. We hope that both evaluations yield the same result. The only difference between them is that the left margin can change (we hope that the sum of the left

and right margins are the same). All these variables will be used by \FOSetPage, and forgotten after that.

```

585 \def\jg@flowIII{%
586   \expandafter\Pass\csname P0dd:xsl-region-body\endcsname\%
587   \csname Atomic:\P0dd\endcsname
588   \global\oddsidemargin\MasterLeftMargin
589   \csname Atomic:\PEven\endcsname
590   \global\evensidemargin\MasterLeftMargin
591   \jg@set@headings
592   \FOSetPage}

```

The purpose of this command is to compute the text height and text width, and to store it wherever needed (\hsize, \vsize, \@colht, etc). We also remember three quantities: \bottommargin, \headsep and \topmargin. There are two kinds of changes in V2. Some lines are commented out because some quantities are now computed differently. On the other hand, this command is called from \jg@flowIII, hence from \outputpage, hence inside the \output command; this explains while assignments must be global. Moreover, since this is called for every page, the current page is no more special, and the assignment to \if@specialpage has to be moved elsewhere.

```

593 \def\FOSetPage{%
594   \global\bottommargin\Marginbottom
595   % \global\headsep\Margintop

650   \jg@flowV
651 }
```

## 4.8 Borders

A border has three properties: a color, a style and a width. There are four borders. They are called ‘before’, ‘after’, ‘start’ and ‘end’. These quantities are called relative, because they depend on the `writing-mode` trait. We assume that this is ‘lr-td’ (Inline components and text within a line are written left-to-right. Lines and blocks are placed top-to-bottom). In such a case, ‘before’ is ‘top’, ‘after’ is ‘bottom’, ‘start’ is ‘left’ and ‘end’ is ‘right’, see schema section 4.5. Quantities like ‘top’ and ‘bottom’ are called absolute. We shall use absolute quantities only to set relative quantities.

Here we declare the relative attributes.

```

652 \XMLNSA{fo}{border-before-color}{\FOborderbeforecolor}{\FOcolor}
653 \XMLNSA{fo}{border-after-color}{\FOborderaftercolor}{\FOcolor}
654 \XMLNSA{fo}{border-start-color}{\FOborderstartcolor}{\FOcolor}
655 \XMLNSA{fo}{border-end-color}{\FOborderendcolor}{\FOcolor}
656
657 \XMLNSAX{fo}{border-before-style}{\FOborderbeforestyle}{none}
```

```

658 \XMLNSAX{fo}{border-after-style}{\FOborderafterstyle}{none}

731 \XMLNSAX{fo}{padding-end}{\f0paddingend}{\z@}

```

Here we declare the attributes for the margins, and we define default values. These values are absolute. The corresponding relative properties are `space-before`, `space-after`, `space-start`, and `space-end`. The quantities `space-before` and `space-after` are defined for block level formatting objects (in `\SpaceAttributes`), while `space-start`, and `space-end` are for inline objects<sup>9</sup>. There are also two quantities `start-indent`, `end-indent` which are related to margins, but are a bit complicated. They are defined later.

```

732 \XMLNSAX{fo}{margin}{\f0margin}={}
733 \XMLNSAX{fo}{margin-left} {\f0marginleft} {0pt}
734 \XMLNSAX{fo}{margin-right} {\f0marginright} {0pt}
735 \XMLNSAX{fo}{margin-top} {\f0margintop} {0pt}
736 \XMLNSAX{fo}{margin-bottom} {\f0marginbottom} {0pt}
737
738 \gdef\f0marginbottom{\z@}
739 \gdef\f0marginleft{\z@}

```

---

<sup>8</sup>It seems that fotex does not use absolute values.

<sup>9</sup>They are unused by fotex.

```
740 \gdef\FOmarginright{\z@}
741 \gdef\FOmargintop{}
```

Absolute values have precedence over relative values, for the style, width and color of a border, hence the 12 first lines of the code. The case of the border is a bit special, and explained above. In the case of style, width, color, and margin, you can either set a single value, or four values. This code copies the single value in the four slots whenever adequate. In the case of color, there is a little problem: the code here makes no difference between black and no value. Finally, we hack the border style. The value can be one of ‘none’, ‘hidden’, ‘dotted’, ‘dashed’, ‘solid’, ‘double’, ‘groove’, ‘ridge’, ‘inset’, or ‘outset’. Currently, only ‘solid’ is implemented. In all other cases, we set the width to zero and ignore it. In the case where one of the four borders is solid, we set a boolean value to true. The line marked ‘JG’ was not in the original...

## 4.9 Spacing for blocks

In XSL/Format a block is the equivalent of a TeX box. It can define some space before it, and after it. If we have two blocks, one with some space  $x$  after it and another one, with some space  $y$  before it, there are some precedence rules that explain what to do. These are not implemented in fotex. However assume that we have a sequence of spaces; each such sequence is defined by a triple  $(x_1, x_2, x_3)$ , optimum, maximum, and minimum value. If I understand correctly, the following happens. First, the largest sequence of spaces is considered. Then, conditionality is considered; this is used at the start or end of a page, at the start or end of a line (in L<sup>A</sup>T<sub>E</sub>X, it is the difference between `\hspace` and `\hspace*`); in such a case, all initial conditional spaces are removed. If any of these spaces is forcing, the result is the sum of the forcing spaces, otherwise, the merge of them. When merging spaces, only those of highest priority are used. Consider two of them  $(x_1, x_2, x_3)$ , and  $(y_1, y_2, y_3)$ . If  $x_1 \neq y_1$  (different optimum values), then the one with lowest optimum value is discarded. Otherwise, the result is  $(x_1 = y_1, \min(x_2, y_2), \max(x_3, y_3))$ .

These spaces are local to a block, hence are not globally defined.

```

816 \def\SpaceAttributes{
817   \XMLattributeX{space-after.optimum}{\F0spaceafteroptimum}{\z@}
818   \XMLattributeX{space-after.maximum}{\F0spaceaftermaximum}{\z@}
819   \XMLattributeX{space-after.minimum}{\F0spaceafterminimum}{\z@}
820   \XMLattributeX{space-before.optimum}{\F0spacebeforeoptimum}{\z@}
821   \XMLattributeX{space-before.maximum}{\F0spacebeforemaximum}{\z@}
822   \XMLattributeX{space-before.minimum}{\F0spacebeforeminimum}{\z@}
823   \XMLattributeX{space-after}{\F0spaceafter}{}
824   \XMLattributeX{space-before}{\F0spacebefore}{}

```

This is how we use these `space-after.xxx` attributes. Original code was inlined. Let A, B, and C be the optimum, minimum and maximum values. The specifications say that, if `\F0spaceafter` is given, this should be the value of non-provided A, B and C. It also states that, if `margin-top` is defined, then setting `space-before.minimum` will have no effect. The code that follows does not implement these subtleties. Assume that the values are 2, 3 and 4pt. Then we could use some glue of value `3pt plus 1pt minus 1pt`. The shrink part is  $A - B$ , the stretch part is  $C - A$ . This code uses  $A + C$  instead (strange). In fact, the stretch value can grow arbitrarily in T<sub>E</sub>X; said otherwise, we cannot implement exactly the XSL/Format mechanism. The argument of this command is a skip register, that contains the desired glue, or a T<sub>E</sub>X command that uses the glue.

```

825 \def\jg@usespaceafter#1{
826   \ifx\@empty\F0spaceafter
827     \tempdima\F0spaceafteroptimum
828     \advance\tempdima by -\F0spaceafterminimum
829     \tempdimb\F0spaceafteroptimum
830     \advance\tempdimb by \F0spaceaftermaximum
831     #1\F0spaceafteroptimum plus \tempdimb minus \tempdima
832   \else
833     #1\F0spaceafter
834   \fi}

```

This is how we use these `space-before.xxx` attributes. Original code was inlined. The code is as above.

```

835 \def\jg@usespacebefore#1{
836   \ifx\@empty\F0spacebefore
837     \tempdima\F0spacebeforeoptimum
838     \advance\tempdima by -\F0spacebeforeminimum
839     \tempdimb\F0spacebeforeoptimum
840     \advance\tempdimb by \F0spacebeforemaximum
841     #1\F0spacebeforeoptimum plus \tempdimb minus \tempdima
842   \else
843     #1\F0spacebefore
844   \fi}

```

Attributes for `keep-together`. There are three sub-cases: within line, page, column. The value can be ‘always’, ‘auto’, or a number. It corresponds in T<sub>E</sub>X to some penalty: 0 for ‘auto’, 10000 for ‘always’. Otherwise, the number should produce something between these two values (currently ignored). Keep-within-line means a penalty in horizontal mode, otherwise in vertical mode. Note that it is not possible to associate a penalty to a column-break (in T<sub>E</sub>X switching from one column to the other is the same as switching from one page to the other; the difference is how `\output` handles these cases). The within-line case is not implemented.

```

845 \XMLNSAX{fo}{keep-together}{\F0keeptogether}{\inherit}
846 \XMLNSAX{fo}{keep-together.within-column} {\F0keeptogetherColumn}{\inherit}

```

```
847 \XMLNSAX{fo}{keep-together.within-page} {\FOkeepTogetherPage}{\inherit}
848 \XMLstringX{att@always}<>always</>
```

Attributes for keep-with-next. As above. There is also a keep-with-previous, but this is not implemented. Too bad.

```
849 \XMLNSAX{fo}{keep-with-next}{\FOkeepWithNext}{auto}
850 \XMLNSAX{fo}{keep-with-next.within-column}{\FOkeepWithNextColumn}{auto}
851 \XMLNSAX{fo}{keep-with-next.within-page} {\FOkeepWithNextPage}{auto}
```

This was inlined. We call `\samepage` if no page break should occur.

```
852 \def\jg@keep@together{%
853   \ifx\FOkeepTogether\att@always\samepage\fi
854   \ifx\FOkeepTogetherColumn\att@always\samepage\fi
855   \ifx\FOkeepTogetherPage\att@always\samepage\fi}
```

This is a bit more complicated: we set a switch that says that we have to keep this item with the next one.

```
856 \def\jg@keepnext{%
857   \tempswafalse
858   \ifx\FOkeepWithNext\att@always\tempswatrue\fi
859   \ifx\FOkeepWithNextColumn\att@always\tempswatrue\fi
860   \ifx\FOkeepWithNextPage\att@always\tempswatrue\fi}
```

In order to understand the following code, you must know that there are four kinds of blocks. If `\ifFOinOutput` is true, we are typesetting a static area (page headers and footers). If `\FOinTable` is positive, we are in a table, and a special case is when we typeset the label of an item in a list. Originally, the code did some action if `\FOTableNesting` was positive; however, it is currently impossible to nest tables, and the counter is never modified.

This inserts some vertical space. We compute in `\@tempskipa` the quantity to add and in `\@tempswa` a boolean value that says whether or not a penalty should be inserted. We insert the penalty and the skip. This resets to zero the value of `\FOspacebefore`. Moreover another quantity is computed but not used, it is not indicated here.

```
861 \def\FOvspacebefore{%
862   \ifFOinOutput
863   \else
864     \jg@usespacebefore{\@tempskipa}
865     \jg@keepnext
866     \if@tempswa\addpenalty\secpenalty\fi
867     \addvspace{\@tempskipa}
868   \fi
869   \def\FOspacebefore{\z@}}
```

This adds some vertical space after a block. Nothing is done in table headings. Changes in V2: infinite penalty `\@M` before `\vspace` was replaced by a finite one, namely 9996, after `\vspace`.

```
870 \newskip\FOafterskip
871 \def\FOvspaceafter{%
872   \ifFOinOutput
873   \else
874     \jg@usespaceafter{\FOafterskip}
875     \jg@keepnext
876     \addvspace{\FOafterskip}
877     \if@tempswa\addpenalty{9996}\fi
878   \fi}
```

Note : the package redefines `\addpenalty`, but the old code is the same as the new one, not shown here.

The code above was modified in the following way. Consider the case of a section title, A, followed by a subsection title B, followed by some text C. Both titles forbid a page break, hence `\if@tempswa` is true in both commands above, this means that we add twice a very high penalty (was infinite in V1). However, when we add a space at the start of B and C, this inserts some penalty (found in `\@secpenalty`). This is a negative one, hence encourages a page break before B and C, said otherwise, after A and B. The modification consists in remembering in a global variable the value of the second `@tempswa` (true if `keep-with-next.within-page` is ‘always’ for a given block), and to modify the action at the start of a block: we discard the value of `@tempswa` (that depends on `keep-with-next`), and instead, if the global variable is true insert a high positive penalty, and otherwise, a negative one. This gives much better page breaks; however, there is little stretchability between blocks, so that the height of the pages varies considerably.

## 4.10 Quadding

The value of the `text-align` can be one of the following: ‘start’, ‘end’, ‘center’, ‘justify’, ‘insid’e, ‘outside’, ‘left’, ‘right’, or a string. The value of `text-align-last` can be any of these, plus ‘relative’. The value ‘relative’ means that forced lines behave like other ones, except if the text is justified, case where forced lines are left aligned (in T<sub>E</sub>X, this corresponds to a default `\parfillskip`). By forced line, we mean either the last in a paragraph, or one induced by evaluation of the character U+000A (this is not implemented in fotex; note however that U+2028 calls `\newline`). This is a CSS property, adapted to XSL/Format; for this reason ‘left’ is the same as ‘start’ and ‘right’ as ‘end’. If alignment is ‘start’, it means that there is no space between the first character and the margin, if it is ‘end’, then there is no space between the last character and the margin.

We declare the attributes.

```
879 \XMLNSAX{fo}{text-align}{\FOtextalign}{\inherit}
880 \XMLNSAX{fo}{text-align-last}{\FOtextalignlast}{\inherit}
881 \XMLstringX\att@relative<>relative</>
882 \gdef\FOtextalign{start}
883 \gdef\FOtextalignlast{relative}
```

The indentation (left and right) is given by two quantities, stored in `\FOstartindent` and `\FOendindent`. In the case where we have a list and an item in a list, the start of the body is defined by `body-start()` and the end of the label by `label-end()`. In fact, there are two traits, one that indicates the distance between the starts of the label and the body, and one that indicates the distance between the end of the label and the start of the body.

```
884 \XMLNSA{fo}{start-indent}{\FOstartindent}{\inherit}
885 \XMLNSA{fo}{end-indent}{\FOendindent}{\inherit}
886 \XMLstring\att@labelend<>label-end()</>
887 \XMLstring\att@bodystart<>body-start()</>
```

We use here two commands that return zero in the case where the attribute value is one of the functions mentioned above, and a third one that set these quantities to zero.

```
888 \gdef\EndIndent{\ifx\FOendindent\att@labelend\z@\else\FOendindent\fi}
889 \gdef\StartIndent{\ifx\FOstartindent\att@bodystart\z@\else\FOstartindent\fi}
890 \def\jg@hackindent{
  \ifx\FOstartindent\att@bodystart \let\FOstartindent\z@ \fi
  \ifx\FOendindent\att@labelend \let\FOendindent\z@ \fi}
```

We use three commands `\QuaddingStart`, `\Quadding` and `\QuaddingEnd`. The first function is defined as follows. This does not seem to correspond to the explanations given above.

```

893 \def\QuaddingStart{%
894   \ifx\F0textalignlast\att@relative
895     \csname startQ@\F0textalign\endcsname
896   \else
897     \csname startQ@\F0textalignlast\endcsname
898   \fi}
899   Function two for quadding.
900 \def\QuaddingEnd{%
901   \ifx\F0textalignlast\att@relative
902     \csname endQ@\F0textalign\endcsname
903   \else
904     \csname endQ@\F0textalignlast\endcsname
905   \fi}
906   Function three for quadding.
907 \def\Quadding{%
908   \ifx\F0textalignlast\att@relative
909     \csname Q@\F0textalign\endcsname
910   \else
911     \csname Q@\F0textalignlast\endcsname
912   \fi}

```

Remaining code in this paragraph comes from the file `mnames.sty`. These commands describe the action in the case where the text should be centered. Note that line separator character U+2028 is bound to `\newline`, and needs to be redefined. Why is `\Q@centered` defined? The code of `\Q@center` is interesting. Assume that start- and end-indent are  $a$  and  $b$  respectively. In order to center the text in a region where  $a$  has been removed on the left and  $b$  on the right, we can put  $a$  plus 1fil in `\leftskip`,  $b$  plus 1fil in `\rightskip`. In fact we subtract  $a + b$  from both these quantities (this does not change the alignment). Question: why do we change `\@rightskip`? In V2, fil was replaced by fill.

```

913 \def\startQ@center{\hskip\z@ plus 1fill}
914 \def\endQ@center{\hskip\z@ plus 1fill}
915 \def\Q@center{%
916   \let\newline@centercr
917   \rightskip-\StartIndent plus 1fill%
918   \rightskip\rightskip
919   \leftskip-\EndIndent plus 1fill%
920   \parfillskip\z@skip
921 }
922 \let\Q@centered\Q@center

```

This is in the case right-justified, case where alignment is ‘right’ or ‘end’. Changes in V2: `\rightskip` and `\@rightskip` added.

```

923 \def\Q@end{
924   \let\newline@centercr
925   \leftskip\StartIndent plus 1fill % fill
926   \rightskip\EndIndent
927   \rightskip\rightskip
928   \parfillskip\z@skip
929 }
930 \let\startQ@right\startQ@end

```

```
931 \let\endQ@right\endQ@end
932 \let\Q@right\Q@end
```

This is in the case left-justified, case where alignment is ‘start’ or ‘left’.

```
933 \def\startQ@start{}
934 \def\endQ@start{\hfill}
935 \def\Q@start{
936   \let\newline\@centercr
937   \rightskip\EndIndent plus 1fil
938   \rightskip\rightskip
939   \leftskip\StartIndent
940   \parfillskip\z@skip
941 }
942 \let\startQ@left\startQ@start
943 \let\endQ@left\endQ@start
944 \let\Q@left\Q@start
```

This is in the case left and right justified. Why do we need a definition for ‘justified’?

```
945 \def\startQ@justify{}
946 \def\endQ@justify{}

947 \def\startQ@justified{%
948   \leftskip\StartIndent
949   \rightskip\EndIndent
950   \rightskip\rightskip
951 }
952 \def\Q@justified{%
953   \parfillskip\@flushglue
954   \leftskip\StartIndent
955   \rightskip\EndIndent
956   \rightskip\rightskip
957 }
958 \def\endQ@justified{}
959 \let\Q@justify\Q@justified
```

Case empty. Strange.

```
960 \let\startQ@\startQ@justified
961 \let\endQ@\endQ@justified
962 \let\Q@\Q@justified
```

This is what the documentation says if the value of `text-align` is ‘inside’: If the page binding edge is on the start-edge, the alignment will be ‘start’. If the binding is the end-edge, the alignment will be ‘end’. If neither, use ‘start’ alignment. For ‘outside’, it is the opposite. If I understand correctly, this may depend on the parity of the page, hence cannot be implemented in T<sub>E</sub>X.

```
964 \def\startQ@pageoutside{\hfill}
965 \def\endQ@pageoutside{}

966 \def\startQ@pageinside{}
967 \def\endQ@pageinside{\hfill}
```

## 4.11 Arrays

Implementing arrays is a bit complicated. It uses a lot of variables. There were also different tentatives, so that some variables and tests have no usage anymore.

We start with a piece of code that remembers the column widths. This declares a counter.

```
969 \newcount\arraylength
```

After `\Array{foo}[bar]{gee}`, the command `\foobar` contains `gee`. This is assumed to be the width of column ‘bar’ of array ‘foo’.

```
970 \def\Array#1[#2]#3{%
```

```
971   \expandafter\xdef\csname #1#2\endcsname{#3}}
```

Initialization of the `foo` array. Column 0 of the array is set to empty. In the original code, this constructed `\foo` so that `\foo[bar]` calls `\foobar`, but the command was never used.

```
972 \def\DeclareArray#1{%
```

```
973   \Array{#1}[0]{}}
```

This finds the length of an array by considering the first `\csname` that produces `\relax` as result (i.e. first undefined slot).

```
974 \def\getArraylength#1{%
```

```
975   \arraylength0
```

```
976   \loop\expandafter\ifx\csname #1\the\arraylength\endcsname\relax%
```

```
977     \else\advance\arraylength by1\repeat%
```

We find the end of the array, then insert something there.

```
978 \def\addToArray#1#2{\getArraylength{#1}{%
```

```
979   \Array{#1}[\the\arraylength]{#2}}%
```

This removes from memory everything associated to this table. Since it is not possible to remove the command from the hash table, we set it to `\relax` (not undefined!).

```
980 \def\clearArray#1{\getArraylength{#1}{%
```

```
981   \loop\ifnum\arraylength >0%
```

```
982     \global\expandafter\let\csname #1\the\arraylength\endcsname\relax%
```

```
983     \advance\arraylength by-1\repeat}%
```

These are the variables used below.

```
984 \newcount\AbsoluteTableCount % unique Id for a table
```

```
985 \newcount\CellCount % index of a cell in a row
```

```
986 \newcount\F0inTable % >0 if in a table
```

```
987 \newcount\Ncols % non-zero if col specs given
```

```
988 \newdimen\CurrentCellWidth % width of current cell
```

```
989 \newdimen\TableWidth % width of the table
```

```
990 \newif\ifF0FirstCell % unused...
```

```
991 \def\TableHeader{} % current table header
```

```
992 \newtoks\BoxedFootnotes % this contains the notes of the table
```

```
993 \Ncols0
```

```
994 \F0inTable0
```

```
995 % \newcount\RowCount % unused
```

```
996 % \newtoks\ColSpecs % unused
```

We do not want `TEX` to insert vertical space between rows of our table. There is a command `\offinterlineskip` designed for this purpose (it is like the code shown here, with `\maxdimen` instead of  $2^{14} - 1$ ). The command saves some parameters.

```
997 \def\saveinterlineskip{%
```

```
998   \edef\savedbaselineskip{\the\baselineskip}%
```

```

999  \edef\savedlineskip{\the\lineskip}%
1000  \edef\savedlineskiplimit{\the\lineskiplimit}%
1001  \baselineskip=-1000pt\relax
1002  \lineskiplimit=16383pt\relax
1003  \lineskip=0pt
1004 }

```

This restores the settings saved by the previous command.

```

1005 \def\restoreinterlineskip{%
1006   \baselineskip\savedbaselineskip\relax
1007   \lineskip\savedlineskip\relax
1008   \lineskiplimit\savedlineskiplimit\relax
1009 }

```

In version two, some quantities are stored in global variables, associated to the array whose number is in \AC (short for \AbsoluteTableCount). This is the function that stores the parameters.

```

1010 \def\jg@save@parameters{
1011   \addToArray{fotabletextalign\the\AC:}{\F0textalign}%
1012   \addToArray{fotableborderbeforestyle\the\AC:}{\F0borderbeforestyle}%
1013   \addToArray{fotableborderafterstyle\the\AC:}{\F0borderafterstyle}%
1014   \addToArray{fotableborderstartstyle\the\AC:}{\F0borderstartstyle}%
1015   \addToArray{fotableborderendstyle\the\AC:}{\F0borderendstyle}%
1016   \addToArray{fotableborderbeforewidth\the\AC:}{\F0borderbeforewidth}%
1017   \addToArray{fotableborderafterwidth\the\AC:}{\F0borderafterwidth}%
1018   \addToArray{fotableborderstartwidth\the\AC:}{\F0borderstartwidth}%
1019   \addToArray{fotableborderendwidth\the\AC:}{\F0borderendwidth}%
1020   \addToArray{fotableborderbeforecolor\the\AC:}{\F0borderbeforecolor}%
1021   \addToArray{fotableborderaftercolor\the\AC:}{\F0borderaftercolor}%
1022   \addToArray{fotableborderstartcolor\the\AC:}{\F0borderstartcolor}%
1023   \addToArray{fotableborderendcolor\the\AC:}{\F0borderendcolor}%
1024 }

```

This is the command that declares the parameters.

```

1025 \def\jg@declare@parameters{%
1026   \DeclareArray{fotabletextalign\the\AC:}%
1027   \DeclareArray{fotableborderbeforestyle\the\AC:}%
1028   \DeclareArray{fotableborderafterstyle\the\AC:}%
1029   \DeclareArray{fotableborderstartstyle\the\AC:}%
1030   \DeclareArray{fotableborderendstyle\the\AC:}%
1031   \DeclareArray{fotableborderbeforewidth\the\AC:}%
1032   \DeclareArray{fotableborderafterwidth\the\AC:}%
1033   \DeclareArray{fotableborderstartwidth\the\AC:}%
1034   \DeclareArray{fotableborderendwidth\the\AC:}%

1068   \inheritfromcolumn{border-end-color}{borderendcolor}%
1069 }

```

The following command takes two arguments, say ‘foo’ and ‘bar’. It looks at the attribute list of the current element, to see if ‘foo’ is in the list. If so, the command `\isexplicit` is set to a non-`\relax` value. Otherwise, we define `\FObar` to the value found in the table (this is the command that holds the value of the attribute ‘foo’ in case it is explicitly given).

```

1070 \def\inheritfromcolumn#1#2{%
1071   \explicitattribute{#1}%
1072   \ifx\isexplicit\relax
1073     \expandafter\edef\csname F0#2\endcsname{%
1074       \csname fotable#2\the\AbsoluteTableCount:\the\CellCount\endcsname}%
1075   \fi
1076 }

```

This sets the width of the table to be the argument, minus the `\tabcolsep`, the left margin and the right margin.

```

1077 \def\jg@settablewidth#1{%
1078   \TableWidth#1%
1079   \advance\TableWidth by -\tabcolsep
1080   \advance\TableWidth by -\FOmarginleft
1081   \advance\TableWidth by -\FOmarginright}
    Same code, without the \tabcolsep.
1082 \def\jg@settablewidth@alt#1{%
1083   \TableWidth#1%
1084   \advance\TableWidth by -\FOmarginleft
1085   \advance\TableWidth by -\FOmarginright}

```

This initializes some other quantities.

```
1086 \def\jg@tablesetup{%
1087   \Ncols0
1088   \gdef\TableHeader{}%
1089   \NoTableSetup}
```

New in V2. If footnotes appear in a table, they are stored in a token list and inserted later on. This inserts the list, kills it, and resets the command that typesets footnotes.

```
1090 \def\NoTableFinish{
1091   \ifnum\F0inTable=0
1092     \the\BoxedFootnotes
1093     \global\BoxedFootnotes={}
1094     \global\let\F0foottext\F0plainfoottext
1095   \fi
1096 }
```

This is the command used at the start of a table. In this case and the previous one, if a table is in another one, the action is executed only for the outer table.

```
1097 \def\jg@start@tablenotes{
1098   \ifnum\F0inTable=0
1099     \global\BoxedFootnotes={}
1100     \global\let\F0foottext\F0boxedfoottext
1101   \fi
1102 }
```

This piece of code is executed at the start of a table or tabular. In the case of a tabular in a table, it will be executed twice. We commented out the code that increments the table counter: this is because it is currently impossible to put tables in tables; and once a table is typeset, all information about it is discarded. However, some names remain in the hash table.

```
1103 \def\NoTableSetup{%
1104   \ifx\F0width\att@auto\else    %% this test added by JG

```

We declare here an attribute for the placement of tables. This is in the fotex namespace. We declare also the reference orientation. This can be used in an inline container, for turning things.

```
1113 \XMLNSAX{fo}{fotex:placement}{\F0kplacement}{}
1114 \XMLNSAX{fo}{reference-orientation}{\F0referenceorientation}{0}
1115 \XMLname{fo:inline-container}{\F0InlineContainer}
1116 \gdef\F0kplacement{}
```

A table is defined by the `<fo:table-and-caption>` element, has `<fo:table-caption>` (optional) and `<fo:table>` (required) as children.

In the case of `<fo:table-and-caption>`, we use a floating environment. This can be a table or a sideways table. We must close the same environment at the end.

```
1117 \XMLElement{fo:table-and-caption}
1118   {}
1119 {
```

```

1120   \jg@settablewidth{\linewidth}
1121   \jg@tablesetup
1122     \ifx\XML@parent\FOInlineContainer
1123       \ifnum\F0referenceorientation=0
1124         \else \begin{sidewaystable}\fi
1125       \else
1126         \ifnum\F0referenceorientation=0
1127           \ifx\F0kplacement\empty
1128             \begin{table}[^htbp]\F0label
1129               \else \edef\ktable{\noexpand\begin{table}[\F0kplacement]}\ktable \fi
1130             \else \begin{sidewaystable}\fi
1131           \fi
1132           \F0label
1133         }
1134       \ifx\XML@parent\FOInlineContainer
1135         \ifnum\F0referenceorientation=0 \else \end{sidewaystable} \fi
1136       \else
1137         \ifnum\F0referenceorientation=0 \end{table} \else \end{sidewaystable} \fi
1138       \fi
1139       \NoTableFinish
1140     }

```

Typesetting the caption is trivial. In particular, we do not call `\caption`. The table has a `caption-side` trait that explains where to put the caption. This will be ignored.

```

1141 \XMLelement{fo:table-caption}
1142   {}
1143   {}
1144   {\par}

```

A `<fo:table>` can be used inside or outside of a `<fo:table-and-caption>`. The content: some `<fo:table-column>` elements, an optional `<fo:table-header>`, an optional `<fo:table-footer>` and some `<fo:table-body>` elements. Translation is trivial.

This is what we do for a table (equivalent of a L<sup>A</sup>T<sub>E</sub>X `tabular`). It has no header. Changes in V2: the whole table is put in a vbox, that starts with a top border and finishes with a bottom border.

```

1145 \XMLelement{fo:table}
1146   {}
1147   {
1148     \F0expandattributes
1149     \jg@settablewidth@alt{\linewidth}
1150     \jg@tablesetup
1151     \vbox\bgroup\F0BorderTop
1152   }
1153   {\F0BorderBottom\egroup
1154     \NoTableFinish}

```

The header of a table is not typeset now, but later. The footer is currently ignored. Too bad. The global definition here is one that forbids putting tables in tables.

```

1155 \XMLelement{fo:table-header}
1156   {}
1157   {\xmlgrab}
1158   {\gdef\TableHeader{\#1}}

```

This command is used to specify the width and other properties of one or more columns. The doc says: The **number-columns-repeated** property specifies the repetition of a **<fo:table-column>** specification *n* times; with the same effect as if the **<fo:table-column>** formatting object had been repeated *n* times in the result tree. The **column-number** property, for all but the first, is the **column-number** of the previous one plus the value of the **number-columns-spanned** property.

Changes in V2: attribute text-align added, but why? Some attributes are saved by the routines explained above. The list of these is larger than the list of attributes defined by the standard.

```

1159 \XMLElement{fo:table-column}
1160 {
1161   \XMLattributeX{text-align}{\FOtextalign}{\inherit}
1162 }
1163 {
1164   \tempcnta0
1165   \loop\ifnum\FOnumbercolumnsrepeated>\tempcnta
1166     \advance\tempcnta by 1
1167     {\NoTableColumn}%
1168   \repeat
1169 }
1170 {}
```

There is something wrong in this procedure: the column number is unused (said otherwise, if specifications are not in the order 1, 2, 3, etc, they will be stored in random order). Note: the column-number should not be zero. If at least one table column has been given, then **\Ncols** is not zero. The test to proportional-column-width is strange: what if the argument is not one? If the value is a percentage, it refers to the width of the table. The computed value is stored in **\tempdima**, and then in the array data structure.

```

1171 \def\NoTableColumn{%
1172   \ifx\empty\FOcolumnnumber
1173     \global\advance\Ncols by 1
1174   \else
1175     \global\Ncols\FOcolumnnumber
1176   \fi
1177   \ifx\prop@width\FOcolumnwidth\def\FOcolumnwidth{1in}\fi
1178   \ifx\empty\FOcolumnwidth\def\FOcolumnwidth{1in}\fi
1179   \TablePercentToDimen{\FOcolumnwidth}%
1180   \addToArray{fotable}{\the\AbsoluteTableCount}{\the\tempdima}%
1181   \jg@save@parameters
1182 }
1183 \XMLstringX{\prop@width}>proportional-column-width(1)</>
```

The table body, header and footer contain either rows, or cells. Footers are currently ignored. Inside a table **\FOinTable** is 1. Since V2, the interlineskip parameters are saved and set to zero. Each row of the table is a box (a hbox in a vbox), and we do not want additional vertical space between the rows.

```

1184 \XMLElement{fo:table-body}
1185   {
1186     \FOFirstCelltrue
1187     \FOinTable1
1188     \saveinterlineskip
1189     \expandafter\NoTableStart{\TableHeader}%
1190   }
1191   { \NoTableEnd }
```

Action is trivial.

```
1192 \def\NoTableStart#1{#1}
1193 \def\NoTableEnd{%
1194   \clearArray{fotable\the\AbsoluteTableCount:}%
1195   \jg@clear@parameters
1196 }
```

We use a command for typesetting a row.

```
1197 \XMLElement{fo:table-row}
1198 {}
1199 {\xmlgrab}
1200 {\NoTableRow{#1}}
```

We use two passes for our table rows. For the first pass the height of the row may be unknown; hence we use a boolean that says that it is the first or the second pass.

```
1201 \newdimen\NoTableCellHeight
1202 \newif\ifNoTableCheckHeight
```

This is for the first pass. We use a `\strut`, a capital letter and a letter with a descender. Note: it is two small if the cell has a border or padding. Changes in V2. If a height attribute is given, it will be used instead this string for computation of the strut.

```
1203 \def\jg@default@cell@height{%
1204   \setbox0=\vbox{
1205     \ifx\fOheight\att@auto%
1206       \strut They
1207     \else
1208       \rule{\z@\fOheight}%
1209     \fi
1210   }%
1211   \NoTableCellHeight=\ht0
1212   \advance\NoTableCellHeight by \dp0
1213   \NoTableCheckHeightfalse}
```

In the first pass, we put the row in a box, and we compute the total height plus depth of the box. Changes in V2: a hbox in a vbox is used instead of a simple hbox. Footnotes are ignored (in the second pass they will move). Then we look at page parameters to see if there is enough place on the current page; we may call `\clearpage`.

```
1214 \def\jg@tablerow@firstpass#1{%
1215   \setbox0=\vbox{\hbox{\let\fOfoottext\fOnofoottext#1}}%
1216   \tempdima=\ht0
1217   \advance\tempdima by \dp0
1218   \fOspaceleft=\pagegoal
1219   \advance\fOspaceleft by -\pagetotal
1220   \ifdim\fOspaceleft<\tempdima \clearpage \fi}
```

Second pass: we use the actual height as target height. In V1, we could use the box if not too big; but in V2, we have to process the table again, because otherwise we could lose footnotes.

```
1221 \def\jg@tablerow@secondpass#1{
1222   \ifdim\tempdima>\NoTableCellHeight
1223     \NoTableCellHeight=\tempdima
1224   \fi
1225   \global\CellCount0
1226   \NoTableCheckHeighttrue
1227   \vbox to \NoTableCellHeight {\hbox{#1}}}
```

The code looks like this. In V1, we inserted the opposite of `\lineskip`; this assumes that TeX places a glue of value `\lineskip`, because the height of the box is greater than the baselineskip limit. It can fail if the height is small. In V2, we inhibit insertion of this glue, hence the code is not needed anymore.

```

1228 \def\NoTableRow#1{%
1229   \jg@default@cell@height
1230   \global\CellCount0 \jg@tablerow@firstpass{#1}%
1231   \jg@tablerow@secondpass{#1}%
1232   \%vskip-\lineskip
1233 }

```

In the case of a table cell, we call some functions. A table body can consist of rows, or cells. In the case of cells, we have an attribute that says if the cell starts or ends a row. We set `\F0inTable` to 2, meaning “in cell”.

```

1234 \XMLelement{fo:table-cell}
1235 {
1236   \XMLattributeX{ends-row}{\F0endsrow}{false}
1237   \XMLattributeX{starts-row}{\F0startsrow}{false}
1238 }
1239 {\xmlgrab}
1240 {\F0label
1241 \F0expandattributes
1242 \F0inTable2
1243 \NoTableCell{#1}}

```

This reduces the argument by the width of the padding, margin and border width on both sizes. Thus, we have in #1, a dimension register, the width of the region in which we can typeset the cell.

```

1244 \def\jg@removemarg#1{
1245   \advance#1 by -\F0paddingstart
1246   \advance#1 by -\F0paddingend
1247   \ifx\F0borderstartstyle\att@solid\advance#1 by -\F0borderstartwidth\fi
1248   \ifx\F0borderendstyle\att@solid\advance#1 by -\F0borderendwidth\fi
1249   \advance#1 by -\F0marginright
1250   \advance#1 by -\F0marginleft}

```

We increment the cell count, or reset it, in case there is an attribute that says this cell is the first in a row.

```

1251 \def\jg@test@startrow{%
1252   \ifx\F0startsrow\att@true
1253     \%vskip-\lineskip % not needed in V2
1254     \global\CellCount1
1255   \else
1256     \global\advance\CellCount by 1
1257   \fi}

```

If this cell is the last in a row, set the counter to zero.

```

1258 \def\jg@test@endrow{%
1259   \ifx\F0endsrow\att@true
1260     \%vskip-\lineskip % not needed in V2
1261     \global\CellCount0
1262   \fi}

```

Write `\CCWidth` instead of `\CurrentCellWidth` for simplicity. This is the width of the cell. If `\Ncols` is zero, no specifications are given for the table. In this case, we use the natural width of the cell. Otherwise we use the stored value. We must reset the interline skip to its normal value.

```

1263 \def\jg@getCCwidth#1{
1264   \ifnum\Ncols<1
1265     \CCWidth\z@
1266     \setbox0=\hbox{\restoreinterlineskip#1\strut}%
1267     \CCWidth=\wd0
1268   \else
1269     \CCWidth=\csname fotable\the\AbsoluteTableCount:\the\CellCount\endcsname
1270     \jg@compute@parameters
1271     \interpretwidth
1272   \fi}

```

If the cell spans more than one column, we assume that specifications are given for all columns. We compute the sum of these quantities.

```

1273 \def\jg@getCCwidth@aux{%
1274   \ifnum\F0numbercolumnsspanned>1
1275     \tempcnta1
1276     \loop\ifnum\tempcnta<\F0numbercolumnsspanned
1277       \advance\tempcnta by 1
1278       \global\advance\CellCount by 1
1279       \advance\CCWidth\csname fotable\the
1280         \AbsoluteTableCount:\the\CellCount\endcsname
1281     \repeat
1282   \fi}

```

This is now the code of a cell. The parent is a table row or a table. If we are in a row, all cells are typeset (see next section) and the resulting boxes are put in a row-box, these row-boxes are put one above the other. These cells align nicely, because a cell in row  $i$  column  $j$  has a common height  $H_i$  and a width  $W_j$  (these values depend only on  $i$  and  $j$  and not the cell, the height is in `\NoTableCellHeight` and used only for the second pass, the width is in `\CCwidth`, real name of command shown above). In the case where the cell is directly in a table, the cell is put in a hbox, and `\leavevmode` is called. The attributes telling this is the first or last cell in a row have as only purpose to change the cell count. As a consequence, all cells are on a single line<sup>10</sup>.

```

1283 \def\NoTableCell#1{%
1284   \jg@test@startrow
1285   \jg@getCCwidth{#1}%
1286   \jg@removemarg{\CCWidth}
1287   \jg@getCCwidth@aux
1288   \ifx\XML@parent\FOTableRow
1289     \FOTableCellBlock#1\FOEndTableCellBlock
1290   \else
1291     \leavevmode\hbox{\FOTableCellBlock#1\FOEndTableCellBlock}%
1292   \fi
1293   \jg@test@endrow}

```

Some declarations.

```

1294 \XMLNSA{fo}{column-width}{\F0columnwidth}{}
1295 \XMLNSAX{fo}{number-columns-repeated}{\F0numbercolumnsrepeated}{1}

```

---

<sup>10</sup>The `\vskip` commands, commented out in V2 as “not needed” on lines 1253 and 1260, have as side effect to end the paragraph. This gives unexpected side effects. In the Raweb case, cells are not directly in a table.

```

1296 \XMLNSAX{fo}{number-columns-spanned}{\FOnumbercolumnsspanned}{1}
1297 \XMLNSAX{fo}{column-number}{\FOcolumnnumber}{}

```

## 4.12 Boxed blocks

We typeset a cell by opening in a lrbox (this is really a `\hbox`) in which we open a `\vbox`. Since V2, a color group is added only if the `\ifFOinOutput` switch is false.<sup>11</sup> We hack spacing. We removed a test to an undefined variable, that could center vertically the box.

```

1298 \def\FOTableCellBlock{%

```

This is a bit longish, but easy to understand. We finish our `\vbox` and our lrbox. After that, we construct some boxes. Let's denote by PA, PB, PS, and PE the padding before, after (vertical), start, end (horizontal), by BA, BB, BS, and BE the border width (whenever the border is solid), and by ML, MR, MT, and MB the margins (left, right, top, bottom). Let  $a$  be the sum of MT, PB and BB, and let  $b$  be the sum of PS, PE and the width of the cell box. The first box we construct is A, the cell box. The second box we construct is B, an hbox containing PS, A and PE. The third box is C, a vbox containing PB, filler, B, filler, and PA. The filler is a `\vfil`, which is inserted in certain circumstances : if `NoTableCheckHeight` is true, we insert the filler if some attributes have the right value. In this case C is a `\vtop` to the height of the table computed earlier (this is the height of the row, we are in the second pass). The width of this box is the quantity  $b$  defined above. Now we construct a box D, an hbox with BS, bg, C, and BE, where bg may be empty if no background is desired. Otherwise it consists of a rule of width  $b$ , followed by a kern of width minus  $b$  (the height of the rule is the height of C). Then comes a box E, this is a vbox containing BB, D and BA. Note that BS, BE, BB, and BA are borders: they are implemented via hrules or vrules. Then comes a box F, it is a vbox containing MT, E and MB, and a box G, this is an hbox that contains ML, F and MR. This box is shifted down by the quantity  $a$ . Finally, we put everything in an hbox.

Changes in V2: Horizontal margins use `\hskip`, but vertical margins use `\kern` instead of `\vskip`. In the case of BoxedBlock, `\kerns` are used for both horizontal and vertical margins.

## 4.13 Lists

In XSL/Format four formatting objects construct lists: the main element is `<fo:list-block>`, the children are one or more `<fo:list-item>`, each containing a pair of `<fo:list-item-label>` and `<fo:list-item-body>`. There are two attributes, specific to lists. We shall abbreviate the names to PLS and PDDBS.

```

1439 \XMLNSAX{fo}{provisional-label-separation}
1440     {\FOprovisionallabelseparation}{\inherit}
1441 \XMLNSAX{fo}{provisional-distance-between-starts}
1442     {\FOprovisionaldistancebetweenstarts}{\inherit}

```

This command is used twice: at the start of a list, and at the start of a block in a list. It defines some parameters (item indent, left margin, right margin, and label width) that are used by the `\item` command. Changes in V2: PDDBS can be a percentage.

```

1443 \def\jg@use@listparams{
1444     \itemindent=\FOstartindent
1445     \PercentToDimen{\FOprovisionaldistancebetweenstarts}%
1446     \leftmargin=\@tempdima\relax
1447     \rightmargin=\FOmarginright
1448     \labelwidth=\@tempdima\relax
1449     \advance\labelwidth by -\FOprovisionallabelseparation}

```

The translation of <fo:list-block> is essentially a call to the `list` environment (it takes two arguments, explained below). We globally change (increase by one) the `\FOinList` counter. The `text-align` attribute will be used for alignment of the labels, for instance, if it is ‘start’, we call the command `\Liststart`, that defines `\makelabel` adequately (it will left justify the label). We use `\csname` for this purpose; the `\expandafter` before it is useless.

Changes in V2: Call to `\FOSetFont` commented out. Setting of `\partopsep` added. Conditional call to `\leavevmode` and final `\par` commented out. As a consequence a list could be inline. This means that some checks have to be made elsewhere.

There is a second change in V2, it concerns `\linewidth`. The question is: how should this be defined? what command uses it? In general, the value is the same as `\hsize`. It is used and modified by `\list` (as shown below), and used by tables (in a non-trivial manner by `\@stoline`, but this is not used by fotex). However, we have already seen that the fotex implementation of tables uses this value, and we have seen another use of the variable. Now comes the trick. Let X be the command `\This@LineWidth`, and Y its value, let H be the value of `\hsize`. The command `\setaccordingtomaster` is called for each page, and for each flow; it calls `\F0ResetPageParts` that redefines `\hsize`. It also redefines `\linewidth` to Y, if X is defined, and to H otherwise. The question is whether or not the value should be modified (whenever a new flow is created, it is clear that we should set it to H, when a new page is entered, the value should not change). Given this scheme, the variable X, whenever it has a value, should contain the right quantity. The code here defines two scopes: the <fo:list-block> element and the `list` environment, let’s call them A and B. The first definition is in scope A, and the purpose is to restore the value of the line width (it will be globally modified). The second definition is in scope B, it is used only in the case where a page break occurs while typesetting the list.

```

1450 \XMLElement{fo:list-block}
1451   {\SpaceAttributes}
1452   {
1453     \jg@hackindent
1454     \%FOSetFont{normal}%
1455     \advance\FOinList by 1\relax
1456     \%ifnum\FOinList>1\relax\leavevmode\fi
1457     \edef\This@LineWidth{\the\linewidth}%
1458     \begin{list}{}{%
1459       \jg@use@listparams
1460       \advance\leftmargin by \FOmarginleft
1461       \expandafter\csname List\FOtextalign\endcsname
1462       \labelsep\FOprovisionallabelseparation
1463       \itemsep\z@\parsep\z@\partopsep\z@\topsep\z@\parskip\z@
1464       \jg@usespacebefore{\topsep} }
1465       \%edef\This@LineWidth{\the\linewidth}% comment JG
1466     }
1467     \end{list}
1468     \global\linewidth\This@LineWidth\relax
1469     \advance\FOinList by -1\relax
1470     \%par
1471   }

```

These are the definitions used in the code above. The default value (reset by `\list` in any case) corresponds to ‘end’.

```

1472 \def\Listjustified{ \gdef\makelabel##1{##1}}
1473 \def\Liststart{ \gdef\makelabel##1{##1\hfil}}
1474 \def\Listend{ \gdef\makelabel##1{\hfil##1}}

```

```
1475 \def\Listcentered{ \gdef\makelabel##1{\hfil##1\hfil}}
1476 \def\Listcenter{ \gdef\makelabel##1{\hfil##1\hfil}}
```

The command `\list` has been changed in V2, as explained above. It takes two arguments. The first defines `\@itemlabel`, the value to be used when `\item` has no optional argument (unused here), and the second contains a list of commands to be executed before the call to `\@trivlist`. The standard `\list` command increments `\@listdepth` and tests it for overflow; this is useless in our case, especially because the effects of command that depends on the list level (for instance `\@listii`) are neutralized via the second argument. In effect we define `\itemsep`, `\parsep`, `\partopsep`, `\listparindent`, and `\parskip` to be zero, `\topsep` to be the value of the `space-before` attribute, `\itemindent` to be the value of `start-indent`. After that, the left and right margin will take the value of the corresponding attribute, but the left margin is increased by the value of PDBS, `\labelwidth` will contain PDBS minus PLS and `\labelsep` will contain PLS. After `\@trivlist`, we copy two zero quantities in `\parskip` and `\parindent`. We subtract left and right margin from `\linewidth`. Note: this is done globally in V2, and the caller restores the old value (this is a bit strange). Finally, we call `\parshape`, so that the first line (holding the item) is typeset differently.

```
1477 \def\list#1#2{%
1478   \ifnum \@listdepth >5\relax \@toodeep
1479   \else \global\advance\@listdepth\@ne
1480   \fi
1481   \rightmargin\z@
1482   \listparindent\z@
1483   \itemindent\z@
1484   \csname @list\romannumeral\the\@listdepth\endcsname
1485   \def\@itemlabel{\#1}%
1486   \let\makelabel\@mklab
1487   \nmbrrlistfalse
1488   #2\relax
1489   \@trivlist
1490   \parskip\parsep
1491   \parindent\listparindent
1492   \global\advance\linewidth -\rightmargin      % V2
1493   \global\advance\linewidth -\leftmargin       % V2
1494   \advance\@totalleftmargin \leftmargin
1495   \parshape \@ne \@totalleftmargin \linewidth
1496   \ignorespaces}
```

The `\endlist` command calls `\endtrivlist` (shown below) and decrements the list depth counter. For completeness, we show here the code of `\@trivlist`. The command on the first line is “a switch set true by a sectioning command when it is creating an in-text heading with `\everypar`” according to Lamport. In such a case, the heading is kept in a variable, and output only when a new paragraph is started, hence the `\leavevmode`. Then comes a piece of code shown below, and settings of three skip parameters (for justification). We copy `\parskip` somewhere, set a boolean to true and start checking for missing items.

```
1497 \def\@trivlist{%
1498   \if@noskipsec \leavevmode \fi
1499   \jg@trivlist@A
1500   \leftskip \z@skip
1501   \rightskip \@rightskip
1502   \parfillskip \@flushglue
1503   \jg@trivlist@B
1504   \global \newlisttrue
1505   \outerparskip \parskip}
```

Four boolean variables control how lists are typeset. We have already seen `@newlist`. This is true as long as the list is new. Said otherwise, it is set to true at the start of the list, and set to false at the start of the first paragraph (`\everypar` in an item). This redefines `\par`, to be `\@@par` (the primitive command) if the list is not new, and otherwise to do nothing (however, after a thousand calls an error will be signaled). As a consequence, if there is some text before the first item, even if there are `\par` commands, the current mode will be horizontal.

```
1506 \def\jg@trivlist@B{%
1507   \par@deathcycles \z@
1508   \setpar{%
1509     \if@newlist
1510       \advance\par@deathcycles \one
1511       \ifnum \par@deathcycles >\cm \noitemerr {\@@par}\fi
1512     \else {\@@par} \fi}}%
```

The second switch, `@inlabel`, “is false except between the time an `\item` is encountered and the time that T<sub>E</sub>X actually enters horizontal mode”, the quote is from Lamport. At the end of a list, or inside `\newpage`, if the switch is true, `\leavevmode` is executed, and the switch reset to false; this has as effect to flush pending labels. Otherwise, the switch is set to true in `\jg@itemA` shown below, and to false by `\jg@itemB`. There is third switch, `@noparitem`, it is set by `\list` to true if `@inlabel` is true. This is the case when the user says, for instance `\item[foo]` `\begin{itemize}``\item[bar]`. In this case, we have two items in a row. Finally `@noparlist` is set at the start of a list as a copy of `@inlabel`.

Two dimensions are defined. The first is `\@topsepadd`, containing `\topsep` plus `\partopsep` (omitted in horizontal mode); this is copied in `\@topsep`, unless we are in a label (case where `\@topsep` is left unchanged). If `\noparlist` is false, the command `\endparenv` is called at the end of the list, and inserts the `\@topsepadd` vertical glue. Denote this by  $T'$ , denote by  $P$  the value of `\parskip`, and let  $T$  be the sum of these two quantities; we put  $T$  in `\@topsep`; it will be inserted by `\item`.

```
1513 \def\jg@trivlist@A{%
1514   \@topsepadd \topsep
1515   \ifvmode \advance\@topsepadd \partopsep \else \unskip \par \fi
1516   \if@inlabel \noparitemtrue \noparlisttrue
1517   \else
1518     \if@newlist \noitemerr \fi
1519     \noparlistfalse
1520     \@topsep \@topsepadd
1521   \fi
1522   \advance\@topsep \parskip}
```

Second part of `\endtrivlist`. This is used when `\noparlist` is false, said otherwise, if the list was not inside a label. Let  $L$ ,  $P$  and  $O$  be the values of the last skip, the `\parskip`, and `\outerparskip` (the `\parskip` that was in effect before the list). If the last item in the vertical list is glue, then  $L$  contains this value, otherwise it will be zero. If  $L$  is negative or zero, nothing is done; otherwise, the opposite of  $L$  is added, followed by  $L + P - O$ . This gives three items of glue; there are similar cases where a penalty is inserted after the second glue.

```
1523 \def\jg@endtrivlist@B{%
1524   \ifdim\lastskip >\z@
1525     \tempskipa\lastskip \vskip -\lastskip
1526     \advance\tempskipa\parskip \advance\tempskipa -\outerparskip
1527     \vskip\tempskipa
1528   \fi}
```

The code that follows handles the special case of a list A, containing an item B, that starts with a list C; in this case the `@noparitem` switch is true. When we see the first item D in the list C, we call this piece of code (the source has a comment: “this clause hardly every taken, so made a macro”). The action is divided into three parts: first, we set the switch to false, second, we shift the labels left by the value of `\leftmargin` (note that this is how much the current list is indented with respect to its environment), finally, we adjust vertical space. We add two items of glue. With the the same notations as before, we insert are  $-L$  and  $L + O - P$ . When the label is finally printed, TeX will use the current `\parskip`, hence P. This gives a total of  $L + O$ : the old glue plus the old `\parskip`. Note that the code above inserts  $L + P - O$ .

```

1540   \fi}

```

First part of `\endtrivlist`. If we are still in the label, we enter horizontal mode, and say that we are no more in the label. An error is signaled if the list is new (case where no item was found).

```

1541 \def\jg@endtrivlist@A{%
1542   \if@inlabel
1543     \leavevmode
1544     \global \c@inlabelfalse
1545   \fi
1546   \if@newlist
1547     \c@noitemerr
1548     \global \c@newlistfalse
1549   \fi}

```

This is now `\endtrivlist`, as defined by V2. The test `\ifInInsertion` was added. An error test (if the end of the list occurs in math mode) was removed for no clear reason.

```

1550 \def\endtrivlist{%
1551   \jg@endtrivlist@A
1552   \ifhmode\unskip \par\fi %% else error omitted
1553   \if@noparlist \else\ifInInsertion\else
1554     \jg@endtrivlist@B\fi
1555     \c@endparenv
1556   \fi}

```

Quoted from the L<sup>A</sup>T<sub>E</sub>X source: “When you leave a list environment, returning either to an enclosing list or normal text mode, L<sup>A</sup>T<sub>E</sub>X begins a new paragraph if and only if you leave a blank line after the `\end` command. This is accomplished by the `\c@endparenv` command. Blank lines are ignored every other reasonable place”. Later on, there is “Instead of redefining `\par` and `\everypar`, `\c@endparenv` was changed to set the `\c@endpe` switch, letting `\end` redefine `\par` and `\everypar`”. The fotex V2 file redefines the command by adding a test to `\ifInInsertion` (true in a footnote).

```

1557 \def\c@endparenv{%
1558   \ifInInsertion\else

```

```

1559   \addpenalty\@endparpenalty
1560   \addvspace\@topsepadd
1561   \@endpetrue
1562 \fi}

```

The `\fotex` file redefines `\item` like this. Note that `\leavevmode` could be used to flush pending labels.

```

1563 \let\olditem\item
1564 \def\item{\ifinlabel\leavevmode\fi\olditem}

```

We now redefine the `\item` command. This is a bit complicated. For this reason, we split the command into smaller pieces.

```

1565 \def\@item[#1]{%
1566   \@itemA
1567   \@itemB
1568   \@itemC
1569   \@itemD{#1}%
1570   \@itemE
1571   \ignorespaces}

```

The first idea is that the label is typeset in a box, and this box will be used later. The `\sbox` command produces essentially a `hbox`. The L<sup>A</sup>T<sub>E</sub>X source file says that the `\label` command should produce some glue, for instance, the code on lines 1473 to 1476 is OK, the code on line 1472 is not. The first line was added because it corrects a bug. See explanations later.

```

1572 \def\@itemD#1{%
1573   \%savebox{\ItemBox}{#1}%
1574   \sbox\@tempboxa{\makelabel{#1}}%

```

We can have more than one consecutive labels. For this reason, we put in the box `\@labels` all these labels. We consider three dimensions, say A, B, and C, that contain the space after the label, the nominal width of the label, and the total space allowed for the label and its surrounding space. We emit four items of glue, first, three items that correspond to  $C - A - B$ , then the label box, then A. In the case where the width of the label is smaller than B, we use `\hbox to XX`, with a `\unhbox`: here it is important that the box contains glue that can stretch without producing underfull boxes.

```

1575 \def\@itemE{%
1576   \global\setbox\@labels\hbox{%
1577     \unhbox\@labels
1578     \hskip \itemindent
1579     \hskip -\labelwidth
1580     \hskip -\labelsep
1581     \ifdim \wd\@tempboxa >\labelwidth
1582       \box\@tempboxa
1583     \else
1584       \hbox to\labelwidth {\unhbox\@tempboxa}%
1585     \fi
1586     \hskip \labelsep}%

```

In the case of an enumeration, there is a counter, whose name is in `\@listctr`, that has to be incremented. We know that we are in an enumeration, because `\if@nmbrlist` is true (in the FO case, it is false). In the case `\item` has an optional argument, `\if@noitemarg` is false, and in this case the user gives a number, so that the counter is not modified.

```

1587 \def\@itemC{%
1588   \if@noitemarg

```

```

1589     \c@noitemargfalse
1590     \if@nmbrlist \refstepcounter\c@listctr \fi
1591 \fi}

```

The following piece of code is executed if `\if@newlist` is true (hence for the first item in a list). The effect of `\c@nbitem` is to add some vertical space (the value is  $O - P$ , according to the description above). The L<sup>A</sup>T<sub>E</sub>X source has a comment that says: “Kludge if list follows `\section`”. This was commented out by `fotex.sty`. Otherwise, we use two `\addvspace` instead of a single one, namely T and minus P; remember that T’ is  $T - P$ .

```

1592 \def\c@itemAA{%
1593 %     \if@nobreak \c@nbitem \else  %% REMOVED
1594 %         \addpenalty\c@beginparpenalty
1595 %         \addvspace\c@topsep
1596 %         \addvspace{-\parskip}%
1597 %     \fi
1598 }

```

This is now how `\item` manages vertical space. The code on line 1603 is strange: remember that `\indent` inserts current paragraph indentation, while `\par` terminates the current paragraph (all we need is to insert the `\everypar` token list, in order to flush previous items). On the next line, we have a double `\unskip`; the reason is that commands like `\addvspace` add a double skip in order to make it more difficult to remove it. However, this is generally not done in horizontal mode, strange... Changes in V2: `\ifInInsertion` added (this test is true inside a foot note).

```

1599 \def\c@itemA{%
1600   \if@noparitem
1601     \c@donoparitem
1602   \else
1603     \if@inlabel \indent \par \fi
1604     \ifhmode \unskip\unskip \par \fi
1605     \ifInInsertion \else
1606       \if@newlist \c@itemAA
1607       \else \addpenalty\c@itempenalty \addvspace\itemsep \fi
1608     \fi
1609     \global\c@inlabeltrue
1610   \fi
1611 }

```

Now, the `\everypar` token list is redefined. The difference with the original L<sup>A</sup>T<sub>E</sub>X code is that some `\global` declarations have been added. In the case `\if@inlabel` is true, we set it to false, and output the label box. We kill `\itemindent`, in the case where the user says `\noindent` (in other cases, a new paragraph is created by an explicit or implicit `\indent`, that inserts a box of width `\parindent`). There is another change in V2: the call to `\F0label`; we commented it out, because the `\F0label` is also called after the item is completely typeset (and before the box is flushed, but can a page break appear just after the link? this is not so clear).

```

1612 \def\c@itemB{%
1613   \global\everypar{\%  %% Global added
1614     \c@minipagefalse
1615   \global\c@newlistfalse
1616   \if@inlabel
1617     \global\c@inlabelfalse
1618     {\setbox\z@\lastbox
1619      \ifvoid\z@ \kern-\itemindent \fi\%}
1620   \box\c@labels\F0label \% added in V2

```

```

1621     \penalty\z@
1622     \fi
1623     \if@nobreak
1624         \global\@nobreakfalse % Global added
1625         \clubpenalty \OM
1626     \else
1627         \clubpenalty \clubpenalty
1628         \global\everypar{}% % Global added
1629     \fi}}
```

A list should contain `<fo:list-item>` elements. We insert some vertical space at the start of the item. The `\par` was missing in the first version. Without it, the following happens: the command `\jg@usespacebefore` computes some quantity in `\@tempdima`, and calls `\vskip`. This, being a vertical mode command, terminates the current paragraph, and may start a new page. In this case, the command (with the arguments) is evaluated after the page is shipped out; in this case, `\@tempdima` is modified, it contains now Xpt, the text width), and the argument of `\vskip` is now 4pt plus 4pt minus Xpt. In one case, TeX found an optimum break point with 30% of glue set (meaning: the actual glue between the two items is 4pt minus one third of the text width, this is minus 125 pt, say ten lines). In the case there is a label, we handle it after the `\vskip`.

```

1630 \XMLElement{fo:list-item}
1631   {\SpaceAttributes}
1632   {
1633     \FOSetHyphenation
1634     \par
1635     \jg@usespacebefore{\vskip}%
1636     % noskip if spacebefore is zero V2
1637     \ifdim\FOspacebefore=0pt\relax\else\vskip\FOspacebefore\fi
1638     \FOLabel
1639   {}
```

An item is declared via `<fo:list-item-label>`. Question: why do we put the argument into `\ItemBox`? the box is never used! There is a similar code on line 1573. This is to correct a bug, see explanations below.

```

1639 \newsavebox\ItemBox
1640 \XMLElement{fo:list-item-label}
1641   {}
1642   {\xmlgrab}
1643   {\jg@hackindent
1644     \savebox{\ItemBox}{\item[\#1]\FOLabel}
```

This is called in the case where the current block is the label of a list. This computes some quantities (left margin, right margin, itemsep, etc). It is not clear whether or not these quantities need to be computed. Note that the last line of code defines `\makelabel`.

```

1645 \def\FOListBlock{%
1646   \FOSetFont{normal}%
1647   \get@external@font\xdef\FOlistlabelfont{\external@font}%
1648   \jg@usespacebefore{\itemsep}
1649   \jg@use@listparams
1650   \expandafter\csname List\FOtextalign\endcsname}
```

Bug explanation. The content of `<fo:list-item-label>` is evaluated twice, fake and real, see line 1644 (occurrence A, fake), line 1573 (occurrence B, fake), and line 1574 (occurrence C, real). We once thought it better to move the fake code from A to B (as near as possible to C); the trouble is the preceding like above: it defines globally `\makelabel`, according to the `text-align` attribute of the `<fo:block>` of the item. Since `\makelabel` is used to typeset this block, redefining it inside

C is useless (hence, without A, the first item in a list was justified according to the list, and each other was justified according to the previous one). While debugging, we found that the `text-align` attribute of the list item was ‘justify’, and `\Listjustify` was not defined. We added a definition, making it equivalent to ‘center’.

This piece of code sets the switch `FOListInnerPar` to true if we are inside a list and this is not the first block. The `\relax` was missing in V1, as a consequence the test was evaluated before the assignment is complete; consequences of this are explained below. Also equals to one was replaced by less than two.

```

1651 \def\jg@setlistinnerpar{%
1652   \ifx\XML@parent\FOListItemBody
1653     \global\advance\FOListBlocks by 1\relax%
1654     \ifnum\FOListBlocks<2\relax\else\FOListInnerPartrue\fi
1655   \else
1656     \ifFOListBody \FOListInnerPartrue \fi
1657   \fi}

```

We explain here a second bug, that occurs when dvi is produced instead of Pdf. If you look at lines 1620 and 1644, you will see two occurrences of `\FOLabel`; only one of these two will be used because `\FOLabel` kills `\FOid` (the command is defined in section 4.22). Consider the scenario where we have only a command at line 1644, and we generate a Pdf file; it will contain some glue and a penalty, then a `\write` with `\newlabel`, and a `\pdfdest` command (each followed by an infinite penalty), then `\parskip` and `\baselineskip` (let’s hope that a page break does not occur here, but at the penalty mentioned above), then a paragraph, starting with the label. Now, it happens that adding a hyper anchor in a dvi file calls `\leavevemode` (via `\pdfmark` and `\pdf@rect`), and this flushes the label (the `\everypar` token list defined on line 1613 is executed, and the line 1620 is executed). This has as consequence that the dvi file contains: first some glue and a penalty, then the `\write` then `\parskip` and `\baselineskip`, then a paragraph starting with the label, followed by some `\special` commands.

Now, if we have a command at lines 1620 and 1644, the command on line 1620 is executed before the other one is complete, and the `\write` is executed twice. This means that the command should be used only on line 1620. Now the bug is that the first paragraph of the item is not considered as such, and a `\par` command is executed (line 1826). If the label is not flushed, this command does nothing, otherwise, it inserts a line break after the label; thus we have a different behavior in the Pdf and dvi file.

The body of the item is declared via `<fo:list-item-body>`. We say that we are in the body of the list, and start a counter with zero. This counter is (globally) incremented for each paragraph (i.e., `<fo:block>`) that is not the child of a list item label, nor in a static section, neither a table cell, but is the child of a list item body (see line 1653); the counter is local to the list item, hence must be saved in a local variable `\This@FOListBlocks`, and restored at the end of the element.

```

1658 \XMLElement{fo:list-item-body}
1659   {}
1660   {\ifx\FOstartindent\att@bodystart \let\FOstartindent\z@ \fi
1661   \edef\This@FOListBlocks{\the\FOListBlocks}%
1662   \FOListBodytrue\global\FOListBlocks0}
1663   {\global\FOListBlocks\This@FOListBlocks\relax}
      Default values for the attributes.
1664   \gdef\FOstartindent{\z@}
1665   \gdef\FOendindent{\z@}
1666   \gdef\FOprovisionaldistancebetweenstarts{24.0pt}
1667   \gdef\FOprovisionallabelseparation{6.0pt}

```

```

1668 \newcount\FOListBlocks
1669 \edef\This@FOListBlocks{\the\FOListBlocks}

```

## 4.14 Blocks

The <fo:block> is an important object.

We have seen cases where the switch `FOBlockGrab` has to be set to true. Here is another one: when the border style is solid or when the background is not transparent.

```

1670 \def\jg@hack@background{%
1671   \ifx\FObackgroundcolor\att@transparent
1672     \ifx\FOborderstyle\att@solid \FOBlockGrabtrue \fi
1673   \else
1674     \FOBlockGrabtrue
1675   \fi}

```

This is the major addition in V2. If the current block should span the whole page, but the current page has more than one column, we stop and restart the multi-columns environment. Test of widows and orphans added. The documentation says: the orphans (widows) property specifies the minimum number of line-areas in the first (last) area generated by the formatting object; default value is 2. This code is correct if the value is one or two; better than that cannot be done in T<sub>E</sub>X.

```

1676 \def\jg@block@span{%
1677   \ifx\FOspan\att@all
1678     \ifnum\NColumns>1\relax \interendmulticols \fi
1679   \fi
1680   \ifnum\FOwidows>1\relax\widowpenalty10000\relax\else\widowpenalty0\relax\fi
1681   \ifnum\FOorphans>1\relax\clubpenalty10000\relax\else\clubpenalty0\relax\fi}
1682   Action at end of block.
1683 \def\jg@endblock@span{%
1684   \ifx\FOspan\att@all
1685     \ifnum\NColumns>1\relax \interbeginmulticols{\NColumns}\fi
1686   \fi}

```

This is the action associated to a block.

We define two commands, `\w@t` and `\@whattonext`, to be executed at the start of the element, and at the end. The first is followed by `\jg@keep@together`, the second is preceded by `\jg@keep@together`. This is a command that may evaluate a `\samepage` command. There are four cases to consider. Case 1: the parent is a list-item-label. In this case, we execute `\FOListBlock` and `\FOEndBlock`. Case 2: `FOInOutput` is true. The actions are `\FOOutputBlock` and `\FOEndOutputBlock`. Case 3: In a table. Actions are `\FOBoxedBlock` and `\FOEndBoxedBlock`. Case 4 (otherwise): actions are `\FONormalBlock` and `\FOendBlock`. Remember, when we typeset a static block (page headers), we are in case 2, and the parent is empty; can this element contain lists? this would give strange page headings.

```

1686 \XMLelement{fo:block}
1687   {\SpaceAttributes}
1688   {%

1719 \XMLNSA{fo}{background-color}{\FObackcolor}{transparent}
1720 \XMLstringX\att@transparent<>transparent</>
1721 \XMLstringX\att@solid<>solid</>

```

This piece of code is executed at the end of a block (except output, or boxed). We do nothing if this is a label of a list (see later). We emit a `\par` if this block is somewhere else in a list and `FOListInnerPar` is true. We call `\FOEndBlockTwo` in the case where the block is neither in a list nor in a table.

```

1722 \def\FOEndBlock{%
1723   \ifx\XML@parent\FOListInputLabel
1724   \else
1725     \ifnum\F0inList>0
1726       \ifInInsertion\start@strut\fi
1727       \ifFOListInnerPar\unskip\par\fi
1728     \else
1729       \ifnum\FOTableNesting>0
1730         \else \FOEndBlockTwo \fi
1731     \fi
1732   \fi}

```

This is the end of a normal block. We first terminate the paragraph. After that, we call `\FOEndBoxedBlock` if the block is boxed, or else add some vertical space and some padding. After that, we decide if a new page, or a new double page should be started here. We instantiate the switch `@tempswa` with a boolean value that says whether or not it is wise to start a new page here. If it is, we just insert some vertical space, otherwise, we insert a penalty, some vertical space, and call a command `\@afterheading` (a standard L<sup>A</sup>T<sub>E</sub>X command). Changes in V2: instead of adding

an infinite penalty, this calls `\addpenalty`, a L<sup>A</sup>T<sub>E</sub>X command that can do strange things (included signal a missing `\item` error). Normally it inserts a penalty, a large one here.

```

1733 \def\FOEndBlockTwo{%
1734   \par
1735   \ifFOBlockGrab
1736     \FOEndBoxedBlock
1737   \else
1738     \ifdim\FOpaddingafter>\z@ \vskip\FOpaddingafter \fi
1739     \FOBorderBottom
1740   \fi
1741   \jg@handle@breakafter
1742   \jg@keepnext
1743   \if@tempswa\addpenalty{9993}\fi
1744   \FOvspaceafter
1745   \% \if@tempswa\@afterheading\fi
1746 }
1747 \XMLstringX\att@oddpage<>odd-page</>
1748 \XMLstringX\att@evenpage<>even-page</>
```

This considers the `break-after` attribute. The value can be one of ‘auto’, ‘column’, ‘page’, ‘even-page’ or ‘odd-page’. The code was improved in V2, but still is strange. In particular the second `\cleardoublepage` seems ineffective. In my opinion, we should use a blank page or a double-blank page here.

```

1749 \def\jg@handle@breakafter{%
1750   \ifx\FObreakafter\att@page
1751     \clearpage
1752   \else \ifx\FObreakafter\att@oddpage
1753     \ifodd\c@page\cleardoublepage\else\clearpage\fi
1754   \else \ifx\FObreakafter\att@evenpage
1755     \ifodd\c@page\clearpage\else\cleardoublepage\fi
1756   \fi\fi\fi
1757 }
```

In principle, a break before a block should be interpreted in the same way as a break after. Note that here, we have a blank page.

```

1758 \def\jg@handle@breakbefore{%
1759   \ifx\FObreakbefore\att@page
1760     \penalty -\@M
1761   \else
1762     \ifx\FObreakbefore\att@oddpage
1763       \penalty -\@M
1764       \ifodd\c@page\else\BlankPage\newpage\fi
1765     \fi
1766 }
```

This is the start of an output block. It is not complicated. We call functions that specify how to align (justify) the text. If the switch `BlockGrab` is true, we put the text in a box with a given size. Note: We added `\@inlabelfalse` because the `\color` command says `\leavevmode` if this is true. This gives an empty line if a page break occurs because of an `\item`. We kill also `\FOid`. I’m not sure that this is useful, but the page head or foot should contain no anchor. Changes in V2: conditional part moved from before quadding to after quadding. Command `\Quadding` commented out.

```

1767 \def\FOOutputBlock{%
1768   \FOSetFont{output}%
1769   \c@inlabelfalse\let\FOId\c@empty
1770   \QuaddingStart
1771   \%Quadding
1772   \ifF0BlockGrab \FOBoxedBlock{\textwidth} \fi
1773 }

```

The end code is easy. If we have opened a grab block, we must close it.

```

1774 \def\FOEndOutputBlock{%
1775   \QuaddingEnd
1776   \ifF0BlockGrab \FOEndBoxedBlock \fi
1777   \par}

```

This is used at the start of a border block. If the border is solid and has non-zero width, we insert the `\hrule`.

```

1778 \def\F0BorderTop{%
1779   \ifdim\FOborderbeforewidth>\z@
1780   \ifx\FOborderbeforestyle\att@solid
1781     {\color{\FObordercolor}\hrule height \FOborderbeforewidth}%
1782   \fi
1783 }

```

This is used at the end of a border block. If the border is solid and has non-zero width, we insert the `\hrule`. Note: This may set the switch `F0BlockGrab` to true. This is very strange (isn't it too late?).

```

1784 \def\F0BorderBottom{%
1785   \ifx\FOborderafterstyle\att@solid

```

This will be used later. It redefines the behavior of space and end-of-line. The value of `white-space` can be ‘normal’, ‘pre’, or ‘nowrap’. Its effect is to specify some other properties; first `white-space-treatment`, that can be ‘ignore’, ‘preserve’, ‘ignore-if-before-linefeed’, ‘ignore-if-after-linefeed’, ‘ignore-if-surrounding-linefeed’; then `white-space-collapse` that can be ‘true’ or ‘false’; then `linefeed-treatment` can be ‘ignore’, ‘preserve’, ‘treat-as-space’, ‘treat-as-zero-width-space’; finally,

wrap-option can be ‘wrap’ or ‘no-wrap’. It is not clear to me if the code that follows has anything to do with the XSL/Format recommendations.

```
1806 \def\jg@activeview{%
1807   \ifx\fOwhitespace\att@pre\obeyspaces\obeylines\fi
1808   \ifx\fOwhitespacecollapse\att@false\obeyspaces\fi

```

This is what we do in the case of a normal block. The code was a bit simplified: We removed a reference to \Cx (always \relax), the code executed in case of tables in tables (this cannot happen), and the code that saves \FOid if a page is started here.

If we are in a list, three actions are taken: a) we evaluate the label, b) emit a \par and some vertical space (provided that this is allowed), and c) look at translation of spaces and new lines. In the general case, more actions are taken. If there is an attribute that says that we must change page we do it (this test was modified in V2). We emit a \par. If we must grab, we start a grab box. Otherwise we add some vertical space (note: a page break can occur here; in this case the label is on the wrong page; for this reason we moved the \F0label near the end). We define \leftskip, \rightskip and some other quantities. We execute action c) above.

Changes in V2: \unskip added before \par; \ifInInsertion test added; minus infinite penalty replaced by \newpage; test added: we change to normal font only if the parent is not \FOFootnoteBody.

```

## 4.15 Percentages

This command is a helper for percentage. If it is called with argument ‘`foo\relax%.\\@{A}{B}`’, and `foo` has no `%` character in it, then `#2` is a dot, the test is false, `B` is evaluated. If `foo` has the form `33.33%`, then the test is true, the number `33.33` is put in `\percentval` and `A` is evaluated.

```

1869 {\catcode`%=12
1870     \gdef\percenttest#1#2#3\@{\ifx#2\relax
1871         \def\percentval{#1}\expandafter\@firstoftwo
1872     \else
1873         \expandafter\@secondoftwo
1874     \fi}

```

We define here `\defpercentother`, a command that globally defines an active percent character to be `\percentother` that evaluates to a non-active percent character (in V1, the category code of the percent sign above was 13, and this trick was not needed). There is a little problem with this code: the old value of the percent character as an active character is never restored. In the case where the percent character was made active in order to typeset it, this piece of code is fine; otherwise, we might get unexpected results.

```

1875 {\catcode`%=12\relax
1876 \gdef\percentother{%

```

```

1877 }
1878 {\catcode`%=13\relax
1879 \gdef\defpercentother{\xdef{\percentother}}
1880 }

```

In version 1, percentages were computed using the first line shown here. In V2, we change the category code of the percent sign, so that the second line is used now.

```

1881 %%\expandafter\percenttest#1\relax%.@%
1882 %%\performpercent{#1}

```

The command `\performpercent` fully expands the argument as well as the percent sign. Result is put in a temporary command that is evaluated again.

```

1883 \gdef\performpercent#1{
1884   \defpercentother
1885   \edef\dopercent{\noexpand\percenttest#1\relax%.@%}
1886   \dopercent}

```

This takes an argument, a dimension or a percentage. In the case of a dimension, it is put in `\@tempdima`. Otherwise it is converted. Conversion is strange: Assume that the number is 33.33. We put 33.33pt in a skip register, divide this by 100, and use `\strip@pt`, a command that returns the value (without the unit, here 0.3333). This is then used as a multiplier for `\TableWidth`. The result is in `\SCALE`.

```

1887 \gdef\TablePercentToDimen#1{\performpercent{#1}
1888   {\@tempdimb\percentval pt\relax\divide\@tempdimb by 100
1889    \edef\SCALE{\strip@pt\@tempdimb}\global\@tempdima
1890      =\SCALE\TableWidth}{\global\@tempdima#1}}

```

Same code, but we use `\hsize` instead of `\TableWidth`. The result is in `\SCALE`.

```

1891 \gdef\PercentToDimen#1{\performpercent{#1}
1892   {\@tempdimb\percentval pt\relax\divide\@tempdimb by 100
1893    \edef\SCALE{\strip@pt\@tempdimb}\global\@tempdima
1894      =\SCALE\hsize}{\global\@tempdima#1}}

```

Same code, but we use `\Gin@nat@width`. We use the value of `\F0contentwidth`. The result is in `\WSCALE`, is used for `\setkeys{Gin}{width=something}`.

```

1895 \gdef\F0SetGWidth{\performpercent{\F0contentwidth}
1896   {\@tempdima\percentval pt\relax\divide\@tempdima by 100
1897    \edef\WSCALE{\strip@pt\@tempdima}\setkeys{Gin}%
1898      {width=\WSCALE\Gin@nat@width}}{\setkeys{Gin}{width=\F0contentwidth}}}

```

Same code, but we use `\Gin@nat@height` instead of `\TableWidth`. We use the value of `\F0contentheight`. The result is in `\HSCALE`, used for `\setkeys{Gin}{height=something}`.

```

1899 \gdef\F0SetGHeight{\performpercent{\F0contentheight}
1900   {\@tempdima\percentval pt\relax\divide\@tempdima by 100
1901    \edef\HSCALE{\strip@pt\@tempdima}\setkeys{Gin}%
1902      {height=\HSCALE\Gin@nat@height}}{\setkeys{Gin}{height=\F0contentheight}}}

```

Same idea. However, we divide `\f@size` by 100. The result is in `\F0fontsizefinal`.

```

1903 \gdef\PlayWithFSize#1{\@default\f@size pt
1904   \performpercent{#1}
1905     {\dimen@0.01\@default
1906      \multiply\dimen@\percentval\relax}{\dimen@#1}%
1907      \edef\F0fontsizefinal{\the\dimen@}}

```

Same code, but we use `\baselineskip` instead of `\TableWidth`. Result in `\dimen@`.

```

1908 \gdef\PlayWithShift{performpercent{\FOverticalalign}
1909   {\dimen@0.01\baselineskip\multiply\dimen@\percentval\relax}%
1910   {\dimen@\FOverticalalign}%
1911 %

```

## 4.16 Fonts

We show here some commands that deal with fonts. This is bit longish... This defines some values for the sizes.

```

1912 \expandafter\def\csname size-xx-small\endcsname{7pt}
1913 \expandafter\def\csname size-x-small\endcsname{8pt}
1914 \expandafter\def\csname size-small\endcsname{9pt}
1915 \expandafter\def\csname size-medium\endcsname{10pt}
1916 \expandafter\def\csname size-large\endcsname{14.4pt}
1917 \expandafter\def\csname size-x-large\endcsname{18pt}
1918 \expandafter\def\csname size-xx-large\endcsname{20pt}

```

This puts in `\FOfontsizefinal` a size (could be 10pt, 100% or medium).

```

1919 \def\computeFOfontSize{%
1920   \expandafter\ifx\csname size-\FOfontSize\endcsname\relax
1921     \PlayWithFontSize\FOfontSize
1922   \else
1923     \edef\FOfontsizefinal{\csname size-\FOfontSize\endcsname}%
1924   \fi}

```

The `mlnames.tex` file defines `\Family@foo`, for different values of `foo`, for instance monospace, sansserif, serif, or Arial, Helvetica, or Avant-Garde, New-Century-Schoolbook, or cmr, cmss, etc.

```

1925 \def\FOSetFont#1{%
1926   \FOSetHyphenation
1927   \edef\LaTeXshape{\csname Width@\FOfontstretch\endcsname
1928     \csname Weight@\FOfontweight\endcsname}%
1929   \ifx\LaTeXshape\empty\def\LaTeXshape{m}\fi
1930   \edef\fFamName{\FOfontfamily}%
1931   \edef\f@series{\LaTeXshape}%
1932   \edef\f@shape{\csname Posture@\FOfontstyle\endcsname}%
1933   \ifx\FOfontvariant\att@smallcaps \def\f@shape{sc}\fi
1934   \let\f@family\relax
1935   \@for\FOfoo:=\FOfontfamily\do{%
1936     \ifx\f@family\relax
1937       \expandafter\let\expandafter\f@family
1938         \csname Family@\FOfoo\endcsname
1939     \fi}%
1940     \ifx\f@family\relax
1941       \def\f@family{\csname Family@\Defaultx@fontfamily\endcsname}%
1942     \fi
1943   \FOSetFontSize
1944   \selectfont
1945   \ifx\FOcolor\empty \else \color{\FOcolor}\fi
1946 }

```

This command computes some parameters for font changing. If no `line-height` is given, we use the font size plus twenty percent.

```

1947 \def\FOSetFontSize{%
1948   \computeFOfontsize
1949   \ifx\FOlineheight\att@normal
1950     \atempdima\FOfontsizefinal
1951     \multiply\atempdima by 12
1952     \divide\atempdima by 10
1953     \set@fontsize\baselinestretch{\FOfontsizefinal}{\atempdima}%
1954   \else
1955     \set@fontsize\baselinestretch{\FOfontsizefinal}{\FOlineheight}%
1956   \fi}

```

Same code as above. However `\set@fontsize` is not executed, but saved, as well as its argument in the command `\FORestoreFontSize`.

```

1957 \def\FOSaveFontSize{%
1958   \computeFOfontsize
1959   \ifx\FOlineheight\att@normal
1960     \atempdima\FOfontsizefinal

2082 \def\Width@ultraexpanded{ux}

```

## 4.17 Links

The XSL/Format standard defines three attributes: target-presentation-context, target-processing-context, and target-stylesheet, but they are ignored. The code make use of a variable that is not defined. We removed the test. I don't understand these two `\let\xx\empty`, hence commented them out. Note: the code was modified in January 2007, using `\url` to typeset the argument; this removes overful hboxes for long URLs; however the `\urlstyle` has to be changed to 'same', so as to use the current font, and the `url` package has to be loaded with the 'obeyspaces' option, so as to keep spaces.

```

2083 \XMLElement{fo:basic-link}
2084   {
2085     {\xmlgrab}
2086   {

```

```

2087 \ifx\FOverticalalign\att@auto
2088   \let\FOverticalalign\FObaselineshift
2089 \fi
2090 \protectCS{\FOinternaldestination}%
2091 \protectCS{\FOexternaldestination}%
2092 \ifx\FOexternaldestination\@empty
2093   \hyperlink{\FOinternaldestination}{\FO@inlinesequence{#1}}%
2094   \% \let\FOinternaldestination\@empty %% JG
2095 \else
2096   \href{\FOexternaldestination}{\FO@inlinesequence{#1}}
2097   \% \let\FOexternaldestination\@empty %% JG
2098 \fi
2099 }

```

These are the attributes used above.

```

2100 \XMLNSAX{fo}{external-destination}{\FOexternaldestination}{}
2101 \XMLNSAX{fo}{internal-destination}{\FOinternaldestination}{}

```

## 4.18 Footnotes

Case of `<fo:footnote>mark text</fo:footnote>`. The specifications say that the first child is a `<fo:inline>` formatting object that gives the citation, and the second is a `<fo:footnote-body>`, containing the body of the note. In version V2, we handle the case where the footnote is in a table: since cells are evaluated twice, the command `\FOfoottext` has a meaning depending on the context. New in V2: `\FOplainfoottext` renamed to `\FOfoottext`.

```

2102 \XMLElement{fo:footnote}
2103   {}
2104   {\xmlgrab}
2105   {\FOSaveFontSize\xmltexttwochildren\FOplainfootmark\FOfoottext#1}
      This is transparent.
2106 \XMLElement{fo:footnote-body}
2107   {} {} {}
2108 \XMLname{fo:footnote-body}{\FOFootnoteBody}

```

This saves some parameters. All these `\global` prefixes are useless. Note that we move the content of the `\@labels` box, we do not copy it (said otherwise, the box is empty while typesetting the footnote). All these parameters have something to do with the `\item` command, whose code is shown above, so that I wonder if the easier solution would not be a complete rewrite of the `\item` command, without all these ugly hacks.

```

2109 \def\jg@save@footnote{%
2110   \xdef\Sav@FOListBlocks{\the\FOListBlocks}
2111   \global\let\sav@if@inlabel\if@inlabel
2112   \global\let\sav@if@nobreak\if@nobreak
2113   \global\let\sav@if@newlist\if@newlist
2114   \global\setbox\sav@labels\box@\labels
2115   \expandafter\global\expandafter\sav@everypar\expandafter{\the\everypar}
2116 }

```

This restores the parameters saved above. Question: is it safe to restore `\everypar`? Is it wise to do it globally?

```

2117 \def\jg@restore@footnote{%
2118   \global\FOListBlocks\Sav@FOListBlocks\relax

```

```

2119   \global\let\if@inlabel\sav@if@inlabel
2120   \global\let\if@nobreak\sav@if@nobreak
2121   \global\let\if@newlist\sav@if@newlist
2122   \global\setbox\@labels\box\sav@labels
2123   \expandafter\global\expandafter\everypar\expandafter{\the\sav@everypar}
2124 }

```

This modifies some commands that are saved above. The `\relax` tokens are useless. Same question as above for `\everypar`. Is global modification needed?

```

2125 \def\jg@set@footnote{%
2126   \F0ListBlocks0\relax
2127   \global\everypar{}\relax
2128   \F0inList0\relax
2129   \F0ListBodyfalse
2130   \InInsertiontrue
2131 }

```

The command that typesets footnotes is a modification of the standard L<sup>A</sup>T<sub>E</sub>X command, shown here. The command `\makefntext` is defined in a class file, it should typeset the argument, plus the mark found in `\makefnmark`. There are two major changes in the fotex implementation: no label is defined, and the mark is not printed (the text should start with a copy of the mark).

```

\long\def\@footnotetext#1{\insert\footins{%
  \reset@font\footnotesize
  \interlinepenalty\interfootnotelinepenalty
  \splittopskip\footnotesep
  \splitmaxdepth \dp\strutbox \floatingpenalty \z@MM
  \hsize\columnwidth \parboxrestore
  \protected@edef\@currentlabel{%
    \csname p@footnote\endcsname\@thefnmark
  }%
  \color@begingroup
  \makefntext{%
    \rule\z@\footnotesep\ignorespaces#1\finalstrut\strutbox}%
  \color@endgroup}%

```

This is now the code.

```

2132 \long\def\F0plainfoottext#1{%
2133   \insert\footins{\relax
2134     \reset@font\footnotesize
2135     \F0RestoreFontSize
2136     \size@update
2137     \interlinepenalty\interfootnotelinepenalty
2138     \splittopskip0pt\relax
2139     \splitmaxdepth \dp\strutbox \floatingpenalty \z@MM
2140     \hsize\columnwidth\parboxrestore
2141     \color@begingroup
2142     \jg@save@footnote
2143     \jg@set@footnote
2144     #1%
2145     \ifhmode\nobreak\fi
2146     \jg@restore@footnote \relax
2147     \color@endgroup}%
2148 }

```

We define here two other commands. The first one is used in the first pass of a table: the text of the footnote is ignored. The other one is used for the second pass, where the text and the typesetting command is put in a token register. Note: we have seen in section 2.7 how to add tokens at the end of a token list  $\text{\T}$ . The idea is to put the value of the token list in a command  $\text{\t}$  defined via  $\text{\edef}$ , then to fill  $\text{\T}$  with  $\text{\t}$  and additional material (for instance  $\text{\W}\{\#\#1\}$ ). For some strange reason, the command  $\text{\W}$  is inserted in  $\text{\t}$ , hence must be preceded by  $\text{\noexpand}$ .

```
2149 \def\FOnofoottext#1{  
2150  
2151 \def\FOboxedfoottext#1{  
2152   \edef\boxedfootnotetext{\the\BoxedFootnotes\noexpand\FOplainfoottext} %  
2153   \global\BoxedFootnotes=\expandafter{\boxedfootnotetext{\#1}}%  
2154 }
```

Useful function. It inserts a vertical rule, whose vertical dimensions are those of the  $\text{\strutbox}$ .

```
2155 \def\start@strut{  
2156   \vrule height \ht\strutbox depth \dp\strutbox width \z@\relax  
2157 }
```

Bootstrap code. We declare a token list that contain the copy of the  $\text{\everypar}$ , a box that contains a copy of the unprocessed item labels. The command with a long name holds the name of a XSL region: the one between normal text and a footnote.

```
2158 \let\FOfoottext\FOplainfoottext  
2159 \newtoks\sav@everypar  
2160 \newbox\sav@labels  
2161 \XMLstringX\att{xsl@footnote@separator}>xsl-footnote-separator</>
```

Changes in V2: the command  $\text{\@makecol}$  was redefined, without the line that sets  $\text{\@elt}$  to  $\text{\relax}$ . This is strange.

## 4.19 Inline material

Handling of  $\langle\text{fo: inline } att\rangle body\langle/\text{fo: inline}\rangle$ . We call one of two alternatives, depending on whether the border is solid or not. As usual, we evaluate ‘thin’, ‘thick’ or ‘medium’.

```
2162 \XMLElement{fo:inline}  
2163   {}  
2164   {\xmlgrab}  
2165   {  
2166     \ifx\FOverticalalign\att{auto} \let\FOverticalalign\FObaselineshift \fi  
2167     \FOlabel  
2168     \ifx\FOborderstyle\att{solid}  
2169       \interpretwidth  
2170       \FOboxedsequence{\#1} %  
2171     \else  
2172       \FO@inlinesequence{\#1} %  
2173   \fi}
```

Helper function for letter spacing added in V2. The recommendation says that the attribute `letter-spacing` is either ‘normal’, a  $\langle\text{length}\rangle$  or a  $\langle\text{space}\rangle$  (this is something like a T<sub>E</sub>X glue, with conditionality and precedence). This handles only the case of a length, using the  $\text{\sodef}$  command of the soul package. Note that the last three arguments of the command are glues (the first one is a font switch, unless empty), so that the case of  $\langle\text{space}\rangle$  could be implemented. The last two parameters define inter-word spacing. Are the values given here the good ones? The test seems strange to me: what if the command is already defined with a different value of the attribute?

```

2174 \def\jg@so#1{%
2175   \ifx\FOletterspacing\att@normal
2176     \def\pre@sequence{{#1}}%
2177   \else
2178     \def\pre@sequence{%
2179       \@ifundefined{thisso}
2180         {\sodef>thisso{}{\FOletterspacing}{.4em}{.5em}}%
2181         {}%
2182       {\thisso{#1}}}%
2183   \fi
2184 }

```

Second helper function. This applies a function depending on \FOtextdecoration to the \FOlabel and text computed above.

```

2185 \jg@apply@deco{%
2186   \csname DECO@\FOtextdecoration\endcsname{\FOlabel\pre@sequence}

```

Normal (non-boxed) inline sequence. We take into account three attributes: letter spacing, decoration, and vertical alignment. The alignment can be ‘baseline’, this is the normal behavior; it can be ‘super’ or ‘sub’, case where we raise or lower using special command; otherwise alignment is a dimension (or a percentage), and we use \raisebox to raise the box. Other possibilities, not yet implemented, are ‘middle’ (equivalent of \vcenter in T<sub>E</sub>X), ‘text-top’, ‘text-bottom’, ‘top’, or ‘bottom’.

We use \csname for the decoration. Question: do we really need the \FOlabel command after the \csname? Maybe we could put it *after* the last \fi.

```

2187 \def\FO@inlinesequence#1{%
2188   \FOSetFont{normal}%
2189   \jg@so
2190   \ifx\FOverticalalign\att@baseline
2191     \jg@apply@deco
2192   \else \ifx\FOverticalalign\att@super
2193     \textsuperscript{\jg@apply@deco}%
2194   \else \ifx\FOverticalalign\att@sub
2195     \textsubscript{\jg@apply@deco}%
2196   \else
2197     \PlayWithShift
2198     \raisebox{\dimen@}{\jg@apply@deco}%
2199   \fi\fi\fi
2200 }

```

The original code uses two booleans \ifFOSuper and \ifFOSub. They are never defined, hence we removed the code that uses them. However, the code should be the same as before, with a frame. So, is this a bug? Letter spacing should be added here also.

```

2201 \def\FOboxedsequence#1{%
2202   \FOSetFont{normal}%
2203   \ifx\FOborderwidth\empty\else\interpretwidth\fboxrule\FOborderwidth\fi
2204   \ifx\FOverticalalign\att@baseline
2205     \fbox{\csname DECO@\FOtextdecoration\endcsname{\FOlabel#1}}%
2206   \else
2207     \PlayWithShift \fbox{\raisebox{\dimen@}{\FOlabel#1}}%
2208   \fi}

```

This declares the attribute.

```

2209  \XMLNSAX{fo}{text-decoration}{\FOtextdecoration}{none}
2210  \XMLNSAX{fo}{baseline-shift}{\FObaselineshift}{baseline}
2211  \XMLstringX{att@sub}>sub</>
2212  \XMLstringX{att@super}>super</>
2213  \XMLstringX{att@baseline}>baseline</>
```

The following decorations are known. Notice the first: if no decoration is given, the argument is typeset, without the braces. The recommendation says that, for each foo in ‘blink’, ‘underline’, ‘overline’, ‘strike-out’, there is also no-foo; this is not implemented.

```

2214  \def\DECO@{\@firstofone}
2215  \def\DECO@blink{\uwave}
2216  \def\DECO@underline{\uline}
2217  \expandafter\def\csname DECO@line-through\endcsname{\sout}
2218  \def\DECO@overline{\oline}
2219  \def\oline#1{$\overline{\mbox{#1}}$}
```

## 4.20 Floats and images

Support for .gif format. Is this needed?

```

2220  \g@addto@macro\Gin@extensions{,.gif}
2221  \namedef{\Gin@rule@.gif}{\#1{{png}{.png}{`giftopng #1}}}
```

The fotex file defines Gin/scale in the same way as graphicx.sty. We do not repeat the code here.

```
2222  \define@key{Gin}{scale}{ ... }
```

Comment by S. Rahtz: “Taken from Heiko Oberdiek’s *epstopdf.sty* but the redefinitions need to be global”. This allows on the fly conversions from one image type to another. For instance, this may call *giftopng*.

```

2223  \global\let\orgGin@setfile\Gin@setfile
2224  \global\def\Gin@setfile#1#2#3{%
2225    \if`@\car #3\relax@nil
2226      \let\Gin@base\filename@base
2227      \immediate\write18{\@cdr #3\@empty@nil}%
2228      \orgGin@setfile{#1}{#2}{\filename@base #2}%
2229    \else
2230      \orgGin@setfile{#1}{#2}{#3}%
2231    \fi}
```

This is trivial.

```

2232  \XMLelement{fo:float}
2233    {\XMLattributeX{float}{\FOfloat}{float}}
2234    {\ifx\FOfloat\att@none \begin{figure}[!htp] \else \begin{figure} \fi
2235      \FOlabel}
2236    {\end{figure}}
```

The following is a bit more complicated. One problem is that we have to merge *content-height* and *height*, the same for the width. Question: is this the desired result? In order to make the code easier to understand, we have added three auxiliary functions. The first function sets *\FOcontentheight* and *\FOcontentwidth* to the values of *\FOheight* and *\FOwidth*, unless both values are ‘auto’.

```

2237  \def\jg@merge@aux{%
2238    \ifx\FOwidth\att@auto
```

```

2239      \ifx\FOheight\att@auto          \relax
2240      \else
2241          \def\FOcontentheight{\FOheight}%
2242          \def\FOcontentwidth{\auto}%
2243          \fi
2244      \else
2245          \def\FOcontentwidth{\FOwidth}%
2246          \ifx\FOheight\att@auto
2247              \def\FOcontentheight{\auto}%
2248          \else
2249              \def\FOcontentheight{\FOheight}%
2250          \fi
2251      \fi
2252 }

```

These commands perform a non trivial action if the value of the attribute is not ‘auto’. It can be ‘scale-to-fit’ or a dimension, or percentage (using code shown above).

```

2253 \def\jg@mergeW{%
2254     \ifx\FOcontentwidth\att@scaleofit
2255         \setkeys{Gin}{width=\hsize}%
2256     \else
2257         \ifx\FOcontentwidth\att@auto\else\FOSetGWidth\fi
2258     \fi
2259 }
2260 \def\jg@mergeH{%
2261     \ifx\FOcontentheight\att@scaleofit
2262         \setkeys{Gin}{height=\vsize}%
2263     \else
2264         \ifx\FOcontentheight\att@auto\else\FOSetGHeight\fi
2265     \fi
2266 }

```

This piece of code considers `text-align` but we could also take into account `display-align`, that can be ‘before’, ‘after’ or ‘center’ (as well as ‘auto’). Note that `text-align` can be ‘start’ or ‘end’ as well.

If `scaling` is ‘uniform’, the aspect ratio should be preserved; is the default value of the `Gin` variable true?

```

2267 \XMLElement{fo:external-graphic}
2268 {
2269     \XMLAttributeX{content-height}{\FOcontentheight}{auto}
2270     \XMLAttributeX{content-width}{\FOcontentwidth}{auto}
2271 }
2272 {
2273     \jg@filetest
2274     \jg@merge@aux
2275     \jg@mergeW
2276     \jg@mergeH
2277     \def\aligntype{center}
2278     \ifthenelse{\equal{\FOtextalign}{right}}{\def\aligntype{flushright}}{}
2279     \ifthenelse{\equal{\FOtextalign}{left}}{\def\aligntype{flushleft}}{}
2280     \def\Picscaled{\begin{\aligntype}%
2281         \includegraphics{\FOsrcname}\end{\aligntype}}
2282     \ifx\FOscaling\att@uniform\else\setkeys{Gin}{keepaspectratio=false}\fi

```

```
2283     \ifx\FOborderstyle\att@solid\fbox{\Picsscaled}\else\Picsscaled\fi  
2284     }  
2285     {}
```

Attributes used here.

```
2286 \XMLNSAX{fo}{scaling}{\FOscaling}{uniform}
2287 \XMLNSAX{fo}{height}{\FOheight}{auto}
2288 \XMLstringX\att@scaleofit<>scale-to-fit</>
2289 \XMLstringX\att@uniform<>uniform</>
```

This makes the string canonical. This is used in some places; it has an alternate name elsewhere.

```
2290 \def\protectCS{\%  
2291 \begingroup  
2292 \utfeight@protect@chars  
2293 \xdef\F0tempCS{\#1}\%  
2294 \endgroup  
2295 \let#1\F0tempCS\%
```

This function does something if the argument starts with ‘url’. Otherwise, it removes a prefix of the form ‘file:///’ or ‘file:’. The result is in \F0srcname.

These lines were added instead of lines 2307 and 2208. Guess why.

Version with all the arguments.

This function puts foo in \FOsrcname if the argument is url(file://foo) or url(file:foo) or url(foo) (the prefix ‘url(‘ has already been removed).

```
2319 \def\f0urlfiletest{\#1\#2\#3\#4\#5\#6\#7\#8}{%
2320   \def\f0tempa{\#1\#2\#3\#4\#5\#6\#7}{%
2321   \def\f0tempb{\#1\#2\#3\#4\#5}{%
2322   \ifx\f0file\f0prefix\f0tempa
2323     \xdef\f0srcname{\#8}{%
```

```

2324   \else
2325     \ifx\@tempb\file@shortprefix
2326       \xdef\F0srcname{\#6\#7\#8}%
2327     \else
2328       \xdef\F0srcname{\#1\#2\#3\#4\#5\#6\#7\#8}%
2329     \fi \fi}

```

These are the strings needed by the function above.

```

2330 \XMLstring\file@urlprefix<>url(</>
2331 \XMLstring\file@prefix<>file://</>
2332 \XMLstring\file@shortprefix<>file:</>

```

## 4.21 Markers

We consider here a list of the form X<sub>1</sub>Y<sub>1</sub>X<sub>2</sub>Y<sub>2</sub>...X<sub>n</sub>Y<sub>n</sub>. The list ends with X<sub>n</sub> being \relax. This command puts in the token list \toks@ all pairs {X<sub>i</sub>} {Y<sub>i</sub>} for which X<sub>i</sub> is not equal to the value of the attribute marker-class-name. The name of the command is misleading; after this command has been evaluated, we are ready to add a marker.

```

2333 \gdef\F0addmarker#1#2{%
2334   \ifx\relax#1
2335   \else
2336     \def\F0temp{\#1}%
2337     \ifx\F0temp\F0markerclassname
2338       \else \toks@\expandafter{\the\toks{\#1}{\#2}} \fi
2339     \expandafter\F0addmarker
2340   \fi}

```

Handling of <fo:marker marker-class-name=*X*>*mark*</fo:marker>. We consider the content of \F0marks, apply the command defined above, then add a new pair at the end; the pair is defined by *X* and *mark*. We copy the token list into the \F0marks command (using full expansion, assignment is global), and then put it in a T<sub>E</sub>X mark.

```

2341 \XMLelement{fo:marker}
2342 {}
2343 {\xmlgrab}
2344 {\toks@{}%
2345   \expandafter\F0addmarker\F0marks\relax{}%
2346   \toks@\expandafter{\the\expandafter\toks@\expandafter{\F0markerclassname{\#1}}%
2347   \xdef\F0marks{\the\toks@{}%
2348   \mark{\F0marks}}}

```

Here we assume that the list is terminated by a double \relax. The command finds and typesets the value associated to \F0thisretrieveclassname. In fact, we assume that X<sub>i</sub> is in #1, Y<sub>i</sub> in #2. If the first argument is \relax, this is the end of the list, and we are done. If it is not the desired marker, we continue. Otherwise, we call a command that reads everything up to the double \relax at high speed. This will first read #2, this is Y<sub>i</sub> with a pair of additional braces that will disappear as argument #1 of the next routine. It will then read \fi, two tokens, a second \fi and the list. The two \fi tokens are read again.

```

2349 \gdef\F0getmarker#1#2{%
2350   \ifx\relax#1
2351   \else
2352     \def\F0temp{\#1}%
2353     \ifx\F0temp\F0thisretrieveclassname

```

```

2354     \F0markergobble{\#2}%
2355     \fi
2356     \expandafter\FOgetmarker
2357     \fi}
2358 \gdef\FOmarkergobble#1#2\relax\relax{\fi\fi#1}

```

Handling of `<fo:retrieve-marker retrieve-class-name=X retrieve-position=Y/>`. We fetch one of the marks (`\firstmark` or `\botmark`), and extract what is needed. Changes in V2: commands `\FirstOnPage` and `\LastOnPage` replaced by others with longer names, same value; `\topmark` replaced by `\firstmark`

```

2359 \XMLElement{fo:retrieve-marker}
2360 {}
2361 {\xmlgrab}
2362 {\begingroup
2363   \utfeight@protect@chars

## 4.22 Page numbers and anchors

The command `\FOlabel` will be explained later, it defines the anchor associated to a label A. This defines two quantities: a static and a dynamic one. If a L<sup>A</sup>T<sub>E</sub>X file contains a `\pageref` command, associated to a label A, then the printed document will contain some number, say 17, we call this the static quantity associated to the label; this number is written in the auxiliary file, and read at the start of the job, allowing forward references. If you read the document using a computer (in dvi, PostScript, or Pdf format), it can happen that the region containing the number is active, and you can click on it. What happens exactly depends on the software used, and is controlled by the `\hyperref` package; we call this the dynamic part. It happens that the static part is formed of two token lists in standard L<sup>A</sup>T<sub>E</sub>X, five lists when using the hyperref package. These are in the command `\r@A`. The `\pageref` command extracts the second item in the list.

The XSL/Format equivalent of `\pageref` is a `<fo:page-number-citation>` defining the static part, in a `<fo:basic-link>` defining the dynamic part. These elements have an attribute X and Y, containing the identification of the anchor. The attribute names are different, but the values

are the same. The code shown here makes the assumption that the static part is used only for getting the correct page number. Hence, all fields but the second are empty, and all we need to do is evaluate the whole thing, it is in \r@A for the anchor A.

```

2383 \XMLElement{fo:page-number-citation}
2384   {\XMLAttributeX{ref-id}{\FOrefid}{[]}}
2385   {}
2386   {\fopagecitation}
2387 \%def\fopagecitation{\pageref{\FOrefid}}
2388 \def\fopagecitation{\csname r@\FOrefid\endcsname}
```

Handling of <fotex:sort>...</fotex:sort>. The content is a sequence of page-number-citation elements; we want to typeset the numbers, in increasing order, removing duplicates, and compacting them. The idea is the following: We redefine \fopagecitation, the command that handles the citations, it will construct a sorted list. When the end tag is seen, we shall compact and print the list.

```

2389 \XMLElement{fotex:sort}
2390   {\XMLAttributeX{range-char}{\FOrangechar}{\textendash}}
2391   {\let\fopagecitation\fosortpagecitation
2392     \global\sorttoks{}}
2393   {\global\sortcount-2\let@\elt\focompress@elt
2394     \let\fosep@\empty
2395     \let\foheld\relax
2396     \the\sorttoks
2397     \ifx\foheld\relax\else\FOrangechar\fi
2398     \foheld}
```

We are faced here with the following problem: insert a number in an ordered list (increasing order). Assume that the list contains  $X_1, X_2, X_3$ , etc., and the number to insert is  $Y$ . The idea is to consider each  $X_i$ , renaming it locally  $X$ . There are three cases to consider. If  $X < Y$ , it is too early, if  $X = Y$  we do nothing, if  $X > Y$  we insert  $Y$  here. Note that, if  $X_i > Y$ , then  $X_{i+1} > Y$ . As a consequence, we shall replace  $Y$  by  $\infty$  after insertion. At the end of the loop, we can consult the value of  $Y$ : if it is not  $\infty$ , we have to insert it at the end.

In practice, we proceed as follows. First, each  $X_i$  is of the form \elt{3} or \elt{12}. These quantities are in the token list \sorttoks. We shall see in a minute how to evaluate this list in such a way that, at the start of the evaluation, the list is empty. Moreover we change the meaning of \elt to \fosort@elt. The quantity  $Y$  is in the counter \sortcount. In the case  $X < Y$ , we have to re-insert \elt{X} in the list (line 2408). In the case  $X > Y$ , we insert \elt{Y} and \elt{X} in the list. The non trivial point is to evaluate  $Y$  (there is no problem for  $X$ , since this is in #1), this requires four \expandafter commands on lines 2403 and 2404. Remember: since \sorttoks is a reference to a token list, if you say \global\sorttoks\foo, then \foo is expanded, but the tokens in the list are not. Here we have \expandafter instead of \foo, so that the \the after the brace is expanded. Since \the fully expands what follows, its effect is first to expand the \expandafter (and as a consequence the next \the) and second, to replace \sorttoks by its value (this is a bit unusual).

```

2399 \newcount\sortcount
2400 \newtoks\sorttoks
2401 \def\fosort@elt#1{%
2402   \ifnum#1>\sortcount
2403     \global\sorttoks\expandafter{\the\expandafter\sorttoks\expandafter\@elt
2404       \expandafter{\the\sortcount}\@elt{#1}}%
2405   \global\sortcount\maxdimen
2406   \else
```

```

2407     \ifnum#1<\sortcount
2408     \global\sorttoks\expandafter{\the\sorttoks\@elt{#1}}%
2409     \fi
2410 \fi}

```

The `\fosortpagecitation` is used to add a page reference into a sorted list. Assume that `\label{foo}` has been executed somewhere. This defines `\r@foo`, to be a command that can be used by `\ref` or `\pageref`. In what follows, we want the number used by `\pageref`. For the case where `\pageref` is used before `\label`, L<sup>A</sup>T<sub>E</sub>X provides a mechanism in which information is printed in the auxiliary file, and read at the start of the job (and also at the end; sometimes you will see “labels may have changed”). If you compile a file for the first time, the `\r@foo` command is undefined, and `\pageref` has to consider this case; this is the reason why we cannot use this command directly. We shall assume here that the hyperref package has been loaded, so that, when defined, `\r@foo` contains a list of five items, the second one being the page number. On line 2413 we call the command that returns this second argument. On the line that follows, we insert five `\relax` tokens, in order to make sure that there are at least five tokens. On the preceding line, there are three `\expandafter`: if we had only one, the effect would be to replace `\csname` by `\r@foo`; since we have three, the effect is to replace it by the value of `\r@foo`. There is a little trick. If the command is undefined, `\csname` sets `\r@foo` to `\relax`, and `\@secondoffive` produces `\relax`. In some cases, the command might produce some junk. We can avoid the “missing number” error by inserting a zero in front of the token list. We get rid of the junk by evaluating everything else in a `\hbox`, that is copied in `\box0`, and discarded. Thus, this converts our page number in an integer, stored in `\sortcount`.

Our second job is then to sort. What we do is: we define `\sortoks` to be the empty token list, with an `\expandafter` that puts the content of the token list in the input stream. This means that we evaluate this token list in a context where the list is empty. Evaluating the list may have as side effect to insert this new element and replace the value by `\maxdimen`. Otherwise, we must insert it at the end.

```

2411 \def\fosortpagecitation{%
2412   \setbox0\hbox{\global\sortcount=0\expandafter\expandafter\expandafter
2413   \@secondoffive\csname r@\F0refid\endcsname
2414   \relax\relax\relax\relax\relax}%
2415   \let\@elt\fosort@elt
2416   \global\sorttoks\expandafter{\expandafter}\the\sorttoks
2417   \ifnum\sortcount<\maxdimen
2418   \global\sorttoks\expandafter{%
2419     \the\expandafter\sorttoks\expandafter\@elt\expandafter{\the\sortcount}}%
2420 \fi}

```

Let's compress the list. Consider the case where we have a list of numbers, say 1, 2, 3, 6, 8, and 9. We apply the next command to every element, in order. We assume that our numbers are positive, the counter is initialized to  $-2$ , so that the initial test is false. This means that the first number, 1, is typeset and remembered. The original code was wrong. We give here a correct version.

```

2421 \gdef\focompress@elt#1{%
2422   \global\advance\sortcount\@ne
2423   \ifnum#1=\sortcount\relax
2424     \edef\foheld{\#1}%
2425   \else
2426     \ifx\foheld\relax\else\FOrangechar\fi
2427     \foheld\fosep#1\relax
2428     \let\foheld\relax
2429 \fi

```

```
2430 \global\sortcount#1\relax
2431 \def\fosep{, }
```

This converts a XSLT format into a L<sup>A</sup>T<sub>E</sub>X command. There are examples in chapter 7 of this feature. It can be used to convert a section reference (defined by some numbers) into something like IV.7-2. If you say `format = '[1.a]'`, and if the numbers are 4 and 2, the result is '`[4.b]`'. If we have only one number, the result is '`[4]`'. This mechanism is very complicated. We need only to typeset pages numbers (everything else is done by the XSLT processor), so that only one number has to be converted.

```
2432 \expandafter\let\csname Format-1\endcsname\@arabic
2433 \expandafter\let\csname Format-i\endcsname\@roman
2434 \expandafter\let\csname Format-I\endcsname\@Roman
2435 \expandafter\let\csname Format-a\endcsname\@alph
2436 \expandafter\let\csname Format-A\endcsname\@Alpha
```

Handling of `<fo:page-number/>`. We call a command that formats the page number.

```
2437 \XMLElement{fo:page-number}
2438   {}
2439   {}
2440   {\expandafter\FOgeneratePage\FOformat\@null}
```

The call to the `\FOgeneratePage` command is a bit strange. The arguments #1#2 is the result of the expansion of the format. Hence, #1 is the first character of the format. This piece of code works if the format has the form '`1.`': it applies `\@arabic` to the page number and puts a dot after it. For later use, we put the interesting part in a command.

```
2441 \def\FOgeneratePage#1#2\@null{\csname Format-#1\endcsname{\c@page}#2}
2442 \def\jgF0label#1{\csname Format-#1\endcsname{\c@page}}
```

We define now `\F0label`. The idea of the command is to create a label associated to the current id, stored in `\FOid`, provided that this is not empty (the command may be called more than once for the same id, but only one label will be created). We do not execute the `\label` command, but instead, we write directly something in the `.aux` file, and create an anchor. As explained above, what we print is the command `\newlabel`, followed by the id, followed by a list of five items, all empty but the second one, containing the formatted page number. Note: the sort-page-citation shown above assumes that integer values are used,

The implementation was modified. Originally, the quantity printed on the `.aux` file was the same as the body of `<fo:page-number>`. The trouble is that all quantities in the `\write` command are expanded; thus `\@arabic` is expanded; its value is `\number`, so that the current page number (from `\c@page`) is used. This is wrong. The `\protected@write` command redefines temporarily `\thepage` to be `\relax`, so that, in the case of `\label`, the page number is not evaluated (it will be later, when the page is shipped out). We corrected this in the following way. We add a local redefinition of `\jgF0label` to `\relax`. As a consequence, the `\write` will store the command and the value of the format attribute, the command will be expanded later. There is no need to this `\@null` hacking.

```
2443 \def\F0label{%
2444   \ifx\@empty\FOid\else
2445     \obspack
2446     \protected@write\mainaux{\let\jgF0label\relax}%
2447     {\string\newlabel{\FOid}{}{\jgF0label\FOformat}{}{}{}}
2448   \espack
2449   \hyper@anchor{\FOid}{\relax}%
2450   \global\let\FOid\@empty
2451 }
2452 }
```

## 4.23 Other elements

The fotex.sty file defines a command \@declaredcolor that is unused. It defines this one:

```

2453 \def\HTMLColor#1#2#3#4#5#6#7#8{%
2454   \definecolor{#1}{RGB}{#3#4, "#5#6, "#7#8}}
      This predefines some colors.
2455 \HTMLColor{aqua}.00FFFF
2456 \HTMLColor{black}.000000
2457 \HTMLColor{blue}.0000FF
2458 \HTMLColor{fuchsia}.FF00FF
2459 \HTMLColor{gray}.808080
2460 \HTMLColor{green}.008000
2461 \HTMLColor{lime}.00FF00
2462 \HTMLColor{maroon}.800000
2463 \HTMLColor{navy}.000080
2464 \HTMLColor{olive}.808000
2465 \HTMLColor{purple}.800080
2466 \HTMLColor{red}.FF0000
2467 \HTMLColor{silver}.C0C0C0
2468 \HTMLColor{teal}.008080
2469 \HTMLColor{white}.FFFFFF
2470 \HTMLColor{yellow}.FFFF00
2471 \definecolor{orange}{cmyk}{0,0.61,0.87,0}

```

Leaders: This might produce `-----.....` in the case where the style is dashed, or dotted, or if the thickness is 1pt. If the width is zero, we emit the leader command, otherwise put it in a hbox of the desired width.

```

2472 \XMLElement{fo:leader}
2473   {}
2474   {
2475     \leavevmode
2476     \ifx\FOleaderpattern\leader@pattern@rule

## Chapter 5

# Converting XML to XML

This chapter, and the next one, describes three types of style sheets: they convert XML to XML, to XSL/Format and HTML. Originally, in 2002 and 2003, the XML files created by Tralics were used directly for production of the HTML and Pdf version, but in 2004, a new DTD was designed for the Raweb. The name of this new DTD was unclear for a long time; it is now ‘raweb2.dtd’ and the old name is ‘raweb3.dtd’ (the 3 here is for 2003). We shall explain here the style sheets that convert from the old DTD to the new one, and from this to HTML; we shall also explain the style sheets that convert from the old DTD to XSL/Format (those for the new one are similar).

The style sheets for converting into XSL/Format are adaptations by José Grimm of the TEI code (by Sebastian Rahtz). These are part of the Tralics distribution. Other files were written by J. Grimm (conversion to HTML) or Tahia Benhaj Abdellatif (conversion to XML) and maintained by Marie-Pierre Durolet and Bruno Marmol. The Tralics files have a Copyright notice that looks like this:

```
<!-- Copyright Inria 2003-2004 Jose Grimm. This file is an adaptation of
files from the TEI distribution. See original Copyright notice below.
-->
```

The “original Copyright notice” is given here:

```
<!--
Copyright 1999-2001 Sebastian Rahtz/Oxford University
<sebastian.rahtz@oucs.ox.ac.uk>
```

Permission is hereby granted, free of charge, to any person obtaining a copy of this software and any associated documentation files (the “Software”), to deal in the Software without restriction, including without limitation the rights to use, copy, modify, merge, publish, distribute, sublicense, and/or sell copies of the Software, and to permit persons to whom the Software is furnished to do so, subject to the following conditions:

The above copyright notice and this permission notice shall be included in all copies or substantial portions of the Software.

```
-->
```

Let’s consider an example. This is the start of a document created by Tralics:

```
<?xml version='1.0' encoding='iso-8859-1'?>
<!DOCTYPE raweb SYSTEM 'raweb3.dtd'>
<!-- translated from latex by tralics 2.4-->
```

```
<raweb language='english' creator='Tralics version2.4' year='2004'>
<accueil isproject='false' html='apics'>
```

Two years later, the team has become a project, and the header is:

```
<!-- translated from latex by tralics 2.8.1-->
<raweb language='english' creator='Tralics version 2.8.1' year='2006'>
<accueil isproject='true' html='apics'>
```

This is the start of the translation to the new DTD:

```
<?xml version="1.0" encoding="iso-8859-1"?>
<!--translated from old xml 2003 by with 2XMLvalideDTD2.xsl-->
<!DOCTYPE raweb PUBLIC "-//INRIA//DTD Raweb 2" "raweb2.dtd">
<raweb xmlns:html="http://www.w3.org/1999/xhtml" xml:lang="en" year="2006">
  <identification isproject="true" id="apics">
    <shortname>Apics</shortname>
```

There is a second style sheet that adds ids to all elements. The resulting file starts like this:

```
<?xml version="1.0" encoding="iso-8859-1"?>
<!DOCTYPE raweb SYSTEM "raweb.dtd">
<raweb xmlns:html="http://www.w3.org/1999/xhtml"
       xmlns:xlink="http://www.w3.org/1999/xlink" id="id2243496"
       xml:lang="en" year="2004">
  <identification id="apics" isproject="false">
    <shortname id="id2267539">apics</shortname>
```

In 2006, ‘SYSTEM’ was replaced by ‘PUBLIC’, and ids are added only when needed.

```
<?xml version="1.0" encoding="iso-8859-1"?>
<!DOCTYPE raweb PUBLIC "-//INRIA//DTD Raweb 2" "raweb2.dtd">
<raweb xmlns:html="http://www.w3.org/1999/xhtml"
       xmlns:xlink="http://www.w3.org/1999/xlink"
       xml:lang="en" year="2006">
  <identification id="apics" isproject="true">
    <shortname>Apics</shortname>
```

Note the following details: Tralics uses simple quotes when it outputs its tree; the XSLT processor used by the Raweb uses double quotes; in the style files random values are used. In this example the output of the XSLT processor is ‘indented’, this is an option that depends on the style sheet. Tralics never indents.

## 5.1 Converting the XML to the new DTD

All files start like this, we shall not repeat this line.

```
1  <?xml version="1.0" encoding="iso-8859-1" ?>
```

The root element here is `<xsl:transform>`; in some other files, it can be `<xsl:stylesheet>`, this is the same. We declare the namespaces. The ‘html’ namespace is not used here.

```
2  <xsl:transform
3    xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0"
4    xmlns:xlink="http://www.w3.org/1999/xlink"
5    xmlns:html="http://www.w3.org/1999/xhtml"
6    exclude-result-prefixes="xlink">
```

We use an auxiliary file for the bibliography; this will be defined in the next section.

```
7  <xsl:import href="2XMLvalideDTD2-biblio.xsl"/>
```

The style sheet contains this line, but it is useless since we will use `<xsl:document>`.

```
8 <xsl:output method='xml' doctype-system='raweb2.dtd' indent='yes'
9   encoding='iso-8859-1'/>
```

Spaces are removed in some elements, listed here. The list contains a single name, `<UR>`.

```
10 <xsl:strip-space elements="UR"/>
```

The root of the Raweb is the `<raweb>` element. Its children are `<accueil>` (that gives some information about the team; this is used to produce a title page<sup>1</sup>), `<moreinfo>` (this is optional, it is a short piece of text, annexed to a section, or the whole document), `<composition>` (this describes the members of the team), `<presentation>`, `<fondements>`<sup>2</sup>, `<domaine>`, `<logiciels>`<sup>3</sup>, `<resultats>`, `<contrats>`, `<international>`, `<diffusion>` (these eight elements are called ‘sections’, they have the same structure and contain text, that can be divided into subsections, etc.), and `<biblio>` (this is the bibliography).

The table of contents of the Raweb has ten entries: Members, Overall Objectives, Scientific Foundations, Application Domains, Software, New Results, Contracts and Grants with Industry, Other Grants and Activities, Dissemination, Bibliography. Each entry comes from one of these elements, except `<accueil>` and `<moreinfo>`, that play a special role. In particular the `html` attribute of `<accueil>` is the Team’s name in lower case ASCII 7bits. This is also the name of the source file, and a prefix for output files. We store in `$LeProjet` this name<sup>4</sup>.

```
11 <xsl:variable name="LeProjet" select="/raweb/accueil/@html"/>
```

The `<raweb>` element has two important attributes, `language` and `year`. We put in the variable `$year` this quantity with a default value of 2004.

```
12 <xsl:variable name="year">
13   <xsl:choose>
14     <xsl:when test='/raweb/@year'><xsl:value-of select="/raweb/@year"/></xsl:when>
15     <xsl:otherwise>2004</xsl:otherwise>
16   </xsl:choose>
17 </xsl:variable>
```

This is the main rule. The translation of `<raweb>` is the file `apics-dtd2.xml` (assuming that `$LeProjet` is ‘apics’), its root element is `<raweb>`. This element has some attributes, namely namespaces, `year` (from the `$year` variable) and `xml:lang` from the `language` attribute. The content is formed by the transformation of the eight standard sections, followed by the bibliography, preceded by the transformation of `<accueil>` and `<composition>`.

```
18 <xsl:template match="/raweb">
19   <xsl:document href="{$LeProjet}-dtd2.xml" method="xml"
20     doctype-public="//INRIA//DTD Raweb 2" doctype-system="raweb2.dtd"
21     indent='yes' encoding='iso-8859-1'>
22   <xsl:comment>translated from old xml 2003 by with 2XMLvalideDTD2.xsl</xsl:comment>
23   <raweb
24     xmlns:xlink="http://www.w3.org/1999/xlink"
25     xmlns:html="http://www.w3.org/1999/xhtml">
26     <xsl:attribute name="lang" namespace="http://www.w3.org/XML/1998/namespace">
27       <xsl:choose>
28         <xsl:when test="@language='english'">en</xsl:when>
29         <xsl:when test="@language='french'">fr</xsl:when>
30         <xsl:otherwise><xsl:value-of select="@language"/></xsl:otherwise>
31       </xsl:choose>
32     </xsl:attribute>
33     <xsl:attribute name="year"><xsl:value-of select="{$year}"/></xsl:attribute>
```

<sup>1</sup>In French, `accueil` means reception, welcome.

<sup>2</sup>Fondements = foundations

<sup>3</sup>Logiciel = software

<sup>4</sup>‘LeProjet’ is French for ‘TheTeam’.

```

34     <xsl:apply-templates select="accueil"/>
35     <xsl:call-template name="topic"/>
36     <xsl:apply-templates select="presentation |
37                         fondements | domaine | logiciels | resultats |
38                         contrats | international | diffusion"/>
39     <xsl:apply-templates select="biblio"/>
40   </raweb>
41 </xsl:document>
42 </xsl:template>
```

A topic is an attribute of a module. Modules can be ordered by section or by topic; for this reason there are two style sheets that convert the XML into HTML. The table of contents of the HTML version has a button that switches from one view to the other; there is only one style sheet for the Pdf, it ignores these topic attributes. A topic attribute is a reference to a topic declaration like `<topic num='1'><t_titre> High-level modeling</t_titre></topic>`. The value of the num attribute is computed by Tralics; specifications say that it should be an integer. In the new DTD, it should be an ID, so that we transform it to t\_1 (the IDs generated by Tralics are of the form uid125 or bid125, so that this transformation does not conflict with already existing IDs). The `<t_titre>` element is useless here; it was removed in the new DTD. The topic declarations are moved from inside `<accueil>` to after `<identification>`.

```

43 <xsl:template name="topic">
44   <xsl:for-each select="accueil/child::topic">
45     <xsl:element name="topic">
46       <xsl:attribute name="id">t_<xsl:value-of select="@num"/></xsl:attribute>
47       <xsl:value-of select=".//t_titre"/>
48     </xsl:element>
49   </xsl:for-each>
50 </xsl:template>
```

This piece of code is a copy from the TEI. The idea is to leave math formulas unchanged. It will be used in all style sheets.

```

51 <xsl:template match="*|@*|comment()|processing-instruction()|text()" mode="math">
52   <xsl:copy>
53     <xsl:apply-templates mode="math" select="*|@*|processing-instruction()|text()"/>
54   </xsl:copy>
55 </xsl:template>
```

A `<formula>` is a wrapper for a `<math>` expression. The action here is to copy the attributes and the content.

```

56 <xsl:template match="formula">
57   <xsl:element name="formula">
58     <xsl:copy-of select="@*"/><xsl:apply-templates mode="math"/>
59   </xsl:element>
60 </xsl:template>
```

If a formula has the attribute type = ‘display’, it is a display math formula, outside any paragraph. We put it in a `<p>` element.

```

61 <xsl:template match="formula[@type='display']">
62   <p>
63     <xsl:element name="formula">
64       <xsl:copy-of select="@*"/><xsl:apply-templates mode="math"/>
65     </xsl:element>
66   </p>
67 </xsl:template>
```

We convert `<accueil>` into `<identification>`. We copy the isproject attribute (this is ‘true’ in the case where the team is a project, ‘false’ otherwise). We copy the html trait, renaming it id.

After that, we add the transformations of the following elements: <projet>, <projetdeveloppe>, <theme>, <composition> (this is a sibling), <UR>, and <moreinfo> (this is optional).

```

68 <xsl:template match="accueil">
69   <xsl:element name="identification">
70     <xsl:attribute name="isproject"><xsl:value-of select="@isproject"/></xsl:attribute>
71     <xsl:attribute name="id"><xsl:value-of select="@html"/></xsl:attribute>
72     <xsl:apply-templates select="projet"/>
73     <xsl:apply-templates select="projetdeveloppe"/>
74     <xsl:apply-templates select="theme"/>
75     <xsl:apply-templates select="../composition"/>
76     <xsl:apply-templates select="UR"/>
77     <xsl:if test="/raweb/moreinfo">
78       <xsl:apply-templates select="/raweb/moreinfo"/>
79     </xsl:if>
80   </xsl:element>
81 </xsl:template>
```

We copy the <theme> element, replacing lowercase letters by uppercase ones.

```

82 <xsl:template match="accueil/theme">
83   <xsl:element name="theme">
84     <xsl:value-of select="translate(., 'abcdefghijklmnopqrstuvwxyz',
85                           'ABCDEFGHIJKLMNOPQRSTUVWXYZ')"/>
86   </xsl:element>
87 </xsl:template>
```

We copy the <projet> element, renaming it <shortname>. Note that, for the L<sup>A</sup>T<sub>E</sub>X team, this could be <LaTeX>, so that a simple copy is not enough.

```

88 <xsl:template match="accueil/projet">
89   <xsl:element name="shortname"> <xsl:apply-templates /> </xsl:element>
90 </xsl:template>
```

We copy the <projetdeveloppe> element, renaming it < projectName><sup>5</sup>. Note that this element can have font changes, hence we must process the content.

```

91 <xsl:template match="accueil/projetdeveloppe">
92   <xsl:element name="projectName"> <xsl:apply-templates /> </xsl:element>
93 </xsl:template>
```

In the case of <UR>, we consider only the content; it should be a sequence of elements of the form <URxxx>, these elements are listed below.

```

94 <xsl:template match="UR">
95   <xsl:apply-templates />
96 </xsl:template>
```

We replace <URRocquencourt>, <URRhôneAlpes>, <URRennes>, <URLorraine>, <URFuturs>, and <URSophia> by <UR name='Rocquencourt' />, etc. These elements are empty, they represent one of the six INRIA's research units. We use here a literal result element, the actual code uses <xsl:element> and <xsl:attribute>.

```

97 <xsl:template match="URRocquencourt">
98   <UR name="Rocquencourt" />
99 </xsl:template>
100 <xsl:template match="URRhôneAlpes">
101   <UR name="RhôneAlpes"/>
102 </xsl:template>
103 <xsl:template match="URRennes">
104   <UR name="Rennes"/>
```

---

<sup>5</sup>Here the French word développé is used in the sense of expanded. All tag names are ASCII 7bits, although XML allows any Unicode character.

```

105  </xsl:template>
106  <xsl:template match="URLorraine">
107      <UR name="Lorraine"/>
108  </xsl:template>
109  <xsl:template match="URFuturs">
110      <UR name="Futurs" />
111  </xsl:template>
112  <xsl:template match="URSophia">
113      <UR name="Sophia" />
114  </xsl:template>

Translation of <presentation>, <fondements>, <domaine>, <logiciels>, <resultats>, <contrats>, <international>, and <diffusion>. The result is an element of the same name. The only difference is that we convert the titre attribute in a <bodyTitle> element. This attribute is constant, defined in the DTD, see page 337 and following, lines 181, 186, 191, 196, 201, 206, 211, 216, and 221.

115  <xsl:template match="presentation | fondements | domaine | logiciels |"
116      resultats | contrats | international | diffusion">
117      <xsl:variable name="nodename" select="name()"/>
118      <xsl:element name="${nodename}">
119          <xsl:attribute name="id"> <xsl:value-of select="@id"/> </xsl:attribute>
120          <xsl:element name="bodyTitle">
121              <xsl:value-of select="@titre"/>
122          </xsl:element>
123          <xsl:apply-templates/>
124      </xsl:element>
125  </xsl:template>

```

We simplified a bit the code above by assuming that the id attribute is present. The following code should be used instead of line 119.

```

<xsl:choose>
    <xsl:when test="@id">
        <xsl:attribute name="id">
            <xsl:value-of select="@id"/>
        </xsl:attribute>
    </xsl:when>
    <xsl:when test="@num">
        <xsl:attribute name="id">
            <xsl:value-of select="@num"/>
        </xsl:attribute>
    </xsl:when>
    <xsl:otherwise>
        <xsl:attribute name="id">
            <xsl:value-of select="position()"/>
        </xsl:attribute>
    </xsl:otherwise>
</xsl:choose>

```

Translation of <module>. The result is a <subsection>. We convert, in order, <head> (this is the title of the module), <participant>, <participante>, <participants>, <participantes> (four variants that indicate the participants to the action described in the module), <keywords> (the keywords), <moreinfo> (the ‘moreinfo’ data structure; we grab the first element, its transformation will read the other siblings), and finally everything else. A module has two attributes id and topic that are copied. If the topic is present, we have to convert the value as above line 46 ('12' replaced by 't\_12').

```

126 <xsl:template match="module">
127   <xsl:element name="subsection">
128     <xsl:if test="@topic and @topic!=''">
129       <xsl:attribute name="topic">t_<xsl:value-of select="@topic"/>
130       </xsl:attribute>
131     </xsl:if>
132     <xsl:call-template name="id"/>
133     <xsl:apply-templates select="head" mode="caption"/>
134     <xsl:apply-templates
135       select="participants | participant | participantes | participante"/>
136     <xsl:apply-templates select="keywords"/>
137     <xsl:apply-templates select="moreinfo[position()=1]" />
138     <xsl:apply-templates select="node()[local-name() != 'moreinfo'
139       and local-name() != 'keywords' and local-name() != 'head'
140       and local-name() != 'participants' and local-name() != 'participant'
141       and local-name() != 'participante' and local-name() != 'participantes' ]"/>
142   </xsl:element>
143 </xsl:template>

```

Translation of <div0>, <div1>, <div2>, <div3>, and <div4>. The result is a <subsection>, the code is the same as for a module, except that these elements have no topic attribute.

```

144 <xsl:template match="div0 | div1 | div2 | div3 | div4">
145   <xsl:element name="subsection">
146     <xsl:call-template name="id"/>
147     <xsl:apply-templates select="head" mode="caption"/>
148     <xsl:apply-templates
149       select="participants | participant | participantes | participante"/>
150     <xsl:apply-templates select="keywords"/>
151     <xsl:apply-templates select="moreinfo[position()=1]" />
152     <xsl:apply-templates select="node()[...]" />           <!-- as above l. 139-142-->
153   </xsl:element>
154 </xsl:template>

```

Transformation of <moreinfo>. The result is a <moreinfo> that contains the content of the element and all the following siblings.

```

155 <xsl:template match="moreinfo">
156   <xsl:element name="moreinfo">
157     <xsl:apply-templates/>
158     <xsl:for-each select="following-sibling::moreinfo">
159       <xsl:apply-templates/>
160     </xsl:for-each>
161   </xsl:element>
162 </xsl:template>

```

Transformation of <composition>. The result is a <team> element, containing the <catperso> children and an optional <moreinfo> (let's hope there is only one, because of the code line 158).

```

163 <xsl:template match="composition">
164   <xsl:element name="team">
165     <xsl:call-template name="id"/>
166     <xsl:call-template name="catperso"/>
167     <xsl:apply-templates select="moreinfo"/>
168   </xsl:element>
169 </xsl:template>

```

The transformation of <catperso><head>foo</head>etc</catperso> is a <participants> element with an attribute category = 'foo', with spaces replaced by underscores, and whose content is the translation of all <pers> elements it contains (the semantics is: a <catperso> contains a

title in `<head>`, that could be ‘Ph.D. Students’, followed by some `<pers>` elements, all the students of the team).

```

170 <xsl:template name="catperso">
171   <xsl:for-each select="catperso">
172     <xsl:element name="participants">
173       <xsl:attribute name="category">
174         <xsl:value-of select="translate(./head, ' ', '_')"/>
175       </xsl:attribute>
176       <xsl:apply-templates select="pers"/>
177     </xsl:element>
178   </xsl:for-each>
179 </xsl:template>

```

The transformation of `<participants>` is also a `<participants>` element, where the `category` attribute has value ‘None’. Originally, we had four elements, this one and `<participant>`, `<participante>`, `<participantes>`. This was simplified: the difference between masculine and feminine does not appear in English; the final s is removed, it will be added later if the list contains more than one element.

```

180 <xsl:template match="participants | participant | participantes | participante">
181   <xsl:element name="participants">
182     <xsl:attribute name="category">None</xsl:attribute>
183     <xsl:apply-templates/>
184   </xsl:element>
185 </xsl:template>

```

The transformation of `<pers prenom='Donald' nom='Knuth'>Author of <TeX/> </pers>` is a `<person>` element, with three children, the first is `<firstname>`, the second is `<lastname>`, they contain the `prenom` and `nom`, and the last one is a `<moreinfo>` element that contains the content of this element; it is optional. The test is strange because later on, see lines 1133 and 1147 in the next chapter, we test again for emptiness, but white space is normalised there, not here. The code has changed in 2006, because two required attributes `affiliation` and `profession` were added. Moreover, the `\LaTeX` command has two optional arguments, producing the value of the `hdr` attribute and the content of the `<pers>` element. If only one optional arguments is given, it is the value of the element; this piece of code allows the case where one optional argument is given, with value ‘habilité’,<sup>6</sup>, which is handled as if there were two optional arguments, empty content, non-empty attribute.

```

186 <xsl:template match="pers">
187   <xsl:element name="person">
188     <xsl:call-template name="id"/>
189     <xsl:element name="firstname"><xsl:value-of select="./@prenom"/></xsl:element>

317 </xsl:template>

    Transformation of <label>: the result is <label>.

318 <xsl:template match="label">
319     <xsl:element name="label">
320         <xsl:call-template name="id"/> <xsl:apply-templates/>
321     </xsl:element>
322 </xsl:template>

    Transformation of <table>. The result is a <table>. We set the attribute border to 'solid' in
    case one of the cells in the table has a bottom-border attribute that is true.10 The rend attribute

```

<sup>10</sup>This is strange; the test should be done on the rows, and all borders.

is copied. We copy all `<row>` children, followed by the `<caption>`, if there is one (normally, there is none), followed by `<head>`, renamed to `<caption>`<sup>11</sup>.

```

323 <xsl:template match="table">
324   <xsl:element name="table">
325     <xsl:if test=".//row/cell/@bottom-border='true'">
326       <xsl:attribute name="border">solid</xsl:attribute>
327     </xsl:if>
328     <xsl:if test=".//rend">
329       <xsl:attribute name="rend"><xsl:value-of select=".//rend" /></xsl:attribute>
330     </xsl:if>
331     <xsl:call-template name="id"/>
332     <xsl:apply-templates select="row" />
333     <xsl:apply-templates select="caption"/>
334     <xsl:element name="caption"> <xsl:value-of select="head"/> </xsl:element>
335   </xsl:element>
336 </xsl:template>

```

Transformation of `<row>`. The test here is strange. In the case where the test is false, the result is a `<tr>`, with the same content as the row. There is one attribute `style`<sup>12</sup> obtained from the right-border, top-border, left-border, and bottom-border attributes.

```

337 <xsl:template match="row">
338   <xsl:choose>
339     <xsl:when test="normalize-space(.) = '' and not(cell/child::*)">
340
341     </xsl:when>
342     <xsl:otherwise>
343       <xsl:element name="tr">
344         <xsl:attribute name="style">
345           <xsl:if test="@right-border='true'">
346             >border-right-style:solid; border-right-width:1px;</xsl:if>
347           <xsl:if test="@top-border='true'">
348             >border-top-style:solid; border-top-width:1px;</xsl:if>
349           <xsl:if test="@left-border='true'">
350             >border-left-style:solid; border-left-width:1px;</xsl:if>
351           <xsl:if test="@bottom-border='true'">
352             >border-bottom-style:solid; border-bottom-width:1px;</xsl:if>
353           </xsl:attribute>
354           <xsl:apply-templates/>
355         </xsl:element>
356       </xsl:otherwise>
357     </xsl:choose>
358 </xsl:template>

```

The transformation of `<cell>` is `<td>`, with the same content. There is one attribute `style` obtained from the `halign`, `right-border`, `top-border`, `left-border`, and `bottom-border` attributes. Attributes `rows` and `cols` are copied if the value is greater than one (this is the row span or column span of the cell).

```

359 <xsl:template match="cell">
360   <xsl:element name="td">
361     <xsl:attribute name="style">
362       <xsl:if test="@halign">
363         >text-align:<xsl:value-of select="@halign"/>;</xsl:if>

```

---

<sup>11</sup>This seems to be a bug. Tralics converts both ‘table’ and ‘tabular’ environments to `<table>`, in the first case, there is no caption.

<sup>12</sup>The result is so complicated that the XSL/Format style sheet ignores this attribute. This should be changed in 2005.

```

364     <xsl:if test="@right-border='true'">
365         > border-right-style:solid; border-right-width:1px;</xsl:if>
366     <xsl:if test="@top-border='true'">
367         > border-top-style:solid; border-top-width:1px;</xsl:if>
368     <xsl:if test="@left-border='true'">
369         > border-left-style:solid; border-left-width:1px;</xsl:if>
370     <xsl:if test="@bottom-border='true'">
371         > border-bottom-style:solid; border-bottom-width:1px;</xsl:if>
372 </xsl:attribute>
373 <xsl:if test="./@cols>1">
374     <xsl:attribute name="cols"><xsl:value-of select="./@cols" /></xsl:attribute>
375 </xsl:if>
376 <xsl:if test="./@rows>1">
377     <xsl:attribute name="rows"><xsl:value-of select="./@rows" /></xsl:attribute>
378 </xsl:if>
379     <xsl:apply-templates/>
380 </xsl:element>
381 </xsl:template>

```

Attributes `halign` are always copied. This should be explained, because, a priori, all these attributes were converted to a `style` attribute.

```

382 <xsl:template match="@halign">
383     <xsl:attribute name="halign"><xsl:value-of select=".," /></xsl:attribute>
384 </xsl:template>

```

This converts a `<figure>` element into a `<ressource>` element. The `rend` attribute is copied under the `name` type. Other attributes like `width`, `height`, `scale`, `angle`, and `framed` are just copied.

```

385 <xsl:template name="ressource">
386     <ressource xlink:href="{@file}">
387     <xsl:if test="@rend">
388         <xsl:attribute name="type"><xsl:value-of select="@rend"/></xsl:attribute>
389     </xsl:if>
390     <xsl:if test="@width"> <xsl:copy-of select="@width"/> </xsl:if>
391     <xsl:if test="@height"> <xsl:copy-of select="@height"/> </xsl:if>
392     <xsl:if test="@scale"> <xsl:copy-of select="@scale"/> </xsl:if>
393     <xsl:if test="@angle"> <xsl:copy-of select="@angle"/> </xsl:if>
394     <xsl:if test="@framed"> <xsl:copy-of select="@framed"/> </xsl:if>
395     <xsl:if test="head and ((ancestor::figure) or not(@file))">
396         <xsl:apply-templates select="head" mode="caption"/>
397     </xsl:if>
398     </ressource>
399 </xsl:template>

```

In the case where a `<figure>` is in a `<table>` which is in a `<figure>`, and if it has a `file` attribute, then the result is a ‘ressource’.

```

400 <xsl:template match="figure//table//figure[@file]" priority="5">
401     <xsl:call-template name="ressource"/>
402 </xsl:template>

```

In the case where a `<figure>` has a `file` attribute, is below a figure, but does not match the rule above, then the result is a ‘ressource’, as above, but in a `<td>`.

```

403 <xsl:template match="figure[(ancestor::figure) and @file]">
404     <td><xsl:call-template name="ressource"/></td>
405 </xsl:template>

```

This is the last rule for a `<table>`. Let’s hope no case is forgotten. The result is a `<object>`. It contains a `<table>`: in the case where there is a `file` attribute, the element is empty, and the translation is a `<table>` with a single `<tr>` with a single `<td>` with the `ressource`. In the case where

there is a `<p>` with a table, we consider only these elements (let's hope for the best). Otherwise, we add a `<table>`, and each `<p>` will produce a row. A caption is put at the end.

```

406 <xsl:template match="figure[not(ancestor::figure)]">
407   <xsl:element name="object">
408     <xsl:call-template name="id"/>
409     <xsl:choose>
410       <xsl:when test="@file">
411         <table>
412           <tr><td>
413             <xsl:call-template name="ressource"/>
414           </td></tr>
415         </table>
416       </xsl:when>
417       <xsl:when test="p/table">
418         <xsl:apply-templates select="p/table" />
419       </xsl:when>
420       <xsl:otherwise>
421         <table> <xsl:apply-templates /> </table>
422       </xsl:otherwise>
423     </xsl:choose>
424     <xsl:apply-templates select="head" mode="caption"/>
425   </xsl:element>
426 </xsl:template>

```

This code is applied only in the ‘otherwise’ case of the previous template. For 2005, the best thing to do should be to modify Tralics so that this style sheet can be made more robust.

```

427 <xsl:template match="figure/p">
428   <tr><xsl:apply-templates/></tr>
429 </xsl:template>

```

This copies the `id` attribute if present.<sup>13</sup>

```

430 <xsl:template name="id">
431   <xsl:if test=".//@id">
432     <xsl:attribute name="id"><xsl:value-of select=".//@id"/> </xsl:attribute>
433   </xsl:if>
434 </xsl:template>

```

This interprets `<head>`. If the parent is `<list>`, we put the content of the element in the `title` attribute of the current element.<sup>14</sup> If the parent is `<figure>` or `<table>` we put the content in a `<caption>` element. Otherwise, we put it in a `<bodyTitle>` element. Note that Tralics replaces some empty titles by ‘(Sans Titre)’; Code on line 447 was changed in 2005: if the section has a single module, the name of the section is used, otherwise ‘Introduction’ will be used. You will see twice Xsl instead of xsl, in both these cases, the code contained a `<xsl:text></xsl:text>` that is not shown here (it seems useless to me).

```

435 <xsl:template match="head" mode="caption">
436   <xsl:choose>
437     <xsl:when test="parent::list" >
438       <xsl:attribute name="title"> <xsl:apply-templates/> </xsl:attribute>
439     </xsl:when>
440     <xsl:when test="parent::figure | parent::table">
441       <xsl:element name="caption"> <xsl:apply-templates/> </xsl:element>
442     </xsl:when>
443     <xsl:otherwise>
444       <xsl:element name="bodyTitle">

```

---

<sup>13</sup>Why not a simple copy-of ?

<sup>14</sup>This is strange; Tralics does not produce such a thing.

```

445      <xsl:choose>
446          <xsl:when test=".='(Sans Titre)'>
447              <xsl:choose>
448                  <xsl:when test="count(..../module)=1">
449                      <xsl:value-of select="..../@titre"/>
450                  </xsl:when>
451                  <xsl:otherwise> <Xsl:text>Introduction</xsl:text></xsl:otherwise>
452              </xsl:choose>
453          </xsl:when>
454          <xsl:otherwise> <Xsl:apply-templates/> </xsl:otherwise>
455      </xsl:choose>
456      </xsl:element>
457  </xsl:otherwise>
458 </xsl:choose>
459 </xsl:template>

```

We do nothing with `<head>`, because this element should be handled by the routines given above.

```

460 <xsl:template match="head"></xsl:template>
    We leave the <LaTeX> element unchanged.
461 <xsl:template match="LaTeX"> <LaTeX/></xsl:template>
    We leave the <TeX> element unchanged.
462 <xsl:template match="TeX"> <TeX/> </xsl:template>
    This is the end of the file.
463 </xsl:transform>

```

## 5.2 Addings Ids

There is a style sheet that adds some Ids. Original version (denoted by V1 hereafter) is in `add-id.xsl`, revised one (denoted by V2) in `add-idDTD2.xsl`. There is a comment that says: “Some Ids are missing in some XML files (that were not generated by Tralics) these are required in the bibliography, we add them everywhere”. The revised version has “they are required for the bibliography and subsection, we add them where needed”. As we shall see, Ids are added only for subsections. We propose additional simplifications, see comments below; this gives V3.

This is the header of the file. It declares a namespace (it binds `xmlns:m` to thez MathML namespace), but this declaration is not used.

```

501 <xsl:transform
502     xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0"
503     xmlns:m="http://www.w3.org/1998/Math/MathML"
504     exclude-result-prefixes="m">
    The result is a XML file, conforming the Raweb DTD version 2.
505 <xsl:output method='xml'
506     doctype-public="-//INRIA//DTD Raweb 2" doctype-system='raweb2.dtd'
507     indent='yes' encoding='iso-8859-1' />

```

We do not want to add an ID to each character of a math formula; for this reason we copy recursively the formula. We could remove this code, however a ‘diff’ between the original XML and the resulting file shows that this code does not a simple copy: each `<math>` element in the formula has a useless `xmlns:xlink` attribute, that is removed here. Moreover, the DTD specifies some attributes (like `TEIform`) with a default value; whenever the attribute is missing, the default value is added; for instance, in the case of the ‘apics’ file, the size changes from 377517 to 406132 bytes.

```

508 <xsl:template match="formula">
509   <formula>
510     <xsl:copy-of select="@*"/>
511     <xsl:apply-templates mode="math"/>
512   </formula>
513 </xsl:template>

This is a copy of a rule defined elsewhere.

514 <xsl:template match="*|@*|comment()|processing-instruction()|text()" mode="math">
515   <xsl:copy>
516     <xsl:apply-templates mode="math" select="*|@*|processing-instruction()|text()"/>
517   </xsl:copy>
518 </xsl:template>

```

The whole document is converted.

```

519 <xsl:template match="/">
520   <xsl:apply-templates />
521 </xsl:template>

```

We copy all attributes, and text nodes.

```

522 <xsl:template match="@*|>
523   <xsl:copy />
524 </xsl:template>

525 <xsl:template match="text()">
526   <xsl:copy />
527 </xsl:template>

```

The default template rule says to copy everything.

```

529 <xsl:template match="*|>
530   <xsl:copy>
531     <xsl:apply-templates select="node()|@*" />
532   </xsl:copy>
533 </xsl:template>

```

In the case of `<subsection>`, we add an `id` attribute, if there is none, before copying.

```

534 <xsl:template match="subsection">
535   <xsl:copy>
536     <xsl:if test="not(./@id)">
537       <xsl:attribute name="id">
538         <xsl:value-of select="generate-id()" />
539       </xsl:attribute>
540     </xsl:if>
541     <xsl:apply-templates select="node()|@*" />
542   </xsl:copy>
543 </xsl:template>

```

This is the end of the file.

```
544 </xsl:transform>
```

The code that follows appears in one of the two style sheets distributed with the Raweb2006; we modified them in order to make the code shorter.

The following rule appears in the style sheets V1 and V2, removed in V3. Its effect is to *not* copy the `id` attribute; since the purpose of the file is to add missing ids, keeping existing ones, we have to add another rule. According to [5], “Duplicate attribute nodes are removed. If several

attributes in the sequence have the same name, all but the last are discarded". Thus we can safely remove this rule, as well as the additional rules.

```
545 <xsl:template match="@id">
546   </xsl:template>
```

This is the code of V1. The effect is to add an id to every node; but this is overkill.

```
547 <xsl:template match="*"
548   <xsl:copy use-attribute-sets="ID">
549     <xsl:apply-templates select="node()|@*" />
550   </xsl:copy>
551 </xsl:template>
```

This is the code of V2. The effect is a simple copy of the element and its attributes. By default, the id attribute is not copied, hence an explicit copy is needed.

```
552 <xsl:template match="*"
553   <xsl:copy>
554     <xsl:if test="./@id">
555       <xsl:attribute name="id"><xsl:value-of select="./@id" /></xsl:attribute>
556     </xsl:if>
557     <xsl:apply-templates select="node()|@*" />
558   </xsl:copy>
559 </xsl:template>
```

This rule is added in V2; it effectively adds an id to each `<subsection>`. This is equivalent to the V3 code shown above (but V3 does not use the `use-attribute-set` feature).

```
560 <xsl:template match="subsection">
561   <xsl:copy use-attribute-sets="ADDID">
562     <xsl:apply-templates select="node()|@*" />
563   </xsl:copy>
564 </xsl:template>
```

This rule was named 'ID' in V1 (used on line 548), renamed to 'ADDID' (used on line 561). It uses the 'generate-id' function in order to create a unique id, in the case where there is none.

```
565 <xsl:attribute-set name="ADDID">
566   <xsl:attribute name="id">
567     <xsl:choose>
568       <xsl:when test="./@id"> <xsl:value-of select="./@id" /> </xsl:when>
569       <xsl:otherwise> <xsl:value-of select="generate-id()" /> </xsl:otherwise>
570     </xsl:choose>
571   </xsl:attribute>
572 </xsl:attribute-set>
```

Since putting Ids everywhere is overkill, some templates were added in V2 to inhibit this.

```
573 <xsl:template match="LaTeX"> <LaTeX/> </xsl:template>
574 <xsl:template match="TeX"> <TeX/> </xsl:template>
```

These two variables were used to compute the name of the output file.

```
575 <xsl:variable name="LeProjet"/>
576 <xsl:variable name="year"/>
```

## Chapter 6

# Converting XML to HTML

The Inria's scientific activity report is constructed from contributions by the research teams. Each team writes a L<sup>A</sup>T<sub>E</sub>X file converted to XML by Tralics (or writes it directly in XML); the file is formed of a number of modules, grouped by sections, and each module is transformed into a HTML page. Each module can be read independently of all others; hence it should be possible to take modules from different teams, and group them in a single page (dynamic version of the RA). On the other hand, the home page of each team has a link to its activity report, formed of these modules, chained in some order (static version of the RA).

The raweb package provides two style sheets that produce HTML from an XML source, they are called `dynamic.xsl` and `static.xsl`. The static version is described here, it constructs the document. This is the start of the file.

```
601 <xsl:stylesheet
602   xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0"
603   xmlns:m="http://www.w3.org/1998/Math/MathML"
604   xmlns:xlink="http://www.w3.org/1999/xlink"
605   xmlns:html="http://www.w3.org/1999/xhtml"
606   exclude-result-prefixes="m html xlink" >
```

Some years ago, it was decided to add the notion of 'topic'. If a team has three main research subjects, each one will be a topic. Thus, a module is associated to a topic and a section, and the reader might want to read the document in section order or in topic order. For this reason, if topics are given, the document is translated twice, the only difference being how individual pages are linked together. The file `Topic.xsl` contains code to be executed when topics are present, the file `sansTopic.xsl` contains code for the case without topics, and `biblio.xsl` contains code for the bibliography. Finally, all other template rules are in `common.xsl` if they apply as well to the static and non-static case, or are in `static.xsl` or `dynamic.xsl`.

```
607 <xsl:import href="common.xsl"/>
608 <xsl:import href="Topic.xsl"/>
609 <xsl:import href="sansTopic.xsl"/>
610 <xsl:import href="biblio.xsl"/>
```

### 6.1 Common code for HTML conversion

We describe here the code that is either in `static.xsl` or `common.xsl`. We start with some boolean variables. These are defined in the imported file.

```
611 <xsl:param name="noframe" select="'0'" />
612 <xsl:param name="notoc" select="'0'" />
```

```
613 <xsl:param name="isTopic" select="'0'" />
614 <xsl:param name="xyleme" select="'0'" />
```

These are defined in the main file. The variable \$xyleme is set to true in the dynamic version, to false in the static version. The variable \$isTopic is true if we have topics (it will be set from outside the style sheet). The variable \$noframe is true if there are no frames (this is the case of the dynamic version); some years ago there were three frames: navigation buttons, TOC and main text, in the current version, there are only two frames, the TOC on the left, the main text of the right. The variable \$notoc controls whether a TOC should be inserted on each page, assuming that there is no separate frame with the TOC; finally, \$allHtml is set in the case where the team produces it activity report in HTML, case there conversion from XML to HTML should be inhibited.

```
615 <xsl:param name="xyleme" select="'0'" />
616 <xsl:param name="noframe" select="'0'" />
617 <xsl:param name="notoc" select="'0'" />
618 <xsl:param name="isTopic" select="'0'" />
619 <xsl:param name="allHtml" select="'0'" />
```

A very important point is the difference between a ‘Project-Team’ and a ‘Team’. Of the 160 teams that have written a RA in 2004, 110 were Projects (*Research-teams recognized as project-team by INRIA, according to the web*) at the start of the year. This code uses the isproject attribute of <identification>.

```
620 <xsl:variable name="LeTypeProjet">
621   <xsl:if test='raweb/identification/@isproject="false">'>Team</xsl:if>
622   <xsl:if test='raweb/identification/@isproject="true">'>Project</xsl:if>
623 </xsl:variable>
```

The main file defines the same variable differently.

```
624 <xsl:variable name="LeTypeProjet">
625   <xsl:choose>
626     <xsl:when test='raweb/identification/@isproject="true">'>Project-Team</xsl:when>
627     <xsl:otherwise>Team</xsl:otherwise>
628   </xsl:choose>
629 </xsl:variable>
```

The variable \$LeProjet contains the name of the team and \$DirectoryPasTop contains the directory of the version without topics.

```
630 <xsl:variable name="LeProjet" select="/raweb/identification/@id"/>
631 <xsl:variable name="DirectoryPasTop" select="$LeProjet"/>
```

More variables, defining essentially paths.

```
632 <xsl:variable name="indexPath">../index.html</xsl:variable>
633 <xsl:variable name="iconspath" select="..//icons'" />
634 <xsl:variable name="imgpath" select="..//'" />
635 <xsl:variable name="helpdir" select="..'" />
636 <xsl:variable name="javadir" select="..'" />
637 <xsl:param name="displaycd" />
```

This templates adds a target attribute to the current element, unless the value of the parameter \$theTarget is empty. It is useful if the current element is an anchor.

```
638 <xsl:template name="targetAttrib">
639   <xsl:param name="theTarget" />
640   <xsl:if test="$theTarget!= ''">
641     <xsl:attribute name="target"><xsl:value-of select="$theTarget" /></xsl:attribute>
642   </xsl:if>
643 </xsl:template>
```

These three variables are target attributes, used as parameters of the template above.

```

644 <xsl:variable name="MainwindowTarget" select="'mainraweb06'" />
645 <xsl:variable name="AltwindowTarget" select="_alt'" />
646 <xsl:variable name="TopwindowTarget" select="_top'" />
```

In order to make this document a bit shorter, we have introduced the following templates.

```

647 <xsl:template name="targetAttrib.alt">
648   <xsl:call-template name="targetAttrib">
649     <xsl:with-param name="theTarget" select="$AltwindowTarget" />
650   </xsl:call-template>
651 </xsl:template>
652
653 <xsl:template name="targetAttrib.top">
654   <xsl:call-template name="targetAttrib">
655     <xsl:with-param name="theTarget" select="$TopwindowTarget" />
656   </xsl:call-template>
657 </xsl:template>
658
659 <xsl:template name="targetAttrib.main">
660   <xsl:call-template name="targetAttrib">
661     <xsl:with-param name="theTarget" select="$MainwindowTarget" />
662   </xsl:call-template>
663 </xsl:template>
```

The variable \$year contains the current year or a default value. It is used to construct \$FTPDIRECTORY, the web location of the Activity Report.

```

664 <xsl:variable name="year">
665   <xsl:choose>
666     <xsl:when test='@year'>
667       <xsl:value-of select="/raweb/@year"/>
668     </xsl:when>
669     <xsl:otherwise>2006</xsl:otherwise>
670   </xsl:choose>
671 </xsl:variable>
672 <xsl:variable name="FTPDIRECTORY"
673   select="concat('http://www.inria.fr/rapportsactivite/RA', $year,'/',$LeProjet)"/>
```

This line is useless: all pages are created via <xsl:document>, and use 'xhtml' as document type.

```

674 <xsl:output method='html' encoding='iso-8859-1'
675   doctype-public='-'//W3C//DTD HTML 4.0//EN'/'>
```

### 6.1.1 The main translation rule

The toplevel element is <raweb>, it is translated according to the following rule. The variable \$allHtml when set to one, inhibits translation, assuming that the HTML version of the document has been produced by other means.

```

676 <xsl:template match="/raweb">
677   <xsl:choose>
678     <xsl:when test="$allHtml='1'">
679       <xsl:otherwise>
680       ...
681       </xsl:otherwise>
682     </xsl:choose>
683 </xsl:template>
```

The global action is rather obvious: we call a routine for the title page, one for the presentation, one for each subsection of every main subsection, and one for the bibliography.

```

684   <xsl:apply-templates select="identification" mode="statique"/>
685   <xsl:apply-templates select="identification/team" mode="statique"/>
686   <xsl:for-each select="presentation|fondements|domaine|logiciels|
687     resultats|contrats|international|diffusion">
688     <xsl:for-each select="subsection">
689       <xsl:apply-templates select=". ." mode="statique"/>
690     </xsl:for-each>
691   </xsl:for-each>
692   <xsl:for-each select="biblio">
693     <xsl:apply-templates select=". ." mode="statique"/>
694   </xsl:for-each>
```

In each case, a **HTML** page is constructed. We start with the easy case: the bibliography. The resulting page is in the directory defined by **\$Directory** and is named **bibliography.html**.

```

695 <xsl:template match="biblio" mode="statique">
696   <xsl:document href="{{$Directory}}/bibliography.html"
697     indent="yes" method="xml"
698     doctype-public="-//W3C//DTD XHTML 1.0 Transitional//EN"
699     doctype-system="http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
700   <html>
701     <xsl:apply-templates select=". ." />
702   </html>
703 </xsl:document>
704 </xsl:template>
```

In the case of a **<subsection>**, we distinguish between sections of level one (originally called **<module>**) or below (**<div2>**, **<div3>**, etc.). This piece of code handles only modules, so that the test is useless: the ‘otherwise’ is not used.

```

705 <xsl:template match="subsection" mode="statique">
706   <xsl:choose>
707     <xsl:when test="not(parent::subsection)">
708       <xsl:document href="{{$Directory}}/{./@id}.html"
709         method="xml" indent="yes" encoding="iso-8859-1"
710         doctype-public="-//W3C//DTD XHTML 1.0 Transitional//EN"
711         doctype-system="http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
712       <html>
713         <xsl:apply-templates select=". ." />
714       </html>
715     </xsl:document>
716   </xsl:when>
717   <xsl:otherwise>
718     <html> <xsl:apply-templates select=". ." /> </html>
719   </xsl:otherwise>
720 </xsl:choose>
721 </xsl:template>
```

The page with the composition of the team is the second page, it is constructed here, by applying a template to the **<team>** element.

```

722 <xsl:template match="identification/team" mode="statique">
723   <xsl:document href="{{$Directory}}/{@id}.html"
724     method="xml" encoding="iso-8859-1" indent="yes"
725     doctype-public="-//W3C//DTD XHTML 1.0 Transitional//EN"
726     doctype-system="http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
727   <html>
728     <xsl:apply-templates select=". ." />
729   </html>
```

```

730      </xsl:document >
731  </xsl:template>
```

Translation of the <identification> element consists of four HTML pages, one of them containing the team (previous rule). We show here how the three others are created. If the variable \$noframe is true (there is some inconsistency here, let's assume that the value is either one, meaning true, or zero, meaning false) we have no frames. If it is false, we have frames, one of them containing the text, the other containing the table of contents.

```

732  <xsl:template match="identification" mode="statique">
733    <xsl:if test="$noframe!='1'">
734      <xsl:call-template name="creer.frameset" />
735    </xsl:if>
```

We construct here the page containing the TOC (tdm in French). This is the only page that has no navigation buttons.

```

736  <xsl:document href="{{$Directory}}/{{$LeProjet}}_tdm.html"
737    method="xml" encoding="iso-8859-1" indent="yes"
738    doctype-public='-'//W3C//DTD XHTML 1.0 Transitional//EN'
739    doctype-system="http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
740    <html>
741      <xsl:call-template name="page.head" />
742      <body>
743        <xsl:call-template name="tdm" />
744      </body>
745    </html>
746  </xsl:document>
```

This is now the main page. Its name is uid0.html, the assumption being that the first ID generated by Tralics is 'uid1'. Before 2005, the value of the variable \$LeProjet was used instead. Thus adage2004/adage.html is now replaced by apics/uid0.html.

```

747  <xsl:document href="{{$Directory}}/uid0.html" method="xml"
748    indent="yes" encoding="iso-8859-1"
749    doctype-public='-'//W3C//DTD XHTML 1.0 Transitional//EN'
750    doctype-system="http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
751    <html>
752      <xsl:apply-templates select=".." />
753    </html>
754  </xsl:document>
755 </xsl:template>
```

### 6.1.2 Creating pages

Converting XML to HTML is rather easy, compared to conversion into Pdf. The non-trivial point concerns the layout of the page, navigation buttons, meta data, etc. One question is: should we put navigation buttons on the top and bottom of the page? If a page is large, it can be interesting to have a 'next' button near the end, this avoids the need to scroll to the top, if you want to continue reading. Starting in 1995, the Raweb was produced by latex2html, which can conditionnally insert navigation buttons<sup>1</sup>; but this depends on the number of characters in the page, and not the effective size; as a consequence, the layout of the page seems to be random. The situation changed in 1999<sup>2</sup>, the text is in a frame, and the navigation buttons are in an another frame, placed above the text; the buttons appear only in the first frame. In 2003<sup>3</sup> the situation changed again. There

---

<sup>1</sup>See for instance <http://www.inria.fr/rapportsactivite/RA96/algo/algo.html>

<sup>2</sup>See for instance <http://www.inria.fr/rapportsactivite/RA99/algo/algo.html>.

<sup>3</sup>See for instance <http://www.inria.fr/rapportsactivite/RA2003/algo2003/algo.html>; this is the version without the TOC.

are two possible views. By default, there are no frames, but a button (the ‘TOC’ button) that creates two frames: the TOC on the left, the text on the right. The text has navigation buttons on the top and the bottom (but there are fewer buttons on the bottom). The same idea is used in 2004 and explained in this document. The first page of each Team contains a link to the previous and next year (when available). See figure 6.2.

Here is a helper for producing an `<img>`. It takes two arguments `$alt` and `$src`. Icons are in a shared directory defined by `$iconpath`.

```
756 <xsl:template name="icon.image">
757   <xsl:param name="alt" />
758   <xsl:param name="src" />
759   
760 </xsl:template>
```

The next command takes three arguments, `$nom`, `$position`, and `$accesskey`. If `$nom` is empty, the result is a simple image (for instance named `next_motif_gr.gif`, where ‘gr’ stands for ‘grey’ instead of black and white). Otherwise, it is the name of a HTML file, and the result is an anchor `<a>`, whose `href` attribute is this file name. The image is different (for instance named `next_motif.gif`, the images are designed so that it is obvious that they have the same purpose, one of them being active, the other inactive), but the `alt` field is the same; the `accesskey4` attribute is set only in this case. In any case, there is some white space after the button. Note: in certain cases, a anchor has a `target` attribute. This can be `_alt` (this is a name not recognised by the standard; the effect is that the browser opens a new window); this can be `_top` or `_parent` (these names are defined by the standard); it can also be `mainraweb2004` (this is needed for links from the toc to the main frame). The buttons created by this procedure are in the main frame and point to the main frame; they have no `target` attribute.

```
761 <xsl:template name="make.icon">
762   <xsl:param name="nom" />
763   <xsl:param name="position" />
764   <xsl:param name="accesskey" />
765   <xsl:choose>
766     <xsl:when test="$nom=''">
767       <xsl:call-template name="icon.image">
768         <xsl:with-param name="alt" select="$position" />
769         <xsl:with-param name="src" select="concat($position,'_motif_gr')" />
770       </xsl:call-template>
771     </xsl:when>
772     <xsl:otherwise>
773       <a>
774         <xsl:attribute name='href'>
775           <xsl:call-template name="formaturl">
776             <xsl:with-param name="base" select="$nom" />
777           </xsl:call-template>
778         </xsl:attribute>
779         <xsl:if test="$accesskey!=''">
780           <xsl:attribute name="accesskey">
781             <xsl:value-of select="$accesskey" />
782           </xsl:attribute>
783         </xsl:if>
784         <xsl:call-template name="icon.image">
785           <xsl:with-param name="alt" select="$position" />
786           <xsl:with-param name="src" select="concat($position,'_motif')" />
787         </xsl:call-template>
```

<sup>4</sup>If the acceskey is, say N, pressing down the alt key together with the letter N has the same effect as clicking on the icon, at least with my browser.

The screenshot shows a web page layout for a team named "adage". At the top, there's a header bar with links for "HELP", "INDEX", "Put in folder", and "Show folder". Below the header, the text "Team : adage" and "Section: Other Grants and Activities" is displayed. A section titled "Regional Initiatives" follows, with a note about the team's involvement in a project. At the bottom, there are navigation icons and the INRIA logo.

Figure 6.1: The layout of a sample page for a Team without topics.

The screenshot shows a web page layout for a project team named "aoste". The structure is similar to Figure 6.1, with a header, main content sections for the team and its topics, and a footer with navigation icons and the INRIA logo.

Figure 6.2: The layout of a sample page for a Project-Team with topics.

```

788     </a>
789     </xsl:otherwise>
790   </xsl:choose>
791   <xsl:text>
792     </xsl:text>
793   </xsl:template>

```

The next piece of code creates five buttons, and two other items, and puts them in a `<div>`. The first three are created by `make.icon`; this is something that takes three arguments; in order to make this document shorter, we have indicated only the value of the parameters, the names being `$nom`, `$position` and `$accesskey` in order. In the same fashion, `icon.image` is called with two parameters, named `$alt` and `$src`, we show only the value. The three quantities `$precedent`, `$suivant` and `$haut` are arguments to the procedure. They refer to the previous page, next page and top page, which may exist or not; if the page exists, the button is in an anchor, otherwise it is just an image. The following buttons are anchors to ‘`..../adage2004/adage.pdf`’ and ‘`..../adage2004/adage.ps.gz`’, assuming that `$year` contains 2004, and `$LeProjet` contains ‘adage’. Since 2005, there is also an anchor to the XML file. These items are followed a link to the TOC and the javascript. Implementation details are given later.

The main Raweb location is `http://www.inria.fr/rapportsactivite`, this contains a subdirectory for each year, for instance RA2004. In this directory, we have some common files and directories (the css, the icons, etc.), and the teams, for instance adage2004. For a HTML page under adage2004, the next page can be `foo.html` or `..../adage2004/foo.html`, the style sheet is in `..../raweb.css`.

Notes for the 2006 version. This document is written before the RA2006 is put on the web, so that the style sheets are not yet definitive. Nevertheless, it seems that the main directory for a team does not contain the year. Hence the Pdf file is in ‘`..../adage/adage.pdf`’. In the code shown here, you will see the 2004 anchor, and later on the actual code used in 2006.

```

795 <xsl:template name="page.icons">
796   <xsl:param name="precedent" />
797   <xsl:param name="suivant" />
798   <xsl:param name="haut" />
799   <div class="NavigationIcones">
800     <xsl:call-template name="make.icon">("$precedent", "'previous'", "'P'")</xsl:call-template>
801     <xsl:call-template name="make.icon">("$haut", "'up'", "'U'")</xsl:call-template>
802     <xsl:call-template name="make.icon">("$suivant", "'next'", "'N'")</xsl:call-template>
803   <!-- Links to ps, pdf and xml... see below -->
804   <a href="../{$LeProjet}{$year}/{$LeProjet}.pdf"> ...</a>
805   <xsl:text> </xsl:text>
806   <a href="../{$LeProjet}{$year}/{$LeProjet}.ps.gz"> ... </a>
807   <a href="../{$LeProjet}{$year}/{$LeProjet}.xml"> ... </a>
808   <xsl:call-template name="jg.toclink" />
809   <a id="toclink">...</a>
810   <java ... />
811 </div>
812 </xsl:template>

```

In the code above, we have a comment, followed by two links to the PostScript, Pdf, and XML versions of the document. In each case, we have lines like the following. We call some template with two arguments, the team name and some text (which is in fact a button, created by `icon.image`). The template is defined in the static and dynamic versions.

```

816   <xsl:call-template name="url-pdf-file">
817     <xsl:with-param name="projet" select="$LeProjet" />

```

```

818     <xsl:with-param name="Text">
819         <xsl:call-template name="icon.image"> ("PDF", "pdf_motif")
820         </xsl:call-template>
821     </xsl:with-param >
822 </xsl:call-template>
```

This is the template called in the above code, static version. All three templates `url-ps-file`, `url-pdf-file` and `url-xml-file` are similar. The effect is to create an anchor, depending on the name of the team, containing the text. As you can see, the file name is `../adage/adage.pdf`.

```

823 <xsl:template name="url-pdf-file">
824     <xsl:param name="projet" />
825     <xsl:param name="Text" />
826     <a href="../{$LeProjet}/{$LeProjet}.pdf"><xsl:copy-of select="$Text" /></a>
827 </xsl:template>
```

A similar procedure is used to create a link to the Team's homepage. The anchor has a `target` attribute.

```

828 <xsl:template name="url-fiche-projet">
829     <xsl:param name="FicheProjetName" />
830     <xsl:param name="Text" />
831     <a href="http://www.inria.fr/recherche/equipes/{$FicheProjetName}.en.html" >
832         <xsl:call-template name="targetAttrib.alt" />
833         <xsl:copy-of select="$Text" />
834     </a>
835 </xsl:template>
```

The previous template is called twice. Here is the first occurrence. The text is simply 'Project-Team Apics'.

```

836 <xsl:template name="jg.url-fiche-projet-A">
837     <xsl:call-template name="url-fiche-projet-A">
838         <xsl:with-param name="FicheProjetName" select="$FicheProjetName" />
839         <xsl:with-param name="Text">
840             <xsl:value-of select="$LeTypeProjet" />;
841             <xsl:value-of select="/raweb/identification/shortname" />
842         </xsl:with-param>
843     </xsl:call-template>
844 </xsl:template>
```

Here is the second occurrence. The text is 'Presentation of the project'.

```

845 <xsl:template name="jg.url-fiche-projet-B">
846     <xsl:call-template name="url-fiche-projet">
847         <xsl:with-param name="FicheProjetName" select="$FicheProjetName" />
848         <xsl:with-param name="Text">
849             <xsl:choose>
850                 <xsl:when test='/@isproject="true"’>
851                     Presentation of the project</xsl:when>
852                     <xsl:otherwise>Presentation of the team</xsl:otherwise>
853                 </xsl:choose>
854             </xsl:with-param>
855         </xsl:call-template>
856 </xsl:template>
```

The semantics of the Raweb says: a team name is formed of letters and digits; a name like `pop_art` is refused (this team did not exist when the rule was established). This rule was never changed, until January 2007 and version 2.9.4 (essentially because underscore characters are not always properly handled by L<sup>A</sup>T<sub>E</sub>X and Tralics). This implies that we must compute the real name (used by the procedure given above) and store it in a variable, say `$FicheProjetName`. Question: is there any reason why the template uses a parameter and not the global variable?

```

857 <xsl:variable name="FicheProjetName">
858   <xsl:choose>
859     <xsl:when test="string(/raweb/identification/@id)='popart'">pop_art</xsl:when>
860     <xsl:when test="string(/raweb/identification/@id)='led'">langue_et_dialogue</xsl:when>
861     <xsl:when test="string(/raweb/identification/@id)='virtualplants'">
862       virtual_plants</xsl:when>
863     <xsl:otherwise><xsl:value-of select="/raweb/identification/@id" /></xsl:otherwise>
864   </xsl:choose>
865 </xsl:variable>
```

The page contains an anchor, whose id is ‘toclink’, and whose href is something as complicated as ‘adage\_tf.html?.../adage2004/uid4.html’: after the question mark, there is the address of the current page, and before it is the name of the page with the frames.

```

866 <xsl:template name="jg.toclink.old">
867   <a id="toclink">
868     <xsl:attribute name="href">
869       <xsl:value-of select="$LeProjet"/>_tf.html?...<xsl:value-of
870         select="$LeProjet"/><xsl:value-of select="$year"/>/<xsl:value-of
871           select="@id"/>.html</xsl:attribute>
872     
874   </a>
875 </xsl:template>
```

The code changed in 2006. If the variable \$noframe is zero, meaning that we have frames, the anchor has ‘toclink’ as id, otherwise it does not. The class of the anchor depends also on this variable (but in all cases the value is the same, so that the test is not shown here). The content of the alt attribute was changed: the French abbreviation TDM was replaced by the English equivalent TOC. Finally, the value of the link is computed by some piece of code.

```

876 <xsl:template name="jg.toclink">
877   <a>
878     <xsl:if test="$noframe='0'">
879       <xsl:attribute name="id">toclink</xsl:attribute>
880     </xsl:if>
881     <xsl:attribute name="class">toc</xsl:attribute>
882     <xsl:attribute name="href">
883       <xsl:call-template name="toclink" />
884     </xsl:attribute>
885     <img align="bottom" border="0" alt="Access to toc" >
886       src="${iconspath}/contents_motif.gif" />
887   </a>
888 </xsl:template>
```

This constructs something like ‘adage\_tf.html?.../adage/uid4.html’, without the year. In the case of the main page, we use ‘uid0’ instead. The link to the TOC depends on whether topics are used or not. However, the code is the same: `toclink_Topic` is identical to `toclink_sansTopic`.

```

889 <xsl:template name="toclink_Topic">
890   <xsl:value-of select="$LeProjet" />
891   <xsl:text>_tf.html?...</xsl:text>
892   <xsl:value-of select="$LeProjet" />
893   <xsl:text>/</xsl:text>
894   <xsl:choose>
895     <xsl:when test="@id=$LeProjet">uid0</xsl:when>
896     <xsl:otherwise>
897       <xsl:value-of select="@id" />
898     </xsl:otherwise>
899   </xsl:choose>
```

```
900     <xsl:text>.html</xsl:text>
901 </xsl:template>
```

Then comes a javascript (it is defined in lib.js). The raweb.css file gives ‘display:none’ as property for the element identified by the `toclink` id. As a consequence, the button is invisible. However, if the name of the frame is ‘mainraweb2004’, the code on line 908 sets the ‘display’ style of elements with id ‘toclink’ to ‘inline’, so that the button is visible.

Assume that the button is visible, and you click on it. This will load the ‘adage\_tf.html’ file; its content is explained later; all that you have to know is that the browser constructs a page with two frames, on the left the TOC, on the right is the current page (what follows the question mark); the name of this second frame is ‘mainraweb2004’, as a consequence the button is invisible. There are two modifications in 2006. The first one is that the frame name is now in the variable `$MainwindowTarget`. The second is that there are options `$noframe` (if set, there are no frames, hence no possibility to switch) and `$notoc` (if set, there is no table of contents). In these cases, the java script is not executed.

```
902 <xsl:choose>
903     <xsl:when test="$noframe='0' and $notoc='0'" >
904         <script type="text/javascript">
905             <xsl:comment>
906                 var cible=this.location;
907                 if (self.name != "<xsl:value-of select=\"$MainwindowTarget\" />")
908                     changestyle('toclink','inline');
909                 //</xsl:comment>
910             </script>
911         </xsl:when>
912     </xsl:choose>
```

The bottom of the page contains only two buttons: previous and next. We have used the same conventions as above. The parameters `$precedent` and `$suivant` contain the locations of the previous and next pages. We insert another item, a javascript. These three items are each in a `<div>`, with an id attribute, the raweb.css file says that these should be flushed left or right, or centered. There is a `<br>` element before and after these three `<div>` elements. There was also an empty `<p>`, removed in 2006.

```
913 <xsl:template name="pagedown.icons">
914     <xsl:param name="precedent" />
915     <xsl:param name="suivant" />
916     <xsl:comment>FIN du corps du module</xsl:comment>
917     <br/>
918     <div id="tail_agache">
919         <xsl:call-template name="make.icon">("$precedent",'previous','','P')
920         </xsl:call-template>
921     </div>
922     <div id="tail_adroite">
923         <xsl:call-template name="make.icon"> ("$suivant",'next','','N')
924         </xsl:call-template>
925     </div>
926     <div id="tail_aucentre"> <xsl:call-template name="classeurlink2" /> </div>
927     <br />
928 </xsl:template>
```

The bottom of the page contains, between the previous and next button, a javascript `<div>` that reads: “You are interested in this page Put in folder !”.

```
929 <xsl:template name="classeurlink2">
930     <div class="folderLine">
931         <script type="text/javascript" src="{$javadir}/classeur/classeurInOut.js" />
932         <noscript><p>Using javascript allows access to folder</p></noscript>
```

```

933     </div>
934 </xsl:template>
```

The top of the page contains, on the right, a `<div>` element (whose color is a kind of blue, the `raweb.css` file says it is BCBCF9), with an image and a pointer to the help page for the folder. There is also a `<script>`, that allows you to put the current page in the folder (same action as on the bottom of the page), or to view and manipulate the folder.

```

935 <xsl:template name="classeurlink1">
936     <div class="folderButtons noscript">
937         <a id="folderIconRef" href=".../classeur/aide.html">
938             
940         </a>
941         <script type="text/javascript" src="${javadir}:classeur/classeurInOutShow.js" />
942     </div>
943     <noscript> Using JavaScript allows access to folder </noscript>
944 </xsl:template>
```

The middle part of the head of the page consists in two buttons vertically aligned (because of the `<br>`) in a `<small>` element<sup>5</sup>. If you click on them, you get the help, and the index. On the right of these, you will find the search form.

```

945 <xsl:template name="head-middle">
946     <div id="head_aucentre">
947         <xsl:call-template name="formRechercheExalead" />
948         <a href="${helpdir}/aide.html" target="aide" onclick="displayHelp(this)">HELP</a>
949         <br /> <br />
950         <a href=".../index/index.html">
951             <xsl:call-template name="targetAttrib.alt" />
952             INDEX
953         </a>
954     </div>
955 </xsl:template>
```

This constructs the search `<form>`. We do not indicate here all the attributes, and the hidden fields.

```

956 <xsl:template name="formRechercheExalead">
957     <form ...>
958         Search in Activity Report, year <xsl:value-of select="$year" />:<br />
959         <input name="_q" size="20" maxlength="800" value="" />
960     </form>
961 </xsl:template>
```

Another form. Why are two forms required? The search engine was AltaVista until July 2005, and Exalead after that. The version of the style sheet we present here is dated 2006/09/21. Apparently, this form is used, rather than the preceding one. The difference is tiny (of course, the result of the search engine is completely different, but this has nothing to do with the HTML input).

```

962 <xsl:template name="formRecherche">
963     <form id="recherche" ... >
964         <input name="q1" size="20" maxlength="800" value="" />
965     </form>
966 </xsl:template>
```

At the very bottom of the page, we have the Inria logo and a link to Inria's home page. The `<div>` and `<span>` elements have an id that is interpreted by the `raweb.css` style sheet.

---

<sup>5</sup>The 'small' was removed in 2006

```

967 <xsl:template name="bandeau_inria">
968   <div id="bandeau">
969     <a id="bandeau_logo" href="http://www.inria.fr">
970       <span id="logotext" >Logo Inria</span>
971     </a>
972   </div>
973 </xsl:template>

```

This creates the top of the page. It takes four arguments, namely `$precedent`, `$haut`, `$suivant`, which are the names of the previous, up or next page, and `$couleur`. This last value is not a color, it is a symbolic name (it is ‘premiere’ or ‘autre’, French for ‘first’ and ‘other’) that will be added as `class` attribute to the main `<div>` element. This `<div>` element has three `<div>` children, that explain what should be put on the left, the middle, and the right of the page. We have already explained what is on the middle and the right. On the left, there are three lines, separated by `<br>`, using a `<small>` font. The first line contains something like “Inria / Raweb 2004”, with two links, the second line contains “Team: Adage”, with a link to the team’s home page (note that ‘Adage’ comes from `<shortname>`, and the link points to ‘adage’, that comes from `$LeProjet`). The last line contains the navigation buttons, created by `page.icons` (arguments are obvious, they are not indicated here, but replaced by a question mark).

```

974 <xsl:template name="bandeau-sup">
975   <xsl:param name="couleur"/>
976   <xsl:param name="precedent" />
977   <xsl:param name="haut" />
978   <xsl:param name="suivant" />
979   <div id="toplign">
980     <xsl:attribute name="class"><xsl:value-of select="$couleur" /></xsl:attribute>
981     <div id="head_agache">
982       <small>
983         <a href="http://www.inria.fr">
984           <xsl:call-template name="targetAttrib.top" />
985           Inria
986         </a> /
987         <a href="{{$indexPath}}>Raweb

989           <br />
990           <xsl:call-template name="jg.url-fiche-projet-A" />
991         </small>
992         <br />
993         <xsl:call-template name="page.icons"> (? , ? , ? )
994       </xsl:call-template>
995     </div>
996     <xsl:call-template name="head-middle" />
997     <div id="head_adroite"> <xsl:call-template name="classeurlink1" /> </div>
998   </div>
999 </xsl:template>

```

This piece of code constructs the start of a page. In order to make things easier to understand, we split the code in two parts. In the first part, we construct three variables. One contains the authors; this was used for the value `dc.creator`, but in the current version, there is one `dc.creator` per author, and the variable has become useless. The second variable contains the toplevel keywords, from `<keyword>`. The last variable contains the title, from `<bodyTitle>`, preceded by the section title (which is a bit more complicated to compute; this was added in 2006).

```

1000 <xsl:template name="page.head">
1001   <xsl:param name="title" />
1002   <xsl:variable name="MTAUT" />
1003   <xsl:variable name="MTMCL">

```

```

1004     <xsl:for-each select=".//keyword">
1005         <xsl:apply-templates /> <xsl:text>/</xsl:text>
1006     </xsl:for-each>
1007 </xsl:variable>
1008 <xsl:variable name="MTDES">
1009     <xsl:if test="name()='identification'">
1010         <xsl:value-of select=" projectName" />
1011     </xsl:if>
1012     <xsl:if test="name()='biblio'"> <xsl:text>Bibliography</xsl:text></xsl:if>
1013     <xsl:if test="name()='team'"> <xsl:text>Members</xsl:text></xsl:if>
1014     <xsl:if test="name(..)='presentation' or name(..)='fondements' or
1015         name(..)='domaine' or name(..)='logiciels' or name(..)='resultats'
1016         or name(..)='contrats' or name(..)='international'
1017         or name(..)='diffusion'">
1018         <xsl:value-of select="..//bodyTitle"/><xsl:text> - </xsl:text>
1019     </xsl:if>
1020     <xsl:value-of select=".//bodyTitle" />
1021 </xsl:variable>
```

Action is trivial. The `<title>` of any HTML page produced by the Adage team in 2004 has the form “Team-Adage”, while `dc.title` contains the title of the module. Since 2006, a parameter `$title` was added, so that the title of the HTML page could be “Project-Team-Adage:Introduction”; this is strange in case the parameter is empty.

```

1022 <head>
1023     <title>
1024         <xsl:value-of select="$LeTypeProjet" />-<xsl:value-of
1025             select="/raweb/identification/shortname" />
1026             :<xsl:value-of select="$title" />
1027     </title>
1028     <link rel="Stylesheet" href="../raweb.css" type="text/css" />
1029     <meta name="description" content="${MTDES}" />
1030     <meta name="dc.title" content="${MTDES}" />
1031     <xsl:for-each select=".//person">
1032         <meta name="dc.creator">
1033             <xsl:attribute name="content">
1034                 <xsl:value-of select="firstname" />
1035                 <xsl:text> </xsl:text>
1036                 <xsl:value-of select="lastname" />
1037             </xsl:attribute>
1038         </meta>
1039     </xsl:for-each>
1040     <meta name="dc.subject" content="${MTMCL}" />
1041     <meta name="dc.publisher" content="INRIA" />
1042     <meta name="dc.date" content="(SCHEME=ISO8601) 2004-01" />
1043     <meta name="dc.type" content="Report" />
1044     <meta name="dc.language" content="(SCHEME=ISO639-1) en" />
1045     <meta name="projet">
1046         <xsl:attribute name="content">
1047             <xsl:value-of select="/raweb/identification/shortname" />
1048         </xsl:attribute>
1049     </meta>
1050     <xsl:call-template name="classeurDecl"/>
1051     <xsl:call-template name="interrogationDecl"/>
1052     <script type="text/javascript" src="../lib.js"></script>
1053     </head>
1054 </xsl:template>
```

This declares the three javascripts.

```
1055 <xsl:template name="interrogationDecl">
1056   <script type="text/javascript" src="${javadir}/interro.js" />
1057 </xsl:template>
1058 <xsl:template name="classeurDecl">
1059   <script type="text/javascript" src="${javadir}/classeur/classeur.js" />
1060   <script type="text/javascript" src="${javadir}/lib.js" />
1061 </xsl:template>
```

We generate one HTML page for each module, one for the composition of the team (that comes before the first module), and one for the bibliography that comes last. The first page (the title page) will contain the full table of contents. Since 2006, the code is split in two parts; two templates are used for each page, the first has already been described, and we show now the second one, whose objective is to produce the `<head>` and `<body>` of the `<html>` part of the page.

There is a possibility to generate the Raweb without frames (`$noframe` is true). In general, one frame contains the text and the other one the TOC, thus, in the case of a single frame, there is no direct access to the TOC. For this reason if `$notoc` is false, a copy of the table of contents is added at the start of every page (except the main page that contains the full TOC).

```
1062 <xsl:template name="jg.toc">
1063   <xsl:if test="$noframe='1' and $notoc='0'">
1064     <xsl:call-template name="tdm" />
1065   </xsl:if>
1066 </xsl:template>
```

For the first page, the links to the top and previous pages are identical, they point to the title page (`uid0.html`), the link to the next page is to the first `<subsection>` (the name of the page is the `id` attribute, with a `.html` extension). In order to reduce the size of this document, we do not show the parameters to `bandeau-sup` and `pagedown.icons`, the value is obvious, it is replaced by a question mark. The `page.head` template takes a `title` parameter, not shown here, it is empty.

We have explained above how page headers and footers are created, let's explain here how the body is constructed. First, we extract all `<moreinfo>` elements that come from this element or the `<identification>` part, they are output in a `<blockquote>` element. After that, we insert the title in a `<h1>` heading. This is followed by all the `<participants>` elements; each such element has a `category` attribute, that gives a subtitle, a `<h3>` element. We convert underscores back to spaces. Each `<person>` of these participants is inserted, with a `<br>` as separator.

```
1067 <xsl:template match="identification/team">
1068   <xsl:variable name="precedent" select="'uid0'" />
1069   <xsl:variable name="haut" select="'uid0'" />
1070   <xsl:variable name="suivant" select="/raweb/*/subsection[1]/@id" />
1071   <xsl:call-template name="page.head" />
1072   <body>
1073     <xsl:call-template name="jg.toc"/>
1074     <xsl:call-template name="bandeau-sup">
1075       <xsl:with-param name="couleur" select="'autre'" /> (? , ? , ? )
1076     </xsl:call-template>
1077     <div id="main">
1078       <xsl:for-each select="/raweb/identification/moreinfo">
1079         <blockquote> <xsl:apply-templates /> </blockquote>
1080       </xsl:for-each>
1081       <xsl:for-each select=".//moreinfo">
1082         <blockquote> <xsl:apply-templates /> </blockquote>
1083       </xsl:for-each>
1084       <h1>Team</h1>
1085       <xsl:for-each select="participants">
1086         <h3> <xsl:value-of select="translate(@category, '_ ', ' ')"/> </h3>
```

```

1087     <xsl:for-each select="person">
1088         <xsl:apply-templates select=". " /> <br />
1089     </xsl:for-each>
1090     <br />
1091     <xsl:call-template name="pagedown.icons" > ( ?, ? )
1092     </xsl:call-template>
1093     <xsl:call-template name="bandeau_inria" />
1094     </div>
1095   </body>
1096 </xsl:template>
```

This constructs the page with the bibliography.

```

1098 <xsl:template match="biblio">
1099   <xsl:variable name="precedent"
1100     select="preceding-sibling::*[1]/subsection[position()=last()]/@id"/>
1101   <xsl:variable name="haut" select="'uid0' "/>
1102   <xsl:variable name="suivant" select=" '' "/>
1103   <xsl:call-template name="page.head"/>
1104   <body>
1105     <xsl:call-template name="jg.toc"/>
1106     <xsl:call-template name="bandeau-sup" >( ?, ?, ? )
1107       <xsl:with-param name="couleur" select=" 'autre' " />
1108     </xsl:call-template>
1109     <h1> Bibliography </h1>
1110     <xsl:call-template name="tri-par-publis"/>
1111     <xsl:call-template name="pagedown.icons" > ( ?, ? )
1112     </xsl:call-template>
1113     <xsl:call-template name="bandeau_inria" />
1114   </body>
1115 </xsl:template>
```

In the case of `<subsection>`, we have to distinguish between modules and normal sections. A module is a subsection whose parent is not a subsection, and a full HTML page must be created. In this case, we generate a page, like above (arguments of `bandeau-sup` and `pagedown.icons` are not shown, the non-trivial part is to find the previous and next pages, in `$precedent` and `$suivant`). The page body contains the following: it starts with a title (for instance “Team : adage” in a `<h1>`, followed by the title of the section (it could be “Section: Overall Objectives” in a `<h2>`, this depends on whether `$isTopic` is set), followed by a horizontal rule, a `<hr>`. This is followed by the title (value of `<bodyTitle>`) in a `<h3>` and the keywords<sup>6</sup>. Then comes the content of the subsection.

```

1116 <xsl:template match="subsection">
1117   <xsl:variable name="haut" select=" 'uid0' " />
1118   <xsl:variable name="precedent" ><xsl:call-template name="precedent" /> </xsl:variable>
1119   <xsl:variable name="suivant" ><xsl:call-template name="suivant" /></xsl:variable>
1120   <xsl:choose>
1121     <xsl:when test="not(parent::subsection)" >
1122       <xsl:call-template name="page.head" >
1123         <xsl:with-param name="title" >
1124           <xsl:value-of select=" ./bodyTitle " />
1125         </xsl:with-param>
1126       </xsl:call-template>
1127     <body>
1128       <xsl:call-template name="jg.toc"/>
1129       <xsl:call-template name="bandeau-sup" >( ?, ?, ? )
```

---

<sup>6</sup>The order of these two items changed between 2005 and 2006

```

1130         <xsl:with-param name="couleur" select="'autre'" />
1131     </xsl:call-template>
1132     <div id="main">
1133         <xsl:call-template name="use-id" />
1134         <h1>
1135             <xsl:value-of select="$LeTypeProjet" />
1136             <xsl:text> : </xsl:text>
1137             <xsl:value-of select="$LeProjet" />
1138         </h1>
1139         <xsl:choose>
1140             <xsl:when test="$isTopic='1'">
1141                 <xsl:call-template name="section_title_Topic" />
1142             </xsl:when>
1143             <xsl:otherwise>
1144                 <xsl:call-template name="section_title_sansTopic" />
1145             </xsl:otherwise>
1146         </xsl:choose>
1147         <hr />
1148         <xsl:apply-templates select="bodyTitle" mode="titre3"/>
1149         <xsl:call-template name="jg.keywords" />
1150         <xsl:apply-templates />
1151         <xsl:call-template name="pagedown.icons" /> (? , ?)
1152     </xsl:call-template>
1153     <xsl:call-template name="bandeau_inria"/>
1154 </div>
1155 </body>
1156 </xsl:when>
```

In the case where `<subsection>` is in a subsection, we output its title (value of `<bodyTitle>`) using `<h4>` or `<h5>`, depending on whether the parent is in a subsection, then the keywords, then the content.

```

1157     <xsl:otherwise>
1158         <xsl:call-template name="use-id" />
1159         <xsl:choose>
1160             <xsl:when test="(./parent::subsection)">
1161                 <xsl:apply-templates select="bodyTitle" mode="titre5"/>
1162             </xsl:when>
1163             <xsl:otherwise>
1164                 <xsl:apply-templates select="bodyTitle" mode="titre4"/>
1165             </xsl:otherwise>
1166         </xsl:choose>
1167         <xsl:call-template name="keywords-list" />
1168         <xsl:apply-templates />
1169     </xsl:otherwise>
1170 </xsl:choose>
1171 </xsl:template>
```

This piece of code creates the title page, the TOC, and the frameset. In the case of the adage team, the files are `adage.html`, `adage_tdm.html`, and `adage_tf.html` in the `adage2004` directory. Let's consider the title page first. It looks like a normal page, except that `bandeau_inria` (the banner with the logo) is before the text.

```

1172 <xsl:template match="identification">
1173     <xsl:variable name="precedent" select="" />
1174     <xsl:variable name="haut" select="uid0" />
1175     <xsl:variable name="suivant" select="team/@id" />
1176     <xsl:call-template name="page.head" />
1177 <body>
```

```

1178     <xsl:call-template name="bandeau-sup">
1179         <xsl:with-param name="couleur" select="'premiere'" /> (? ,? ,?)
1180     </xsl:call-template>
1181     <xsl:call-template name="bandeau_inria"/>
1182     <xsl:comment>DEBUT du corps du module</xsl:comment>
1183     <xsl:call-template name="jg.titlepage"/>
1184     <hr class="rose"/>
1185     <xsl:call-template name="table.matieres" />
1186     <xsl:call-template name="pagedown.icons"> (? ,? )
1187     </xsl:call-template>
1188 </body>
1189 </xsl:document>

```

The title page is divided in two parts, the first part contains the identification of the team, it is followed by the TOC. We start with a `<h1>` element that contains the full name of the team, from `<projectName>`. This is followed by the short name, from `<shortname>`. It is followed by “2006 research project activity reports”, a link to the UR (Research Unit), a link to the team, to the PostScript, Pdf and XML versions of the report.

```

1190 <xsl:template name="jg.titlepage">
1191     <h1 class="center"> <xsl:value-of select="projectName" /> </h1>
1192     <div class="entete">
1193         <div class="bigspace"><h2><xsl:value-of select="shortname" /></h2></div>
1194         <xsl:value-of select="$year" /> research project activity reports
1195         <xsl:call-template name="UR"/>
1196         <div class="bigspace">
1197             <xsl:call-template name="jg.find-theme"/>
1198         </div>
1199         <xsl:call-template name="jg.url-fiche-projet-B" />
1200         <xsl:call-template name="url-ps-file">
1201             <xsl:with-param name="projet" select="$LeProjet" />
1202             <xsl:with-param name="Text">PostScript</xsl:with-param>
1203         </xsl:call-template>
1204         <xsl:text>, </xsl:text>
1205         <xsl:call-template name="url-pdf-file">
1206             <xsl:with-param name="projet" select="$LeProjet" />
1207             <xsl:with-param name="Text">PDF</xsl:with-param>
1208         </xsl:call-template>
1209         <xsl:text> or </xsl:text>

1211             <xsl:with-param name="projet" select="$LeProjet" />
1212             <xsl:with-param name="Text">XML</xsl:with-param>
1213         </xsl:call-template>
1214         <xsl:text> format</xsl:text>
1215     </div>
1216 </xsl:template>

```

This is the piece of code that inserts the theme, a bit arranged for clarity. It depends on whether `$xyleme` is true. The value of the variable is something like ‘num’ in the XML file produced by Tralics, converted to ‘NUM’ (all uppercase) in the new DTD. We convert it to ‘Num’ for the link<sup>7</sup>.

```

1217 <xsl:template name="jg.find-theme">
1218     <xsl:variable name="path"
1219         select="http://www.inria.fr/recherche/equipes/listes/theme_"/>
1220     <xsl:variable name="themeurl">
1221         <xsl:choose>

```

<sup>7</sup>This is new in 2005; but `theme_NUM.html` and `theme_Num.html` are handled the same by the Web server.

```

1222     <xsl:when test="$xyleme='1'">
1223         <xsl:value-of select="$indexPath" />
1224         <xsl:text>?theme=</xsl:text/>
1225         <xsl:value-of select="substring(theme,1,3)" />
1226     </xsl:when>
1227     <xsl:otherwise>
1228         <xsl:value-of select="$path" />
1229         <xsl:value-of select="substring(theme,1,1)" />
1230         <xsl:value-of select="translate(substring(theme,2,3),
1231             'ABCDEFGHIJKLMNOPQRSTUVWXYZ','abcdefghijklmnopqrstuvwxyz')" />
1232         <xsl:text>.en.html</xsl:text>
1233     </xsl:otherwise>
1234 </xsl:choose>
1235 </xsl:variable>
1236 Theme:
1237 <a href="{{$themeurl}}>
1238     <xsl:call-template name="targetAttrib.alt" />
1239     <xsl:value-of select="theme" />
1240 </a>
1241 </xsl:template>

```

Translation of <UR>. We look at the `name` attribute. The code is easy, perhaps a bit longish (we do not show the complete code here). We test the value against Rocquencourt, Rennes, Sophia, Lorraine, RhoneAlpes and Futurs.

```

1242 <xsl:template name="UR">
1243     <xsl:variable name="orga">http://www.inria.fr/inria/organigramme/fiche</xsl:variable>
1244     <div class="bigspace">

1262         <xsl:if test="position() != last()"> - </xsl:if>
1263     </xsl:for-each>
1264 </div>
1265 </xsl:template>

```

This contains the HTML page with the frameset. An interesting point is that this contains the table of contents, for the case where frames are refused. Note that this is an HTML document, not an XML one (the `method` attribute is different); more important, all other HTML files have XHTML1.0 as doctype, this one has HTML4.01. The document contains two frames; one of them points to an HTML page whose name is dynamically constructed. The idea is the following. Normally, the `location.search` variable is empty and the result of line 1282 is ‘uid0.html’; however, in the case of an URL like line 869 or 891, that contains a question mark, the variable is not empty, what follows the question mark is used.

```

1266 <xsl:template name="creer.frameset">
1267   <xsl:document href="${Directory}/{$id}_tf.html" method="html" encoding="iso-8859-1"

1298 </xsl:document>
1299 </xsl:template>

```

### 6.1.3 Titles, keywords, persons

This outputs the current section title, the `<bodyTitle>` of the parent, using `<h2>` as heading.

```

1299 <xsl:template name="section_title_sansTopic">
1300   <h2>Section: <xsl:value-of select="..//bodyTitle" /></h2>
1301 </xsl:template>

```

This outputs the current title, found in `<bodyTitle>`, using `<h2>`, `<h3>`, `<h4>`, or `<h5>` as heading.

```

1302 <xsl:template match="bodyTitle" mode="titre2">
1303   <h2 class="titre2"> <xsl:apply-templates/></h2>
1304 </xsl:template>
1305 <xsl:template match="bodyTitle" mode="titre3">
1306   <h3 class="titre3"> <xsl:apply-templates/></h3>
1307 </xsl:template>
1308 <xsl:template match="bodyTitle" mode="titre4">
1309   <h4 class="titre4"><xsl:apply-templates/> </h4>
1310 </xsl:template>
1311 <xsl:template match="bodyTitle" mode="titre5">
1312   <h5 class="titre5"><xsl:apply-templates/> </h5>
1313 </xsl:template>

```

In the case of topics, the layout is a bit different, and titles are handled by the routines that follow. At level one, the result is a `<h1>`. If the title is missing, it will be replaced by the title of the section (presentation, fondements, etc.). The result is empty if the parent has no topic. Note: Tralics refuses to create a section with an empty title. In some cases, for instance if this is the first module in a sequence of more than one modules, the title will be ‘Introduction’. Otherwise, it will be ‘(Sans Titre)’ and the style sheet is assumed to do something in this case.

```

1314 <xsl:template match="(presentation|fondements|domaine|logiciels
1315   |resultats|contrats|international|diffusion)/subsection/bodyTitle"
1316   priority="1">
1317   <xsl:call-template name="use-id" />
1318   <xsl:if test="..../subsection/@topic">
1319     <h1> <xsl:apply-templates /> </h1>
1320   </xsl:if>
1321 </xsl:template>

```

A title is always output by the routines shown above, hence the default action is empty.

```
1322 <xsl:template match="bodyTitle" />
```

This is how we typeset a title in the TOC. We use a `<li>` element and a link to the page. This fills the anchor (text and attributes). If the title is empty, the title of the parent is used instead.

```

1323 <xsl:template name="item_title_or_not_title">
1324   <xsl:call-template name="targetAttrib.main" />
1325   <xsl:attribute name='href'>
1326     <xsl:call-template name="formaturl">
1327       <xsl:with-param name="base" select="@id" />
1328     </xsl:call-template>
1329   </xsl:attribute>
1330   <xsl:choose>
1331     <xsl:when test="bodyTitle">
1332       <xsl:value-of select=".//bodyTitle" />
1333     </xsl:when>
1334     <xsl:otherwise>
1335       <xsl:value-of select="..//bodyTitle" />
1336     </xsl:otherwise>
1337   </xsl:choose>
1338 </xsl:template>

```

Section titles are typeset twice: in the text, and in the TOC. When we are in the TOC, ids are not added. This is not very important for the HTML, because the TOC is a separated file. For the Pdf version it is necessary; it could be necessary if we decided to add a local TOC to each page (à la minitoc, this was done, for instance in 1996).

```

1339 <xsl:template match="bodyTitle" mode="tocsection">
1340   <xsl:apply-templates mode="section" />
1341 </xsl:template>

```

This rule says that keywords are handled via `keywords-list`, except if we are in a toplevel subsection that has subsections, case where `keywords-list2` is used instead.

```

1342 <xsl:template name="jg.keywords">
1343   <xsl:choose>
1344     <xsl:when test="not(..//subsection)">
1345       <xsl:call-template name="keywords-list" />
1346     </xsl:when>
1347     <xsl:otherwise>
1348       <xsl:call-template name="keywords-list2" />
1349     </xsl:otherwise>
1350   </xsl:choose>
1351 </xsl:template>

```

We modified a bit the code that follows: there was a `<p>`, moved inside the template `listvir`<sup>8</sup>. In general, when a keyword is seen, we take all `<keyword>` elements from the subtree, and pass them to the template.

```
1352 <xsl:template name="keywords-list">
1353   <xsl:if test=".//keyword">
1354     <xsl:call-template name="listvir">
1355       <xsl:with-param name='liste' select="(./keyword)" />
1356       <xsl:with-param name='deco' select="string('keyword')" />
1357     </xsl:call-template>
1358   </xsl:if>
1359 </xsl:template>
```

However, in the case of a toplevel subsection (a module) with subsections, the action is different: we take only the `<keyword>` elements of this subsection.

```
1360 <xsl:template name="keywords-list2">
1361   <xsl:if test=".//keyword">
1362     <xsl:call-template name="listvir">
1363       <xsl:with-param name='liste' select="(./keyword)" />
1364       <xsl:with-param name='deco' select="string('keyword')" />
1365     </xsl:call-template>
1366   </xsl:if>
1367 </xsl:template>
```

This is the action when we have a list of keywords to convert. The test (is there a keyword on the tree?) should probably be replaced by a better one (is the list empty?). If `$xyleme` is true, each keyword has a link (code omitted).

```
1368 <xsl:template name="listvir">
1369   <xsl:param name="liste" />
1370   <xsl:param name="deco" />
1371   <p>
1372     <xsl:if test=".//keyword"> <span clas="KW">Keywords</span> : </xsl:if>
1373     <xsl:for-each select="$liste" >
1374       <span class="${deco}"><xsl:apply-templates /></span>
1375       <xsl:call-template name="separateur.objet" />
1376     </xsl:for-each >
1377   </p>
1378 </xsl:template>
```

The previous routines takes all keywords, so that the default action is empty.

```
1379 <xsl:template match="keyword"> </xsl:template>
```

In the presentation part, a `<person>` is handled by this code. We output the `<firstname>`, a space, the `<lastname>`, and the `<moreinfo>`, provided that this is not empty. Brackets are added. Since 2006, three new fields were added, only `<hdr>` produces something. Assume that our guy is called Jean Dupont, the result is then one of ‘Jean Dupont [HdR]’, ‘Jean Dupont [CR, HdR]’, ‘Jean Dupont [CR]’, ‘Jean Dupont’. Each bracket is preceded and followed by space, ‘CR’ is the content of the `<moreinfo>` element, and ‘HdR’ is produced by the templates given below (we gave a name to `jg.hdr`, this makes the code easier to understand). We also removed a useless test (it tested that the element is non-empty, instead of testing `<moreinfo>`, but we know that `<moreinfo>`, when present, is non-empty).

```
1380 <xsl:template match="person">
1381   <xsl:value-of select=".//firstname" />
1382   <xsl:text> </xsl:text>
1383   <xsl:value-of select=".//lastname" />
1384   <xsl:choose>
```

---

<sup>8</sup>This is a strange name. It has no obvious meaning

```

1385     <xsl:when test="moreinfo">
1386         <xsl:text> [ </xsl:text>
1387         <xsl:apply-templates select=".//moreinfo/node()" />
1388         <xsl:apply-templates select="hdr" />
1389         <xsl:text> ] </xsl:text>
1390     </xsl:when>
1391     <xsl:otherwise>
1392         <xsl:call-templates select="jg.hdr" />
1393     </xsl:otherwise>
1394     </xsl:choose>
1395 </xsl:template>
```

Both templates shown here produce the string ‘habilité(e)’ which is non-sense in an English document. This will change in the final version of the RA2006, using the acronym ‘HdR’. The first template is called when there is no `<moreinfo>` in the current `<pers>`, it outputs the funny string with the brackets if `<hdr>` is present; the second one is called if there is a `<moreinfo>`, it just outputs the funny string, preceded by a comma.

```

1396 <xsl:template name="jg.hdr">
1397     <xsl:if test="hdr">
1398         <xsl:text> [ habilité(e) ] </xsl:text>
1399     </xsl:if>
1400 </xsl:template>
1401 <xsl:template match="hdr">
1402     <xsl:text>, </xsl:text>
1403     <xsl:text> habilité(e) </xsl:text>
1404 </xsl:template>
```

In the other sections, a `<person>` is similarly handled, but the code is a bit different. If `$xyleme` is set, an anchor is added (this is the same as for keywords, code not shown here). There are no additional fields like `<hdr>` to consider here.

```

1405 <xsl:template name="xperson">
1406     <xsl:value-of select=".//firstname"/>
1407     <xsl:text> </xsl:text>
1408     <xsl:value-of select=".//lastname"/>
1409     <xsl:apply-templates select="moreinfo" mode="inpers"/>
1410 </xsl:template>
```

If you look carefully, you can see that spaces around square brackets are different here and in the previous case.

```

1411 <xsl:template match="moreinfo" mode ="inpers">
1412     <xsl:if test="not(normalize-space(string(.)) = '')">
1413         <xsl:text> [</xsl:text><xsl:apply-templates/><xsl:text>]</xsl:text>
1414     </xsl:if>
1415 </xsl:template>
```

This takes a list as argument, it outputs an s if there are more than one element in the list.

```

1416 <xsl:template name="pluriel-p">
1417     <xsl:param name="liste" />
1418     <xsl:if test="count($liste)>1">s</xsl:if>
1419 </xsl:template>
```

In a `<subsection>`, the translation of `<participants>` is formed of every `<person>`, with comma as separator.

```

1420 <xsl:template match="subsection//participants">
1421     <p class="participants">
1422         <span class="part">Participant
1423             <xsl:call-template name="pluriel-p">
```

```

1424         <xsl:with-param name="liste" select="person" />
1425     </xsl:call-template>
1426   </span> :
1427   <xsl:for-each select="person">
1428     <xsl:call-template name="xperson" />
1429     <xsl:call-template name="separateur.objet" />
1430   </xsl:for-each>
1431   </p>
1432 </xsl:template>
```

#### 6.1.4 Other elements

Let's consider some trivial commands. We leave `<i>` unchanged.

```

1433 <xsl:template match="i">
1434   <i><xsl:apply-templates /></i>
1435 </xsl:template>
```

Ditto for `<b>`.

```

1436 <xsl:template match="b">
1437   <b> <xsl:apply-templates /> </b>
1438 </xsl:template>
```

Ditto for `<tt>`.

```

1439 <xsl:template match="tt">
1440   <tt><xsl:apply-templates /> </tt>
1441 </xsl:template>
```

Ditto for `<small>`.

```

1442 <xsl:template match="small">
1443   <small> <xsl:apply-templates /> </small>
1444 </xsl:template>
```

Ditto for `<big>`.

```

1445 <xsl:template match="big">
1446   <big> <xsl:apply-templates /> </big>
1447 </xsl:template>
```

Ditto for `<sup>`.

```

1448 <xsl:template match="sup">
1449   <sup> <xsl:apply-templates /> </sup>
1450 </xsl:template>
```

Ditto for `<sub>`.

```

1451 <xsl:template match="sub">
1452   <sub> <xsl:apply-templates /> </sub>
1453 </xsl:template>
```

This code is the same as above. This is used for evaluation of a title in the TOC.

```

1454 <xsl:template match="sup" mode="section">
1455   <sup> <xsl:apply-templates /> </sup>
1456 </xsl:template>
1457 <xsl:template match="sub" mode="section">
1458   <sub> <xsl:apply-templates /> </sub>
1459 </xsl:template>
```

The translation of `<em>` is a `<i>` in the case where the `style` attribute is 'UNDERLINE', is 'HIGHLIGHT' or is something else. We simplified a bit the code.

```
1460 <xsl:template match="em">
1461   <i> <xsl:apply-templates /> </i>
1462 </xsl:template>
```

This could be used by Xyleme.

```
1463 <xsl:template match="highlight">
1464   <span class="xyHighlight">
1465     <xsl:apply-templates />
1466   </span>
1467 </xsl:template>
```

The translation of `<span>` is the same element. We copy the `class` attribute, but not the other ones (why?).

```
1468 <xsl:template match="span">
1469   <span class="@class"> <xsl:apply-templates /> </span>
1470 </xsl:template>
```

We could do better.

```
1471 <xsl:template match="center">
1472   <xsl:apply-templates />
1473 </xsl:template>
```

A `<term>` is converted into a `<tt>`.

```
1474 <xsl:template match="term">
1475   <tt> <xsl:apply-templates /> </tt>
1476 </xsl:template>
```

A `<simplelist>` is converted into a `<ul>`.

```
1477 <xsl:template match="simplelist">
1478   <ul> <xsl:apply-templates /> </ul>
1479 </xsl:template>
```

A `<orderedlist>` is converted into a `<ol>`.

```
1480 <xsl:template match="orderedlist">
1481   <ol> <xsl:apply-templates /> </ol>
1482 </xsl:template>
```

A `<descriptionlist>` is converted into a `<dl>`.

```
1483 <xsl:template match="descriptionlist">
1484   <dl> <xsl:apply-templates /> </dl>
1485 </xsl:template>
```

Elements `<glosslist>` or `<descriptionlist>` should contain a `<label>`, a `<li>`, a `<label>`, a `<li>`, etc. These are converted into a `<dd>` or `<dd>` in the obvious way.

```
1486 <xsl:template match="glosslist/label | descriptionlist/label">
1487   <dt> <xsl:apply-templates /> </dt>
1488 </xsl:template>
1489 <xsl:template match="glosslist/li | descriptionlist/li">
1490   <dd> <xsl:apply-templates /> </dd>
1491 </xsl:template>
```

A `<li>` is converted into a `<li>` in cases not shown above. If preceded by a `<label>`, the value of the label is added.

```
1492 <xsl:template match="li">
1493   <li>
1494     <xsl:apply-templates select="@*" />
1495     <xsl:apply-templates mode="li" select="preceding-sibling::label[position()=1]" />
1496     <xsl:apply-templates />
```

```
1497     </li>
1498 </xsl:template>
```

Two rules are needed: one that says that `<label>` should be ignored, and one that says that it should be translated (from inside the `<li>`, where the mode is correct).

```
1499 <xsl:template match="label" />
1500
1501 <xsl:template match="label" mode="li">
1502     <xsl:apply-templates />
1503 </xsl:template>
```

A `<glosslist>` is converted into a `<dl>`. It has a title, is put in a `<div>`, preceded and followed by a horizontal rule, a `<hr>` element.

```
1504 <xsl:template match="glosslist">
1505     <hr />
1506     <div id="glossaire" style="margin-left: 2em; margin-right: 2em;">
1507         <dl title="Glossary"> <xsl:apply-templates /> </dl>
1508     </div>
1509     <hr />
1510 </xsl:template>
```

The translation of `<moreinfo>` is a `<blockquote>`, unless it is in a `<pers>`, case where the code on lines 1387 or 1409 applies.

```
1511 <xsl:template match="moreinfo">
1512     <blockquote> <xsl:apply-templates /> </blockquote>
1513 </xsl:template>
```

Action is empty here. Normally, there should be no `<moreinfo>` in `<raweb>`, it should be in `<identification>`.

```
1514 <xsl:template match="/raweb/moreinfo" priority="1"/>
```

The translation of `<simplemath>` is `<i>`. Such an element is generated by Tralics in the case of a trivial formula like `$x$`.

```
1515 <xsl:template match="simplemath">
1516     <i> <xsl:apply-templates /> </i>
1517 </xsl:template>
```

Math formulas are copied verbatim, with their context. We assume that either the browser understands MathML or that a postprocessor converts the math.

```
1518 <xsl:template match="m:math">
1519     <xsl:copy>
1520         <xsl:apply-templates mode="math" />
1521     </xsl:copy>
1522 </xsl:template>
1523
1524 <xsl:template mode="math" match="*|@*|text()">
1525     <xsl:copy>
1526         <xsl:apply-templates mode="math" select="*|@*|text()" />
1527     </xsl:copy>
1528 </xsl:template>
```

This is for the case where the math appears in a title in the TOC.

```
1529 <xsl:template match="m:math" mode="section">
1530     <m:math>
1531         <xsl:copy-of select="@*" />
1532         <xsl:apply-templates mode="math" />
1533     </m:math>
1534 </xsl:template>
```

Translation of <formula>. It depends on the type attribute. If this is not ‘display’, the result is a simple <span>, with attribute class=‘math’. If the type is ‘display’, the result is a <div>, with attribute class=‘mathdisplay’, and align=‘center’. Moreover, if there is an id, an equation number is added. For this reason a <table> is created, with a single <tr> and two <td>, first the formula, centered, then its number, right aligned.

```

1535 <xsl:template match="formula">
1536   <xsl:choose>
1537     <xsl:when test="@type = 'display' and @id">
1538       <div align="center" class="mathdisplay">
1539         <xsl:call-template name="use-id" />
1540         <table width='100%'>
1541           <tr valign='middle'>
1542             <td align='center'> <xsl:apply-templates /> </td>
1543             <td class="eqno" width="10" align="right">(<xsl:number
1544               level="any" count="formula[@id]" />)</td>
1545           </tr>
1546         </table>
1547       </div>
1548     </xsl:when>
1549     <xsl:when test="@type = 'display'">
1550       <div align="center" class="mathdisplay"> <xsl:apply-templates /> </div>
1551     </xsl:when>
1552     <xsl:otherwise>
1553       <span class="math"> <xsl:apply-templates /> </span>
1554     </xsl:otherwise>
1555   </xsl:choose>
1556 </xsl:template>
```

The translation of <footnote>Text</footnote> is ‘(Text)’, this is much more legible than a link to the text.

```

1557 <xsl:template match='footnote'>
1558   <xsl:text>(</xsl:text><xsl:apply-templates /><xsl:text>)</xsl:text>
1559 </xsl:template>
```

Because of the code above, a <p> in a footnote cannot be transformed into a paragraph.

```

1560 <xsl:template match="footnote/p">
1561   <xsl:apply-templates />
1562 </xsl:template>
```

The translation of <p> is a <blockquote> if the rend attribute is ‘quoted’. Otherwise, it is a <p>. If rend is ‘center’ or ‘centered’, we add align=‘center’. If noindent is given<sup>9</sup>, we add class=‘notaparagraph’.

```

1563 <xsl:template match="p">
1564   <xsl:choose>
1565     <xsl:when test="@rend='quoted'">
1566       <blockquote> <xsl:apply-templates /> </blockquote>
1567     </xsl:when>
1568     <xsl:otherwise>
1569       <p>
1570         <xsl:choose>
1571           <xsl:when test="@rend='centered' or @rend='center'">
1572             <xsl:attribute name="align">center</xsl:attribute>
1573           </xsl:when>
1574           <xsl:when test="@noindent">
1575             <xsl:attribute name="class">notaparagraph</xsl:attribute>
```

---

<sup>9</sup>We should test the value.

```

1576         </xsl:when>
1577     </xsl:choose>
1578     <xsl:apply-templates />
1579   </p>
1580   </xsl:otherwise>
1581 </xsl:choose>
1582 </xsl:template>
```

This is a bit strange. Currently<sup>10</sup> Tralics does not produce `<anchor>` elements. Note: the `<a>` element as shown here is empty, in reality, it contains a space. Why?

```

1583 <xsl:template name="use-id">
1584   <xsl:if test="@id"> <a name="{@id}" /> </xsl:if>
1585   <xsl:if test="anchor/@id"><a name="{anchor/@id}" /> </xsl:if>
1586 </xsl:template>
```

Translation of `<table>`. We call some template. The result will be in a `<div>`.

```

1587 <xsl:template match="table">
1588   <div class="notinline" align='center' style="margin-top:20px">
1589     <xsl:call-template name="use-id" />
1590     <xsl:call-template name='generate-table' />
1591   </div>
1592 </xsl:template>
```

If the table is inline, there is no reference to it (we can omit the id), and we do not produce a `<div>`.

```

1593 <xsl:template match="table[@rend='inline']">
1594   <xsl:call-template name='generate-table' />
1595 </xsl:template>
```

This is called when the table comes from an object. Note that the ‘mode’ is useless in the `xsl:call-template`.

```

1596 <xsl:template match="table" mode="object">
1597   <xsl:call-template name="use-id" />
1598   <xsl:call-template name='generate-table' mode="object" />
1599 </xsl:template>
```

Translation of `<table>`. The result is a table, that contains the translation of the `<caption>`, followed by some `<tr>` elements. Each such elements is the translation of a `<tr>`, it is formed of the translation of all cells, the `<td>` and `<th>` sub-elements. The `style` attribute of each cell is copied, as well as the style of the row<sup>11</sup>, in the case where the cell is empty, a height of three pixels is added. If an attribute `rows` or `cols` is present, it is transformed into `rowspan` or `colspan`. If a child of a cell is a `<ressource>`, the `align` attribute is set to center<sup>12</sup>.

```

1600 <xsl:template name="generate-table">
1601   <table>
1602     <xsl:apply-templates select="caption" />
1603     <xsl:for-each select="tr">
1604       <tr>
1605         <xsl:for-each select="td|th">
1606           <xsl:element name="{name()}">
1607             <xsl:attribute name="style">
1608               <xsl:if test="normalize-space(.) = ''">height:3px;</xsl:if>
1609               <xsl:value-of select="@style" />
1610               <xsl:value-of select="../@style" />

```

<sup>10</sup>Anchors were added in version 2.8.5, in order to make \index work.

<sup>11</sup>Question: what says the DTD about this style attribute?

<sup>12</sup>What if the initial XML document specifies a different horizontal alignment, something hidden in the `style` attribute?

```

1611     </xsl:attribute>
1612     <xsl:if test="@cols">
1613         <xsl:attribute name="colspan"><xsl:value-of select="@cols" /></xsl:attribute>
1614     </xsl:if>
1615     <xsl:if test="@rows">
1616         <xsl:attribute name="rowspan"><xsl:value-of select="@rows" /></xsl:attribute>
1617     </xsl:if>
1618     <xsl:if test="ressource">
1619         <xsl:attribute name="align">center</xsl:attribute>
1620     </xsl:if>
1621     <xsl:apply-templates />
1622     </xsl:element>
1623     </xsl:for-each>
1624     </tr>
1625 </xsl:for-each>
1626 </table>
1627 </xsl:template>
```

A style attribute is always copied.

```

1628 <xsl:template match="@style">
1629     <xsl:attribute name="style"><xsl:value-of select=".." /></xsl:attribute>
1630 </xsl:template>
```

A align attribute is converted to a style attribute.<sup>13</sup>

```

1631 <xsl:template match="@align">
1632     <xsl:attribute name="style">text-align:<xsl:value-of select=".." /></xsl:attribute>
1633 </xsl:template>
```

The translation of a <caption> in a table is a <caption> element. It contains the table number (it should be the same as the one given by calculateTableName).

```

1634 <xsl:template match="table/caption" >
1635     <caption align="bottom">
1636         <strong>Table
1637             <xsl:number count="table[not(ancestor::object)]" level="any" />
1638             <xsl:text>. </xsl:text>
1639         </strong>
1640         <xsl:apply-templates />
1641     </caption>
1642 </xsl:template>
```

The translation of a <caption> in a table in a figure. The result is a simple <caption>. There should be no reference to it.

```

1643 <xsl:template match="object//table/caption" priority="1">
1644     <caption> <xsl:apply-templates /> </caption>
1645 </xsl:template>
```

Translation of <img>. We copy the attributes width, height, align, border, alt, and src. Note: the <img> element is not defined by the DTD. Thus, the author of the document should not create them; on the other hand, there is a post-processor that replaces some math formulas by images that match this usage. In the case where \$xyleme is set and there is an attribute xylemeAttach, the src attribute is computed differently.

```

1646 <xsl:template match="img">
1647     <img>
1648         <xsl:if test="@width">
1649             <xsl:attribute name="width"><xsl:value-of select="@width" /></xsl:attribute>
```

---

<sup>13</sup>What happens if both style and align are given? who wins? In fact, the question has no sense, because Tralics never emits a 'align', so that this template shoud never be called.

```

1650     </xsl:if>
1651     <xsl:if test="@height">
1652       <xsl:attribute name="height"><xsl:value-of select="@height" /></xsl:attribute>
1653     </xsl:if>
1654     <xsl:attribute name="align"><xsl:value-of select="@align" /></xsl:attribute>
1655     <xsl:attribute name="border"><xsl:value-of select="@border" /></xsl:attribute>
1656     <xsl:attribute name="alt"><xsl:value-of select="@alt" /></xsl:attribute>
1657     <xsl:attribute name="src">
1658       <xsl:choose>
1659         <xsl:when test="($xyleme='1') and @xylemeAttach">
1660           <xsl:value-of select="$imgpath" />
1661           <xsl:apply-templates select="@xylemeAttach" />
1662         </xsl:when>
1663         <xsl:otherwise>
1664           <xsl:value-of select="@src" />
1665         </xsl:otherwise>
1666       </xsl:choose>
1667     </xsl:attribute>
1668   </img>
1669 </xsl:template>
```

Given a string \$str, of the form ‘foo.bar.gee’, this procedure returns what follows the last dot, namely ‘gee’. It is a recursive procedure.

```

1670 <xsl:template name="get-extention" >
1671   <xsl:param name="str" />
1672   <xsl:choose>
1673     <xsl:when test="substring-after($str,'.')=''">
1674       <xsl:value-of select="$str" />
1675     </xsl:when>
1676     <xsl:otherwise>
1677       <xsl:call-template name="get-extention">
1678         <xsl:with-param name="str" select="substring-after($str,'.')" /> <!--$-->
1679       </xsl:call-template>
1680     </xsl:otherwise>
1681   </xsl:choose>
1682 </xsl:template>
```

Consider an image that has an attribute src with value ‘toto.png’ or aux with value ‘titi.gif’, and attribute xylemeAttach with value ‘foo’, this gives ‘foo.png’ or ‘foo.gif’ (we assume that only one extension will be found).

```

1683 <xsl:template match="@xylemeAttach">
1684   <xsl:value-of select="." />
1685   <xsl:text>.</xsl:text>
1686   <xsl:call-template name="get-extention">
1687     <xsl:with-param name="str" select="../@src|../@aux" />
1688   </xsl:call-template>
1689 </xsl:template>
```

Translation of <ressource>. The attribute media is ‘WEB’ by default. No rule applies otherwise.

```

1690 <xsl:template match="ressource[@media='WEB']">
1691   <xsl:call-template name='generate-graphics' />
1692   <xsl:apply-templates select="caption" />
1693 </xsl:template>
```

There is something strange here. If you specify both width and height, only the last attribute will be put in style. Perhaps, something like the code on lines 1607-1611 should be used instead. In the current version, a complicated procedure is used to get the name of the image.

```

1694 <xsl:template name="generate-graphics">
1695   <img>
1696     <xsl:if test="@width">
1697       <xsl:attribute name="style">width:<xsl:value-of select="@width" /></xsl:attribute>
1698     </xsl:if>
1699     <xsl:if test="@height">
1700       <xsl:attribute name="style">height:<xsl:value-of select="@height" /></xsl:attribute>
1701     </xsl:if>
1702     <xsl:attribute name='alt'><xsl:value-of select="@xlink:href" /></xsl:attribute>
1703     <xsl:attribute name='src'>
1704       <xsl:value-of select="$imgpath" />
1705     <xsl:choose>
1706       <xsl:when test="($xyleme='1') and @xylemeAttach">
1707         <xsl:apply-templates select="@xylemeAttach" />
1708       </xsl:when>
1709       <xsl:when test="@png">
1710         <xsl:value-of select="$LeProjet"/><xsl:value-of select="@png" />
1711       </xsl:when>
1712       <xsl:when test="@gif">
1713         <xsl:value-of select="$LeProjet"/><xsl:value-of select="@gif" />
1714       </xsl:when>
1715       <xsl:when test="@jpg">
1716         <xsl:value-of select="$LeProjet"/><xsl:value-of select="@jpeg" />
1717       </xsl:when>
1718       <xsl:when test="@aux">
1719         <xsl:value-of select="$LeProjet"/><xsl:value-of select="@aux" />
1720       </xsl:when>
1721       <xsl:otherwise>
1722         <xsl:value-of select="$LeProjet"/><xsl:value-of select="@xlink:href"/>
1723       </xsl:otherwise>
1724     </xsl:choose>
1725   </xsl:attribute>
1726   </img>
1727 </xsl:template>

```

Translation of `<object>`. The result is a `<div>`, that contains a `<table>`. Each table in the object is converted into a single `<td>` in a `<tr>`.

```

1728 <xsl:template match="object">
1729   <div align='center' style='margin-top:10px'>
1730     <a name=".//@id"></a>
1731     <table title="{@title}" class="objectContainer">
1732       <xsl:call-template name="objectCaption" />
1733       <xsl:for-each select="table">
1734         <tr align="center">
1735           <td> <xsl:apply-templates select=". mode="object" /> </td>
1736         </tr>
1737       </xsl:for-each>
1738     </table>
1739   </div>
1740 </xsl:template>

```

Translation of a `<caption>` of a `<object>`. It is like the caption of a table, but with name ‘Figure’ instead of ‘Table’.

```

1741 <xsl:template name="objectCaption">
1742   <caption align='bottom'>
1743     <strong>Figure
1744     <xsl:call-template name="calculateObjectNumber" />

```

```

1745     <xsl:text>. </xsl:text></strong>
1746     <xsl:apply-templates select="caption" />
1747   </caption>
1748 </xsl:template>

```

If the caption is in a resource in a cell, we output a `<br>`, and the value of the caption.

```

1749 <xsl:template match="td/ressource/caption" priority="1">
1750   <br />
1751   <xsl:apply-templates />
1752 </xsl:template>
1753

```

If the caption is in a ressource, we output the value of the caption.

```

1754 <xsl:template match="ressource/caption">
1755   <xsl:apply-templates />
1756 </xsl:template>
1757

```

If the caption matches none of the rules above, we output the value of the caption.

```

1758 <xsl:template match="caption">
1759   <xsl:apply-templates />
1760 </xsl:template>

```

These two elements exist so that we can transform them into `\TeX` or `\LaTeX` in the Pdf result. In the `HTML`, it is better to use letters only.

```

1761 <xsl:template match="LaTeX">LaTeX</xsl:template>
1762 <xsl:template match="TeX">TeX</xsl:template>

```

This is a helper function. It adds a comma if the element is not the last.

```

1763 <xsl:template name="separateurED.objet">
1764   <xsl:if test="position() < last()", </xsl:if>
1765 </xsl:template>

```

This is a helper function. It adds a comma if the element is not the last, a dot otherwise.

```

1766 <xsl:template name="separateur.objet">
1767   <xsl:choose>
1768     <xsl:when test="position() < last()", </xsl:when>
1769     <xsl:otherwise>.</xsl:otherwise>
1770   </xsl:choose>
1771 </xsl:template>

```

### 6.1.5 References

The translation of `<ref>` is an `<a>`. The non trivial point is to compute the value (the reference is much easier). If the link does not start with a `#`, it is an external link, this will be handled later. Otherwise some variables are used. First, `$curid` is the target id (the link without the `#`), and `$curelement` is the target. In Tralics, this can be a section, a math formula, an image, a table, a bibliographic entry, a footnote, an item in a list<sup>14</sup>. In the Raweb, other elements might be referenced. We consider three variables: `$cursubsection`, `$curbiblio` and `$curidentification`, that contains ancestors of the target. These variables hold nodesets; their intersection is empty.

```

1772 <xsl:template match="ref">
1773   <xsl:choose>
1774     <xsl:when test="starts-with(@xlink:href, '#')">
1775       <xsl:variable name="curid"
1776         select="substring-after(@xlink:href, '#')"/>

```

---

<sup>14</sup>Or an anchor, since version 2.8.5

```

1777      <xsl:variable name="curelement"
1778          select="/raweb//*[@id=$curid]" />
1779      <xsl:variable name="cursubsection"
1780          select="$curelement/ancestor-or-self::subsection" />
1781      <xsl:variable name="curbiblio"
1782          select="$curelement/ancestor-or-self::biblio" />
1783      <xsl:variable name="curidentification"
1784          select="$curelement/ancestor-or-self::identification" />
```

Case one. \$curidentification is not empty. This assumes that only one target exists in the page. A safer solution would be to replace \$curid by the id of the <team> element. Case two, the target is in a subsection. We consider the first subsection (in document order), its id gives the name of the HTML page, it suffices to add the local part. The content of the link is computed elsewhere. In the third case, the target is in the bibliography. Otherwise, let's hope that the target is a section, we use the first subsection of it.

```

1785      <xsl:choose>
1786          <xsl:when test="$curidentification">
1787              <a>
1788                  <xsl:attribute name='href'>
1789                      <xsl:call-template name="formaturl">
1790                          <xsl:with-param name="base" select="$curid"/>
1791                      </xsl:call-template>
1792                  </xsl:attribute>
1793              </a>
1794          </xsl:when>
1795          <xsl:when test="$curbiblio">
1796              <xsl:apply-templates select=". " mode="ref2biblio" >
1797                  <xsl:with-param name="curelement" select="$curelement" />
1798              </xsl:apply-templates>
1799          </xsl:when>
1800          <xsl:when test="$cursubsection">
1801              <a href="./{$cursubsection[1]/@id}.html{@xlink:href}">
1802                  <xsl:apply-templates mode="xref" select="$curelement" />
1803              </a>
1804          </xsl:when>
1805          <xsl:when test="$cursubsection" > <!-- vers la meme section --&gt;
1806              &lt;a&gt;
1807                  &lt;xsl:attribute name='href'&gt;
1808                      &lt;xsl:call-template name="formaturl"&gt;
1809                          &lt;xsl:with-param name="base" select="$cursubsection[1]/@id" /&gt;
1810                      &lt;/xsl:call-template&gt;
1811                  &lt;xsl:value-of select="@xlink:href" /&gt;
1812              &lt;/xsl:attribute&gt;
1813              &lt;xsl:attribute name="title"&gt;
1814                  &lt;xsl:value-of select="$cursubsection/bodyTitle" /&gt;
1815              &lt;/xsl:attribute&gt;
1816              &lt;xsl:apply-templates mode="xref" select="$curelement" /&gt;
1817          &lt;/a&gt;
1818      &lt;/xsl:when&gt;
1819      &lt;xsl:otherwise&gt;
1820          &lt;a&gt;
1821              &lt;xsl:attribute name="title"&gt;
1822                  &lt;xsl:value-of select="$curelement/subsection[1]/subsection" /&gt;
1823              &lt;/xsl:attribute&gt;
1824              &lt;xsl:attribute name="href"&gt;
1825                  &lt;xsl:call-template name="formaturl"&gt;</pre>

```

```

1826         <xsl:with-param name="base" select="$curelement/subsection[1]/@id" />
1827         </xsl:call-template>
1828     </xsl:attribute>
1829     <xsl:apply-templates mode="xref" select="$curelement" />
1830   </a>
1831   </xsl:otherwise>
1832 </xsl:choose>
1833 </xsl:when>
```

In the case of an external reference, things are easier. The value of the `<ref>` element is assumed non-empty.<sup>15</sup>

```

1834 <xsl:otherwise>
1835   <a>
1836     <xsl:attribute name="href"><xsl:value-of select="@xlink:href" /></xsl:attribute>
1837     <xsl:call-template name="targetAttrib.alt" />
1838     <xsl:apply-templates />
1839   </a>
1840 </xsl:otherwise>
1841 </xsl:choose>
1842 </xsl:template>
```

For every element, like `<formula>`, that can be the target of a `<ref>`, we must compute its number. This is the value seen on the screen. In the case of a formula, this is easy, we just count all formulas with a number (i.e., with an id). Note: this behavior is different from what happens in the Pdf case. For this reason it would be safer to replace the code on line 1637 by a call to this template.<sup>16</sup>

```

1843 <xsl:template match="formula" mode="xref">
1844   <xsl:number level="any" count="formula[@id]" />
1845 </xsl:template>
```

In the case of a `<table>`, computation is non trivial. We use an intermediate command.

```

1846 <xsl:template match='table' mode="xref">
1847   <xsl:call-template name="calculateTableNumber" />
1848 </xsl:template>
```

This is how we count them: if the `<table>` is in an `<object>` it is not counted.

```

1849 <xsl:template name="calculateTableNumber">
1850   <xsl:number count="table[not(ancestor::object)]" level="any" />
1851 </xsl:template>
```

The same idea is used for `<object>` and `<ressource>`: we use a command.

```

1852 <xsl:template match="ressource" mode="xref">
1853   <xsl:call-template name="calculateRessourceNumber" />
1854 </xsl:template>
1855 <xsl:template match="object" mode="xref">
1856   <xsl:call-template name="calculateObjectNumber" />
1857 </xsl:template>
```

In order to understand this, remember that an `<object>` can contain a `<table>` that can contain some `<ressource>`. If an object contains more than one image, there is currently no way to refer to a specific image (Tralics allows you to reference the object, not the images). Hence, the number of a ressource is the number of its parent object.

```

1858 <xsl:template name="calculateObjectNumber">
1859   <xsl:number count="object" level="any" />
1860 </xsl:template>
```

---

<sup>15</sup>This sets the `target` attribute of the anchor. This behaviour is sometimes annoying.

<sup>16</sup>If you look at the code line 487, you can see that conversion from one DTD to the other does not add ids to formulas. Hence, if Tralics adds no useless ids, you will see the same equation number in the Pdf and the HTML.

```

1861 <xsl:template name="calculateRessourceNumber">
1862   <xsl:apply-templates select="ancestor::object[1]" mode="xref" />
1863 </xsl:template>
```

This returns the number of the section in which the element is. Note that ‘fondements’ are numbered 3, even if ‘presentation’ is missing<sup>17</sup>. If you don’t like this, then you should fill all sections<sup>18</sup>.

```

1865 <xsl:template name="sec.num">
1866   <xsl:choose>
1867     <xsl:when test="ancestor-or-self::*[self::identification]"> 0</xsl:when>
1868     <xsl:when test="ancestor-or-self::*[self::presentation]"> 1</xsl:when>
1869     <xsl:when test="ancestor-or-self::*[self::fondements]"> 2</xsl:when>
1870     <xsl:when test="ancestor-or-self::*[self::domaine]"> 3</xsl:when>
1871     <xsl:when test="ancestor-or-self::*[self::logiciels]"> 4</xsl:when>
1872     <xsl:when test="ancestor-or-self::*[self::resultats]"> 5</xsl:when>
1873     <xsl:when test="ancestor-or-self::*[self::contrats]"> 6</xsl:when>
1874     <xsl:when test="ancestor-or-self::*[self::international]"> 7</xsl:when>
1875     <xsl:when test="ancestor-or-self::*[self::diffusion]"> 8</xsl:when>
1876     <xsl:when test="ancestor-or-self::*[self::biblio]"> 9</xsl:when>
1877     <xsl:otherwise>*-</xsl:otherwise>
1878   </xsl:choose>
1879 </xsl:template>
```

The number associated to each section is given by the procedure above.

```

1880 <xsl:template match="identification|presentation|fondements|domaine|
1881   logiciels|resultats|contrats|international|diffusion|biblio"
1882   mode="xref">
1883   <xsl:call-template name="sec.num" />
1884 </xsl:template>
```

This computes the number of a subsection.

```

1885 <xsl:template match="subsection" mode="xref">
1886   <xsl:call-template name="calculateNumbersubsection" />
1887 </xsl:template>
```

We count the number of subsections, this is preceded by the section number. We removed here the variable \$numbersuffix, replacing it by a simple <xsl:text> element.

```

1888 <xsl:template name="calculateNumbersubsection">
1889   <xsl:call-template name="sec.num" />
1890   <xsl:text>.</xsl:text>
1891   <xsl:number level="multiple" grouping-separator="."
1892     from="raweb" format="1.1" count="subsection" />
1893 </xsl:template>
```

In the case of a title or an anchor, we call a template (originally, there were two templates).

```

1894 <xsl:template match="bodyTitle|anchor" mode="xref">
1895   <xsl:call-template name="calculateNumber" />
1896 </xsl:template>
```

The number we compute in the generic case is the number of its subsection.

```

1897 <xsl:template name="calculateNumber">
1898   <xsl:call-template name="sec.num" />
1899   <xsl:text>.</xsl:text>
```

---

<sup>17</sup>The first section is numbered zero for no obvious reason, so that ‘fondements’ is numbered 3 in the Pdf file and 2 in the HTML file.

<sup>18</sup>Why is there a space before the number? The L<sup>A</sup>T<sub>E</sub>X equivalent would be wrong. It seems that my browser discards these spaces.

```

1900     <xsl:number level="multiple" from="raweb" format="1.1" count="subsection" />
1901 </xsl:template>
      That's the end of the file.
1902 </xsl:stylesheet>
1903 <xsl:template match="@id">
1904   <xsl:attribute name="id"><xsl:value-of select=". " /></xsl:attribute>
1905 </xsl:template>
```

## 6.2 Dealing with topics

The following three templates do nothing in static mode, but add a `class` attribute to the current element. For simplicity, the calls to these templates are often omitted.

```

1906 <xsl:template name="isSamePage" />
1907 <xsl:template name="isPageTeam" />
1908 <xsl:template name="isPageBiblio"/>
```

There are two views: with and without topics. The difference resides in how pages are linked together, hence has an influence on the table of contents. We show here how to compute the next page.

```

1909 <xsl:template name="suivant">
1910   <xsl:choose>
1911     <xsl:when test="$isTopic='1'">
1912       <xsl:call-template name="suivant_avec_topic" />
1913     </xsl:when>
1914     <xsl:otherwise>
1915       <xsl:call-template name="suivant_sans_topic" />
1916     </xsl:otherwise>
1917   </xsl:choose>
1918 </xsl:template>
```

There are additional templates that follow the same scheme. The template `precedent` returns the previous page, `tdm` and `table.matieres` create the table of contents, `toclink` produces a link to the TOC.

```

1919 <xsl:template name="precedent">
1920   choose one of "precedent_avec_topic""precedent_sans_topic"
1921 </xsl:template>
1922
1923 <xsl:template name="noframe_p">
1924   choose one of "noframe_p_Topic" "noframe_p_sansTopic"
1925 </xsl:template>
1926
1927 <xsl:template name="tdm">
1928   choose one of "tdm_Topic" "tdm_sansTopic"
1929 </xsl:template>
1930
1931 <xsl:template name="table.matieres">
1932   choose one of "table.matieres_Topic" "table.matieres_sansTopic"
1933 </xsl:template>
1934
1935 <xsl:template name="toclink">
1936   choose one of "toclink_Topic" "toclink_sansTopic"
1937 </xsl:template>
```

In the static version, these produce nothing (and more than often we shall omit the call).

```
1938 <xsl:template name="noframe_p_sansTopic" />
1939 <xsl:template name="noframe_p_Topic"/>
```

Now comes the delicate part: what is the previous or next page? Finding the previous module is rather easy: if there is a previous module in the section, we chose it; if there is a previous section we chose the last module of it; otherwise it is the front page.

```
1940 <xsl:template name="precedent_sans_topic">
1941   <xsl:choose>
1942     <xsl:when test="preceding-sibling::subsection">
1943       <xsl:value-of select="preceding-sibling::subsection[1]/@id" />
1944     </xsl:when>
1945     <xsl:when test="..../preceding-sibling::*[1]/subsection">
1946       <xsl:value-of select="..../preceding-sibling::*[1]/subsection[position()=last()]/@id"/>
1947     </xsl:when>
1948     <xsl:otherwise>
1949       <xsl:value-of select="/raweb/identification/team/@id" />
1950     </xsl:otherwise>
1951   </xsl:choose>
1952 </xsl:template>
```

Finding the next module is easy too: if there is a next module in the section, we chose it; if there is a next section we chose the first module of it; otherwise it is the bibliography.

```
1953 <xsl:template name="suivant_sans_topic">
1954   <xsl:choose>
1955     <xsl:when test="following-sibling::subsection">
1956       <xsl:value-of select="following-sibling::subsection[1]/@id" />
1957     </xsl:when>
1958     <xsl:when test="..../following-sibling::*[1]/subsection">
1959       <xsl:value-of select="..../following-sibling::*[1]/subsection[1]/@id" />
1960     </xsl:when>
1961     <xsl:otherwise>
1962       <xsl:text>bibliography</xsl:text>
1963     </xsl:otherwise>
1964   </xsl:choose>
1965 </xsl:template>
```

The situation is a bit more complicated in the case of topics. Assume that S3M4 is module 4 in section 3 and T2S3M4 is module 4 in section 3 with topic 2. Topics are allowed only in sections 3 to 6. The ordering is the following: S1M1, S1M2, S2M1, S2M2, T1S3M1, T1S3M2, T1S4M1, T1S4M2, T1S5M1, T1S5M2, T1S6M1, T1S6M2, T2S3M1, T2S3M2, T2S4M1, T2S4M2, T2S5M1, T2S5M2, T2S6M1, T2S6M2, S7M1, S7M2, S8M1, S8M2, S9M1, S9M2, S10M1, S10M2. We assume that a module has a `topic` attribute if and only if it is in a section with topics. This attribute has a symbolic value, say A, B, C. The start of the document contains a list of `<topic>` elements, say `<tA>`, `<tB>`, `<tC>`, with id A, B and C, that define the order (A comes before B if `<tA>` is before `<tB>`).

This finds the previous module. There are two cases to consider: it depends on whether we are in the topic part, or non-topic part. We use two variables: `$var` is the current topic id and `$precedentTopic` is the previous topic (or is empty if there is no previous topic).

```
1966 <xsl:template name="precedent_avec_topic">
1967   <xsl:variable name="var" select=".//@topic" />
1968   <xsl:variable name="precedentTopic"
1969     select="/raweb/topic[@id=$var]/preceding-sibling::topic[1]" />
1970 <xsl:choose>
```

First assume that the module has a topic. The easy case is when there is a preceding sibling with the same topic. We chose the first one. Otherwise, we consider all modules that have as topic

the previous topic; we select the last one; if this fails, we select the last module of the presentation section.

```

1971 <xsl:when test="./@topic">
1972   <xsl:choose>
1973     <xsl:when test="preceding::subsection[@topic=$var]">
1974       <xsl:value-of select="preceding::subsection[@topic=$var][1]/@id" />
1975     </xsl:when>
1976     <xsl:when test="/raweb/descendant::subsection[@topic=($precedentTopic/@id)]">
1977       <xsl:variable name="precedentTopicId" select="$precedentTopic/@id" />
1978       <xsl:variable name="lastSubsection"
1979         select="/raweb/descendant::subsection[@topic=($precedentTopic/@id)][last()]" />
1980       <xsl:value-of select="$lastSubsection/@id" />
1981     </xsl:when>
1982     <xsl:otherwise>
1983       <xsl:value-of select="/raweb/presentation/subsection[last()]/@id" />
1984     </xsl:otherwise>
1985   </xsl:choose>
1986 </xsl:when>
```

We consider now the case where the module has no topic. In the case where there is a preceding sibling in the same section without topic, we chose the first one. In the case where the section is the presentation, our module is located before the modules with topics, thus the preceding page is that with the composition. If there is a preceding module without topic, we use it. Otherwise, if there are topics, and if there is a module with a topic, we chose the last module of the last topic. Otherwise, we chose the page with the team.

```

1987 <xsl:otherwise>
1988   <xsl:choose>
1989     <xsl:when test="parent::presentation and position()=1">
1990       <xsl:value-of select="/raweb/identification/team/@id" />
1991     </xsl:when>
1992     <xsl:when test="preceding-sibling::subsection[not(./@topic)]">
1993       <xsl:value-of select="preceding-sibling::subsection[not(./@topic)][1]/@id" />
1994     </xsl:when>
1995     <xsl:when test=".../preceding-sibling::*[1]/subsection[not(./@topic)]">
1996       <xsl:value-of select=".../preceding-sibling::*[1]/
1997         subsection[not(./@topic)][last()]/@id" />
1998     </xsl:when>
1999     <xsl:when test="/raweb/topic and /raweb/descendant::subsection[@topic]">
2000       <xsl:variable name="lastTopic" select="/topic[last()]/@id" />
2001       <xsl:variable name="lastSubsection"
2002         select="/raweb/descendant::subsection[@topic=$lastTopic][last()]" />
2003       <xsl:value-of select="$lastSubsection/@id" />
2004     </xsl:when>
2005     <xsl:otherwise>
2006       <xsl:value-of select="/raweb/identification/team/@id" />
2007     </xsl:otherwise>
2008   </xsl:choose>
2009 </xsl:otherwise>
2010 </xsl:choose>
2011 </xsl:template>
```

This finds the next module. The algorithm is the same as above (to be precise: if X precedes Y, then Y follows X).

```

2012 <xsl:template name="suivant">
2013   <xsl:variable name="var" select="./@topic" />
2014   <xsl:variable name="followingTopic"
```

```

2015     select="/raweb/topic[@id=$var]/following-sibling::topic[1]" />
2016 <xsl:choose>
2017
2018     <xsl:when test="./@topic">
2019         <xsl:choose>
2020             <xsl:when test="following::subsection[@topic=$var]">
2021                 <xsl:value-of select="following::subsection[@topic=$var][1]/@id" />
2022             </xsl:when>
2023             <xsl:when test="/raweb/descendant::subsection[@topic=$followingTopic/@id]">
2024                 <xsl:value-of select="/raweb/descendant::subsection
2025                               [@topic=$followingTopic/@id][1]/@id" />
2026             </xsl:when>
2027             <xsl:when test="not($followingTopic) and
2028                 /raweb/*[name()!='presentation']/subsection[not(@topic)]">
2029                 <xsl:value-of select="/raweb/*[name()!='presentation']/
2030                               subsection[not(@topic)][1]/@id" />
2031             </xsl:when>
2032             <xsl:otherwise>
2033                 <xsl:text>bibliography</xsl:text>
2034             </xsl:otherwise>
2035         </xsl:choose>
2036     </xsl:when>

```

We consider here the case where the module has no topic. The easy case is when the section contains a following module without topic. Then comes the case where we are in the presentation section, it is the last module, and there is a module with a topic: in this case we chose the first module with the first topic. Otherwise we consider the case where there is a following module without topic, we chose the first one. Otherwise, we select the bibliography.

```

2036     <xsl:otherwise>
2037         <xsl:choose>
2038             <xsl:when test="following-sibling::subsection[not(@topic)]">
2039                 <xsl:value-of select="following-sibling::subsection[not(@topic)][1]/@id" />
2040             </xsl:when>
2041             <xsl:when test="parent::presentation and (position()=last())
2042                         and /raweb/descendant::subsection[@topic]">
2043                 <xsl:variable name="firstTopicId" select="/raweb/topic[1]/@id" />
2044                 <xsl:value-of select="/raweb/descendant::subsection
2045                               [@topic=$firstTopicId][1]/@id" />
2046             </xsl:when>
2047             <xsl:when test=".../following-sibling::*[1]/subsection[not(@topic)]">
2048
2049                 <xsl:value-of select=".../following-sibling::*[1]/subsection
2050                               [not(@topic)][1]/@id" />
2051             </xsl:when>
2052             <xsl:otherwise>
2053                 <xsl:text>bibliography</xsl:text>
2054             </xsl:otherwise>
2055         </xsl:choose>
2056     </xsl:otherwise>
2057     </xsl:choose>
2058 </xsl:template>

```

This is strange. We removed all tests concerning the \$type parameter (which is never provided). If the \$base is ‘foo’, this constructs ./foo.html.

```
2059 <xsl:template name="formaturl">
2060   <xsl:param name="base" />
2061   <xsl:param name="type" />
2062   ./<xsl:value-of select="$base" />.html
2063 </xsl:template>
```

In the case where topics are present, there are two possible views: with topics or without; you can switch from one view to the other by clicking somewhere in the frame with the TOC.

This piece of code is used in the case where the document has topics, and we generate the TOC without topics; you will see a line containing ‘View by sections’ and ‘View by topics’. These pieces of text have different colors, the second one is associated to an anchor (that has a style attribute that says: no decoration, the change of color should be enough).

Note that the target is ‘\_parent’, so that the loading the aoste\_tf.html file (or the same with ‘Topics’) will remove this page and the sibling frame, replacing them by two pages (TOC and main page).

```
2064 <xsl:template name="acces.topic">
2065   <div id="bouton">
2066     <div id="clair">View by sections</div>
2067     <div id="fonce">
2068       <a style="text-decoration:none" target="_parent">
2069         <xsl:call-template name="lienVersTopics" />
2070         <div id="bouton_tdm_click">
2071           <font color="#FFFFFF">View by topics</font>
2072         </div>
2073       </a>
2074     </div>
2075   </div>
2076   <br />
2077 </xsl:template>
```

This constructs the name ..../aoste\_Topics/aoste\_tf.html of the file with topics.

```
2078 <xsl:template name="lienVersTopics">
2079   <xsl:attribute name="href" >
2080     <xsl:value-of select="concat('../', $LeProjet, '_Topics/', $LeProjet, '_tf.html')"/>
2081   </xsl:attribute>
2082 </xsl:template>
```

This piece of code is used in the case where the document has topics, and we generate the TOC with topics; you will see the same text as above; but colors are different and the link points to ..../aoste/aoste\_tf.html.

```
2083 <xsl:template name="acces.topic_Topic">
2084   <br />
2085   <div id="bouton">
2086     <div id="fonce_T">
2087       <a href="../{$LeProjet}/{$LeProjet}_tf.html"
2088         style="text-decoration:none" target="_parent">
2089         <div id="bouton_tdm_click">
2090           <font color="#FFFFFF">View by sections</font>
2091         </div>
2092       </a>
2093     </div>
2094     <div id="clair_T">View by topics</div>
2095   </div>
2096 </xsl:template>
```

Our next object is the table of contents. There are four cases to consider. The main page contains the TOC defined by `table.matieres`, and there is a frame containing the TOC (defined by `tdm`), they exist in two versions, with or without topics. Let's start with the frame.

This creates the full table of contents, that is on the front page. We have three parts: composition, main TOC, bibliography.

```
2097 <xsl:template name="table.matieres_sansTopic">
2098   <ul class="tdm_frame">
2099     <xsl:call-template name="jg.tdm.members"/>
2100     <xsl:call-template name="table.section_sansTopic"/>
2101     <xsl:call-template name="table.bibliography" />
2102   </ul>
2103 </xsl:template>
```

The case of topics is a bit more complicated. Instead of `table.section` that shows everything but the composition and the bibliography, we have three parts: the presentations, all modules that have a topics, then modules without topic. The second part is preceded by 'View by topics' and delimited by colored rules.

```
2104 <xsl:template name="table.matieres_Topic">
2105   <div class="non-topic">
2106     <ul class="tdm_window">
2107       <xsl:call-template name="jg.tdm.members"/>
2108       <li> <xsl:call-template name="presentation_tdm_entry_Topic" /> </li>
2109     </ul>
2110   </div>
2111   <div class="topicIdent">
2112     <br />
2113     <hr class="topic_color" />
2114     View by topics
2115   </div>
2116   <xsl:call-template name="table.topic_Topic">
2117     <xsl:with-param name="class">tdm_window</xsl:with-param>
2118   </xsl:call-template>
2119   <hr class="topic_color" />
2120   <ul class="tdm_window">
2121     <xsl:call-template name="table.section_Topic" />
2122     <li>
2123       <xsl:call-template name="table.bibliography" />
2124     </li>
2125   </ul>
2126 </xsl:template>
```

This is now the TOC frame. The structure is easy: we have, from top to bottom, the logo, the name of the team, the composition of the team, the presentation, the sections that might have a topic, and the bibliography.

```
2127 <xsl:template name="tdm_sansTopic">
2128   <div>
2129     <xsl:call-template name="jg.tdm-common"/>
2130     <xsl:call-template name="jg.tdm.team.sans"/>
2131     <xsl:call-template name="presentation_tdm_entry_sansTopic" />
2132     <xsl:call-template name="table.tdm_sansTopic" />
2133     <xsl:call-template name="table.bibliography" />
2134   </div>
2135 </xsl:template>
```

In the case of topics, the layout of the page with the frame is the same as the layout of the title page, but there are no rules.

```

2136 <xsl:template name="tdm_Topic">
2137   <div>
2138     <xsl:call-template name="jg.tdm-common"/>
2139     <xsl:call-template name="jg.tdm.team.topic"/>
2140     <br />
2141     <xsl:call-template name="presentation_tdm_entry_Topic" />
2142     <xsl:call-template name="acces.topic_Topic" />
2143     <xsl:call-template name="table.topic_Topic">
2144       <xsl:with-param name="class">tdm_frame</xsl:with-param>
2145     </xsl:call-template>
2146     <xsl:call-template name="tdm.section_Topic" />
2147     <xsl:call-template name="table.bibliography" />
2148   </div>
2149 </xsl:template>

```

The link to the composition of the team in the TOC is constructed via this template.

```

2150 <xsl:template name="jg.team.link">
2151   <a href="/raweb/identification/team/@id}.html">
2152     <xsl:call-template name="targetAttrib.main" />
2153     Members
2154   </a>
2155 </xsl:template>

```

In fact, there are three variants of the previous template: in one case, the team is an item in a list, otherwise, it is in a `<div>` with class ‘non-topic’ or ‘TdmEntry’.

```

2156 <xsl:template name="jg.tdm.team.topic">
2157   <div class="non-topic">
2158     <xsl:call-template name="jg.team.link"/>
2159   </div>
2160 </xsl:template>
2161
2162 <xsl:template name="jg.tdm.team.sans">
2163   <div class="TdmEntry">
2164     <xsl:call-template name="jg.team.link"/>
2165   </div>
2166 </xsl:template>
2167
2168 <xsl:template name="jg.tdm.members">
2169   <li>
2170     <xsl:call-template name="jg.team.link"/>
2171   </li>
2172 </xsl:template>

```

The frame TOC is in a `<div>` element that has a `class` attribute formed of ‘tdmdiv’ and optionally ‘noframe’. It contains the Inria logo with a link to Inria’s home page, and the name of the team.

```

2173 <xsl:template name="jg.tdm-common">
2174   <xsl:attribute name="class">tdmdiv
2175     <xsl:if test="$noframe='1'">noframe</xsl:if>
2176   </xsl:attribute>
2177   <div class="logo">
2178     <a href="http://www.inria.fr">
2179       <xsl:call-template name="targetAttrib.main" />
2180       
2181     </a>
2182   </div>
2183   <br />

```

```

2184 <div class="entete">
2185   <xsl:if test="/raweb/identification[@isproject]='true'">
2186     <xsl:text>Project </xsl:text>
2187   </xsl:if>
2188   <xsl:text>Team </xsl:text>
2189   <xsl:value-of select="/raweb/identification/shortname" />
2190 </div>
2191 <hr />
2192 </xsl:template>

```

The bibliography is divided into three major parts, and since 2006, these appear in the TOC, unless they are empty.

```

2193 <xsl:template name="table.bibliography">
2194   <div class="TdmEntry">Bibliography</div>
2195   <div class="TdmEntry">
2196     <ul>
2197       <xsl:if test="//biblio/biblStruct/note[@type='from']='refer'">
2198         <li>
2199           <a id="tdmbibentmajor" href="bibliography.html#Major" >
2200             <xsl:call-template name="targetAttrib.main" />
2201             Major publications
2202           </a>
2203         </li>
2204       </xsl:if>
2205       <xsl:if test="//biblio/biblStruct/note[@type='from']='year'">
2206         <li>
2207           <a id="tdmbibentyear" href="bibliography.html#year" >
2208             <xsl:call-template name="targetAttrib.alt" />
2209             Year Publications
2210           </a>
2211         </li>
2212       </xsl:if>
2213       <xsl:if test="//biblio/biblStruct/note[@type='from']='foot'">
2214         <li>
2215           <a id="tdmbibentfoot" href="bibliography.html#Bibliography" >
2216             <xsl:call-template name="targetAttrib.main" />
2217             References in notes
2218           </a>
2219         </li>
2220       </xsl:if>
2221     </ul>
2222   </div>
2223 </xsl:template>

```

In order to make the code easier to understand we have introduced the following templates. It outputs the title, maybe in a `<a>` or a `<li>`. The void template is used when the title of a module is empty; in this case the title of the section containing the module is used instead.

```

2224 <xsl:template name="jg.tdm.basic">
2225   <xsl:call-template name="item_title_or_not_title" />
2226 </xsl:template>
2227
2228 <xsl:template name="jg.tdm.a">
2229   <a> <xsl:call-template name="item_title_or_not_title" /></a>
2230 </xsl:template>
2231
2232 <xsl:template name="jg.tdm.a.li">
2233   <li><a><xsl:call-template name="item_title_or_not_title" /></a></li>

```

```

2234 </xsl:template>
2235
2236 <xsl:template name="jg.tdm.void">
2237   <li>
2238     <a href="#">{@id}.html">
2239       <xsl:call-template name="targetAttrib.main" />
2240       <xsl:value-of select="/raweb/presentation/bodyTitle" />
2241     </a>
2242   </li>
2243 </xsl:template>
```

Same as above, but `item_title_or_not_title` is not used. Instead, if the value is empty, some other quantity is used (shown here in `$varTitle`). Attributes of the anchor are computed by `table.tdm.xref`, and the title is output in 'tocsection' mode.

```

2244 <xsl:template name="jg.tdm.sans.ali">
2245   <li>
2246     <a>
2247       <xsl:call-template name="targetAttrib.main" />
2248       <xsl:call-template name="table.tdm.xref" />
2249       <xsl:apply-templates mode="tocsection" select="bodyTitle" />
2250     </a>
2251   </li>
2252 </xsl:template>
2253
2254 <xsl:template name="jg.tdm.sans.ali.default">
2255   <li>
2256     <a>
2257       <xsl:call-template name="targetAttrib.main" />
2258       <xsl:call-template name="table.tdm.xref" />
2259       <xsl:apply-templates mode="tocsection" select="#"> ${$varTitle}" />
2260     </a>
2261   </li>
2262 </xsl:template>
2263
2264 <xsl:template name="jg.tdm.avec.ali">
2265   <li>
2266     <a name="#">{@id}" href="#">{@id}.html#{@id}">
2267       <xsl:call-template name="targetAttrib.main" />
2268       <xsl:apply-templates mode="tocsection" select="bodyTitle" />
2269     </a>
2270   </li>
2271 </xsl:template>
```

This is not valid XSLT code, but you get the idea. In the case where the presentation section has a single module, its title is very often the same as the section, and we show it only once. The code is the same, with and without topics.

```

2272 <xsl:template name="jg.tdm.special">
2273   <xsl:when test="count(/raweb/presentation/subsection)=1
2274     and /raweb/presentation/bodyTitle=
2275       /raweb/presentation/subsection/bodyTitle">
2276     <xsl:for-each select="/raweb/presentation/subsection">
2277       <xsl:call-template name="jg.tdm.a" />
2278     </xsl:for-each>
2279   </xsl:when>
2280 </xsl:template>
```

This is the code for the presentation in the general case with topics. For each module, we print the section title and the module title.

```

2281 <xsl:template name="jg.tdm.with-topics">
2282   <ul>
2283     <xsl:for-each select="/raweb/presentation/subsection">
2284       <xsl:value-of select="/raweb/presentation/bodyTitle" />
2285       <xsl:call-template name="jg.tdm.a.li" />
2286     </xsl:for-each>
2287   </ul>
2288 </xsl:template>
```

The same without topics. We print the section title (if the module has a fake name) or the module title (otherwise).

```

2289 <xsl:template name="jg.tdm.without-topics">
2290   <ul>
2291     <xsl:for-each select="/raweb/presentation/subsection">
2292       <xsl:choose>
2293         <xsl:when test="bodyTitle='(Sans Titre)'">
2294           <xsl:call-template name="jg.tdm.void" />
2295         </xsl:when>
2296         <xsl:otherwise>
2297           <xsl:call-template name="jg.tdm.a.li" />
2298         </xsl:otherwise>
2299       </xsl:choose>
2300     </xsl:for-each>
2301   </ul>
2302 </xsl:template>
```

A non-obvious point is: where is the ‘presentention’ section put in the TOC? In the case with topics, the following template is called, so that, if no module of the section has a topic, it will be output here, otherwise by `table.topic_Topic`. In the case without topics, it will be `presentation_tdm_entry_sansTopic` (framed case) `table.section_sansTopic` (otherwise). Full code of the presentation, case with topics.

```

2303 <xsl:template name="presentation_tdm_entry_Topic">
2304   <xsl:if test="not(/raweb/presentation/subsection/@topic)">
2305     <div class="non-topic">
2306       <xsl:choose>
2307         <xsl:call-template name="jg.tdm.special" />
2308         <xsl:otherwise>
2309           <xsl:call-template name="jg.tdm.with-topics" />
2310         </xsl:otherwise>
2311       </xsl:choose>
2312     </div>
2313   </xsl:if>
2314 </xsl:template>
```

Full code of the presentation, case without topics.

```

2315 <xsl:template name="presentation_tdm_entry_sansTopic">
2316   <div class="TdmEntry">
2317     <xsl:choose>
2318       <xsl:call-template name="jg.tdm.special" />
2319       <xsl:otherwise>
2320         <xsl:value-of select="bodyTitle" />
2321         <xsl:call-template name="jg.tdm.without-topics" />
2322       </xsl:otherwise>
2323     </xsl:choose>
```

```

2324     </div>
2325 </xsl:template>
```

Let's consider the following sections: `<fondements>`, `<domaine>`, `<logiciels>`, `<resultats>`, `<contrats>`, `<international>`, and `<diffusion>`, in the case of a frame, without topics. We start with sections that have a module with a topic, and then the other ones; note the `<div>` element; the CSS says that this element has a different color; it is preceded by a link (created by `access.topic`) that switches to the alternate view.

```

2326 <xsl:template name="table.tdm_sansTopic">
2327   <xsl:if test="/raweb/child::*[self::fondements or ...
2328           or self::diffusion]//subsection[@topic]">
2329     <xsl:call-template name="acces.topic"/>
2330     <div class="topic">
2331       <xsl:call-template name="table.maybetopic"/>
2332     </div>
2333   </xsl:if>
2334   <xsl:call-template name="table.maybe-not-topic"/>
2335 </xsl:template>
```

This is a loop over all sections, only those that have a module with a topic are chosen.

```

2336 <xsl:template name="table.maybetopic">
2337   <xsl:for-each select="/raweb/child::*[self::fondements or ... or self::diffusion]">
2338     <xsl:if test=".//subsection[@topic]">
2339       <xsl:call-template name="table.tdm.entry_sansTopic" />
2340     </xsl:if>
2341   </xsl:for-each>
2342 </xsl:template>
```

This is a loop over all sections, sections not selected above are selected here.

```

2343 <xsl:template name="table.maybe-not-topic">
2344   <xsl:for-each select="/raweb/child::*[self::fondements or ... or self::diffusion]">
2345     <xsl:if test="not(.//subsection[@topic])">
2346       <xsl:call-template name="table.tdm.entry_sansTopic" />
2347     </xsl:if>
2348   </xsl:for-each>
2349 </xsl:template>
```

For each section, we output its name, and the modules in it. We simplified the code, by adding a variable, instead of looking at some strange location, in the case when the title of the module is empty.

```

2350 <xsl:template name="table.tdm.entry_sansTopic">
2351   <xsl:variable name="varTitle" select="bodyTitle" />
2352   <div class="TdmEntry">
2353     <xsl:value-of select="../bodyTitle" />
2354     <ul>
2355       <xsl:for-each select="subsection">
2356         <xsl:choose>
2357           <xsl:when test=".//bodyTitle">
2358             <xsl:call-template name="jg.tdm.sans.ali" />
2359           </xsl:when>
2360           <xsl:otherwise>
2361             <xsl:call-template name="jg.tdm.sans.ali" />
2362           </xsl:otherwise>
2363         </xsl:choose>
2364       </xsl:for-each>
2365     </ul>
```

```
2366     </div>
2367 </xsl:template>
```

Assume that the element has id ‘uid4’. We shall add (to the anchor constructed below), two attributes, href with value ‘uid4.html?B#tdmBuid4ent’ and id with value ‘tdmBuid4ent’, where B has to be replaced by some newline character and white space; this seems a bit obscure (the file uid4.html does not contain the string ‘uid4ent’). In the case **table.section**, the link will be ‘uid4.html#uid’, and this is a valid link.

```
2368 <xsl:template name="table.tdm.xref">
2369   <xsl:attribute name="href">
2370     <xsl:value-of select="@id" />
2371     .html?
2372     <xsl:call-template name="noframe_p" />
2373     #tdm
2374     <xsl:value-of select="@id" />
2375     ent
2376   </xsl:attribute>
2377   <xsl:attribute name="id">
2378     tdm
2379     <xsl:value-of select="@id" />
2380     ent
2381   </xsl:attribute>
2382 </xsl:template>
```

This outputs the name of the section, and all modules in it. There is a variant that uses **jg.tdm.avec.li** instead of **jg.tdm.a.li**, and another one that selects only modules having the same topic (which is in the variable **\$num-topic**)

```
2383 <xsl:template name="jg.tdm.modules">
2384   <xsl:value-of select=".//bodyTitle" />
2385   <ul>
2386     <xsl:for-each select="subsection">
2387       <xsl:call-template name="jg.tdm.a.li" />
2388     </xsl:for-each>
2389   </ul>
2390 </xsl:template>
2391
2392 <xsl:template name="jg.tdm.modules.avec">
2393   <!-- Same, but use jg.tdm.avec.ali -->
2394 </xsl:template>
2395
2396 <xsl:template name="jg.tdm.modules.topic">
2397   <!-- Same, but select= "subsection[@topic=$num-topic]"-->
2398 </xsl:template>
```

This inserts, in topics mode, all sections that have no topics (presentation is excluded here).

```
2399 <xsl:template name="tdm.section_Topic">
2400   <xsl:for-each select="/raweb/child::*[ self::fonements or ...or self::diffusion]">
2401     <xsl:if test="not(child::subsection/@topic)">
2402       <xsl:call-template name="jg.tdm.modules" />
2403     </xsl:if>
2404   </xsl:for-each>
2405 </xsl:template>
```

Same code as above, with a **<li>**. This is used in these case without frame (the previous code was used in the case of frames).

```
2406 <xsl:template name="table.section_Topic">
2407   <xsl:for-each select="/raweb/child::*[ self::fonements or ...or self::diffusion]">
```

```

2408     <xsl:if test="not(child::subsection/@topic)">
2409         <li>
2410             <xsl:call-template name="jg.tdm.modules" />
2411         </li>
2412     </xsl:if>
2413     </xsl:for-each>
2414 </xsl:template>

This considers in the case without frames, without topics, all sections. If the section has a single module, with the same name, we insert the module, otherwise the section name, and all the modules.

2415 <xsl:template name="table.section_sansTopic">
2416     <xsl:for-each select="/raweb/child::*[self::presentation or ... or self::diffusion]">
2417         <xsl:variable name="varTitle" select="bodyTitle" />
2418         <xsl:choose>
2419             <xsl:when test="count(subsection)=1 and ./bodyTitle=subsection/bodyTitle">
2420                 <xsl:for-each select="subsection">
2421                     <xsl:call-template name="jg.tdm.avec.ali" />
2422                 </xsl:for-each>
2423             </xsl:when>
2424             <xsl:otherwise>
2425                 <li>
2426                     <xsl:call-template name="jg.tdm.modules" />
2427                 </li>
2428             </xsl:otherwise>
2429         </xsl:choose>
2430     </xsl:for-each>
2431 </xsl:template>

```

The structure of the TOC in the case of topics is: for each topic, for each section, for each module, insert an entry. This code takes as parameter \$class, that will be used for the `<ul>`. The current topic name is in \$num-topic.

```

2432 <xsl:template name="table.topic_Topic">
2433     <xsl:param name="class" />
2434     <div class="topic">
2435         <xsl:for-each select="/raweb/topic">
2436             <xsl:variable name="TOP" select="normalize-space(.)" />
2437             <xsl:variable name="num-topic" select="@id" />
2438             <h3 class="smallcap"> <xsl:apply-templates /> </h3>
2439             <ul>
2440                 <xsl:attribute name="class">
2441                     <xsl:value-of select="$class" />
2442                 </xsl:attribute>
2443                 <xsl:for-each select="/raweb/child::*[self::presentation or ... or self::diffusion]">
2444                     <xsl:call-template name="table.topic.aux" />
2445                 </xsl:for-each>
2446             </ul>
2447         </xsl:for-each>
2448     </div>
2449     <br />
2450 </xsl:template>

```

This template works on a section; if no modules has \$num-topic as topic, nothing is done. Otherwise, we have two variables \$TOP and \$SUB containing the name of the topic, and the title of the module. If they are different, we output all relevant modules. Otherwise, the situation is unclear. Note: assume that the topic is A, its name (value of \$TOP) is 'foo', and the test is true, let's say that modules B and C have A as topic attribute. Then \$SUB is the concatenation of the

titles of B and C; more than often this will not be ‘foo’. It might happen that a unique module has topic A, and that this module has the same title as the topic. In this case, you will see the title of the section, and a link to the first module<sup>19</sup>

```

2451 <xsl:template name="table.topic.aux">
2452   <xsl:if test="subsection[@topic=$num-topic]">
2453     <xsl:variable name="SUB"
2454       select="normalize-space(subsection[@topic=$num-topic]/bodyTitle)" />
2455     <xsl:choose>
2456       <xsl:when test="$TOP=$SUB">
2457         <li>
2458           <a href="{subsection/@id}.html">
2459             <xsl:value-of select="bodyTitle" />
2460           </a>
2461         </li>
2462       </xsl:when>
2463       <xsl:otherwise>
2464         <li>
2465           <xsl:call-template name="jg.tdm.modules.topic" />
2466         </li>
2467       </xsl:otherwise>
2468     </xsl:choose>
2469   </xsl:if>
2470 </xsl:template>
```

Are these used?

```

2471 <xsl:template match="subsection/bodyTitle" mode="sansTopic" />
2472 <xsl:template match="subsection/bodyTitle" mode="Topic" />
2473 <xsl:template match="subsection/bodyTitle" />
```

This template is used when we construct the page associated to a module. If the module has no topic attribute, we just print the title of its parent (this is the section title). Otherwise, we produce ‘Topic foo’, ‘Section bar’, using a `<h2>` twice.

```

2474 <xsl:template name="section_title_Topic">
2475   <xsl:choose>
2476     <xsl:when test=".//@topic">
2477       <xsl:variable name="VarTop" select="@topic" />
2478       <h2>Topic :
2479         <xsl:value-of select="/raweb/topic[@id=$VarTop]" /></h2>
2480       <h2>Section :
2481         <xsl:value-of select="../bodyTitle" /></h2>
2482     </xsl:when>
2483     <xsl:otherwise>
2484       <h2>Section :
2485         <xsl:value-of select="../bodyTitle" /></h2>
2486     </xsl:otherwise>
2487   </xsl:choose>
2488 </xsl:template>
```

This is the end of the file.

```
2489 </xsl:stylesheet>
```

---

<sup>19</sup>According to M. Kay, in XSLT2.0, if the style sheet starts with ‘version=2.0’, all id attributes of all modules are concatenated, and the result is a link to nowhere; if the style sheet has version=1.0, only the id is used. In any case, it would be better to check that there is a single module that matches, and make the link to it.

### 6.3 Converting the bibliography

This auxiliary file converts the bibliography from the old DTD to the new one.<sup>20</sup>

```

2490 <xsl:transform
2491   xmlns:tei="http://www.tei-c.org/ns/1.0"
2492   xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
2493   version="1.0">
2494   Usual header.
2495   <xsl:output method='xml'
2496     doctype-public="http://www.inria.fr/xml/raweb/biblio.dtd"
2497     doctype-system='biblio.dtd'
2498     indent='no'
2499     encoding='iso-8859-1' />
```

We simplified the code, by assuming that the id is ‘bibliography’. The transformation of `<biblio>` is an element of the same name. We consider all `<citation>` elements.

```

2500 <xsl:template match="biblio">
2501   <xsl:element name="biblio">
2502     <xsl:attribute name="id">bibliography</xsl:attribute>
2503     <xsl:apply-templates select="citation"/>
2504   </xsl:element>
2505 </xsl:template>
```

Translation of a `<citation>` element. The result is a `<biblStruct>`, depending on the type, it can have one of two alternatives (on page 228, we have the template that converts the entry to HTML, and a comment that says that we check the validity; nothing is done here, we assume that the first or second if-test is true). The last three `<note>` elements will be used to sort the entries, or for debug.

```

2506 <xsl:template match="citation">
2507   <xsl:element name="biblStruct">
2508     <xsl:attribute name="id"><xsl:value-of select="./@id"/></xsl:attribute>
2509     <xsl:if test="@type='article' or @type='inbook' or @type='incollection'
2510       or @type='inproceedings' or @type='conference'">
2511       <xsl:call-template name="citation.analy"/>
2512     </xsl:if>
2513     <xsl:if test="@type='book' or @type='booklet' or @type='proceedings' or
2514       @type='phdthesis' or @type='techreport' or @type='unpublished' or
2515       @type='misc' or @type='masterthesis' or @type='mastersthesis' or
2516       @type='manual'">
2517       <xsl:call-template name="citation.mono"/>
2518     </xsl:if>
2519     <xsl:apply-templates select="bhowpublished"/>
2520     <xsl:element name="note">
2521       <xsl:attribute name="type">classification</xsl:attribute>
2522       <xsl:value-of select="./@type"/>
2523     </xsl:element>
2524     <xsl:element name="note">
2525       <xsl:attribute name="type">from</xsl:attribute>
2526       <xsl:value-of select="./@from"/>
2527     </xsl:element>
2528     <xsl:element name="note">
2529       <xsl:attribute name="type">userid</xsl:attribute>
2530       <xsl:value-of select="./@userid"/>
2531     </xsl:element>
```

---

<sup>20</sup>The bibliography part of this DTD comes from the TEI. See <http://www.tei-c.org/P4X/>

```
2531     </xsl:element>
2532 </xsl:template>
```

In order to make this document shorter, we have used the pseudo command “apply-many-templates” in the first version of this document. It happens that such a kind of shorthand exists in XPath 2.0, with the syntax shown here. The next three templates are specific to the TEI.

```
2533 <xsl:template name="citation.mono">
2534   <xsl:element name="monogr">
2535     <xsl:apply-templates select ="btitle, bbooktitle, bseries, bjurnal,
2536       bauteurs, bediteur, bnote, btype, bedition"/>
2537     <xsl:call-template name="imprint"/>
2538   </xsl:element>
2539 </xsl:template>
```

This is a bit more complicated, because we have three parts `<analytic>`, `<monogr>` and `<imprint>`.

```
2540 <xsl:template name="citation.analy">
2541   <xsl:element name="analytic">
2542     <xsl:apply-templates select="btitle, bauteurs"/>
2543   </xsl:element>
2544   <xsl:element name="monogr">
2545     <xsl:apply-templates select="bediteur, bbooktitle, bseries,
2546       bjurnal, bnote, btype"/>
2547     <xsl:call-template name="imprint"/>
2548   </xsl:element>
2549 </xsl:template>
```

This is used to indicate how the reference is published.

```
2550 <xsl:template name="imprint">
2551   <xsl:element name="imprint">
2552     <xsl:apply-templates select="bvolum, bchapter, bnumber,
2553       bpublisher, bschool, borganization, binstitution"/>
2554     <xsl:call-template name="bdate"/>
2555     <xsl:apply-templates select="bpages,xref"/>
2556   </xsl:element>
2557 </xsl:template>
```

Transformation of the `<btitle>`. The result is a `<title>` element, whose attribute depends on the type. We have not shown the value of the second test. Using ‘choose’ and ‘otherwise’ would make the code more robust.

```
2558 <xsl:template match="btitle">
2559   <xsl:if test=".//@type='article' or .//@type='inbook' or
2560     .//@type='incollection' or .//@type='inproceedings' or .//@type='conference'">
2561     <title level="a"> <xsl:apply-templates /> </title>
2562   </xsl:if>
2563   <xsl:if test=" ... ">
2564     <title level="m"> <xsl:apply-templates /> </title>
2565   </xsl:if>
2566 </xsl:template>
```

Transformation of `<bauteurs>`. The result is a `<author>`, containing the same list of authors. We translate all the `<bpers>`, and replace `<etal>` by a person whose first name is ‘ETAL’.

```
2567 <xsl:template match="bauteurs">
2568   <xsl:element name="author">
2569     <xsl:for-each select="bpers|etal">
2570       <xsl:choose>
2571         <xsl:when test="name()='etal'">
2572           <xsl:element name="persName">
```

```

2573         <xsl:element name="foreName"><xsl:text>ETAL</xsl:text></xsl:element>
2574     </xsl:element>
2575   </xsl:when>
2576   <xsl:otherwise> <xsl:call-template name="personne"/> </xsl:otherwise>
2577   </xsl:choose>
2578   </xsl:for-each>
2579 </xsl:element>
2580 </xsl:template>

```

Transformation of `<beditor>`. The result is a `<editor>`. What about Mister Etal?

```

2581 <xsl:template match="bediteur">
2582   <xsl:element name="editor">
2583     <xsl:for-each select="bpers">
2584       <xsl:call-template name="personne"/>
2585     </xsl:for-each>
2586   </xsl:element>
2587 </xsl:template>

```

Transformation of `<bpers>` in `<persName>`. The attributes `nom` and `prenom` are translated into `<foreName>` and `<surname>`.<sup>21</sup> The raweb specification says in 2006 to use full first names, whenever possible, in the bibliography; these are stored by Tralics in the `prenomcomplet`, copied in `<foreName>`, and the initials are in `<initial>`. Note: the actual code uses four `<xsl:element>` elements instead of literal elements.

```

2588 <xsl:template name="personne">
2589   <persName>
2590     <foreName> <xsl:value-of select="@prenomcomplet"/></foreName>>
2591     <surname> <xsl:value-of select="@nom"/> </surname>
2592     <initial> <xsl:value-of select="@prenom"/> </initial>
2593   </persName>
2594 </xsl:template>

```

We replace `<bseries>` by `<title>`.

```

2595 <xsl:template match="bseries">
2596   <title level="s"> <xsl:value-of select=". "/> </title>
2597 </xsl:template>

```

Ditto for `<bjournal>`, with a different attribute value.

```

2598 <xsl:template match="bjournal">
2599   <title level="j"> <xsl:value-of select=". "/> </title>
2600 </xsl:template>

```

Ditto for `<booktitle>`. In some cases, we add the value of the `<baddress>`.

```

2601 <xsl:template match="bbooktitle">
2602   <title level="m">
2603     <xsl:value-of select=". "/>
2604     <xsl:if test="..//baddress"> <xsl:text>, </xsl:text><xsl:value-of select="..//baddress"/>
2605     </xsl:if>
2606   </title>
2607 </xsl:template>

```

We replace `<bnote>` by `<note>`.

```

2608 <xsl:template match="bnote">
2609   <note type="bnote"> <xsl:value-of select=". "/> </note>
2610 </xsl:template>

```

Ditto for `<btype>`, with a different attribute value.

---

<sup>21</sup>What about `part` and `junior`? Note that Tralics generates an empty `part` attribute, that is omitted from the element, but `junior` should be added to `<surname>`.

```
2611 <xsl:template match="btype">
2612   <note type="typdoc"> <xsl:value-of select="."/> </note>
2613 </xsl:template>
```

Ditto for <bhowpublished>, with a different attribute value.

```
2614 <xsl:template match="bhowpublished">
2615   <note type="howpublished"> <xsl:value-of select="."/> </note>
2616 </xsl:template>
```

The transformation of <bschool> is <publisher>, with an <orgName> that contains the name of the school. It can be followed by the value of the <baddress> field of the entry.

```
2617 <xsl:template match="bschool">
2618   <xsl:element name="publisher">
2619     <xsl:element name="orgName">
2620       <xsl:attribute name="type">school</xsl:attribute>
2621       <xsl:value-of select="."/> </xsl:element>
2622     <xsl:if test=".../baddress"><xsl:apply-templates select=".../baddress"/></xsl:if>
2623   </xsl:element>
2624 </xsl:template>
```

Same idea here. But the implementation is different.

```
2626 <xsl:template match="borganization">
2627   <xsl:element name="publisher">
2628     <xsl:element name="orgName">
2629       <xsl:attribute name="type">organisation</xsl:attribute>
2630       <xsl:value-of select="."/> <xsl:if test=".../baddress">
2631       <xsl:element name="address">
2632         <xsl:apply-templates select=".../baddress"/>
2633       </xsl:element>
2634     </xsl:if>
2635   </xsl:element>
2636 </xsl:element>
2637 </xsl:template>
```

Same idea here.

```
2639 <xsl:template match="binstitution">
2640   <xsl:element name="publisher">
2641     <xsl:element name="orgName">
2642       <xsl:attribute name="type">institution</xsl:attribute>
2643       <xsl:value-of select="."/> <xsl:if test=".../baddress">
2644       <xsl:element name="address">
2645         <xsl:apply-templates select=".../baddress"/>
2646       </xsl:element>
2647     </xsl:if>
2648   </xsl:element>
2649 </xsl:element>
2650 </xsl:template>
```

Strange.

```
2652 <xsl:template match="bedition">
2653   <xsl:element name="edition">
2654     <xsl:value-of select=".//text()"/>
2655     <xsl:copy-of select="./*"/>
2656   </xsl:element>
2657 </xsl:template>
```

Translation of a date into a <dateStruct>. We take the <bmonth> and <byear> and convert them into <month> and <year>. Nothing is done if both fields are missing.

```

2658 <xsl:template name="bdate">
2659   <xsl:if test="string-length(bmonth|byear)>0">
2660     <xsl:element name="dateStruct">
2661       <xsl:if test="string-length(bmonth)>0">
2662         <xsl:element name="month"> <xsl:value-of select="bmonth"/> </xsl:element>
2663       </xsl:if>
2664       <xsl:if test="string-length(byear)>0">
2665         <xsl:element name="year"> <xsl:value-of select="byear"/> </xsl:element>
2666       </xsl:if>
2667     </xsl:element>
2668   </xsl:if>
2669 </xsl:template>
```

Transformation of <bvolume> into a <biblScope>.

```

2670 <xsl:template match="bvolume">
2671   <biblScope type="volume"> <xsl:value-of select=". "/> </biblScope>
2672 </xsl:template>
```

Transformation of <bchapter> into a <biblScope> with a different attribute value.

```

2673 <xsl:template match="bchapter">
2674   <biblScope type="chapter"> <xsl:value-of select=". "/> </biblScope>
2675 </xsl:template>
```

Transformation of <bnumber> into a <biblScope> with a different attribute value.

```

2676 <xsl:template match="bnumber">
2677   <biblScope type="number"> <xsl:value-of select=". "/> </biblScope>
2678 </xsl:template>
```

Transformation of <bpages> into a <biblScope> with a different attribute value.

```

2679 <xsl:template match="bpages">
2680   <biblScope type="number"> <xsl:value-of select=". "/> </biblScope>
2681 </xsl:template>
```

Transformation of <bpublisher> into a <publisher> containing a <orgName>, and sometimes the address.

```

2682 <xsl:template match="bpublisher">
2683   <xsl:element name="publisher">
2684     <xsl:element name="orgName">
2685       <xsl:value-of select=". "/>
2686       <xsl:apply-templates select="../baddress"/>
2687     </xsl:element>
2688   </xsl:element>
2689 </xsl:template>
```

Translation of <baddress> into a <address> containing a <addrLine>.

```

2690 <xsl:template match="baddress">
2691   <xsl:if test="not(..//bbooktitle)">
2692     <xsl:element name="address">
2693       <xsl:element name="addrLine"><xsl:value-of select=". "/></xsl:element>
2694     </xsl:element>
2695   </xsl:if>
2696 </xsl:template>
```

Unused.

```

2697 <xsl:template match="biblio/citation/xref">
2698   ...
2699 </xsl:template>
```

This is the end of the file.

2700 </xsl:transform>

## 6.4 Converting the bibliography into HTML

We explain here what is in the file `biblio.xsl` that converts the bibliography into HTML code. The input is the result of the translation (code shown in the section above) of what Tralics produces, using a TEI syntax. The full TEI is not yet implemented.

We declare the style sheet and all namespaces.

```
2701 <xsl:stylesheet
2702   xmlns:tei="http://www.tei-c.org/ns/1.0"
2703   xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0"
2704   xmlns:m="http://www.w3.org/1998/Math/MathML"
2705   xmlns:xlink="http://www.w3.org/1999/xlink"
2706   xmlns:html="http://www.w3.org/1999/xhtml"
2707   exclude-result-prefixes="m html xlink tei">
```

We remove spaces in most elements.

```
2708 <xsl:strip-space elements="biblStruct monogr analytic author editor
2709   title imprint address addrLine"/>
```

In order to make the following code a bit shorter, we replace ‘`note[@type='from']/text()`’ with `$from` and ‘`note[@type='classification']/text()`’ with `$type`. These two quantities are not defined by the TEI, but are used to sort the bibliography. We make a strong assumption: that `$from` is one of ‘year’ or ‘refer’ or ‘foot’. Entries are sorted by putting ‘refer’ first and ‘foot’ last. We assign category ‘d’ and ‘k’ to these entries. The second assumption is that `$type` is one of ‘article’, ‘book’, ‘booklet’, ‘inbook’, ‘incollection’, ‘inproceedings’, ‘manual’, ‘masterthesis’, ‘misc’, ‘phdthesis’, ‘proceedings’, ‘techreport’, ‘unpublished’. These values are taken from [7, page 763]. Note that Bib<sup>T</sup><sub>E</sub>X defines ‘masterthesis’ and ‘mastersthesis’ as being equivalent; the companion lists the name with an ‘s’, Tralics outputs the other one. We accept also ‘conference’, this is the same as ‘inproceedings’, ‘manuel’ (like ‘manual’, not considered by Tralics) and ‘coursenotes’. All these entries are classified<sup>22</sup>: first book, then Ph.D. theses, then articles in journals, then articles in conferences, then technical reports, then anything else. Their type is a letter between ‘e’ and ‘j’.

The following code is invalid XSLT, because variables are forbidden in `<xsl:key>`, but the idea is there. The construction ‘`1 div X`’ is a bit strange. There is an example in [4], that explains that it returns 1 in case X is the boolean value true, and infinity otherwise, so that the substring contains one or zero characters. In any case, this associates to each entry a value, that happens to be a single letter, because at most one substring produces a non-empty string.

```
2710 <xsl:key name="bibliotypes" match="//biblStruct" use="
2711   concat(
2712     substring('d', 1 div ($from='refer')),
2713     substring('e', 1 div ($from='year' and ($type='book' or
2714       $type='booklet' or $type='proceedings'))),
2715     substring('f', 1 div ($from='year' and ($type='phdthesis'))),
2716     substring('g', 1 div ($from='year' and ($type='article' or
2717       $type='inbook' or $type='incollection'))),
2718     substring('h', 1 div ($from='year' and ($type='inproceedings' or $type='conference'))),
2719     substring('i', 1 div ($from='year' and ($type='techreport' or
2720       $type='manuel' or $type='manual' or $type='coursenotes'))),
2721     substring('j', 1 div ($from='year' and ($type='unpublished' or
```

<sup>22</sup>in the sense of ‘sorted’; secret documents should not appear in the Raweb.

```

2722     $type='misc' or $type='masterthesis'))),
2723     substring('k', 1 div ($from='foot'))
2724   )" />

```

Remember that the structure ‘bibliotypes’ is computed before any global variable is set. As a consequence, we can safely put in a variable the number of entries of each category.

```

2725 <xsl:variable name='d' select="count(key('bibliotypes', 'd'))"/>
2726 <xsl:variable name='e' select="count(key('bibliotypes', 'e'))"/>
2727 <xsl:variable name='f' select="count(key('bibliotypes', 'f'))"/>
2728 <xsl:variable name='g' select="count(key('bibliotypes', 'g'))"/>
2729 <xsl:variable name='h' select="count(key('bibliotypes', 'h'))"/>
2730 <xsl:variable name='i' select="count(key('bibliotypes', 'i'))"/>
2731 <xsl:variable name='j' select="count(key('bibliotypes', 'j'))"/>
2732 <xsl:variable name='k' select="count(key('bibliotypes', 'k'))"/>

```

In order to simplify the code that follows, we show here the source of one of the sections. It is a template with three arguments, a type, for instance ‘f’, a title, and the number of entries before the first of this type.

```

2733 <xsl:call-template name="tri">
2734   <xsl:with-param name="str" select="'f'"/>
2735   <xsl:with-param name="title" select="'some funny title'"/>
2736   <xsl:with-param name="countPrevious" select="$d+$e"/>
2737 </xsl:call-template>

```

The sections are in order from d to k, and the titles are respectively: ‘Major publications by the team in recent years’, ‘Doctoral dissertations and Habilitation theses’, ‘Books and Monographs’, ‘Articles in referred journals and book chapters’, ‘Publications in Conferences and Workshops’, ‘Internal Reports’, ‘Miscellaneous’, ‘Bibliography in notes’. It was decided, in 2006, to make the origin of the publication more explicit; this means to add ‘Year Publications’ before entries of type e to j (all but d and k), and to use a smaller font for the subtitles. For this reason, the template shown above has an additional parameter, ‘title2’ that is the subtitle. We shall abbreviate the previous template as *tri*(‘f’, \$d+\$e, ‘Tit-f,’), using the third title in the list; the last element in the list is the subtitle (one of ‘title’ or ‘title2’ is empty).

The variable **\$except-publis** contains a list of sections that should be omitted. Hence the previous count is a bit more complicated than just computing the sum of **\$d** and **\$e**. For instance, this is the code that computes the first number for section f.

```

2738 <xsl:variable name="countPrevF">
2739   <xsl:choose>
2740     <xsl:when test="contains($except-publis, 'e')">
2741       <xsl:value-of select="$countPrevE" />
2742     </xsl:when>
2743     <xsl:otherwise>
2744       <xsl:value-of select="$countPrevE + $e" />
2745     </xsl:otherwise>
2746   </xsl:choose>
2747 </xsl:variable>

```

In order to make the code shorter, we have abbreviated the previous template as *update-count*(*countPrevF*, ‘e’, *countPrevE*). There is something strange in the code shown here: only section d is conditionally included.

```

2748 <xsl:template name="tri-par-publis">
2749   <xsl:param name="except-publis" />
2750   <div class="publis">
2751     <xsl:if test="not(contains($except-publis, 'd'))">
2752       tri('d', '0', 'Tit-d', '')
2753     </xsl:if>

```

```

2754     update-count(countPrevE, d, 0)
2755     <a name="year"><h2>Year Publications</h2></a>
2756     tri('e', countprevE, '', 'Tit-e')
2757     update-count(countPrevF, e, countprevE)
2758     tri('f', countPrevF, '', 'Tit-f')
2759     update-count(countPrevG, f, countprevF)
2760     tri('g', countPrevG, '', 'Tit-g')
2761     update-count(countPrevH, g, countprevG)
2762     tri('h', countPrevH, '', 'Tit-h')
2763     update-count(countPrevI, h, countprevH)
2764     tri('i', countPrevI, '', 'Tit-i')
2765     update-count(countPrevJ, i, countprevI)
2766     tri('j', countPrevJ, '', 'Tit-j')
2767     update-count(countPrevK, k, countprevJ)
2768     tri('k', countPrevK, 'Tit-k', '')
2769   </div>
2770 </xsl:template>

```

What the code does is obvious: we consider all entries that are of type \$str. If the list is empty, nothing is done. Otherwise, the \$title is output in a <h2>, or \$title2 is output in a <h4>. Note that this code can produce two anchors: ‘Major’ and ‘References’. After that, we output all elements of the list, sorted by author’s name. The template that outputs the entry takes a number: it is the index of the entry, the value of \$countPrevious plus the index in the sorted list.

```

2771 <xsl:template name="tri">
2772   <xsl:param name="str"/>
2773   <xsl:param name="title"/>
2774   <xsl:param name="title2"/>
2775   <xsl:param name="countPrevious"/>
2776   <xsl:if test="key('bibliotypes',$str)[1]">
2777     <xsl:if test="string-length($title)>0">
2778       <a name="{substring-before($title, ')}">
2779         <h2><xsl:value-of select='$title' /></h2>
2780       </a>
2781     </xsl:if>
2782     <xsl:if test="string-length($title2)>0">
2783       <h4><xsl:value-of select='$title2' /></h4>
2784     </xsl:if>
2785     <dl>
2786       <xsl:for-each select="key('bibliotypes',$str)">
2787         <xsl:sort select="descendant::author[1]/persName[1]/surname/text()"/>
2788         <xsl:apply-templates select="..">
2789           <xsl:with-param name="pos">
2790             <xsl:value-of select="$countPrevious+position()"/>
2791           </xsl:with-param>
2792         </xsl:apply-templates>
2793       </xsl:for-each>
2794     </dl>
2795   </xsl:if>
2796 </xsl:template>

```

This is used more than once, hence we introduced this template (this is not valid XSL code, because it uses an undeclared variable \$pos, which is declared by the caller).

```

2797 <xsl:template name="jp.pos">
2798   <xsl:text>[</xsl:text>
2799   <xsl:value-of select="$pos"/>

```

```

2800     <xsl:text>]</xsl:text>
2801 </xsl:template>
```

This template exists in two versions: the version given here terminates if the type is not in the list given above (code omitted). It converts a `<biblStruct>` into a `<dt>`, that contains an anchor, the number and key of the reference, and a `<dd>` that contains the reference. A non trivial point concerns punctuation. The idea is that there is a period after the list of authors, and at the end of the citation. Each item is preceded by a comma, except the author list (that is at the start of an entry) or the title (that comes after the authors).

```

2802 <xsl:template match="biblStruct">
2803     <xsl:param name="pos" select= "position()" />
2804     <xsl:check-this-entry />
2805     <dt class="bib">
2806         <xsl:call-template name="jg.pos" />
2807         <xsl:text>[</xsl:text>
2808         <xsl:value-of select="note[@type='userid']"/>
2809         <xsl:text>]</xsl:text>
2810         <a name="{./@id}"></a>
2811     </dt>
2812     <dd> <xsl:apply-templates/> <xsl:text>.</xsl:text> </dd>
2813     <xsl:text>&#xA; </xsl:text>
2814 </xsl:template>
```

Same code as above, with the following modifications; the user-id field is omitted (this is the cite key of the L<sup>A</sup>T<sub>E</sub>X source, it has nothing to do in the HTML file, but is useful for debug). On the other hand, if the `$xyleme` variable is set, a different anchor is used (the year string should be changed to 2006).

```

2815 <xsl:template match="biblStruct" mode="debug">
2816     <xsl:param name="pos" select="position()" />
2817     <dt class="bib">
2818         <xsl:choose>
2819             <xsl:when test="$xyleme='1'">
2820                 <a name="{./@id}" class="ancre" title="référence en bibtex"
2821                     href=".../2004/publiLatex.text?ref={./@id}&projet={$projet}">
2822                     <xsl:call-template name="jg.pos" />
2823                 </a>
2824             </xsl:when>
2825             <xsl:otherwise>
2826                 <a name="{./@id}" class="ancre">
2827                     <xsl:call-template name="jg.pos" />
2828                 </xsl:otherwise>
2829         </xsl:choose>
2830     </dt>
2831     <dd> <xsl:apply-templates/><xsl:text>.</xsl:text> </dd>
2832 </xsl:template>
```

Most entries are trivial: a comma and the content. The case of `<edition>` is special: the L<sup>A</sup>T<sub>E</sub>X companion says that the value should be something like ‘Second’. There is no such problem for `<orgName>` or `<addrLine>`.

```

2833 <xsl:template match="edition|orgName|addrLine">
2834     <xsl:text>, </xsl:text> <xsl:apply-templates/>
2835 </xsl:template>
```

Translation of `<biblScope>`. This depends on the type attribute. In the case ‘volume’, we output something like “vol. 25”.

```

2836 <xsl:template match="biblScope[@type='volume']">
2837   <xsl:text>, vol.&#xa0;</xsl:text> <xsl:apply-templates/>
2838 </xsl:template>

```

In the case ‘chapter’, we output something like “chap. 25”.

```

2839 <xsl:template match="biblScope[@type='chapter']">
2840   <xsl:text>, chap.&#xa0;</xsl:text> <xsl:apply-templates/>
2841 </xsl:template>

```

In the case ‘number’, we output something like “n° 25”.

```

2842 <xsl:template match="biblScope[@type='number']">
2843   <xsl:text>, n</xsl:text><sup>o</sup><xsl:text>&#xa0;</xsl:text>
2844   <xsl:apply-templates/>
2845 </xsl:template>

```

In the case of ‘pages’ we output something like “p. 10–30”. If the text contains neither a dash nor an en-dash, we output “42 p”.

```

2846 <xsl:template match="biblScope[@type='pages'][text() != '' ]">
2847   <xsl:text>, </xsl:text>
2848   <xsl:choose>
2849     <xsl:when test="string-length(substring-before(., '-'))"
2850       or string-length(substring-before(., '&#8211;'))>0">
2851       <xsl:text>p. </xsl:text>
2852       <xsl:apply-templates/>
2853     </xsl:when>
2854     <xsl:otherwise>
2855       <xsl:apply-templates/>
2856       <xsl:text> p</xsl:text>
2857     </xsl:otherwise>
2858   </xsl:choose>
2859 </xsl:template>

```

Translation of <note>. This is trivial, but used only if the type attribute is ‘bnote’ (a BibT<sub>E</sub>X note), ‘typdoc’ (this could be the type of a report) or ‘howpublished’ (for a non-standard entry).

```

2860 <xsl:template match="note[@type='howpublished' | @type='bnote' | @type='typdoc']">
2861   <xsl:text>, </xsl:text>
2862   <xsl:apply-templates/>
2863 </xsl:template>

```

These notes are used for sorting, their printed value is empty.

```

2864 <xsl:template match="note[@type='from' | @type='userid' | @type='classification']">
2865 </xsl:template>

```

Translation of <title>. Is this really needed?

```

2866 <xsl:template match="title[ancestor::biblio]">
2867   <xsl:text>"</xsl:text> <xsl:apply-templates/><xsl:text>"</xsl:text>
2868 </xsl:template>

```

Translation of <title>. The attribute says that it is the name of a journal.

```

2869 <xsl:template match="title[@level='j']">
2870   <xsl:text>, in: </xsl:text>
2871   <span class="journal"> <xsl:apply-templates/> </span>
2872 </xsl:template>

```

Translation of <title>. The attribute says that it is the name of a series.

```

2873 <xsl:template match="title[@level='s']">
2874   <xsl:text>, </xsl:text> <xsl:apply-templates/>
2875 </xsl:template>

```

Translation of `<title>`. The attribute says that it is the title of an article, a book, or something like that. The result is a `<span>` with an attribute that says to use a different font.

```
2876 <xsl:template match="title[@level='a']">
2877   <span class="journal"> <xsl:apply-templates/> </span>
2878 </xsl:template>
```

Translation of `<title>`. The attribute says that it is something different than the cases considered above. The TEI says something like: If the title appears directly enclosed within an `<analytic>` element, the level, if given, must be ‘a’; if it appears directly enclosed within a `<monogr>` element, level must be ‘m’, ‘j’, or ‘u’; when `<title>` is directly enclosed by `<series>`, level must be ‘s’. As a consequence, if the test is true, we have two titles (for instance a book title, and the title of a part of the book).

```
2879 <xsl:template match="title[@level='m']">
2880   <xsl:choose>
2881     <xsl:when test="string-length(../../analytic/title) > 0">
2882       <xsl:text>, in: </xsl:text>
2883       <span class="journal"><xsl:apply-templates/></span>
2884     </xsl:when>
2885     <xsl:when test="string-length(../../../author) > 0
2886       and string-length(../../../editor) > 0 ">
2887       <xsl:text>, </xsl:text>
2888       <span class="journal"> <xsl:apply-templates/> </span>
2889     </xsl:when>
2890     <xsl:otherwise>
2891       <span class="journal"> <xsl:apply-templates/> </span>
2892     </xsl:otherwise>
2893   </xsl:choose>
2894 </xsl:template>
```

Translation of `<author>`. We consider all `<persName>` in the list, typesetting them one after the other with a comma as separator, and a period at the end. There is a `<br>` at the end of the list. A special case is when the first name is ETAL. Otherwise, we output the forename (either initials in `<initial>` or whatever is in `<foreName>`) and the `<surname>`.

```
2895 <xsl:template match="author">
2896   <xsl:for-each select="persName">
2897     <xsl:choose>
2898       <xsl:when test="foreName='ETAL'">
2899         <small><xsl:text>et al.</xsl:text></small>
2900       </xsl:when>
2901       <xsl:otherwise>
2902         <xsl:choose>
2903           <xsl:when test="initial">
2904             <xsl:apply-templates select="initial"/>
2905           </xsl:when>
2906           <xsl:otherwise>
2907             <xsl:apply-templates select="foreName"/>
2908           </xsl:otherwise>
2909         </xsl:choose>
2910         <xsl:value-of select="foreName"/>
2911         <xsl:text> </xsl:text>
2912         <xsl:apply-templates select="surname" />
2913         <xsl:call-template name="separateur.objet"/>
2914       </xsl:otherwise>
2915     </xsl:choose>
2916   </xsl:for-each>
```

```
2917     <br/>
2918 </xsl:template>
```

The translation of `<editor>` is similar. If an author and an editor are given, they are separated by a comma (remember that there is a line break after the authors). We add a `<br>` at the end in the case where no author is given. Editors are separated by commas, but at the end, we put a '(editor)' or '(editors)' remark.

```
2919 <xsl:template match="editor">
2920   <xsl:if test="...//author">
2921     <xsl:if test="ancestor-or-self/node()/title[@level='a']">
2922       <xsl:text>, </xsl:text>
2923     </xsl:if>
2924   </xsl:if>
2925   <xsl:for-each select="persName">
2926     <xsl:choose>
2927       <xsl:when test="foreName='ETAL'">
2928         <small><xsl:text>et al.</xsl:text></small>
2929       </xsl:when>
2930       <xsl:otherwise>
2931         <xsl:choose>
2932           <xsl:when test="initial">
2933             <xsl:apply-templates select="initial"/>
2934           </xsl:when>
2935           <xsl:otherwise>
2936             <xsl:apply-templates select="foreName"/>
2937           </xsl:otherwise>
2938         </xsl:choose>
2939         <xsl:text> </xsl:text>
2940         <xsl:apply-templates select="surname" />
2941         <xsl:call-template name="separateurED.objet"/>
2942       </xsl:otherwise>
2943     </xsl:choose>
2944   </xsl:for-each>
2945   <xsl:text> (editor</xsl:text><xsl:call-template name="pluriel-p">
2946     <xsl:with-param name="liste" select="persName" /></xsl:call-template>
2947   <xsl:text>).</xsl:text>
2948   <xsl:if test="not(../../../author)"><br/></xsl:if>
2949 </xsl:template>
```

This is used in the case where a name (say Dupont) appears as an autor or editor in the bibliography. We put in in a with 'smallcaps' attribute. Moreover, if is true, and the author is member of the Team (there is a `<person>` with `<lastname> Dupont`), an anchor is created, with value root/Publications/2006/publications.html?name=Dupont&projet=apics.

```
2950 <xsl:template match="surname">
2951   <span class="smallcap">
2952     <xsl:choose>
2953       <xsl:when test="$xyleme='1'
2954         and //person/lastname[text()=current()/text()]">
2955         <a>
2956           <xsl:attribute name="href">
2957             <xsl:value-of select="$rootUrl"/>
2958             /Publications/
2959             <xsl:value-of select="$year" />
2960             /publications.html?name=
2961             <xsl:apply-templates/>&amp;projet=
2962             <xsl:value-of select="$projet" />
2963           </xsl:attribute>
```

```

2964         <xsl:apply-templates />
2965     </a>
2966     </xsl:when>
2967     <xsl:otherwise>
2968         <xsl:apply-templates />
2969     </xsl:otherwise>
2970     </xsl:choose>
2971   </span>
2972 </xsl:template>

    This seems to be useless.

2973 <xsl:template match="bedition"> ? </xsl:template>
    Case of a <dateStruct>. We output the <month> and the <year>.

2974 <xsl:template match="dateStruct">
    <xsl:text>, </xsl:text>
    <xsl:value-of select="month"/><xsl:text> </xsl:text><xsl:value-of select="year"/>
</xsl:template>

    Case of <publisher>. We output the two parts: <orgName> and optionally <address>.

2978 <xsl:template match="publisher">
    <xsl:apply-templates select="orgName"/>
    <xsl:if test=".//address"><xsl:apply-templates select="address"/> </xsl:if>
</xsl:template>

    Case of <address>. No initial comma. This is commented out in the 2006 version.

2982 <xsl:template match="address">
    <xsl:apply-templates/>
</xsl:template>

    Case of a reference. We assume that it is always an external reference. Moreover, the program
    that converts from the old DTD to the new one never adds a url attribute23. The essential difference
    between the two cases is that a <br> is added before the link.

2985 <xsl:template match="biblStruct//ref">
    <xsl:choose>
        <xsl:when test="./@url">
            <a>
                <xsl:attribute name="target">_alt</xsl:attribute>

3043 </xsl:template>

```

Consider the following piece of code; call it *position-in-bib(W)*, where W can be a letter between d and k. Each 'd' should be replaced by W, and "0" by the sum of \$d, \$e, etc, up to, but excluded \$W.

```

3044   <xsl:when test="count($curelement|key('bibliotypes', 'd'))"
3045           =count(key('bibliotypes', 'd'))">
3046     <xsl:call-template name="positionInBib">
3047       <xsl:with-param name="str" select="'d'" />
3048       <xsl:with-param name="current" select="$curelement" />
3049       <xsl:with-param name="countPrevious" select="0" />
3050     </xsl:call-template>
3051   </xsl:when>

```

Here the test compares two values, `count(A|B)` and `count(B)`. The test is true if A is in B (A is a node, B is a node-set, `count(A|B)` is the union of B and the set that contains only A). Such a construct is given as an example in [4] under the entry `<xsl:key>`. It happens that bibliography entries are sorted, by type, a type is a letter between d and k, and, for each type, by author. Consider the  $n$ -th item, let's call it  $X$ ; question: what is  $n$ ? Assume that the entry is of type  $m$ , and there are  $p$  entries of type less than  $m$ ; if this entry is the  $q$ -th of type  $m$ , then  $n=p+q$ . All entries of type  $m$  can be found using `key`, with argument ‘bibliotypes’ and  $m$ . The test in the routine above is then: is `$curelement` of type ‘e’? If so, we call the template with three arguments: `$str` that holds the type, `$current` the entry to test, and `$countPrevious` the quantity  $p$ . The variable `$d` holds the number of entries of type ‘d’, it is computed on line 2728. Thus, we obtain  $p$  by adding some of `$d`, `$e`, `$f`, `$g`, `$h`, `$i`, and `$j` (the quantity `$k` is not used). Computing  $q$  is not trivial: we have a function that computes the index of the current node  $Y$  in a list, it is the `position()` function. We want the position of  $X$ , we obtain it by concatenation of all  $f(Y)$ , where  $f(Y)$  is the position of  $Y$  if  $Y$  is  $X$ , empty otherwise. The nodes  $X$  and  $Y$  are the same if they have the same unique id, not if they have the same text. Normally, the number created here is the same as the one computed on line 2750 (the number associated to the entry), it is created for each reference to the bibliography.

```

3052 <xsl:template name="positionInBib">
3053   <xsl:param name="str" />
3054   <xsl:param name="countPrevious" />
3055   <xsl:param name="current" />
3056   <xsl:for-each select="key('bibliotypes',$str)">
3057     <xsl:sort select="descendant::author[1]/persName[1]/surname/text()" />
3058     <xsl:if test="generate-id(.)=generate-id($current)">
3059       <xsl:value-of select="$countPrevious+position()" />
3060     </xsl:if>
3061   </xsl:for-each>
3062 </xsl:template>

3087 </a>

```

```

3088 </xsl:template>
3089
This is the end of the file.
3090 </xsl:stylesheet>
```

## 6.5 Helper style sheets

We describe here two style sheets, verif-aut.xsl and verif-membres.xsl. The purpose of these two style sheets is to produce small HTML files, containing the list of authors, cited in the bibliography, with their cite key, or the list of members of the team, with their affiliations; this allows authors to quickly check typos in their document.

We shall not show all details, like attributes of the `<xsl:stylesheet>` element, they are similar to those shown elsewhere in this document. The `verif-aut.xsl` file contains a rule for the top-level element, that says to consider only the bibliography.

```

3091 <xsl:template match="/raweb">
3092   <xsl:apply-templates select="biblio" />
3093 </xsl:template>
```

The result is a simple HTML file. It contains a title, and an anchor to the second file, and a list, whose content will be explained later.

```

3094 <xsl:template match="biblio">
3095   <html>
3096     <head>
3097       <title>Verification des auteurs référencés dans la bibliographie </title>
3098       <style type="text/css">
3099         h1 {font-weight:bold;font-size:16pt;}
3100         dt {font-weight:bold;color:blue;}
3101       </style>
3102     </head>
3103     <body>
3104       <h1>Les auteurs référencés dans la bibliographie</h1>
3105       <a href="membres-{$projet}.html">Voir les membres de l'équipe</a> <!--$-->
3106       <dl>
3107       ...
3108       </dl>
3109     </body>
3110   </html>
3111 </xsl:template>
```

This piece of code selects all `<persName>` elements; these are authors or editors. Consider such a person X, with first name A, last name B; we sort these persons, alphabetically, on the last name, then first name. We consider the bibliography entry Y that has X as author or editors (this is a `<biblStruct>`) and its cite key C (this is one of `<note>` children of Y), and output it. Quantities A and B are also printed, but only once.

```

3112 <xsl:for-each select="//persName">
3113   <xsl:sort select="surname"/>
3114   <xsl:sort select="foreName"/>
3115   <xsl:if test="current() [generate-id(.) =
3116     =generate-id(key('authorslist',surname)[1])]">
3117     <dt>
3118       <xsl:apply-templates select="surname"/>
```

```

3119     <xsl:text>, </xsl:text> <xsl:value-of select="foreName"/>
3120     </dt>
3121   </xsl:if>
3122   <dd>
3123     <xsl:apply-templates
3124       select="ancestor::biblStruct/note[@type='userid']"/>
3125   </dd>
3126
3127 </xsl:for-each>
```

This piece of code constructs a ‘key’, an association list, that associates to each author or editor X its last name B. Said otherwise, `key('authorslist', B)` gives the list `<persName>` whose last name is B. If this list is L, then `generate-id(L[1])` is the unique id of the first X with last name B. Assume that there is only one person named B, and that its first name is always given identically; then the test shown above will output the name of the person before its first reference (otherwise, it will be put randomly because of the second sort instruction).

```

3128 <xsl:key name="authorslist"
3129   match="//biblio//persName"
3130   use="surname" />
```

Action is trivial here.

```

3131 <xsl:template match="note">
3132   <xsl:apply-templates />
3133 </xsl:template>
3134
3135 <xsl:template match="surname">
3136   <xsl:apply-templates />
3137 </xsl:template>
```

The second style sheet is similar. It constructs an HTML page, with a link to the first one.

```

3138 <xsl:template match="/raweb">
3139   <html>
3140     <head>
3141       <title>Verification des membres de l'équipe</title>
3142       <style type="text/css">
3143         h1 {font-weight:bold;font-size:16pt;color:blue;}
3144         table {border :2px solid blue; border-collapse:collapse;}
3145         tr {border :1px solid blue;padding:5px;}
3146         td {border :1px solid blue;padding:5px;}
3147         td.head {font-weight:bold; border :1px solid red;padding:5px;
3148           background-color:#ffe3d1;}
3149       </style>
3150     </head>
3151     <body>
3152       <h1>Les membres de l'équipe avec les catégories et affiliations</h1>
3153       <a href="auteurs-{$projet}.html"> <!-- $ emacs -->
3154         Les auteurs référencés dans la bibliographie
3155       </a>
3156     ...
3157     </body>
3158   </html>
3159 </xsl:template>
```

The first item in the file is the number of people entitled to supervise PhD students. It is just the number of <hdr> elements.

```
3160 <p>Nombre de personnes habilitées à diriger des recherches :
3161   <span style="font-weight:bold;">
3162     <xsl:value-of select="count(/hdr)"/>
3163   </span>
3164 </p>
```

Then comes a table, with a header and one line for each team member.

```
3165 <table>
3166   <tr>
3167     <td class="head">Nom</td>
3168     <td class="head">Affiliation</td>
3169     <td class="head">Catégorie profession</td>
3170     <td class="head">Habilité</td>
3171   </tr>
3172   <xsl:apply-templates select="//team/participants/person"/>
3173 </table>
```

The important point here is to output the <categoryPro> and affiliation, since they do not appear in the normal HTML file.

```
3174 <xsl:template match="person">
3175   <tr>
3176     <td>
3177       <xsl:apply-templates select="firstname"/>
3178       <xsl:text> </xsl:text>
3179       <xsl:apply-templates select="lastname"/></td>
3180     <td><xsl:apply-templates select="categoryPro"/></td>
3181     <td><xsl:apply-templates select="affiliation"/></td>
3182     <td><xsl:apply-templates select="hdr"/></td>
3183   </tr>
3184 </xsl:template>
3185
3186 <xsl:template match="firstname|lastname|affiliation|profession">
3187   <xsl:apply-templates />
3188 </xsl:template>
```

We consider now a last style sheet rawebindex.xsl that creates an index. It defines some variables, for instance, \$LeProjet, containing the team name. The main template template here is the following. Note that the output method is plain text.

```
3189 <xsl:template match="raweb">
3190   <xsl:document href="{{$LeProjet}_mcl" method="text" encoding="iso-8859-1">
3191     <xsl:call-template name="keywords"/> <!-- $emacs -->
3192   </xsl:document>
3193 </xsl:template>
```

A rule is applied to each section.

```
3194 <xsl:template name="keywords">
3195   <xsl:apply-templates select="/raweb/composition" mode="mkindex"/>
3196   <xsl:apply-templates select="/raweb/presentation" mode="mkindex"/>
3197   <xsl:apply-templates select="/raweb/fondements" mode="mkindex"/>
3198   <xsl:apply-templates select="/raweb/domaine" mode="mkindex"/>
3199   <xsl:apply-templates select="/raweb/logiciels" mode="mkindex"/>
```

```

3200   <xsl:apply-templates select="/raweb/resultats"      mode="mkindex"/>
3201   <xsl:apply-templates select="/raweb/contrats"      mode="mkindex"/>
3202   <xsl:apply-templates select="/raweb/international" mode="mkindex"/>
3203   <xsl:apply-templates select="/raweb/diffusion"     mode="mkindex"/>
3204 </xsl:template>
```

The code starts by computing a variable in a strange way; we simplified it a bit; it is the name of the current section (for instance, ‘Scientific Foundation’). For each keyword, for instance ‘Rational Approximation’, we convert it to upper case. In order to make the code shorter, we have written ‘S’ instead of ‘ancestor-or-self::subsection’. If we have a section A, with a subsection B, with a subsection C, with a keyword D, then ‘S’ contains C and D (in document order), but the last element on this ancestor-or-self axis is C. If the of this element is uid14, and the team is Apics, this piece of code prints a line of the form *MCL:RATIONAL APPROXIMATION:apics/uid14.html:Team : Apics - Scientific Foundations - Identification and deconvolution*. Here the last item is the title of subsection B, it is omitted when equal to A (modulo case, in all three cases, the two strings given to `translate` have 26 characters.)

```

3205 <xsl:template match="composition|presentation|fondements|domaine|
3206   logiciels|resultats|contrats|international|diffusion"
3207   mode="mkindex" >
3208   <xsl:variable name="SECTION">
3209     <xsl:value-of select="bodyTitle" />
3210   </xsl:variable>
3211   <xsl:for-each select="subsection">
3212     <xsl:for-each select=".//keyword">
3213       <xsl:text>MCL:</xsl:text>
3214       <xsl:value-of select="normalize-space(translate(., 'q', 'Q'))"/>
3215       <xsl:text>:</xsl:text>
3216       <xsl:value-of select="$LeProjet"/>
3217       <xsl:text>/</xsl:text>
3218       <xsl:value-of select="S[position()=last()]/@id"/>
3219       <xsl:text>.html:Team : </xsl:text>
3220       <xsl:value-of select="$PROJET"/><xsl:text> - </xsl:text>
3221       <xsl:value-of select="$SECTION"/>
3222
3223       <xsl:variable name="toto" select="translate(S/bodyTitle, 'Q', 'q')"/>
3224       <xsl:variable name="toti" select="translate($SECTION, 'Q', 'q')"/>
3225       <xsl:if test="$toto!=$toti">
3226         <xsl:text> - </xsl:text>
3227         <xsl:apply-templates select="S[position()=last()]/bodyTitle"/>
3228       </xsl:if>
3229       <xsl:text>&#xA;</xsl:text>
3230     </xsl:for-each>
3231   </xsl:for-each>
3232 </xsl:template>
```

## 6.6 The raweb CSS style sheet

We describe here the content of the file `raweb.css`, containing rendering information for the Raweb. Recall the syntax: we have a keyword K, followed by an open brace, a sequence of properties, and a closing brace. A property is a name, a colon, a value, and a semi-colon as a separator.

If the keyword K is a name, this is the name of the element. Here we say that the `<body>` element (this is the whole HTML page) should have a white background, black foreground, and the font should be Helvetica, or Arial, or some other sans-serif font.

```
3233 body {
3234   background-color:#ffffff;
3235   color:#000000;
3236   font-family: Helvetica, Arial,sans-serif }
```

If the keyword K contains a dot (say ‘foo.bar’), then it applies if the element `<foo>` has ‘bar’ as style. The following rule says that the `<body>` of the TOC has a different background color.

```
3237 body.tdm {
3238   background-color:#DDDDDD;
3239   color:#000000;
3240   font-family: Helvetica, Arial,sans-serif }
```

These rules indicate the size of the headings, `<h1>`, `<h2>`, `<h3>`, `<h4>`, and `<h5>`.

```
3241 h1 { font-size : 150% }
3242 h2 { font-size : 140% }
3243 h3 { font-size : 130% }
3244 h4 { font-size : 110% ; font-style: italic }
3245 h5 { font-size : 90% ;}
```

These lines (as well as following lines with keywords in capital letters) were in the original style sheet, created by `latex2html`; they are not used anymore. The idea is the following: Translation of `\huge` is a `<big>` element, with style ‘huge’. A browser that understands CSS will use a ‘larger’ font, a browser that does not understand CSS will use the font associated to `<big>`. By default, Tralics knows only three sizes of fonts (normal, small and large).

```
3246 SMALL.XTINY      { font-size : xx-small; }
3247 SMALL.TINY       { font-size : x-small;  }
3248 SMALL.SCRIPTSIZE { font-size : smaller; }
3249 SMALL.FOOTNOTESIZE { font-size : small ; }
3250 BIG.XLARGE       { font-size : large ; }
3251 BIG.XXLARGE     { font-size : x-large; }
3252 BIG.HUGE         { font-size : larger ; }
3253 BIG.XHUGE        { font-size : xx-large; }
```

If the keyword has the form ‘.bar’ or ‘\*.bar’, it applies to every element with class ‘bar’. The rules here explain how to locally change the font properties.

```
3254 .smaller{ font-size : smaller   }
3255 .small { font-size : small    }
3256 .large { font-size : large   }
3257 .bold  { font-weight : bold   }
3258 .it    { font-style : italic  }
3259 *.center { text-align:center }
3260 *.smallcap { font-variant:small-caps; }
```

More properties for the `<span>` element. The last rule applies in the case where the element is `<a>` in a `<span>` with style ‘keyword’.

```
3261 SPAN.textit      { font-style: italic  }
3262 SPAN.textbf      { font-weight: bold   }
3263 span.keyword     { font-style: italic  }
3264 span.keyword a   { font-style: italic  }
```

These properties apply to the header of the page, containing the navigation buttons; the first page is white, other are light grey. The first page has a thin border, which has the same color as the big rule that separates the metadata and the TOC (the color is some kind of pink).

```

3265 .premiere { background-color:#ffffff ;
3266         color:#000000 ;
3267         border-width: 1px;
3268         border-color: #D60098;
3269         border-style:solid solid solid solid ;
3270         height: 70px;
3271         padding: 0px 5px 0px 5px
3272     }
3273 .autre { background-color:#dddddd ; height: 70px;}
3274 .rose {background-color: #D60098; height:3px}

```

Properties for math. The first three lines are from `latex2html`, not used anymore (if Tralics sees a font change in a math formula, it constructs a MathML element that will be converted into an image. If the formula needs an equation number, a table will be constructed, in order to get correct alignment. Cells in this table have no border.

```

3275 .MATH { font-family: "Century Schoolbook", serif; }
3276 .MATH I { font-family: "Century Schoolbook", serif; font-style: italic }
3277 .BOLDMATH { font-family: "Century Schoolbook", serif; font-weight: bold }
3278 div.mathdisplay table { border:none }
3279 div.mathdisplay td { border:none }
3280 div.mathdisplay tr { border:none }

```

Figures are generally centered via the use of tables; in these cases we set border and margin to zero. The width of the outer table is 80 percent of the whole page (why?)

```

3281 table.objectContainer { border:none; width:80%; margin:0; }
3282 table.objectContainer td { border:none; margin:0; }
3283 table.objectContainer tr { border:none; margin:0; }
3284 table.objectContainer table { border:none; }
3285 caption {font-size:80%; padding-bottom:10px;}

```

By default, we show border of tables.

```

3286 td { border:1px solid}
3287 tr { border:1px solid}
3288 table { border:1px solid; empty-cells:show; border-collapse:collapse; }

```

A `<ul>` in a `<dd>` is indented by one em (this is strange: what about other lists (dl or ol) inside items of other list, such as li). There are now two rules for `<dt>` elements in the bibliography (containing a cite key). This element is to be shown in a bold font. The next rule has the form ‘foo.bar+gee’, it applies to every ‘gee’ element preceded by a ‘foo’ with style bar. The rule has a negative margin-top, not shown here, because the cite key is overwritten by the author list. We have three rules for list items in the TOC frame.

```

3289 dd ul { margin-top:1em; }
3290 dt.bib { display: inline; font-weight: bold; }
3291 dt.bib + dd { vertical-align:top; margin-bottom: 1em; }
3292 ul.tdm_windows { }
3293 ul.tdm_frame {margin-top:0px;margin-bottom:10px;}
3294 li.tdm_frame {margin-left:-10px;}

```

These two rules explain how ‘Keywords’ and ‘Participants’ should be printed. Currently, they are underlined.

```

3295 *.KW { text-decoration: underline }
3296 *.part { text-decoration: underline }

    These are unused.

3297 .journal { font-style: italic }
3298 *.xyHighlight { background-color: yellow; }

```

The following rules explain how to render the buttons that are on the top right part of the page. A rule of the form #foo applies to every element that has an id attribute with value ‘foo’. A rule of the form #foo:bar applies if this element has status ‘bar’; here the element is an anchor, and we specify how the color of the anchor should change when visited, etc.

```

3299 .folderButtons {
3300     position:absolute;
3301     background-color:#BCBCF9 ;
3302     top:14px;right:12px ;height: 60px ;width: 180px }
3303 .folderLine   { color: #000000 }
3304 .folderText {font-size : smaller; text-align:right; }
3305 #folderIconRef      { border:0px ;float:left; }
3306 #folderIconRef:link { color:#dddddd; }
3307 #folderIconRef:visited { color:#dddddd; }

```

Six rules that say where to put navigation buttons (left, right, center, or top, bottom).

```

3308 #head_adroite   { float:right; }
3309 #head_agache    { float:left; }
3310 #head_aucentre  { text-align:center ; width:70% ;font-size : smaller; }
3311 #tail_agache   { float:left ; }
3312 #tail_adroite  { float:right; }
3313 #tail_aucentre { text-align:center; width:100%; }

```

Four rules that appear in the TOC frame, make the distinction between topics and non-topics obvious. Call these C, F, CT and FT. In the case without topics, we will have C followed by T, otherwise FT followed by CT. The first element is left aligned, the second is right aligned. The C and CT have a lighter color than the F and FT.

```

3314 #clair   {
3315     background-color:#BCBCF9; width:48% ; height:20px;
3316     float:left; border-style:solid solid none solid ;border-width:thin ;
3317     text-align:center;font-size : smaller;}
3318 #fonce   {
3319     background-color:#594FBF; width:48% ; height:20px;
3320     float:right; border-style:solid; border-width:thin ;
3321     text-align:center;font-size : smaller;}
3322 #clair_T {
3323     background-color:#BCBCF9; width:48% ; height:20px;
3324     float:right; border-style:solid solid none solid ;border-width:thin ;
3325     text-align:center;font-size : smaller;}
3326 #fonce_T {
3327     background-color:#594FBF; width:48% ; height:20px;
3328     float:left; border-style:solid; border-width:thin ;
3329     text-align:center;font-size : smaller;}

```

This is for the logo at the bottom of the page. The text has attribute ‘display:none’, so that you will not see it, unless the browser cannot show the image, and uses the text instead.

```

3330 #bandeau {
3331     clear: both;

```

```

3332     width: 100%;  

3333     height: 90px;  

3334     background-color: #594FBF;  

3335     background-image: url(icons/bandeau_g.gif);  

3336     background-repeat: no-repeat;  

3337     text-align:right;}  

3338 #bandeau_logo {  

3339     float: right;  

3340     height: 90px;  

3341     width: 329px;  

3342     padding: 0px;  

3343     background: url(icons/bandeau_d.gif);}  

3344 #logotext { display: none }  

    This is for the logo on the TOC frame.  

3345 *.logo { background-color:#594FBF; color: #FFFFFF; text-align:center; }  

    Other rules use for the TOC frame.  

3346 *.topic_color { color: green; }  

3347 div.bigspace { margin-top:3em; margin-bottom:3em; }  

3348 div.entete { text-align:center; font-weight:bold; }  

3349 div.tdmdiv { position:fixed;top:0;left:0;clear:both;  

    background-color:#dddddd;width:100%; overflow:scroll;max-height: 100% }  

3351 div.noframe { width:20%; }  

3352 div.tdmdiv + div + div#main { margin-left:21%; }  

3353 div.tdmdiv + #toplign { margin-left:20%; width:80%; }  

3354 *.non-topic { margin-bottom:-1em; padding-top:0em;  

    padding-right:1em; padding-bottom:0em; }  

3355 *.topic { border-width:thin ; border-color:black;  

    border-style:none solid solid solid; }  

3356 *.topicIdent { color:green; text-align:right ; }  

3357 div.topic {background-color:#BCBCF9; color: #FFFFFF; padding: 5px 5px 0px 0px;}  

3358 table.topic { background-color:#BCBCF9; color: #FFFFFF; }  

    More rules.  

3361 #bouton { padding:0em }  

3362 .NavigationIcones {margin:4px 0px 0px 0px; }

```

## Chapter 7

# Converting XML to XSL/Format

In this chapter, we consider conversion of XML to XSL/Format, using the initial Raweb DTD, and we shall explain the difference with the new DTD. The files described in this chapter are part of the Tralics distribution (those for the new DTD are in the Raweb package). All these files are adapted from the TEI distribution; the copyright notice is the same as those given in the previous chapter.

### 7.1 The rrrafo3.xsl file

We start with a small file containing some commands that deal with fonts. In the original version of Tralics, the translation of {\tiny etc} was a `<hi>` element, with an attribute `rend = 'small'`. In the current version, Tralics understands more than three sizes (small, large, and normal), and can indicate these in an element, rather than an attribute. Thus, the translation can be `<font-small14>`. In this file, we have a big template, that interprets all values of the `rend` attribute, and a lot of trivial, small templates, that interpret elements like `<small14>`.

This interprets the `rend` attribute. The effect is to add attributes to the current element, in general `<fo:inline>`. In the initial version, the template took two arguments used in case of unknown specification (the default is to use bold font weight). Note: Perhaps, we should replace the value of 'small' by 9pt instead of 8pt.

```

1 <xsl:template name="rend">
2   <xsl:choose>
3     <xsl:when test="@rend='overline'">
4       <xsl:attribute name="text-decoration">overline</xsl:attribute>
5     </xsl:when>
6     <xsl:when test="@rend='underline'">
7       <xsl:attribute name="text-decoration">underline</xsl:attribute>
8     </xsl:when>
9     <xsl:when test="@rend='oldstyle'">
10      <xsl:attribute name="font-family">Concrete</xsl:attribute>
11    </xsl:when>
12    <xsl:when test="@rend='ital'">
13      <xsl:attribute name="font-style">italic</xsl:attribute>
14    </xsl:when>
15    <xsl:when test="@rend='emph'">
16      <xsl:attribute name="font-style">italic</xsl:attribute>
17    </xsl:when>
18    <xsl:when test="@rend='sub'">
19      <xsl:attribute name="vertical-align">sub</xsl:attribute>

```

```

20      </xsl:when>
21      <xsl:when test="@rend='sup'">
22          <xsl:attribute name="vertical-align">super</xsl:attribute>
23      </xsl:when>
24      <xsl:when test="@rend='it'">
25          <xsl:attribute name="font-style">italic</xsl:attribute>
26      </xsl:when>
27      <xsl:when test="@rend='slanted'">
28          <xsl:attribute name="font-style">italic</xsl:attribute>
29      </xsl:when>
30      <xsl:when test="@rend='sc'">
31          <xsl:attribute name="font-variant">small-caps</xsl:attribute>
32      </xsl:when>
33      <xsl:when test="@rend='tt'">
34          <xsl:attribute name="font-family">Computer-Modern-Typewriter</xsl:attribute>
35      </xsl:when>
36      <xsl:when test="@rend='sansserif'">
37          <xsl:attribute name="font-family">sansserif</xsl:attribute>
38      </xsl:when>
39      <xsl:when test="@rend='bold'">
40          <xsl:attribute name="font-weight">bold</xsl:attribute>
41      </xsl:when>
42      <xsl:when test="@rend='ul'">
43          <xsl:attribute name="text-decoration">ul</xsl:attribute>
44      </xsl:when>
45      <xsl:when test="@rend='caps'">
46          <xsl:attribute name="text-decoration">caps</xsl:attribute>
47      </xsl:when>
48      <xsl:when test="@rend='hl'">
49          <xsl:attribute name="text-decoration">hl</xsl:attribute>
50      </xsl:when>
51      <xsl:when test="@rend='so'">
52          <xsl:attribute name="text-decoration">so</xsl:attribute>
53      </xsl:when>
54      <xsl:when test="@rend='st'">
55          <xsl:attribute name="text-decoration">st</xsl:attribute>
56      </xsl:when>
57      <xsl:when test="@rend='small'">
58          <xsl:attribute name="font-size">8pt</xsl:attribute>
59      </xsl:when>
60      <xsl:when test="@rend='small1'">
61          <xsl:attribute name="font-size">9pt</xsl:attribute>
62      </xsl:when>
63      <xsl:when test="@rend='small2'">
64          <xsl:attribute name="font-size">8pt</xsl:attribute>
65      </xsl:when>
66      <xsl:when test="@rend='small3'">
67          <xsl:attribute name="font-size">7pt</xsl:attribute>
68      </xsl:when>
69      <xsl:when test="@rend='small4'">
70          <xsl:attribute name="font-size">5pt</xsl:attribute>
71      </xsl:when>
72      <xsl:when test="@rend='large'">
73          <xsl:attribute name="font-size">12pt</xsl:attribute>
74      </xsl:when>
75      <xsl:when test="@rend='large1'">

```

```

76      <xsl:attribute name="font-size">12pt</xsl:attribute>
77    </xsl:when>
78    <xsl:when test="@rend='large2'">
79      <xsl:attribute name="font-size">14pt</xsl:attribute>
80    </xsl:when>
81    <xsl:when test="@rend='large3'">
82      <xsl:attribute name="font-size">17pt</xsl:attribute>
83    </xsl:when>
84    <xsl:when test="@rend='large4'">
85      <xsl:attribute name="font-size">20pt</xsl:attribute>
86    </xsl:when>
87    <xsl:when test="@rend='large5'">
88      <xsl:attribute name="font-size">25pt</xsl:attribute>
89    </xsl:when>
90    <xsl:otherwise>
91      <xsl:attribute name="font-weight">bold</xsl:attribute>
92    </xsl:otherwise>
93  </xsl:choose>
94 </xsl:template>

```

Replacement code for the `rend` attribute defined above. In all cases, we provide a long and a short name. We produce an `<fo:inline>` element, with some attributes. We start with two templates associated to `<small>` and `<large>`. The attribute we set is `font-size`.

```

95 <xsl:template match='small|font-small'>
96   <fo:inline font-size='8pt'> <xsl:apply-templates/> </fo:inline>
97 </xsl:template>

```

Case large:

```

98 <xsl:template match='large|font-large'>
99   <fo:inline font-size='12pt'> <xsl:apply-templates/> </fo:inline>
100 </xsl:template>

```

We continue with the ten font size commands of L<sup>A</sup>T<sub>E</sub>X. This corresponds to `\tiny`.

```

101 <xsl:template match='small4|font-small4'>
102   <fo:inline font-size='5pt'> <xsl:apply-templates/> </fo:inline>
103 </xsl:template>

```

This corresponds to `\scriptsize`.

```

104 <xsl:template match='small3|font-small3'>
105   <fo:inline font-size='7pt'> <xsl:apply-templates/> </fo:inline>
106 </xsl:template>

```

This corresponds to `\footnotesize`.

```

107 <xsl:template match='small2|font_small2'>
108   <fo:inline font-size='8pt'> <xsl:apply-templates/> </fo:inline>
109 </xsl:template>

```

This corresponds to `\small`.

```

110 <xsl:template match='small1|font-small1'>
111   <fo:inline font-size='9pt'> <xsl:apply-templates/> </fo:inline>
112 </xsl:template>

```

This corresponds to `\normalsize`.

```

113 <xsl:template match='normalsize|font-normalsize'>
114   <fo:inline font-size='10pt'> <xsl:apply-templates/> </fo:inline>
115 </xsl:template>

```

This corresponds to `\large`.

```

116 <xsl:template match='large1|font-large1'>
117   <fo:inline font-size='12pt'> <xsl:apply-templates/> </fo:inline>
118 </xsl:template>
    This corresponds to \Large.
119 <xsl:template match='large2|font-large2'>
120   <fo:inline font-size='14.4pt'> <xsl:apply-templates/> </fo:inline>
121 </xsl:template>
    This corresponds to \LARGE.
122 <xsl:template match='large3|font-large3'>
123   <fo:inline font-size='17.28pt'> <xsl:apply-templates/> </fo:inline>
124 </xsl:template>
    This corresponds to \huge.
125 <xsl:template match='large4|font-large4'>
126   <fo:inline font-size='20.74pt'> <xsl:apply-templates/> </fo:inline>
127 </xsl:template>
    This corresponds to \Huge.
128 <xsl:template match='large5|font-large5'>
129   <fo:inline font-size='24.88pt'> <xsl:apply-templates/> </fo:inline>
130 </xsl:template>
    Now the four shapes. The attribute is font-style or font-variant. This corresponds to \itshape.
131 <xsl:template match='it|font-italic-shape'>
132   <fo:inline font-style='italic'> <xsl:apply-templates/> </fo:inline>
133 </xsl:template>
    This corresponds to \slshape.
134 <xsl:template match='slanted|font-slanted-shape'>
135   <fo:inline font-style='oblique'> <xsl:apply-templates/> </fo:inline>
136 </xsl:template>
    This corresponds to \scshape.
137 <xsl:template match='sc|font-small-caps-shape'>
138   <fo:inline font-variant='small-caps'> <xsl:apply-templates/> </fo:inline>
139 </xsl:template>
    This corresponds to \upshape.
140 <xsl:template match='upright|font-upright-shape'>
141   <fo:inline font-variant='normal'> <xsl:apply-templates/> </fo:inline>
142 </xsl:template>
    Now the three families. The attribute is font-variant or font-family. We provide two different tt
families. This corresponds to \rmfamily.
143 <xsl:template match='roman|font-roman-family'>
144   <fo:inline font-variant='normal'> <xsl:apply-templates/> </fo:inline>
145 </xsl:template>
    This corresponds to \sfamily.
146 <xsl:template match='sansserif|font-sansserif-family'>
147   <fo:inline font-family='sansserif'> <xsl:apply-templates/> </fo:inline>
148 </xsl:template>
    This corresponds to \ttfamily (first variant).
149 <xsl:template match='computer-modern-tt'>
150   <fo:inline font-family='Computer-Modern-Typewriter'>
151     <xsl:apply-templates/>

```

```

152     </fo:inline>
153 </xsl:template>
      This corresponds to \ttfamily (second variant).
154 <xsl:template match='tt|font-typewriter-family'>
155   <fo:inline font-family='monospace'> <xsl:apply-templates/> </fo:inline>
156 </xsl:template>
      Now the two series. The attribute is font-weight. This corresponds to \mdseries.
157 <xsl:template match='medium|font-medium-series'>
158   <fo:inline font-weight='medium'> <xsl:apply-templates/> </fo:inline>
159 </xsl:template>
      This corresponds to \bfseries.
160 <xsl:template match='bold|font-bold-series'>
161   <fo:inline font-weight='bold'> <xsl:apply-templates/> </fo:inline>
162 </xsl:template>
      Superscript, subscript in text fonts. The attribute is vertical-align.
163 <xsl:template match='sup|font-super'>
164   <fo:inline vertical-align='super'> <xsl:apply-templates/> </fo:inline>
165 </xsl:template>
      Case of a subscript (corresponds to a non-standard LATEX command).
166 <xsl:template match='sub|font-sub'>
167   <fo:inline vertical-align='sub'> <xsl:apply-templates/> </fo:inline>
168 </xsl:template>
      Overline, underline in text fonts. The attribute is text-decoration.
169 <xsl:template match='underline|font-underline'>
170   <fo:inline text-decoration='underline'> <xsl:apply-templates/> </fo:inline>
171 </xsl:template>
      Case of overline.
172 <xsl:template match='overline|font-overline'>
173   <fo:inline text-decoration='overline'> <xsl:apply-templates/> </fo:inline>
174 </xsl:template>
      Five elements defined by the soul package. Only the long variant is considered here. The result
      is a text-decoration.
175 <xsl:template match='font-ul'>
176   <fo:inline text-decoration='ul'> <xsl:apply-templates/> </fo:inline>
177 </xsl:template>
178 <xsl:template match='font-caps'>
179   <fo:inline text-decoration='caps'> <xsl:apply-templates/> </fo:inline>
180 </xsl:template>
181 <xsl:template match='font-hl'>
182   <fo:inline text-decoration='hl'> <xsl:apply-templates/> </fo:inline>
183 </xsl:template>
184 <xsl:template match='font-so'>
185   <fo:inline text-decoration='so'> <xsl:apply-templates/> </fo:inline>
186 </xsl:template>
187 <xsl:template match='font-st'>
188   <fo:inline text-decoration='st'> <xsl:apply-templates/> </fo:inline>
189 </xsl:template>
      Translation of <note>. We simplified a bit the code. In the TEI, there is an attribute place,
      whose value can be 'foot' if the note should appear on the foot of the page, it can be 'margin',
      'left', 'right' if the note appears in the margin (or more specifically in the left or right margin), but

```

implementation is incomplete, if can be ‘display’ or ‘divtop’ if the note should appear in the text as a block; otherwise it will be inlined (with parentheses around).

In the case of the Raweb, we consider only the case where the note is a footnote. We first compute the number, and construct an inline element E, containing this number in a small font, vertically aligned as a superscript. We construct an element B, a `<fo:footnote-body>` containing this B followed by the content of the note. The result is then `<fo:footnote>` element, containing E and B.

```

190 <xsl:template match="note">
191   <xsl:variable name="FootID">
192     <xsl:call-template name="calculateFootnoteNumber"/>
193   </xsl:variable>
194   <fo:footnote>
195     <fo:inline font-size="{$footnotenumSize}" vertical-align="super">
196       <xsl:value-of select="$FootID"/>
197     </fo:inline>
198     <fo:footnote-body>
199       <fo:block end-indent="0pt" start-indent="0pt"
200         text-indent="{$parIndent}" font-size="{$footnoteSize}">
201           <fo:inline font-size="{$footnotenumSize}" vertical-align="super">
202             <xsl:value-of select="$FootID"/>
203           </fo:inline>
204           <xsl:apply-templates/>
205         </fo:block>
206       </fo:footnote-body>
207     </fo:footnote>
208   </xsl:template>

This is the end of the file.

209 </xsl:stylesheet>

```

In the new DTD, there is no `<hi>` element anymore. Instead, element `<b>` selects a bold font weight, element `<i>` selects an italic font style, element `<tt>` selects type writer font family, elements `<sup>` and `<sub>` select some vertical alignment, elements `<small>` and `<big>` select a font size, while `<span>` selects a small caps font variant.

```

210 <xsl:template match="b">
211   <fo:inline font-weight="bold"> <xsl:apply-templates /> </fo:inline>
212 </xsl:template>

213 <xsl:template match="i">
214   <fo:inline font-style="italic"> <xsl:apply-templates /> </fo:inline>
215 </xsl:template>

216 <xsl:template match="tt">
217   <fo:inline font-family='Computer-Modern-Typewriter'>
218     <xsl:apply-templates /> </fo:inline>
219 </xsl:template>

220 <xsl:template match="sup">
221   <fo:inline vertical-align="super"> <xsl:apply-templates /> </fo:inline>
222 </xsl:template>

223 <xsl:template match="sub">
224   <fo:inline vertical-align="sub"> <xsl:apply-templates /> </fo:inline>
225 </xsl:template>

226 <xsl:template match="small">
227   <fo:inline>
228     <xsl:apply-templates />
229   </fo:inline>
230 </xsl:template>

```

```

232     <fo:inline font-size="8pt"> <xsl:apply-templates /> </fo:inline>
233   </xsl:template>
234
235   <xsl:template match="span">
236     <fo:inline font-variant='small-caps'> <xsl:apply-templates /> </fo:inline>
237   </xsl:template>
238
239   <xsl:template match="big">
240     <fo:inline font-size="12pt"> <xsl:apply-templates /> </fo:inline>
241   </xsl:template>

```

Finally, the style of a `<em>` is interpreted by this trivial procedure. It adds an attribute pair to the current element. The default behavior is bold font weight.

```

242   <xsl:template name="style">
243     <xsl:param name="defaultvalue"/>
244     <xsl:param name="defaultstyle"/>
245     <xsl:choose>
246       <xsl:when test="@style='UNDERLINE'">
247         <xsl:attribute name="text-decoration">underline</xsl:attribute>
248       </xsl:when>
249       <xsl:when test="@style='overline'">
250         <xsl:attribute name="text-decoration">overline</xsl:attribute>
251       </xsl:when>
252       <xsl:when test="@style='sansserif'">
253         <xsl:attribute name="font-family">sansserif</xsl:attribute>
254       </xsl:when>
255       <xsl:when test="@style='slanted'">
256         <xsl:attribute name="font-style">oblique</xsl:attribute>
257       </xsl:when>
258       <xsl:when test="@style='HIGHLIGHT'">
259         <xsl:attribute name="font-style">cursive</xsl:attribute>
260       </xsl:when>
261       <xsl:otherwise>
262         <xsl:attribute name="${defaultstyle}">
263           <xsl:value-of select="$defaultvalue"/>
264         </xsl:attribute>
265       </xsl:otherwise>
266     </xsl:choose>
267   </xsl:template>

```

## 7.2 The rawebfo file

This is the main file, its name is `raweb3fo.xsl`. It starts like this.

```

268 <xsl:stylesheet
269   xmlns:fotex="http://www.tug.org/fotex"
270   xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0"
271   xmlns:m="http://www.w3.org/1998/Math/MathML"

288   <xsl:apply-templates/>
289 </xsl:template>
```

## 7.3 Page definitions

The first object in the XSL/Format file is the definition of the page layout. In our case, half of the definitions given here are not used, but are taken from the TEI code. Maybe one day somebody wants an index in two columns, in this case, page masters with index 2 can be used. Before 2006, there is no index mechanism offered by Tralics, and the \index command is forbidden in the Raweb.

The `<fo:layout-master-set>` element contains first some `<fo:simple-page-master>` elements. All these use the value of `$pageMarginTop` for the top margin, `$pageMarginBottom` for the bottom margin, `$pageMarginLeft` for the left margin, `$pageMarginRight` for the right margin, `$pageWidth` for the width of the page, and `$pageHeight` for the height of the page (values omitted but for the first occurrence). In any case, we define three regions, `<fo:region-body>`, `<fo:region-before>`, and `<fo:region-after>`. These last two regions have always the same extent, stored in variables `$regionBeforeExtent` and `$regionAfterExtent`.

We start with simple1: no headings, one column, all pages have the same look. The regions before and after have no name.

```

290 <xsl:template name="setupPagemasters">
291   <fo:layout-master-set>
292     <fo:simple-page-master master-name="simple1"
293       page-width="{$pageWidth}"
294       page-height="{$pageHeight}"
295       margin-top="{$pageMarginTop}"
296       margin-bottom="{$pageMarginBottom}"
297       margin-left="{$pageMarginLeft}"
298       margin-right="{$pageMarginRight}">
299     <fo:region-body
300       margin-bottom="{$bodyMarginBottom}"
```

```

301           margin-top="{$bodyMarginTop}"/>
302             <fo:region-before extent="{$regionBeforeExtent}" />
303             <fo:region-after extent="{$regionAfterExtent}" />
304         </fo:simple-page-master>
```

This is for left-hand/even pages in twosided mode, single column.

```

305     <fo:simple-page-master master-name="left1" >
306       <!-- Attributes as above -->
307       <fo:region-body
308         margin-bottom="{$bodyMarginBottom}"
309         margin-top="{$bodyMarginTop}"/>
310       <fo:region-before
311         region-name="xsl-region-before-left"
312         extent="{$regionBeforeExtent}"/>
313       <fo:region-after
314         region-name="xsl-region-after-left"
315         extent="{$regionAfterExtent}"/>
316     </fo:simple-page-master>
```

Case of right-hand/odd pages in twosided mode, single column.

```

317     <fo:simple-page-master master-name="right1" >
318       <!-- Attributes as above -->
319       <fo:region-body
320         margin-bottom="{$bodyMarginBottom}"
321         margin-top="{$bodyMarginTop}"/>
322       <fo:region-before

348         extent="{$regionBeforeExtent}"/>
349       <fo:region-after
350         region-name="DummyRegion"
```

```

351           extent="{$regionAfterExtent}"/>
352     </fo:simple-page-master>

```

For pages in one-side mode, 2 columns per page. We use the value of \$columnCount for the number of columns.

```

353   <fo:simple-page-master master-name="simple2">
354     <!-- Attributes as above -->
355     <fo:region-body
356       column-count="{$columnCount}"
357       margin-bottom="{$bodyMarginBottom}"
358       margin-top="{$bodyMarginTop}"/>
359     <fo:region-before extent="{$regionBeforeExtent}"/>
360     <fo:region-after extent="{$regionAfterExtent}"/>
361   </fo:simple-page-master>

```

For left-hand/even pages in twosided mode, 2 columns per page.

```

362   <fo:simple-page-master master-name="left2">
363     <!-- Attributes as above -->
364     <fo:region-body
365       column-count="{$columnCount}"
366       margin-bottom="{$bodyMarginBottom}"
367       margin-top="{$bodyMarginTop}"/>
368     <fo:region-before
369       region-name="xsl-region-before-left"
370       extent="{$regionBeforeExtent}"/>
371     <fo:region-after
372       region-name="xsl-region-after-left"
373       extent="{$regionAfterExtent}"/>
374   </fo:simple-page-master>

```

For right-hand/odd pages in twosided mode, 2 columns per page.

```

375   <fo:simple-page-master master-name="right2">
376     <!-- Attributes as above -->
377     <fo:region-body
378       column-count="{$columnCount}"
379       margin-bottom="{$bodyMarginBottom}"
380       margin-top="{$bodyMarginTop}"/>
381     <fo:region-before
382       region-name="xsl-region-before-right"
383       extent="{$regionBeforeExtent}"/>
384     <fo:region-after
385       region-name="xsl-region-after-right"
386       extent="{$regionAfterExtent}"/>
387   </fo:simple-page-master>

```

Special case of first page in either mode, two columns per page.

```

388   <fo:simple-page-master master-name="first2">
389     <!-- Attributes as above -->
390     <fo:region-body
391       column-count="{$columnCount}"
392       margin-bottom="{$bodyMarginBottom}"
393       margin-top="{$bodyMarginTop}"/>
394     <fo:region-before
395       region-name="xsl-region-before-first"
396       extent="{$regionBeforeExtent}"/>
397     <fo:region-after
398       region-name="xsl-region-after-first"

```

```

399           extent="{$regionAfterExtent}"/>
400     </fo:simple-page-master>

```

We define now some <fo:page-sequence-master> elements.

They contain a <fo:repeatable-page-master-alternatives> element. These contain some <fo:conditional-page-master-reference>. We start with setup for double-sided, 1 column, no first page.

```

401   <fo:page-sequence-master master-name="twoside1nofirst">
402     <fo:repeatable-page-master-alternatives>
403       <fo:conditional-page-master-reference
404         master-reference="right1"
405         odd-or-even="odd"/>
406       <fo:conditional-page-master-reference
407         master-reference="left1"
408         odd-or-even="even"/>
409     </fo:repeatable-page-master-alternatives>
410   </fo:page-sequence-master>

```

Setup for double-sided, 1 column. Note that this is the only one that defines a page master for blank pages.

```

411   <fo:page-sequence-master master-name="twoside1">
412     <fo:repeatable-page-master-alternatives>
413       <fo:conditional-page-master-reference
414         master-reference="first1"
415         page-position="first"/>
416       <fo:conditional-page-master-reference
417         master-reference="right1"
418         odd-or-even="odd"/>
419       <fo:conditional-page-master-reference
420         master-reference="left1"
421         odd-or-even="even"/>
422       <fo:conditional-page-master-reference
423         master-reference="blank1"
424         blank-or-not-blank="blank"/>
425     </fo:repeatable-page-master-alternatives>
426   </fo:page-sequence-master>

```

Setup for single-sided, 1 column.

```

427   <fo:page-sequence-master master-name="oneside1">
428     <fo:repeatable-page-master-alternatives>
429       <fo:conditional-page-master-reference
430         master-reference="first1"
431         page-position="first"/>
432       <fo:conditional-page-master-reference master-reference="simple1"/>
433     </fo:repeatable-page-master-alternatives>
434   </fo:page-sequence-master>

```

Setup for double-sided, 2 columns.

```

435   <fo:page-sequence-master master-name="twoside2">
436     <fo:repeatable-page-master-alternatives>
437       <fo:conditional-page-master-reference
438         master-reference="first2"
439         page-position="first"/>
440       <fo:conditional-page-master-reference
441         master-reference="right2"
442         odd-or-even="odd"/>
443       <fo:conditional-page-master-reference
444         master-reference="left2"

```

```

445           odd-or-even="even"/>
446     </fo:repeatable-page-master-alternatives>
447   </fo:page-sequence-master>
448   Setup for single-sided, 2 columns.
449     <fo:page-sequence-master master-name="oneside2">
450       <fo:repeatable-page-master-alternatives>
451         <fo:conditional-page-master-reference
452           master-reference="first2"
453           page-position="first"/>
454         <fo:conditional-page-master-reference master-reference="simple2" />
455       </fo:repeatable-page-master-alternatives>
456     </fo:page-sequence-master>
457     <xsl:call-template name="hookDefinepamasters"/>

```

That was a long template! The XSLT processor replaces all the space characters and newline characters by a single space. The resulting element is printed on a single line; it has over 5000 characters. This is much larger than the 500 that appear in the T<sub>E</sub>X source; in fact, in the case of the apics Team, T<sub>E</sub>X used 15174 input buffer positions.

```

457   </fo:layout-master-set>
458 </xsl:template>

```

We define here two `<fo:static-content>` elements, for left and right pages. They contain a `<fo:block>` and a second block (is this really needed?) The inner block says `text-indent='0pt'`, because headings should not be indented. We set `border-after-style` to solid. In the original version, this did not work, and there was a `<pagestylelehrule>` instead. On one end we have page numbers, on the other we have the name of the team or INRIA.

```

459 <xsl:template name="myheaders">
460   <fo:static-content flow-name="xsl-region-before-right">
461     <fo:block text-align="justify" font-size="{$bodySize}">
462       <fo:block border-after-style="solid" text-indent="0pt">
463         <fo:inline font-style="italic"><xsl:value-of select="$PRID"/></fo:inline>
464         <fo:leader rule-thickness="0pt"/>
465         <fo:inline> <fo:page-number/> </fo:inline>
466       </fo:block>
467     </fo:block>
468   </fo:static-content>
469
470   <fo:static-content flow-name="xsl-region-before-left">
471     <fo:block text-align="justify" font-size="{$bodySize}">
472       <fo:block border-after-style="solid" text-indent="0pt">
473         <fo:inline> <fo:page-number/> </fo:inline>
474         <fo:leader rule-thickness="0pt"/>
475         <fo:inline font-style="italic">
476           Activity Report INRIA <xsl:value-of select="$year"/>
477         </fo:inline>
478       </fo:block>
479     </fo:block>
480   </fo:static-content>

```

We use empty footers, and the first page has no header.

```

481 <fo:static-content flow-name="xsl-region-before-first"/>
482 <fo:static-content flow-name="xsl-region-after-right"/>
483 <fo:static-content flow-name="xsl-region-after-left"/>

```

```

484 <fo:static-content flow-name="xsl-region-after-first"/>
485 </xsl:template>
```

The main text is in a page sequence, defined like this. Note that the original file had master-name = ‘twoside1nofirst’. This is useless, but raises the following question: should the first page of text (in general, the fifth page) have a page header, or should it be considered as a first page. The flow-name attribute is useless (used only for static content).

```

486 <xsl:template name="maintext">
487   <fo:page-sequence
488     format="1"
489     text-align="justify"
490     hyphenate="true"
491     language="english"
492     initial-page-number="1"
493     master-reference="twoside1"
494   >
495   <fo:flow
496     flow-name="xsl-region-body"
497     font-family="${bodyFont}"
498     font-size="${bodySize}">
499     <xsl:call-template name="raweb.body"/>
500   </fo:flow>
501 </fo:page-sequence>
502 </xsl:template>
```

The title page is another page sequence, defined like this. The content will be given later; in the new DTD, this is called <identification>.

```

503 <xsl:template match="accueil">
504   <fo:page-sequence
505     format="1"
506     text-align="justify"
507     hyphenate="true"
508     language="english"
509     initial-page-number="1"
510     master-reference="twoside1"
511     force-page-count="end-on-even"
512   >
513   <fo:flow font-style="italic" font-family="${bodyFont}">
514     <xsl:call-template name="accueil.body"/>
515   </fo:flow>
516 </fo:page-sequence>
517 </xsl:template>
```

The TOC is similar.

```

518 <xsl:template name="myTOC">
519   <fo:page-sequence
520     format="1"
521     text-align="justify"
522     hyphenate="true"
523     language="english"
524     initial-page-number="1"
525     master-reference="twoside1"
526     force-page-count="end-on-even"
```

```

527   >
528   <fo:flow flow-name="xsl-region-body">
529     <fo:block>
530       <xsl:call-template name="toc.body"/>
531     </fo:block>
532   </fo:flow>
533 </fo:page-sequence>
534 </xsl:template>
```

## 7.4 The text

The document element is `<raweb>`. The first thing to do is construct the `<fo:layout-master-set>`, then all `<fo:static-content>`. After that, we have three parts: the title page, the table of contents, and the main text. Each of these parts start on a right page (an odd one, but the first page in each section is numbered one). Using `<cleardoublepage>` is a big hack.<sup>1</sup>

```

535 <xsl:template match="raweb">
536   <fo:root xmlns:fo="http://www.w3.org/1999/XSL/Format">
537     <xsl:call-template name="setupPagemasters"/>
538     <xsl:call-template name="myheaders"/>
539     <xsl:apply-templates select="accueil"/>
540     <xsl:call-template name="myTOC"/>
541     <xsl:call-template name="maintext"/>
542   </fo:root>
543 </xsl:template>
```

The `maintext` template selects a page sequence and a flow (see above), then calls this template. The idea is trivial: we consider one section after the other.

```

544 <xsl:template name="raweb.body">
545   <xsl:apply-templates select="composition"/>
546   <xsl:apply-templates select="presentation"/>
547   <xsl:apply-templates select="fondements"/>
548   <xsl:apply-templates select="domaine"/>
549   <xsl:apply-templates select="logiciels"/>
550   <xsl:apply-templates select="resultats"/>
551   <xsl:apply-templates select="contrats"/>
552   <xsl:apply-templates select="international"/>
553   <xsl:apply-templates select="diffusion"/>
554   <xsl:apply-templates select="biblio"/>
555 </xsl:template>
```

This computes the start of a section. The result is a `<fo:block>`, containing the number and title of the section; these are found in attributes. This can call two templates that can parameterize the code. Note: there is a problem with the bookmarks. For this reason, we do not show the code.

```

556 <xsl:template name="secNumberedHeading">
557   <fo:block keep-with-next.within-page="always">
558     <xsl:variable name="divid">
559       <xsl:call-template name="idLabel"/>
560     </xsl:variable>
561     <xsl:attribute name="id"> <xsl:value-of select="$divid"/> </xsl:attribute>
```

---

<sup>1</sup>It is removed in the 2005 version shown here.

```

562     <xsl:attribute name="text-align">start</xsl:attribute>
563     <xsl:attribute name="font-family">
564         <xsl:value-of select="$divFont"/>
565     </xsl:attribute>
566     <xsl:call-template name="setupDiv0"/>
567     <xsl:call-template name="blockStartHook"/>
568     <xsl:value-of select="@numero"/>
569     <xsl:text>. </xsl:text>
570     <xsl:value-of select="@titre"/>
571     <xsl:if test="$pdfBookmarks='true'">
572         <fotex:bookmark ... />
573     </xsl:if>
574     </fo:block>
575 </xsl:template>
```

The code changed a bit in the case of the new DTD. This is because the title of the section is now in `<bodyTitle>`, unless the section is `<identification>`, `<team>`, `<biblio>`, case where ‘Identification’, ‘Team’ or ‘Bibliography’ is used. Moreover, the `numero` attribute is not used. Instead, the effective section number is used instead, via `calculateNumberSection`. These lines are a replacement for lines 568 to 571.

```

576     <xsl:call-template name="calculateNumberSection"/>
577     <xsl:if test="parent::raweb">
578         <xsl:text> </xsl:text>
579     </xsl:if>
580     <xsl:choose>
581         <xsl:when test="name()='identification'">Identification</xsl:when>
582         <xsl:when test="name()='team'"><xsl:text> </xsl:text> Team</xsl:when>
583         <xsl:when test="name()='biblio'">Bibliography</xsl:when>
584         <xsl:otherwise>
585             <xsl:value-of select="bodyTitle"/>
586         </xsl:otherwise>
587     </xsl:choose>
```

This returns an id. Question? do we really need to replace underscores by hyphens?

```

588 <xsl:template name="idLabel">
589     <xsl:choose>
590         <xsl:when test="@id"><xsl:value-of select="translate(@id,'_','-')"/> </xsl:when>
591         <xsl:otherwise><xsl:value-of select="generate-id()"/></xsl:otherwise>
592     </xsl:choose>
593 </xsl:template>
```

This is for a subsection. The title is in `<head>` (and `<bodyTitle>` in the new DTD). The number has to be computed.

```

594 <xsl:template name="NumberedHeading">
595     <xsl:param name="level"/>
596     <fo:block keep-with-next.within-page="always">
597         <xsl:variable name="divid">
598             <xsl:call-template name="idLabel"/>
599         </xsl:variable>
600         <xsl:attribute name="id">
601             <xsl:value-of select="$divid"/>
602         </xsl:attribute>
603         <xsl:attribute name="text-align">start</xsl:attribute>
```

```

604     <xsl:attribute name="font-family">
605         <xsl:value-of select="$divFont"/>
606     </xsl:attribute>
607     <xsl:choose>
608         <xsl:when test="$level=0"><xsl:call-template name="setupDiv0"/></xsl:when>
609         <xsl:when test="$level=1"><xsl:call-template name="setupDiv1"/></xsl:when>
610         <xsl:when test="$level=2"><xsl:call-template name="setupDiv2"/></xsl:when>
611         <xsl:when test="$level=3"><xsl:call-template name="setupDiv3"/></xsl:when>
612         <xsl:when test="$level=4"><xsl:call-template name="setupDiv4"/></xsl:when>
613     </xsl:choose>
614     <xsl:call-template name="blockStartHook"/>
615     <xsl:variable name="Number">
616         <xsl:if test="$numberHeadings and $numberDepth &gt; $level">
617             <xsl:call-template name="calculateNumber">
618                 <xsl:with-param name="numbersuffix" select="$headingNumberSuffix"/>
619             </xsl:call-template>
620         </xsl:if>
621     </xsl:variable>
622     <xsl:value-of select="$Number"/>
623     <xsl:apply-templates mode="section" select="head"/>
624     <xsl:if test="$pdfBookmarks='true'"> <fotex:toto/>
625         <fotex:bookmark ... />
626     </xsl:if>
627     </fo:block>
628 </xsl:template>

```

The translation of the `<composition>` section is trivial. We add the toplevel moreinfo before the text.

```

629 <xsl:template match="composition">
630     <xsl:call-template name="secNumberedHeading"/>
631     <xsl:apply-templates select="/raweb/moreinfo"/>
632     <xsl:apply-templates/>
633 </xsl:template>

```

In the new DTD, the previous piece of code is to be replaced by this one. Note that the toplevel moreinfo is a child of `<identification>`, and the (optional) moreinfo that is a child of `<team>` is lost.

```

634 <xsl:template match="team">
635     <xsl:call-template name="secNumberedHeading"/>
636     <xsl:if test=".../moreinfo"><xsl:apply-templates select=".../moreinfo"/></xsl:if>
637     <xsl:apply-templates select="participants"/>
638 </xsl:template>

```

Other sections. We emit a title, then the content of the element. In the new DTD, the final apply-templates selects all nodes but `<bodyTitle>`.

```

639 <xsl:template
640     match="presentation|fondements|domaine|logiciels|resultats|contrats
641         |international|diffusion">
642     <xsl:call-template name="secNumberedHeading"/>
643     <xsl:apply-templates/>
644 </xsl:template>

```

Modules. This is a subsection. The title is in `<head>`. In the case of dummy titles, nothing is printed.

```

645 <xsl:template match="module">
646   <xsl:if test=".//head!='Sans Titre')'">
647     <xsl:call-template name="NumberedHeading">
648       <xsl:with-param name="level" select="'1'" />
649     </xsl:call-template>
650   </xsl:if>
651   <xsl:apply-templates/>
652 </xsl:template>
```

A section is equivalent to `<div0>`, a module to `<div1>`. We consider here divisions of level 2, 3 and 4.

```

653 <xsl:template match="div2|div3|div4">
654   <xsl:call-template name="NumberedHeading">
655     <xsl:with-param name="level">
656       <xsl:value-of select="substring-after(name(), 'div')"/>
657     </xsl:with-param>
658   </xsl:call-template>
659   <xsl:apply-templates/>
660 </xsl:template>
```

In the case of the new DTD, the two previous templates are replaced by a single one (for the element `<subsection>`). Of course, the `$level` has to be computed differently: it is the number of ancestors (or self) of type `<subsection>`. In the case of a section and subsection, the `apply-templates` is applied to all nodes whose name is not `<bodyTitle>`. Finally, in the case of a `<module>`, keywords are inserted via `keywords-list`, and for other divisions, they are inserted via `keywords-list2`.

## 7.5 The table of contents

The table of contents is formed of a title, followed by all sections and subsections, translated in a special mode.

```

661 <xsl:template name="toc.body">
662   <fo:block font-size="14pt" text-align="center" font-weight="bold"
663     space-after="20pt">
664     <xsl:text>Table of contents</xsl:text>
665   </fo:block>
666   <xsl:for-each select="//composition//presentation//fondements|
667     //domaine//logiciels//resultats//contrats//international|
668     //diffusion//biblio//module//div2//div3">
669     <xsl:apply-templates mode="xtoc" select="(.)"/>
670   </xsl:for-each>
671 </xsl:template>
```

Translation of a section in the TOC. The result is a bold line, containing the section number (computed), its title (from the attribute in the old DTD, computed in the new one), the page number, and a link to it.

```

672 <xsl:template mode="xtoc" match="composition|presentation|
673   fondements|domaine|logiciels|resultats|contrats|international|
674   diffusion|biblio">
675   <xsl:variable name="tocindent">
676     <xsl:value-of select="$div0Tocindent"/>
677   </xsl:variable>
```

```

678 <fo:block>
679   <xsl:attribute name="font-weight">bold</xsl:attribute>
680   <xsl:attribute name="text-indent">
681     <xsl:value-of select="$tocindent"/>
682   </xsl:attribute>
683   <xsl:call-template name="sec.num"/>
684   <xsl:text>&#x2003;</xsl:text>
685   <fo:inline>
686     <xsl:value-of select="@titre"/>
687   </fo:inline>
688   <fo:leader leader-pattern="dots" />
689   <fo:inline color="{$linkColor}">
690     <xsl:variable name="pagref">
691       <xsl:call-template name="idLabel"/>
692     </xsl:variable>
693     <fo:basic-link internal-destination="{$pagref}">
694       <fo:page-number-citation ref-id="{$pagref}" />
695     </fo:basic-link>
696   </fo:inline>
697 </fo:block>
698 </xsl:template>

```

A module in the TOC. If the title (from the `<head>` element) is empty, we do nothing, otherwise call some template that adds a line to the TOC. The parameter of the template is 1 (a module is equivalent to a `<div1>`).

```

699 <xsl:template mode="xtoc" match="module">
700   <xsl:if test="head!='(Sans Titre)'">
701     <xsl:call-template name="tocheading">
702       <xsl:with-param name="level">
703         <xsl:value-of select="1"/></xsl:with-param>
704       </xsl:call-template>
705     </xsl:if>
706   </xsl:template>

```

A division (`<div2>`, `<div3>`, or `<div4>`) in the TOC. Same as for a module, but the parameter of the template, the number, has to be computed. Moreover, an entry is inserted in the TOC even when the title is empty. For the new DTD, this template and the preceding one were replaced by a single template for `<subsection>`, the value of level parameter being the number of ancestors (or self) named `<subsection>`.

```

707 <xsl:template mode="xtoc" match="div2|div3|div4">
708   <xsl:call-template name="tocheading">
709     <xsl:with-param name="level">
710       <xsl:value-of select="substring-after(name(),'div')"/></xsl:with-param>
711     </xsl:call-template>
712   </xsl:template>

```

A division gives an entry in the TOC as follows. The result is a `<fo:block>`, with some indentation that depends on the level, plus a number, and a title (unless empty), leaders, then the page number, and a link.

```

713 <xsl:template name="tocheading">
714   <xsl:param name="level"/>
715   <xsl:variable name="tocindent">
716     <xsl:choose>
717       <xsl:when test="$level='0'">

```

```

718      <xsl:value-of select="$div0Tocindent"/></xsl:when>
719      <xsl:when test="$level='1'">
720          <xsl:value-of select="$div1Tocindent"/></xsl:when>
721          <xsl:when test="$level='2'">
722              <xsl:value-of select="$div2Tocindent"/></xsl:when>
723          <xsl:when test="$level='3'">
724              <xsl:value-of select="$div3Tocindent"/></xsl:when>
725          <xsl:when test="$level='4'">
726              <xsl:value-of select="$div4Tocindent"/></xsl:when>
727          <xsl:otherwise><xsl:value-of select="$div1Tocindent"/></xsl:otherwise>
728      </xsl:choose>
729  </xsl:variable>
730  <fo:block>
731      <xsl:attribute name="text-indent">
732          <xsl:value-of select="$tocindent"/>
733      </xsl:attribute>
734      <xsl:variable name="Number">
735          <xsl:if test="$numberHeadings and $numberDepth &gt; $level">
736              <xsl:call-template name="calculateNumber">
737                  <xsl:with-param name="numbersuffix" select="$tocNumberSuffix"/>
738              </xsl:call-template>
739          </xsl:if>
740      </xsl:variable>
741      <xsl:value-of select="$Number"/>
742      <xsl:text>&#x2003;</xsl:text>
743      <xsl:if test="head!='(Sans Titre)'">
744          <fo:inline>
745              <xsl:apply-templates mode="tocsection" select="head"/>
746          </fo:inline>
747      </xsl:if>
748      <fo:leader rule-thickness="0pt"/>
749      <fo:inline color="{{$linkColor}}">
750          <xsl:variable name="pagref">
751              <xsl:call-template name="idLabel"/>
752          </xsl:variable>
753          <fo:basic-link internal-destination="{{$pagref}}">
754              <fo:page-number-citation ref-id="{{$pagref}}"/>
755          </fo:basic-link>
756      </fo:inline>
757  </fo:block>
758</xsl:template>

```

A `<head>` in the TOC: the ID disappears (as well as all other attributes). Moreover, the content is evaluated in ‘section’ mode. All elements disappear (only text remains), unless specified otherwise.

```

759 <xsl:template match="head" mode="tocsection">
760     <xsl:apply-templates mode="section"/>
761 </xsl:template>

```

We interpret math elements in a title as usual (the title could be “Encoding  $\pi$  in  $\pi_{\text{pa}}$ ”, guess what happens without the math?)

```

762 <xsl:template match="m:math" mode="section">
763     <m:math>
764         <xsl:copy-of select="@*"/>
765         <xsl:apply-templates mode="math"/>

```

```

766   </m:math>
767 </xsl:template>
    A <head> in a section: the ID is in the result (why do we replace underscores by dashes?).
768 <xsl:template match="head" mode="section">
769   <fo:inline>
770     <xsl:if test=". != 'Sans Titre')">
771       <xsl:if test="@id">
772         <xsl:attribute name="id">
773           <xsl:value-of select="translate(@id, '_', '-')"/>
774         </xsl:attribute>
775       </xsl:if>
776       <xsl:apply-templates mode="section"/>
777     </xsl:if>
778   </fo:inline>
779 </xsl:template>

```

In the new DTD, lines 744–746 were replaced by the following, and the previous template was renamed `bodyTitle`. There is one problem: if the title has an ID, it will be inserted in the main text, and in the TOC, this is completely wrong (we are lucky, because a section has an ID, and the title of the section has none).

```

780   <fo:inline space-start="20pt">
781     <xsl:apply-templates mode="section" select="bodyTitle"/>
782   </fo:inline>

```

## 7.6 The bibliography

Translation of the bibliography. There are eight optional parts. We consider them one after the other.

```

783 <xsl:template match="biblio">
784   <xsl:call-template name="secNumberedHeading"/>
785   <xsl:call-template name="biblioA"/>
786   <xsl:call-template name="biblioBA"/>
787   <xsl:call-template name="biblioBC"/>
788   <xsl:call-template name="biblioBD"/>
789   <xsl:call-template name="biblioBE"/>
790   <xsl:call-template name="biblioBH"/>
791   <xsl:call-template name="biblioBJ"/>
792   <xsl:call-template name="biblioC"/>
793 </xsl:template>

```

This outputs the title of a subsection, for the bibliography. This title is in the `$name` parameter, the default value is never used.

```

794 <xsl:template name="biblioname">
795   <xsl:param name="name">Unknown bibliography section</xsl:param>
796   <fo:block font-weight='bold' font-size="14pt" space-before="5pt"
797     keep-with-next='always'>
798     <xsl:value-of select="$name"/>
799   </fo:block>
800 </xsl:template>

```

Bibliography, part one. We select all entries that have a `from` attribute whose value is ‘refer’. The title of the section is “Major publications by the team in recent years”. If no entry matches, the translation is empty.

```

801 <xsl:template name="biblioA">
802   <xsl:if test="citation[@from = 'refer']">
803     <xsl:call-template name="biblioname">
804       <xsl:with-param name="name"> ... </xsl:with-param>
805     </xsl:call-template>
806     <xsl:for-each select="citation[@from = 'refer']">
807       <xsl:apply-templates select=". />
808     </xsl:for-each>
809   </xsl:if>
810 </xsl:template>
```

Bibliography, last part. We select all entries that have a `from` attribute whose value is ‘foot’. The title of the section is “Bibliography in notes”.

```

811 <xsl:template name="biblioC">
812   <xsl:if test="citation[@from = 'foot']">
813   ...
814   </xsl:if>
815 </xsl:template>
```

We select all entries that have a `from` attribute whose value is ‘year’ and `type` is book or booklet or proceedings. The title of the section is “Books and Monographs”.

```

816 <xsl:template name='biblioBA'>
817   <xsl:if test="...">> ... </xsl:if>
818 </xsl:template>
```

We select all entries that have a `from` attribute whose value is ‘year’ and `type` is phdthesis. The title of the section is “Doctoral dissertations and “Habilitation” theses”.

```

819 <xsl:template name='biblioBC'>
820   <xsl:if test="...">> ... </xsl:if>
821 </xsl:template>
```

We select all entries that have a `from` attribute whose value is ‘year’ and `type` is article or inbook or incollection. The title of the section is “Articles in referred journals and book chapters”.

```

822 <xsl:template name='biblioBD'>
823   <xsl:if test="...">> ... </xsl:if>
824 </xsl:template>
```

We select all entries that have a `from` attribute whose value is ‘year’ and `type` is inproceedings or conference. The title of the section is “Publications in Conferences and Workshops”.

```

825 <xsl:template name='biblioBE'>
826   <xsl:if test="...">> ... </xsl:if>
827 </xsl:template>
```

We select all entries that have a `from` attribute whose value is ‘year’ and `type` is manual or techreport or coursenotes. The title of the section is “Internal Reports”.

```

828 <xsl:template name='biblioBH'>
829   <xsl:if test="...">> ... </xsl:if>
830 </xsl:template>
```

We select all entries that have a `from` attribute whose value is ‘year’ and `type` is unpublished or misc or masterthesis or mastersthesis. The title of the section is “Miscellaneous”.

```

831 <xsl:template name='biblioBJ'>
832   <xsl:if test="..."> ... </xsl:if>
833 </xsl:template>
```

A `<citation>` produces a `<fo:block>`, with the same id. It contains the value of the key, in brackets, then the content of the element.

```

834 <xsl:template match="citation">
835   <fo:block space-before="15pt" text-indent="-2em">
836     <xsl:attribute name="id"><xsl:value-of select="@id"/></xsl:attribute>
837     [<xsl:value-of select="@key"/>]
838     <xsl:apply-templates/>
839   </fo:block>
840 </xsl:template>
```

This produces a comma between elements, a period at the end. A similar template rule that produces a comma, but no period, named `separateurED.objet` also exists.

```

841 <xsl:template name="separateur.objet">
842   <xsl:choose>
843     <xsl:when test="position()!<last()"> , </xsl:when>
844     <xsl:when test="position()=<last()">. </xsl:when>
845   </xsl:choose>
846 </xsl:template>
```

This is old code, not used anymore.

```
847 <xsl:template name="separateur.objet.spec"> ? </xsl:template>
```

The translation of `<bvolume>foo</bvolume>` is ‘Bar foo’, where ‘Bar’ is the `name` attribute of the element (it could be ‘volume’ or ‘vol.’; it is defined by the DTD).

```

848 <xsl:template match='bvolume|bnumber|bpages|bchapter|bseries|bedition'>
849   <xsl:value-of select="@bname"/>
850   <xsl:text> </xsl:text><xsl:apply-templates/>
851   <xsl:call-template name="separateur.objet"/>
852 </xsl:template>
```

The translation of `<btitle>` is the title in italics.

```

853 <xsl:template match='btitle'>
854   <fo:inline font-style='italic'><xsl:apply-templates/>. </fo:inline>
855 </xsl:template>
```

The translation of `<bjournal>foo</bjournal>` is “in « foo »”, or something like that.

```

856 <xsl:template match='bjournal|bbooktitle'>
857   <xsl:text>in «&#x00A0;</xsl:text><xsl:apply-templates/>
858   <xsl:text>&#x00A0;»</xsl:text>
859   <xsl:call-template name="separateur.objet"/>
860 </xsl:template>
```

Translation of most bibliographic elements is trivial.

```

861 <xsl:template match='byear|bmonth|btype|bschool|bpublisher|
862   bnote|borganization|binstitution|baddress|bhowpublished'>
863   <xsl:apply-templates/>
864   <xsl:call-template name="separateur.objet"/>
865 </xsl:template>
```

Translation of a `<bdoi>` element. This is a link to ‘<http://dx.doi.org/xxx>’.

```

866 <xsl:template match='bdoi'>
867   <xsl:value-of select="@bname"/><xsl:text> </xsl:text>
```

```

868 <fo:basic-link color="{$linkColor}">
869   <xsl:attribute
870     name="external-destination">http://dx.doi.org/<xsl:value-of select=". "/>
871   </xsl:attribute>
872   <xsl:apply-templates/>
873 </fo:basic-link>
874   <xsl:call-template name="separateur.objet"/>
875 </xsl:template>

Transformation of <cit>. The result is a link to a bibliographical item.

876 <xsl:template match="cit">
877   <fo:basic-link color="{$linkColor}">
878     <xsl:attribute name="internal-destination">
879       <xsl:value-of select="ref/@target"/>
880     </xsl:attribute>
881     <xsl:text>[</xsl:text>
882     <xsl:value-of select="id(ref/@target)/@key"/>
883     <xsl:text>]</xsl:text>
884   </fo:basic-link>
885 </xsl:template>

```

The bibliography has completely changed in the new DTD. You can get an idea of the new code by looking at the HTML version, given in the previous chapter, and replacing all HTML formatting commands, using the templates above as example. We first construct a key, named ‘bibliotypes’, that associates to each bibliography entry its type, a letter between d and k, then for each letter, we put in the variable (for instance \$d) the number of entries of this type. Then comes the following template, it is similar to ‘tri-par-publis’ in section 6.4 (details omitted). The template **biblioname** is no more used, since titles are shown here.

```

886 <xsl:template match="biblio">
887   <xsl:call-template name="secNumberedHeading"/>
888   <xsl:call-template name="tri"/> d
889   <fo:block font-weight='bold' font-size="14pt" space-before="5pt"
890     keep-with-next='always'>Year Publications</fo:block>
891   <xsl:call-template name="tri"/> e
892   <xsl:call-template name="tri"/> f
893   <xsl:call-template name="tri"/> g
894   <xsl:call-template name="tri"/> h
895   <xsl:call-template name="tri"/> i
896   <xsl:call-template name="tri"/> j
897   <xsl:call-template name="tri"/> k
898 </xsl:template>

```

The following template takes four arguments, **\$str**, which is a letter, between d and k, **\$title** and **\$title2**, two titles, and **\$countPrevious** the number of items already put in the bibliography. It outputs all entries, of type **\$str**, in some order (the first sort is useless, of course).

```

899 <xsl:template name="tri">
900   <xsl:param name="str"/>
901   <xsl:param name="title"/>
902   <xsl:param name="title2"/>
903   <xsl:param name="countPrevious"/>
904   <xsl:if test="key('bibliotypes',$str)[1]">
905     <xsl:call-template "bib-title"/>
906     <xsl:for-each select="key('bibliotypes',$str)">

```

```

907         <xsl:sort select="concat(
908             substring('a', 1 div (note[@type='from']/text()='refer')),
909             substring('b', 1 div (note[@type='from']/text()='year')),
910             substring('c', 1 div (note[@type='from']/text()='foot')))" />
911         <xsl:sort select="descendant::author[1]/persName[1]/surname/text()"/>
912         <xsl:apply-templates select=". . .>
913             <xsl:with-param name="pos">
914                 <xsl:value-of select="$countPrevious+position()"/></xsl:with-param>
915             </xsl:apply-templates>
916         </xsl:for-each>
917     </xsl:if>
918 </xsl:template>
```

This outputs one of the two titles (in 14pt for the main title, 12pt for the subtitle).

```

919 <xsl:template name="bib-title">
920     <xsl:if test="string-length($title)>0">
921         <fo:block font-weight='bold' font-size="14pt" space-before="5pt"
922             keep-with-next='always'>
923             <xsl:value-of select='$title' />
924         </fo:block>
925     </xsl:if>
926     <xsl:if test="string-length($title2)>0">
927         <fo:block font-weight='bold' font-size="12pt" space-before="5pt"
928             text-indent="1em" keep-with-next='always'>
929             <xsl:value-of select='$title2' />
930         </fo:block>
931     </xsl:if>
932 </xsl:template>
```

This outputs the entry, in a block shifted left by two ems, starting with the number in brackets, followed by a period, with a new line as separator.

```

933 <xsl:template match="biblStruct">
934     <xsl:param name="pos" />
935     <fo:block space-before="15pt" text-indent="-2em">
936         <xsl:attribute name="id"><xsl:value-of select="@id"/></xsl:attribute>
937         <xsl:text>[</xsl:text>
938         <xsl:value-of select="$pos"/>
939         <xsl:text>] </xsl:text>
940         <xsl:apply-templates/>
941         <xsl:text>.</xsl:text>
942     </fo:block>
943     <xsl:text>#xA;</xsl:text>
944 </xsl:template>
```

Trivial templates, for `<edition>`, `<note>` of type ‘bnote’, ‘typedoc’, ‘howpublished’, `<orgName>`, `<addrLine>`, or `<title>` of level ‘s’ (corresponding to series in BibTeX). The main difference with the code shown above is that we do not call `separateur.objet`, but each item inserts a comma before it (except the first item, see below).

```

945 <xsl:template match="edition | note[@type='bnote' | note[@type='howpublished']
946   | title[@level='s'] | note[@type='typedoc'] | orgName | addrLine">
947     <xsl:text>, </xsl:text>
948     <xsl:apply-templates/>
949 </xsl:template>
```

These notes are used for sorting, hence produce no text.

```
950 <xsl:template match="note[@type='from']" />
951 <xsl:template match="note[@type='userid']" />
952 <xsl:template match="note[@type='classification']"/>
```

These are trivial.

```
953 <xsl:template match="imprint | address">
954   <xsl:apply-templates/>
955 </xsl:template>
```

The case of `<edition>` is a bit more complicated. As already mentioned, the L<sup>A</sup>T<sub>E</sub>X companion says that the value should be something like ‘Second’, and the typeset text should be ‘second edition’<sup>2</sup>.

```
956 <xsl:template match="bedition">
957   <xsl:text>, </xsl:text>
958   <xsl:value-of select="@type"/>
959   <xsl:text> </xsl:text>
960   <xsl:apply-templates/>
961 </xsl:template>
```

Other trivial rules for `<title>`. Level ‘j’ corresponds to the BibT<sub>E</sub>X field journal, while level ‘a’ corresponds to the title (for type inbook, article, incollection, inproceedings and conference). In one case we output something like ‘in "foo"’, using straight double quotes instead of guillemets as was the case of the old DTD; in the other case, we output the value, using italic font style, without an initial comma, because the title follows the author list, which is terminated by a period.

```
962 <xsl:template match="title[@level='j']">
963   <xsl:text>, in "</xsl:text>
964   <xsl:apply-templates/>
965   <xsl:text>"</xsl:text>
966 </xsl:template>
967
968 <xsl:template match="title[@level='a']">
969   <fo:inline font-style='italic'> <xsl:apply-templates/></fo:inline>
970 </xsl:template>
```

A BibT<sub>E</sub>X title gives a `<title>` of level ‘a’ in cases shown above, and level ‘m’ otherwise; as explained in the previous chapter, if `<title>` is below `<analytic>`, then the type should be ‘a’, hence the test is false for this title; as a consequence, if the test is true, there are two titles, and we are proceeding with the second one, handling it the same as level ‘j’, otherwise, it is the first, handling it as level ‘a’.

```
971 <xsl:template match="title[@level='m']">
972   <xsl:choose>
973     <xsl:when test="string-length(..../analytic/title) > 0">
974       <xsl:text>, in "</xsl:text>
975       <xsl:apply-templates/>
976       <xsl:text>"</xsl:text>
977     </xsl:when>
978     <xsl:otherwise>
979       <fo:inline font-style='italic'><xsl:apply-templates/></fo:inline>
980     </xsl:otherwise>
981   </xsl:choose>
982 </xsl:template>
```

---

<sup>2</sup>This implies that the first character has to be lower-casified

Translation of <biblScope>. Depending on the type attribute, this gives ‘vol. 17’, or ‘chap. 25’, or ‘nº 33’, preceded by a comma, as usual.

```

983 <xsl:template match="biblScope[@type='volume']">
984   <xsl:text>, vol. </xsl:text>
985   <xsl:apply-templates/>
986 </xsl:template>

987 <xsl:template match="biblScope[@type='chapter']">
988   <xsl:text>, chap. </xsl:text>
989   <xsl:apply-templates/>
990 </xsl:template>

992 <xsl:template match="biblScope[@type='number']">
993   <xsl:text>, n</xsl:text>
995   <fo:inline vertical-align="super">o</fo:inline>
996   <xsl:text> </xsl:text>
997   <xsl:apply-templates/>
998 </xsl:template>
```

Comment from the preview chapter: *In the case of ‘pages’ we output something like ‘p. 10–30’. If the text contains neither a dash nor an en-dash, we output ‘42 p’.* As you can see, the last sentence is wrong in the Pdf case.

```

999 <xsl:template match="biblScope[@type='pages'][text()!='']">
1000   <xsl:text>, </xsl:text>
1001   <xsl:if test="string-length(substring-before(., '-'))>
1002     or string-length(substring-before(., '&#8211;'))>0">
1003     <xsl:text>p. </xsl:text>
1004   </xsl:if>
1005   <xsl:apply-templates/>
1006 </xsl:template>
```

In the case of <dateStruct>, we output the value of <year> and <month>. Note: is a simple copy enough here?

```

1007 <xsl:template match="dateStruct">
1008   <xsl:text>, </xsl:text>
1009   <xsl:value-of select="month"/>
1010   <xsl:text> </xsl:text>
1011   <xsl:value-of select="year"/>
1012 </xsl:template>
```

In the case of <publisher>, we output the two children, <orgName> and <address>.

```

1013 <xsl:template match="publisher">
1014   <xsl:apply-templates select="orgName"/>
1015   <xsl:if test=".//address">
1016     <xsl:apply-templates select="address"/>
1017   </xsl:if>
1018 </xsl:template>
```

This is wrong and unused.

```

1019 <xsl:template match='bdoi'>
1020   ...
1021 </xsl:template>
```

Case of a reference in the bibliography. The destination of the link is the value of the `url` attribute, or the value of the element is the attribute is absent.

```

1022 <xsl:template match="biblio//ref">
1023   <xsl:choose>
1024     <xsl:when test=".//@url">
1025       <xsl:text>, </xsl:text>
1026       <fo:basic-link color="${linkColor}">
1027         <xsl:attribute name="external-destination">
1028           <xsl:value-of select=".//@url"/>
1029         </xsl:attribute>
1030         <xsl:apply-templates/>
1031       </fo:basic-link>
1032     </xsl:when>
1033     <xsl:otherwise>
1034       <xsl:text>, </xsl:text>
1035       <fo:basic-link color="${linkColor}">
1036         <xsl:attribute name="external-destination">
1037           <xsl:value-of select=".."/>
1038         </xsl:attribute>
1039         <xsl:apply-templates/>
1040       </fo:basic-link>
1041     </xsl:otherwise>
1042   </xsl:choose>
1043 </xsl:template>
```

Same code as in the HTML version, see section 6.4.

```

1044 <xsl:template match="analytic">
1045 ...
1046 </xsl:template>
1047
1048 <xsl:template match="monogr">
1049 ...
1050 </xsl:template>
```

## 7.7 People

There are two kinds of list of people, in the text and in the bibliography, and a person is represented differently. This is a bit annoying; we could imagine the case where we have a global list at the start of the document and references to the list; it would then be easier to associate to each member of the team its publication list. We start with the bibliography.

Translation of `<bauteurs>`. This is a list of `<bpers>`, with an optional `<etal>` (this one seems wrongly translated; it has a `nom` but no `prenom`). For each author, we output the first name, the particle, the last name.<sup>3</sup>

```

1051 <xsl:template match ="bauteurs">
1052   <fo:inline font-variant='small-caps'>
1053     <xsl:for-each select="bpers|etal">
1054       <xsl:value-of select="@prenom"/>
1055       <xsl:text> </xsl:text>
1056       <xsl:if test="@part">
```

---

<sup>3</sup>What about junior?

```

1057         <xsl:value-of select="@part"/>
1058         <xsl:text> </xsl:text>
1059     </xsl:if>
1060     <xsl:value-of select="@nom"/>
1061     <xsl:call-template name="separateur.objet"/>
1062   </xsl:for-each>
1063 </fo:inline>
1064   <xsl:text> </xsl:text>
1065 </xsl:template>
```

Same idea. A comma is put after each editor. After that, ‘editor’ or ‘editors’ is added at the end.

```

1066 <xsl:template match ="bediteur">
1067   <fo:inline font-variant='small-caps'>
1068     <xsl:for-each select="bpers|etal">
1069       <xsl:value-of select="@prenom"/>
1070       <xsl:text> </xsl:text>
1071       <xsl:if test="@part">
1072         <xsl:text> </xsl:text>
1073         <xsl:value-of select="@part"/>
1074       </xsl:if>
1075       <xsl:value-of select="@nom"/>
1076       <xsl:text>, </xsl:text>
1077     </xsl:for-each>
1078   </fo:inline>
1079   <xsl:choose>
1080     <xsl:when test="count(bpers|etal) != 1">
1081       <xsl:text>editors</xsl:text>
1082     </xsl:when>
1083     <xsl:otherwise>
1084       <xsl:text>editor</xsl:text>
1085     </xsl:otherwise>
1086   </xsl:choose>
1087   <xsl:call-template name="separateur.objet"/>
1088 </xsl:template>
```

Translation of an `<author>` (a list of authors) in the new DTD bibliography. Authors are separated by commas, with a period at the end. Initials are used rather than full first name if available.

```

1089 <xsl:template match="author">
1090   <fo:inline font-variant='small-caps'>
1091     <xsl:for-each select="persName">
1092       <xsl:choose>
1093         <xsl:when test="surname='ETAL'">
1094           <xsl:text>et al.</xsl:text>
1095         </xsl:when>
1096         <xsl:otherwise>
1097           <xsl:call-template name="jg.pers"/>
1098           <xsl:call-template name="separateur.objet"/>
1099         </xsl:otherwise>
1100       </xsl:choose>
1101     </xsl:for-each>
1102   </fo:inline>
```

```
1103     <xsl:text> </xsl:text>
1104 </xsl:template>
```

Case of `<editor>`, the list of editors. We add a comma in front if there are authors (otherwise, the element is output just after the title). Nothing special is done in the ‘ETAL’ case.

```
1105 <xsl:template match="editor">
1106   <xsl:if test=". . . //author">   <xsl:text>, </xsl:text></xsl:if>
1107   <fo:inline font-variant='small-caps'>
1108     <xsl:for-each select="persName">
1109       <xsl:call-template name="jg.pers"/>
1110       <xsl:call-template name="separateurED.objet"/>
1111     </xsl:for-each>
1112   </fo:inline>
1113   <xsl:text> (editor</xsl:text>
1114   <xsl:call-template name="pluriel-p">
1115     <xsl:with-param name="liste" select="persName" />
1116   </xsl:call-template>
1117   <xsl:text>). </xsl:text>
1118 </xsl:template>
```

Common code for authors or editors.

```
1119 <xsl:template name=jgpers">
1120   <xsl:choose>
1121     <xsl:when test="initial"><xsl:apply-templates select="initial"/></xsl:when >
1122     <xsl:otherwise> <xsl:apply-templates select="foreName"/> </xsl:otherwise>
1123   </xsl:choose>
1124   <xsl:text> </xsl:text>
1125   <xsl:value-of select="surname"/>
1126 </xsl:template>
```

This outputs an S in case the list has more than one element.

```
1127 <xsl:template name="pluriel-p">
1128   <xsl:param name="liste" />
1129   <xsl:if test="count($liste)>1">s</xsl:if>
1130 </xsl:template>
```

Translation of `<catperso>`. This is like a subsection, with a title (in `<head>`), we select all the `<pers>` children.

```
1131 <xsl:template match="catperso">
1132   <fo:block space-before="3pt">
1133     <fo:block font-weight='bold' text-indent="-15pt">
1134       <xsl:value-of select="head"/>
1135     </fo:block>
1136     <xsl:for-each select="pers">
1137       <fo:block> <xsl:call-template name="pers"/></fo:block>
1138     </xsl:for-each>
1139   </fo:block>
1140 </xsl:template>
```

This replaces the previous template in the case of the new DTD. Changes are obvious.

```
1141 <xsl:template match="team/participants">
1142   <fo:block space-before="3pt">
1143     <fo:block font-weight='bold' text-indent="-15pt">
1144       <xsl:value-of select="translate(@category, ' ', '_')"/>
```

```

1145     </fo:block>
1146     <xsl:for-each select="person">
1147         <fo:block> <xsl:apply-templates select=".."/></fo:block>
1148     </xsl:for-each>
1149     </fo:block>
1150 </xsl:template>

```

Like above, but the result is inline: we do not put `<pers>` in a block, but use commas as separators.

```

1151 <xsl:template match="participants|participant|participante|participantes">
1152     <fo:block space-after.optimum="4pt">
1153         <fo:inline>
1154             <xsl:attribute name="font-weight">bold</xsl:attribute>
1155             <xsl:value-of select="@titre"/>
1156         </fo:inline>
1157         <fo:inline>
1158             <xsl:for-each select="pers">
1159                 <xsl:call-template name="pers"/>
1160                 <xsl:call-template name="separateur.objet"/>
1161             </xsl:for-each>
1162         </fo:inline>
1163     </fo:block>
1164 </xsl:template>

```

There are some differences in the new DTD. Instead of four elements, we have a single one, named `<participants>`, and the title will be ‘Participant’ in the case where is a single `<person>`, ‘Participants’ if there are more than one. Two consecutive `<participants>` are implicitly merged, the persons in the second one are handled with the first. In some cases, the implementation is wrong; the case of `<refperson>` is sometimes considered here (but omitted in the HTML case).

```

1165 <xsl:template match="participants">
1166     <xsl:if test="not(preceding-sibling::participants) and not(parent::team)">
1167         <fo:block space-after.optimum="4pt">
1168             <fo:inline>
1169                 <xsl:attribute name="font-weight">bold</xsl:attribute>
1170                 <xsl:text>Participant</xsl:text>
1171                 <xsl:call-template name="pluriel-p">
1172                     <xsl:with-param name="liste" select="person" />
1173                 </xsl:call-template>;
1174             </fo:inline>
1175             <fo:inline>
1176                 <xsl:for-each select="person | following-sibling::participants/person
1177                     | refperson">
1178                     <xsl:apply-templates select=". " mode="section"/>
1179                     <xsl:call-template name="separateur.objet"/>
1180                 </xsl:for-each>
1181             </fo:inline>
1182         </fo:block>
1183     </xsl:if>
1184 </xsl:template>

```

Transformation of `<pers>`. This is easy: we have two attributes, first name and last name. Unless empty, the content is put in brackets.

```

1185 <xsl:template name="pers">
1186   <xsl:value-of select=".//@prenom"/>
1187   <xsl:text> </xsl:text>
1188   <xsl:value-of select=".//@nom"/>
1189   <xsl:if test="not(normalize-space(string(.)) = '')">
1190     <xsl:text> [</xsl:text>
1191       <xsl:apply-templates/>
1192     <xsl:text>]</xsl:text>
1193   </xsl:if>
1194 </xsl:template>
```

In the case of the new DTD, we have a `<firstname>` and a `<lastname>`, instead of these two attributes, and `<moreinfo>` instead of a content. These are the only changes in the case of a `<refperson>` or a `<person>` outside the team composition<sup>4</sup>.

```

1195 <xsl:template match="person">...</xsl:template>
1196 <xsl:template match="person" mode="section">...</xsl:template>
```

A `<refperson>` is just a reference to a `<person>` defined by its `href` attribute. In this code, we check that the reference is indeed a person.

```

1197 <xsl:template match="refperson" mode="section">
1198   <xsl:variable name ="curid" select="@ref"/>
1199   <xsl:variable name ="curelement" select="/raweb//*[@id=$curid]" />
1200   <xsl:if test="$curelement[name()='person']">
1201     <xsl:apply-templates select="$curelement" mode="section"/>
1202   </xsl:if>
1203 </xsl:template>
```

## 7.8 References

The translation of `<xref>` (external reference) is a link, that points to the value of the `url` attribute. It has some color...

```

1204 <xsl:template match="xref">
1205   <fo:basic-link color="{$linkColor}">
1206     <xsl:attribute name="external-destination">
1207       <xsl:value-of select="@url"/>
1208     </xsl:attribute>
1209     <xsl:apply-templates/>
1210   </fo:basic-link>
1211 </xsl:template>
```

The same code is used in the case when the link is a `<citation>` element; but we add a separator (comma or period) after it.

```

1212 <xsl:template match="citation/xref">
1213   <fo:basic-link color="{$linkColor}">
1214     <xsl:attribute name="external-destination">
1215       <xsl:value-of select="@url"/>
1216     </xsl:attribute>
1217     <xsl:apply-templates/>
1218   </fo:basic-link>
```

---

<sup>4</sup>In the `<team>` element, the `<hdr>` element is taken into account, same method as in the HTML case, see previous chapter.

```

1219   <xsl:call-template name="separateur.objet"/>
1220 </xsl:template>
```

Translation of an internal link. There is an attribute `target` that says to what it points. The `<ref>` element is empty, the link is not: the value of the link element is obtained by evaluating the target in the ‘`xref`’ mode. This should give a number (or a sequence like 12.3.4 for a subsection). In the case of a table, figure, math expression, this should be the number of the table, figure, etc.; in the case of a division, it should be the number associated to the title.

```

1221 <xsl:template match="ref">
1222   <fo:basic-link color="${linkColor}">
1223     <xsl:attribute name="internal-destination">
1224       <xsl:value-of select="translate(@target, '_', '-')"/>
1225     </xsl:attribute>
1226     <xsl:apply-templates mode="xref" select="id(@target)" />
1227     <xsl:apply-templates/>
1228   </fo:basic-link>
1229 </xsl:template>
```

The case of the new DTD, is much more complicated, since we have to compute the number of the reference. The same algorithm is used as in the `HTML` case, see previous chapter, section 6.4. We have a template `positionInBib` (same as line 3054 in the previous chapter), and we define `position-in-bib(W)` in the same way. Then the code looks like this:

```

1230 <xsl:template name="ref-in-bib">
1231   <fo:basic-link color="${linkColor}">
1232     <xsl:attribute name="internal-destination">
1233       <xsl:value-of select="$curid"/>
1234     </xsl:attribute>
1235     <xsl:choose>
1236       position-in-bib(d)
1237       position-in-bib(e)
1238       position-in-bib(f)
1239       position-in-bib(g)
1240       position-in-bib(h)
1241       position-in-bib(i)
1242       position-in-bib(j)
1243       position-in-bib(k)
1244     </xsl:choose>
1245   </fo:basic-link>
1246   <xsl:text>]</xsl:text>
1247 </xsl:template>
```

This is called when the attribute `xlink:href` does not start with a sharp sign; it can be an external reference (otherwise, the document is not valid, and the code is wrong, not shown here).

```

1248 <xsl:template name="external-ref">
1249   <xsl:choose>
1250     <xsl:when test="@location='extern'">
1251       <fo:basic-link color="${linkColor}">
1252         <xsl:attribute name="external-destination">
1253           <xsl:value-of select="@xlink:href"/>
1254         </xsl:attribute>
1255         <xsl:apply-templates/>
1256       </fo:basic-link>
1257     </xsl:when>
```

```

1258     <xsl:otherwise> ... </xsl:otherwise>
1259   </xsl:choose>
1260 </xsl:template>
```

This is called when the attribute xlink:href has the form ‘#foo’, with ‘foo’ in \$curid, and the target \$curelement is `<identification>` or a child. In this case, we replace it by `<team>`. The idea is to evaluate the target in pre-ref, xref and post-ref modes, and put the value obtained in xref mode in the link.

```

1261 <xsl:template name="ref-to-ident">
1262   <xsl:apply-templates select="/raweb/identification/team" mode="pre-ref" />
1263   <fo:basic-link color="{{$linkColor}}" internal-destination="{{$curid}}>
1264     <xsl:apply-templates select="/raweb/identification/team" mode="xref"/>
1265   </fo:basic-link>
1266   <xsl:apply-templates select="/raweb/identification/team" mode="post-ref" />
1267 </xsl:template>
```

This is called when the attribute xlink:href has the form ‘#foo’, with ‘foo’ in \$curid, and the target is \$curelement. Note that empty pre-ref and post-ref are defined for `<table>`, `<formula>`, `<subsection>`, `<biblio>`, `<presentation>`, `<fondements>`, `<domaine>`, `<logiciels>`, `<object>`, `<diffusion>`, `<resultats>`, `<contrats>`, `<identification>`, `<international>`, `<team>`, `<li>`. In all other cases default will be used (let’s hope this case does not occur).

```

1268 <xsl:template name="internal-ref">
1269   <xsl:apply-templates select="$curelement" mode="pre-ref" />
1270   <fo:basic-link color="{{$linkColor}}" internal-destination="{{$curid}}>
1271     <xsl:apply-templates select="$curelement" mode="xref"/>
1272   </fo:basic-link>
1273   <xsl:apply-templates select="$curelement" mode="post-ref" />
1274 </xsl:template>
```

This is now the code for a reference in the new DTD.

```

1275 <xsl:template match="ref">
1276   <xsl:choose>
1277     <xsl:when test="starts-with(@xlink:href, '#')">
1278       <xsl:variable name="curid" select="substring-after(@xlink:href, '#')"/>
1279       <xsl:variable name="curelement" select="/raweb//*[@@id=$curid]"/>
1280       <xsl:variable name="curlabel"
1281         select="$curelement/ancestor-or-self::subsection" />
1282       <xsl:variable name="curlabelidentification"
1283         select="$curelement/ancestor-or-self::identification"/>
1284     <xsl:choose>
1285       <xsl:when test="$curlabelidentification">
1286         <xsl:call-template name="ref-to-ident"/>
1287       </xsl:when>
1288       <xsl:when test="@location='biblio'">
1289         <xsl:call-template name="ref-in-bib"/>
1290       </xsl:when>
1291       <xsl:when test="@location='intern'">
1292         <xsl:call-template name="external-ref"/>
1293       </xsl:when>
1294     </xsl:choose>
1295   </xsl:when>
1296   <xsl:otherwise>
1297     <xsl:call-template name="external-ref"/>
```

```

1298      </xsl:otherwise>
1299    </xsl:choose>
1300  </xsl:template>
```

In the case of a section, computing the number is trivial: we take it from the DTD.

```

1301  <xsl:template
1302    match="biblio|presentation|fondements|domaine|logiciels|resultats|
1303      contrats|composition|international|diffusion" mode = 'xref'>
1304    <xsl:value-of select = "@numero"/>
1305  </xsl:template>
```

In the case of a subsection, computing the number is non trivial. The first component is the section number, followed by a dot.

```

1306 <xsl:template name="sec.num">
1307   <xsl:value-of select =
1308     "ancestor-or-self::*[self::composition or self::presentation
1309       or self::fondements or self::domaine or self::logiciels
1310       or self::resultats or self::contrats or self::international
1311       or self::diffusion or self::biblio]/@numero"/>
1312   <xsl:text>.</xsl:text>
1313 </xsl:template>
```

In the original DTD, the section number was an attribute of the section, hence was easy to compute. This is the replacement code:

```

1314 <xsl:when test="ancestor-or-self::*[self::identification]">1</xsl:when>
1315 <xsl:when test="ancestor-or-self::*[self::presentation]">2</xsl:when>
1316 <xsl:when test="ancestor-or-self::*[self::fondements]">3</xsl:when>
1317 <xsl:when test="ancestor-or-self::*[self::domaine]">4</xsl:when>
1318 <xsl:when test="ancestor-or-self::*[self::logiciels]">5</xsl:when>
1319 <xsl:when test="ancestor-or-self::*[self::resultats]">6</xsl:when>
1320 <xsl:when test="ancestor-or-self::*[self::contrats]">7</xsl:when>
1321 <xsl:when test="ancestor-or-self::*[self::international]">8</xsl:when>
1322 <xsl:when test="ancestor-or-self::*[self::diffusion]">9</xsl:when>
1323 <xsl:when test="ancestor-or-self::*[self::biblio]">10</xsl:when>
```

Some people find it annoying that section 7 is followed by section 9, in case where section ‘International’ is missing. Thus, the correct number is used; for instance, if current section is ‘domaine’, its number is the number of ‘identification’ plus ‘presentation’, plus ‘fondements’ plus one. Full code nor shown, but obvious.

```

1324 <xsl:template name="calculateNumberSection">
1325   <xsl:choose>
1326     <xsl:when test="ancestor-or-self::*[self::identification]">1</xsl:when>
1327     <xsl:when test="ancestor-or-self::*[self::presentation]">
1328       <xsl:value-of select="count(/raweb/identification)+1"/>
1329     </xsl:when>
1330     <xsl:when test="ancestor-or-self::*[self::fondements]">
1331       <xsl:value-of select="count(/raweb/identification)
1332                     +count(/raweb/presentation)+1"/>
1333     </xsl:when>
1334     <xsl:when test="ancestor-or-self::*[self::domaine]">
1335       <xsl:value-of select="count(/raweb/identification)
1336                     +count(/raweb/presentation)+count(/raweb/fondements)+1"/>
1337     </xsl:when>
1338   ...
```

```

1339     <xsl:when test="ancestor-or-self::*[self::biblio]">
1340         ...
1341     </xsl:when>
1342     <xsl:otherwise>Section</xsl:otherwise>
1343   </xsl:choose>
1344   <xsl:text>.</xsl:text>
1345 </xsl:template>
1346
1347 <xsl:template match="biblio|presentation|fondements|domaine|
1348   logiciels|resultats|contrats|identification|international|diffusion|team"
1349   mode = 'xref'>
1350   <xsl:call-template name="calculateNumberSection"/>
1351 </xsl:template>

```

This computes the number associated to a division (module, div2, div3, and div4) by counting these things. It is used twice: when the division is typeset (more exactly, when its title is typeset), and when the division appears in a link.

```

1352 <xsl:template name="calculateNumber">
1353   <xsl:param name="numbersuffix"/>
1354   <xsl:call-template name="sec.num"/>
1355   <xsl:number level="multiple" from="raweb"
1356     count="module|div2|div3|div4"/>
1357   <xsl:value-of select="$numbersuffix"/>
1358 </xsl:template>

```

This is the code for the new DTD, a little bit simpler.

```

1359 <xsl:template name="calculateNumber">
1360   <xsl:param name="numbersuffix"/>
1361   <xsl:call-template name="calculateNumberSection"/>
1362   <xsl:number level="multiple" from="raweb" count="subsection"/>
1363   <xsl:value-of select="$numbersuffix"/>
1364 </xsl:template>

```

This calls the template shown above. Is named <subsection> in the new DTD.

```

1365 <xsl:template mode="xref" match="module|div2|div3|div4">
1366   <xsl:call-template name="calculateNumber"/>
1367 </xsl:template>

```

It is not clear where the anchor of a section should be: on the division or its title. For this reason this rule is added for <head> (or <bodyTitle> in the new DTD); it is useless because we decided finally that the anchor should not be on the title. In a previous version of Tralics, <anchor> elements were generated (then removed, and re-inserted). Anchors should not be used in the Raweb.

```

1368 <xsl:template match="head|anchor" mode ="xref">
1369   <xsl:call-template name="calculateNumber"/>
1370 </xsl:template>

```

The idea is that every math formula (a <formula> element) that has an id is numbered.

```

1371 <xsl:template match="formula" mode="xref">
1372   <xsl:number level = "any" count="formula[@id]"/>
1373 </xsl:template>

```

In the case of a figure, we count only figures that are not inline, via the rend attribute.

```

1374 <xsl:template name="calculateFigureNumber">
1375   <xsl:number count="figure[@rend != 'inline']" level="any"/>
1376 </xsl:template>
1377 <xsl:template match='figure' mode="xref">
1378   <xsl:call-template name="calculateFigureNumber"/>
1379 </xsl:template>

    Same for a table. In the new DTD, the test is: all tables whose ancestors are not <object>.

1380 <xsl:template name="calculateTableNumber">
1381   <xsl:number count="table[@rend != 'inline']" level="any"/>
1382 </xsl:template>
1383 <xsl:template match='table' mode="xref">
1384   <xsl:call-template name="calculateTableNumber"/>
1385 </xsl:template>

```

In the case of a <note>, we count all elements that have a place attribute with value 'foot'. This is called <footnote> in the new DTD.

```

1386 <xsl:template name="calculateFootnoteNumber">
1387   <xsl:number level="any" count="note[@place='foot']"/>
1388 </xsl:template>

```

The case of an item is more complicated. Originally, there was a test: is the parent a <list> of type bibliography? in this case, '[25]' is produced instead of '25'. This test was removed. Thus, the only non trivial point is that numbering depends on the list level.

```

1389 <xsl:template match="item" mode="xref">
1390   <xsl:variable name="listdepth" select="count(ancestor::list)"/>
1391   <xsl:variable name="listNFormat">
1392     <xsl:choose>
1393       <xsl:when test="$listdepth=1"> <xsl:text>1</xsl:text> </xsl:when>
1394       <xsl:when test="$listdepth=2"> <xsl:text>i</xsl:text> </xsl:when>
1395       <xsl:when test="$listdepth=3"> <xsl:text>a</xsl:text> </xsl:when>
1396       <xsl:when test="$listdepth=4"> <xsl:text>I</xsl:text> </xsl:when>
1397     </xsl:choose>
1398   </xsl:variable>
1399   <xsl:number format="{$listNFormat}"/>
1400 </xsl:template>

```

In the new DTD, we use <li> instead of <item>. All items are counted the same, independently of the list depth. There is however a second rule, that looks like the previous one, except that the list level is computed but the sum of the number of ancestors of type <glosslist>, <descriptionlist>, <simplelist>, and <orderedlist>.

```

1401 <xsl:template match='li' mode="xref">
1402   <xsl:number count="li" level="single" />
1403 </xsl:template>

```

Trivial templates added for the new DTD.

```

1404 <xsl:template name="calculateObjectNumber">
1405   <xsl:number count="object" level="any"/>
1406 </xsl:template>
1407
1408 <xsl:template name="calculateRessourceNumber">
1409   <xsl:number count="ressource" level="any"/>
1410 </xsl:template>

```

These are the matching rules.

```

1411 <xsl:template match='object' mode="xref">
1412   <xsl:call-template name="calculateObjectNumber"/>
1413 </xsl:template>
1414
1415 <xsl:template match="ressource" mode="xref">
1416   <xsl:call-template name="calculateRessourceNumber"/>
1417 </xsl:template>
```

## 7.9 Generic elements

A `<p>` element is translated into a `<fo:block>` element. It has some attributes, for instance a constant font size.

```

1418 <xsl:template match="p">
1419   <fo:block font-size="{$bodySize}">
```

If the preceding sibling is a `<p>` element, and the current element has not `noindent = 'true'` as attribute, the paragraph will be indented, said otherwise, it will have a non-zero `text-indent`. The `space-before` attribute is computed as follows. We define a maximum value in the case where the preceding sibling is a `<p>`. We define an optimum value in the case where `spacebefore` is given as attribute to the current element. We define an optimum value if nothing is given, and the preceding sibling is a `<p>`. Note: we should always define all three values, because the default is zero, and this is wrong (but fotex interprets badly these quantities...)

```

1420   <xsl:if test="preceding-sibling::p">
1421     <xsl:if test ="not(@noindent)">
1422       <xsl:attribute name="text-indent">
1423         <xsl:value-of select="$parIndent"/>
1424       </xsl:attribute>
1425     </xsl:if>
1426     <xsl:choose>
1427       <xsl:when test="@spacebefore">
1428         <xsl:attribute name="space-before.optimum">
1429           <xsl:value-of select="@spacebefore"/>
1430         </xsl:attribute>
1431       </xsl:when>
1432       <xsl:otherwise>
1433         <xsl:attribute name="space-before.optimum">
1434           <xsl:value-of select="$parSkip"/>
1435         </xsl:attribute>
1436       </xsl:otherwise>
1437     </xsl:choose>
1438     <xsl:attribute name="space-before.maximum">
1439       <xsl:value-of select="$parSkipmax"/>
1440     </xsl:attribute>
1441   </xsl:if>
1442   <xsl:if test="not(preceding-sibling::p)">
1443     <xsl:if test="@spacebefore">
1444       <xsl:attribute name="space-before.optimum">
1445         <xsl:value-of select="@spacebefore"/>
1446       </xsl:attribute>
1447     </xsl:if>
1448   </xsl:if>
```

In the case where the `rend` attribute is ‘centered’ or ‘center’, we set `text-align` to ‘center’. If it is ‘flushed-left’ or ‘flushed-right’ we set it to left or right. If it is ‘quoted’ or ‘justify’ we set it to ‘justify’ (in the case ‘quoted’, we also set both left and right margins to 1 cm). The new code has a comment that says “ARG, useless with the new DTD but ...”

```

1449   <xsl:choose>
1450     <xsl:when test="@rend = 'centered'">
1451       <xsl:attribute name="text-align">center</xsl:attribute>
1452     </xsl:when>
1453     <xsl:when test="@rend = 'center'">
1454       <xsl:attribute name="text-align">center</xsl:attribute>
1455     </xsl:when>
1456     <xsl:when test="@rend = 'flushed-left'">
1457       <xsl:attribute name="text-align">left</xsl:attribute>
1458     </xsl:when>
1459     <xsl:when test="@rend = 'flushed-right'">
1460       <xsl:attribute name="text-align">right</xsl:attribute>
1461     </xsl:when>
1462     <xsl:when test="@rend = 'quoted'">
1463       <xsl:attribute name="text-align">justify</xsl:attribute>
1464       <xsl:attribute name="margin-left">1cm</xsl:attribute>
1465       <xsl:attribute name="margin-right">1cm</xsl:attribute>
1466     </xsl:when>
1467     <xsl:when test="@rend = 'justify'">
1468       <xsl:attribute name="text-align">justify</xsl:attribute>
1469     </xsl:when>
1470   </xsl:choose>
```

We insert the content of the `<p>` here.

```

1471   <xsl:apply-templates/>
1472 </fo:block>
1473 </xsl:template>
```

Conversion of `<hi>`. The result is an inline object, the non trivial part concerns transformation of the `rend` attribute, but this is defined elsewhere.

```

1474 <xsl:template match="hi">
1475   <fo:inline>
1476     <xsl:call-template name="rend" />
1477     <xsl:apply-templates/>
1478   </fo:inline>
1479 </xsl:template>
```

In the new DTD, `<hi>` has sometimes been replaced by `<em>`.

```

1480 <xsl:template match="em">
1481   <fo:inline>
1482     <xsl:call-template name="style"/>
1483     <xsl:apply-templates/>
1484   </fo:inline>
1485 </xsl:template>
```

This is currently unused.

```

1486 <xsl:template match="code">
1487   <fo:inline font-family="{$typewriterFont}">
1488     <xsl:apply-templates/>
1489   </fo:inline>
1490 </xsl:template>
```

This is currently unused.

```

1491 <xsl:template match="ident">
1492   <fo:inline color="${identColor}" font-family="${sansFont}">
1493     <xsl:apply-templates/>
1494   </fo:inline>
1495 </xsl:template>

      This is trivial.

1496 <xsl:template match="term">
1497   <fo:inline font-style="italic">
1498     <xsl:apply-templates/>
1499   </fo:inline>
1500 </xsl:template>
```

## 7.10 Lists

This translates a `<list>`. In any case, the result is a `<fo:list-block>` with some constant right margin and a left margin that depends on the context: normal list, normal glossary, or glossary in a list. All items in the list are considered.

```

1501 <xsl:template match="list">
1502   <xsl:call-template name="titlelist"/>
1503   <fo:list-block margin-right="${listRightMargin}">
1504     <xsl:call-template name="setListIndents"/>
1505     <xsl:choose>
1506       <xsl:when test="@type='gloss'">
1507         <xsl:attribute name="margin-left">
1508           <xsl:choose>
1509             <xsl:when test="ancestor::list"><xsl:value-of
1510               select="$listLeftGlossInnerIndent"/></xsl:when>
1511             <xsl:otherwise><xsl:value-of select="$listLeftGlossIndent"/></xsl:otherwise>
1512           </xsl:choose>
1513         </xsl:attribute>
1514       </xsl:when>
1515       <xsl:otherwise>
1516         <xsl:attribute name="margin-left">
1517           <xsl:value-of select="$listLeftIndent"/></xsl:attribute>
1518         </xsl:otherwise>
1519       </xsl:choose>
1520       <xsl:apply-templates select="item"/>
1521     </fo:list-block>
1522   </xsl:template>
```

If the first child of a list is `<head>` we start with a block containing the title in italics. This is not used in the Raweb.

```

1523 <xsl:template name="titlelist">
1524   <xsl:if test="child::head">
1525     <fo:block font-style="italic"
1526       text-align="start"
1527       space-before.optimum="4pt">
1528       <xsl:apply-templates select="head"/>
1529     </fo:block>
1530   </xsl:if>
1531 </xsl:template>
```

Note: in the case of the new DTD, there are more than one type of lists. Thus the template named `<list>` has to be replaced by two templates: one for `<orderedlist>`, `<simplelist>`, `<descriptionlist>` and one for `<glosslist>`. The outer test (has this element an attribute type with value ‘gloss’?) becomes: is this element a `<glosslist>` whose answer is trivial. The inner test (is the ancestor a list?) becomes more complicated. A list contains a sequence of `<item>` elements (renamed to `<li>` in the new DTD) optionally preceded by a `<label>`. The code shown above applies a rule to each `<item>`; this was changed to: apply a rule to everything but a `<title>`. Note that the default template for a `<label>` is to ignore it; only in ‘print’ mode is the action non-trivial.

```
1532 <xsl:template match="label"/>
1533
1534 <xsl:template match="label" mode="print">
1535   <xsl:apply-templates/>
1536 </xsl:template>
```

A list has also a `space-before` and `space-after` attributes, that depend on the level. The complete code is not shown here. In the new DTD, computing the list depth is a bit harder, because we must sum up the number of ancestors of type `<glosslist>`, `<descriptionlist>`, `<simplelist>`, and `<orderedlist>` (the list depth is used more than once: here it is used to compute the margins, below, when we typeset the item, and in section 7.8 when a reference is made to the item).

```
1537 <xsl:template name="setListIndents">
1538   <xsl:variable name="listdepth" select="count(ancestor::list)"/>
1539   <xsl:choose>
1540     <xsl:when test="$listdepth=0">
1541       <xsl:attribute name="space-before">
1542         <xsl:value-of select="$listAbove-1"/>
1543       </xsl:attribute>
1544       <xsl:attribute name="space-after">
1545         <xsl:value-of select="$listBelow-1"/>
1546       </xsl:attribute>
1547     </xsl:when>
1548     <!-- Same for listdepth=1 2 or 3 -->
1549   </xsl:choose>
1550 </xsl:template>
```

We use a template for this.

```
1551 <xsl:template match="item">
1552   <xsl:call-template name="makeItem"/>
1553 </xsl:template>
```

Translation of an `<item>`. The result is a `<fo:list-item>` that contains two sub-elements, we start with the first, the `<fo:list-item-label>`. It depends on the `type` attribute of our parent: simple, bullets, ordered, gloss, unordered (in the case of the new DTD, it depends on the name of the parent). In any case, if we have an `id`, we associate it to the element; then we construct a `<fo:block>`. The case where the list is in the bibliography is not shown here. The case where the label has an `n` attribute is not shown here. In the case where the list has `type='ordered'`, we evaluate the item in ‘xref’ mode: this produces a number; this number will be flushed right (alignment end). In the case where the list is a glossary, we will left align the label using a bold font; here the label is either a `<label>` child or a `<label>` sibling. In all other cases, if there is a label sibling it will be used. In both these cases, the label is transformed using a special mode.

```
1554 <xsl:template name="makeItem">
1555   <xsl:variable name="listdepth" select="count(ancestor::list)"/>
1556   <fo:list-item space-before.optimum="{$listItemsep}">
```

```

1557 <fo:list-item-label>
1558   <xsl:if test="@id">
1559     <xsl:attribute name="id"><xsl:value-of select="@id"/></xsl:attribute>
1560   </xsl:if>
1561   <fo:block>
1562     <xsl:attribute name="margin-right">2.5pt</xsl:attribute>
1563     <xsl:choose>
1564       <xsl:when test=".../@type='ordered'">
1565         <xsl:attribute name="text-align">end</xsl:attribute>
1566         <xsl:apply-templates mode="xref" select="./*"/>
1567         <xsl:text>.</xsl:text>
1568       </xsl:when>
1569       <xsl:when test=".../@type='gloss'">
1570         <xsl:attribute name="text-align">start</xsl:attribute>
1571         <xsl:attribute name="font-weight">bold</xsl:attribute>
1572       <xsl:choose>
1573         <xsl:when test="label">
1574           <xsl:apply-templates mode="print" select="label"/>
1575         </xsl:when>
1576         <xsl:otherwise>
1577           <xsl:apply-templates mode="print" select="preceding-sibling::*[1]"/>
1578         </xsl:otherwise>
1579       </xsl:choose>
1580     </xsl:when>
1581     <xsl:when test="name(preceding-sibling::*[1])='label'">
1582       <xsl:apply-templates mode="print" select="preceding-sibling::*[1]"/>
1583     </xsl:when>

```

In all other cases, a default value is chosen, depending on the list level.

```

1584 <xsl:otherwise>
1585   <xsl:attribute name="text-align">center</xsl:attribute>
1586   <xsl:choose>
1587     <xsl:when test="$listdepth=1">
1588       <xsl:value-of select="$bulletOne"/>
1589     </xsl:when>
1590     <xsl:when test="$listdepth=2">
1591       <xsl:value-of select="$bulletTwo"/>
1592     </xsl:when>
1593     <xsl:when test="$listdepth=3">
1594       <xsl:value-of select="$bulletThree"/>
1595     </xsl:when>
1596     <xsl:when test="$listdepth=4">
1597       <xsl:value-of select="$bulletFour"/>
1598     </xsl:when>
1599   </xsl:choose>
1600 </xsl:otherwise>
1601 </xsl:choose>
1602 </fo:block>
1603 </fo:list-item-label>

```

Essentially, the translation is a `<fo:list-item-body>` that contains a `<fo:block>`. This block is constructed implicitly by a `<p>` or explicitly, with a normal weight for the font.

```

1604 <fo:list-item-body>
1605   <xsl:choose>
1606     <xsl:when test="p"> <xsl:apply-templates/> </xsl:when>
1607     <xsl:otherwise>
1608       <fo:block font-weight="normal"><xsl:apply-templates/></fo:block>
1609     </xsl:otherwise>
1610   </xsl:choose>
1611 </fo:list-item-body>
1612 </fo:list-item>
1613 </xsl:template>

```

## 7.11 Images

This converts an image, or something like that. The result is a `<fo:external-graphic>` object. The `src` attribute is taken to be the file attribute. Initially, there was a `$graphicsPrefix` prefix before the image; this was removed: images should be in the current directory. We consider the three attributes `scale`, `width`, `height` and `angle`. Let's hope that `angle` is not used: in T<sub>E</sub>X, putting the angle to ninety degrees exchanges the role of width and height, but you can specify the width after rotation. Since the order of attributes is irrelevant in XML, you lose<sup>5</sup>. But you cannot turn images in HTML. Note: if you specify a scale, you cannot specify a width nor a height. In the new DTD the attribute file is replaced by `xlink:href`. We removed a test to `$autoScaleFigures`, placed after all other tests.

```

1614 <xsl:template name="generate-graphics">
1615   <fo:external-graphic src="{@file}">
1616     <xsl:choose>
1617       <xsl:when test="@scale">
1618         <xsl:attribute name="content-width">
1619           <xsl:value-of select="@scale * 100"/><xsl:text>%</xsl:text>
1620         </xsl:attribute>
1621       </xsl:when>
1622       <xsl:when test="@width">
1623         <xsl:attribute name="content-width"> <xsl:value-of select="@width"/>
1624         </xsl:attribute>
1625         <xsl:if test="@height">
1626           <xsl:attribute name="content-height">
1627             <xsl:value-of select="@height"/>
1628           </xsl:attribute>
1629         </xsl:if>
1630         <xsl:if test="@angle">
1631           <xsl:attribute name="angle">
1632             <xsl:value-of select="@angle"/>
1633           </xsl:attribute>
1634         </xsl:if>
1635       </xsl:when>
1636       <xsl:when test="@height">
1637         <xsl:attribute name="content-height">
1638           <xsl:value-of select="@height"/>
1639         </xsl:attribute>
1640         <xsl:if test="@angle">

```

---

<sup>5</sup>This is a bug in Tralics, of course

```

1641         <xsl:attribute name="angle">
1642             <xsl:value-of select="@angle"/>
1643         </xsl:attribute>
1644     </xsl:if>
1645   </xsl:when>
1646 </xsl:choose>
1647 </fo:external-graphic>
1648 </xsl:template>
```

A `<figure>` element, that has `rend = 'inline'`, produces a graphic object by the routine shown above. If it has a `<head>` (renamed to `<caption>` in the new DTD), this is a caption, shown after the image. In the new DTD, the template is called `<ressource>`; if the attribute `media` is set to 'PRINT', or if the ancestor has no other resource whose `media` attribute is set to 'PRINT', then it will be used, otherwise discarded (this allows a different image in the Pdf or HTML version).

```

1649 <xsl:template match="figure[@rend='inline']">
1650   <xsl:call-template name='generate-graphics'/>
1651   <xsl:if test="head">
1652     <fo:block text-align="center">
1653       <xsl:apply-templates select="head"/>
1654     </fo:block>
1655   </xsl:if>
1656 </xsl:template>
```

All other images produce a `<fo:float>` object. It has an `id`, and contains an `<fo:block>`, this block is created by the procedure shown above, in case there is a `file` attribute, or by evaluating all `<p>` children. The content is centered. There is a second block, that contains the caption (from `<head>`).

```

1657 <xsl:template match='figure'>
1658   <fo:float>
1659     <xsl:call-template name="addID"/>
1660     <fo:block text-align="center">
1661       <xsl:choose>
1662         <xsl:when test="@file">
1663           <xsl:call-template name='generate-graphics'/>
1664         </xsl:when>
1665         <xsl:otherwise><xsl:apply-templates select='p'/'></xsl:otherwise>
1666       </xsl:choose>
1667     </fo:block>
1668     <fo:block>
1669       <xsl:call-template name="figureCaptionstyle"/>
1670       <xsl:value-of select="$figureWord"/>
1671       <xsl:call-template name="calculateFigureNumber"/>
1672       <xsl:text>. </xsl:text>
1673       <xsl:apply-templates select="head"/>
1674     </fo:block>
1675   </fo:float>
1676 </xsl:template>
```

In the new DTD, we have `<object>` elements rather than `<figure>`. The content is always a table (so that there is no need to test for a `file` attribute).

```

1677 <xsl:template match="object" >
1678   <fo:float>
1679     <xsl:call-template name="addID"/>
```

```

1680    <fo:block>
1681        <xsl:apply-templates select="table" mode="object"/>
1682    </fo:block>
1683    <fo:block>
1684        <xsl:call-template name="figureCaptionstyle"/>
1685        <xsl:value-of select="$figureWord"/>
1686        <xsl:call-template name="calculateObjectNumber"/>
1687        <xsl:text>. </xsl:text>
1688        <xsl:apply-templates select="caption"/>
1689    </fo:block>
1690    </fo:float>
1691 </xsl:template>

These are trivial.

1692 <xsl:template match="object/caption"><xsl:apply-templates/></xsl:template>
1693 <xsl:template match="ressource/caption"><xsl:apply-templates/></xsl:template>

```

## 7.12 Tables

Essentially, the table is handled by `blockTable`; this produces a `<fo:table>` element; but if the table is not marked inline, we use `floatTable`, this will produce a `<fo:table-and-caption>`. In the new DTD, a block table is used if the ancestor is an `<object>` (recall that an `<object>` is a floating object that contains a table that contains graphic images as cells).

```

1694 <xsl:template match="table">
1695     <xsl:choose>
1696         <xsl:when test="@rend='inline'"><xsl:call-template name="blockTable"/></xsl:when>
1697         <xsl:otherwise> <xsl:call-template name="floatTable"/> </xsl:otherwise>
1698     </xsl:choose>
1699 </xsl:template>

```

This produces a `<fo:table-and-caption>` containing a table and a caption. The table is computed as in the case without caption. There is a mechanism that turns the whole table-and-caption by ninety degree, this is not used by Tralics. The caption is preceded by something like ‘Figure 99’, and the number has to be computed.

```

1700 <xsl:template name="floatTable">
1701     <fo:table-and-caption>
1702         <xsl:if test="rend='landscape'">
1703             <xsl:attribute name="reference-direction">-90</xsl:attribute>
1704         </xsl:if>
1705         <xsl:call-template name="addID"/>
1706         <fo:table-caption>
1707             <fo:block text-align="{$tableCaptionAlign}">
1708                 space-after="{$spaceBelowCaption}">
1709                 <xsl:value-of select="$tableWord"/>
1710                 <xsl:call-template name="calculateTableName"/>
1711                 <xsl:text>. </xsl:text>
1712                 <xsl:apply-templates select="head"/>
1713             </fo:block>
1714         </fo:table-caption>
1715         <xsl:call-template name="blockTable"/>
1716     </fo:table-and-caption>
1717 </xsl:template>

```

Transforming a table is easy: we select every row, and every cell in the rows. There is however a non trivial point: the current fotex implementation assumes that columns widths are given; hence we must compute them. Note: there is a `<xsl:text>` element, a contains a newline character; this improves the layout of the resulting XML; it seems useless. In the new version, the for-each has been replaced by an apply-templates to all elements of type `<th>` (this is strange) and `<tr>`. Moreover `deriveColSpecs` has been replaced by `calculateTableSpecs` (see below).

```

1718 <xsl:template name="blockTable">
1719   <fo:table text-align="{$tableAlign}">
1720     <xsl:call-template name="addID"/>
1721     <xsl:call-template name="deriveColSpecs"/>
1722     <fo:table-body text-indent="0pt">
1723       <xsl:for-each select="row">
1724         <xsl:text></xsl:text> <!-- this is a newline character -->
1725         <fo:table-row>
1726           <xsl:apply-templates select="cell"/>
1727         </fo:table-row>
1728       </xsl:for-each>
1729     </fo:table-body>
1730   </fo:table>
1731 </xsl:template>

```

This seems useless. One can however imagine the situation where the table specifications are stored somewhere and we need a unique identifier for the table.

```

1732 <xsl:template name="generateTableID">
1733   <xsl:choose>
1734     <xsl:when test="@id"> <xsl:value-of select="@id"/> </xsl:when>
1735     <xsl:otherwise><xsl:text>Table-</xsl:text><xsl:number level='any' />
1736   </xsl:otherwise>
1737 </xsl:choose>
1738 </xsl:template>

```

The procedure that computes the table specifications is in another file. The variable computed here is useless; it is perfectly legitimate to replace the call by this template by a call to inner template.

```

1739 <xsl:template name="deriveColSpecs" >
1740   <xsl:variable name="no"> <xsl:call-template name="generateTableID"/>
1741   </xsl:variable>
1742   <xsl:call-template name="calculateTableSpecs"/>
1743 </xsl:template>

```

## 7.13 Mathematics

This is the same as code given elsewhere. We leave the math unchanged.

```

1744 <xsl:template match="m:math">
1745   <m:math>
1746     <xsl:copy-of select="@*"/>
1747     <xsl:apply-templates mode="math"/>
1748   </m:math>
1749 </xsl:template>

```

```

1750 <xsl:template match="m:*|@*|comment()|processing-instruction()|text()" mode="math">
1751 ...
1752 </xsl:template>

```

We replace a formula by its content.

```

1753 <xsl:template match="formula">
1754   <xsl:apply-templates/>
1755 </xsl:template>

```

A special case is when the formula has ‘display’ as type. If there is an id, then the result is a `<fotex:equation>`, otherwise it is a `<fotex:displaymath>`. In the case of an equation, we use a `<fo:inline>` (why not use it in every case? or add the id to the equation?) Note that the for-each is useless.

```

1756 <xsl:template match="formula[@type='display']">
1757   <xsl:choose>
1758     <xsl:when test="@id">
1759       <fo:inline>
1760         <xsl:attribute name="id"><xsl:value-of select="@id"/></xsl:attribute>
1761         <fotex:equation>
1762           <xsl:for-each select="m:math">
1763             <xsl:apply-templates mode="math"/>
1764           </xsl:for-each>
1765         </fotex:equation>
1766       </fo:inline>
1767     </xsl:when>
1768     <xsl:otherwise>
1769       <fotex:displaymath>
1770         <xsl:for-each select="m:math">
1771           <xsl:apply-templates mode="math"/>
1772         </xsl:for-each>
1773       </fotex:displaymath>
1774     </xsl:otherwise>
1775   </xsl:choose>
1776 </xsl:template>

```

We convert a `<simplemath>` element to a normal math element.

```

1777 <xsl:template match="simplemath">
1778   <m:math><m:mi><xsl:apply-templates/></m:mi></m:math>
1779 </xsl:template>

```

## 7.14 Other elements

Translation of `<head>`. We look at the parent. If it is a division (it starts with ‘div’, or is a `<module>`) we do nothing (already done), otherwise, we just output it. In the case of the new DTD, this is called `<bodyTitle>` and nothing is done if the parent is `<subsection>` or if the grand-father of the parent is `<raweb>`.

```

1780 <xsl:template match="head" priority="10">
1781   <xsl:variable name="parent" select="name(..)"/>
1782   <xsl:if test="not(starts-with($parent,'div')) and not($parent = 'module')">
1783     <xsl:apply-templates/>
1784   </xsl:if>
1785 </xsl:template>

```

We copy all <?xmltex?> instructions.

```

1786 <xsl:template match="processing-instruction() [name()='xmltex']" >
1787   <xsl:message>xmltex pi <xsl:value-of select=". "/></xsl:message>
1788   <xsl:copy-of select=". "/>
1789 </xsl:template>
    Is this needed?
1790 <xsl:variable name="processor">
1791   <xsl:value-of select="system-property('xsl:vendor')"/>
1792 </xsl:variable>
    This is defined like in other style sheets.
1793 <xsl:variable name="LeTypeProjet">
1794   <!-- see elsewhere -->
1795 </xsl:variable>
    Same as above.
1796 <xsl:variable name="year">
1797   <!-- see elsewhere -->
1798 </xsl:variable>
    This could be: 'Team Foo'.
1799 <xsl:variable name="PRID">
1800   <xsl:value-of select="$LeTypeProjet"/>
1801   <xsl:text> </xsl:text>
1802   <xsl:value-of select="/raweb/accueil/projet"/>
1803 </xsl:variable>
```

This creates the first page. We start with a <fo:INRIA> special element, giving it the current year as year attribute. This will insert the logo. After that, we have a link to the Team's home page, with the short and long name. We have a link to each UR. We have also a special element <fo:RATHHEME> that completes our page hacking. For the new DTD, replace attribute html by id, element <projet> by <shortname>, element <projetdeveloppe> by <projectName>, replace UR/\* in the for-each by UR, and for each <UR> element, replace the attribute nom by name and url (which disappeared) by a value that depends on the name attribute.

```

1804 <xsl:template name="accueil.body">
1805   <fo:INRIA year="{$year}"/>
1806   <fo:block font-size= "25pt" text-align="center">
1807     <fo:basic-link external-destination="http://www.inria.fr/recherche/

1827     </fo:block>
1828 </xsl:template>
```

A `<moreinfo>` is typeset in italics.

```

1829 <xsl:template match="moreinfo">
1830     <fo:block font-style="italic"> <xsl:apply-templates/> </fo:block>
1831 </xsl:template>
```

This adds an id.

```

1832 <xsl:template name="addID">
1833     <xsl:attribute name="id">
1834         <xsl:call-template name="idLabel"/>
1835     </xsl:attribute>
1836 </xsl:template>
```

These rules have been added so that TeX and L<sup>A</sup>T<sub>E</sub>X are nicely printed.

```

1837 <xsl:template match="TeX">
1838     <TeX/>
1839 </xsl:template>
1840 <xsl:template match="LaTeX">
1841     <LaTeX/>
1842 </xsl:template>
```

This is a priori useless.

```

1843 <xsl:template match="anchor">
1844     <fo:inline>
1845         <xsl:attribute name="id"><xsl:value-of select="@id"/></xsl:attribute>
1846     </fo:inline>
1847 </xsl:template>
```

Translation of `<keywords>`. We take all the `<term>` elements.

```

1848 <xsl:template match="keywords">
1849     <fo:block space-after.optimum="4pt">
1850         <fo:inline>
1851             <xsl:attribute name="font-weight">bold</xsl:attribute>
1852             <xsl:value-of select="./@titre"/>
1853         </fo:inline>
1854         <xsl:for-each select="term">
1855             <xsl:apply-templates select=". /> <xsl:call-template name="separateur.objet"/>
1856         </xsl:for-each>
1857     </fo:block>
1858 </xsl:template>
```

Keywords in the new DTD. We have a list of `<keyword>` elements. The default behavior is to omit them. In some cases, we output then in italic font style, with a comma as separator.

```

1859 <xsl:template match="keyword" mode="section">
1860     <fo:inline font-style="italic">
1861         <xsl:apply-templates/>
1862     </fo:inline>
1863     <xsl:call-template name="separateur.objet"/>
1864 </xsl:template>
```

```
1865 <xsl:template match="keyword"/>
```

This means: if there is a keyword, we output them all, sorted in alphabetic order (this is strange), preceded by a title.

```
1866   <xsl:template name="keywords-list2">
1867     <xsl:if test=".//keyword">
1868       <fo:block space-after.optimum="4pt">
1869         <fo:inline>
1870           <xsl:attribute name="font-weight">bold</xsl:attribute>
1871           Keywords:
1872         </fo:inline>
1873         <xsl:apply-templates select=".//keyword" mode="section" >
1874           <xsl:sort />
1875         </xsl:apply-templates>
1876       </fo:block>
1877     </xsl:if>
1878   </xsl:template>
```

This code is similar, it is applied to a module (a `<subsection>` that has no `<subsection>` as ancestor). We output all keywords, of the module and its submodules.

```
1880 <xsl:template name="keywords-list">
1881   <xsl:if test=".//keyword">
1882     <fo:block space-after.optimum="4pt">
1883       <fo:inline>
1884         <xsl:attribute name="font-weight">bold</xsl:attribute>
1885         Keywords:
1886       </fo:inline>
1887       <xsl:apply-templates select=".//keyword" mode="section" >
1888         <xsl:sort />
1889       </xsl:apply-templates>
1890     </fo:block>
1891   </xsl:if>
1892 </xsl:template>
```

These include files are describe in the next section.

```
1893 <xsl:include href="raweb3-table.xsl"/>
1894 <xsl:include href="raweb3-makecolspecl.xsl"/>
```

This is the end of the file.

```
1895 </xsl:stylesheet>
```

## 7.15 Computing column specifications

We consider here a file that starts like this. This uses extensions to XSLT. It is taken from the TEI distribution, see Copyright notice in the preceding chapter.

```
1896 <?xml version="1.0" encoding="utf-8"?>
1897 <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
1898   xmlns:fotex="http://www.tug.org/fotex"
1899   xmlns:exsl="http://exslt.org/common"
1900   exclude-result-prefixes="saxon exsl"
1901   extension-element-prefixes="saxon exsl fotex"
```

```

1902  xmlns:saxon="http://icl.com/saxon"
1903  xmlns:fo="http://www.w3.org/1999/XSL/Format" version="1.0">

```

The computations are the following. For each cell in the table, we construct a variable, named \$stuff, that contains the value of the cell (some templates are applied). We construct a <cell> element, that has a <col> attribute whose value is the position of the cell; hence this algorithm does not work in the case where the cell spans multiple columns. The content of the cell is its width (i.e., is the width of the cell to typeset); this is hard to compute (consider two cells, one with an image of size 10cm, another one with a caption for it). In order to make this guess more usable, we added 100<sup>6</sup>. All these cells are put in a variable \$tds. Consider for instance the case where the cells are of width 1, 2, 3, and 4, there are two rows, the first two cells are in the first row. We compute the total, namely 10. The columns totals are 4 and 6, so that the width of the columns are 40% and 60%; these two quantities are computed by sorting the cells by column. For each cell that is the first (has no preceding sibling) we compute the sum of the following siblings. In the new DTD, <cell> is replaced by <td>, etc.

```

1904  <xsl:template name="calculateTableSpecs">
1905      <xsl:variable name="tds">
1906          <xsl:for-each select=".//cell">
1907              <xsl:variable name="stuff">
1908                  <xsl:apply-templates/>
1909              </xsl:variable>
1910              <cell>
1911                  <xsl:attribute name="col"><xsl:number /></xsl:attribute>
1912                  <xsl:value-of select="string-length($stuff) + 100"/>
1913              </cell>
1914          </xsl:for-each>
1915      </xsl:variable>
1916      <xsl:variable name="total">
1917          <xsl:value-of select="sum(exsl:node-set($tds)/cell)" />
1918      </xsl:variable>
1919      <xsl:for-each select="exsl:node-set($tds)/cell">
1920          <xsl:sort select="@col" data-type="number"/>
1921          <xsl:variable name="c" select="@col"/>
1922          <xsl:if test="not(preceding-sibling::cell[$c=@col])">
1923              <xsl:variable name="len">
1924                  <xsl:value-of select="sum(following-sibling::cell[$c=@col]) + current()"/>
1925              </xsl:variable>
1926              <xsl:text>
1927                  </xsl:text>
1928              <fo:table-column column-number="{@col}">
1929                  fotex:column-align="L" column-width="{$len div $total * 100}%" />
1930          </xsl:if>
1931      </xsl:for-each>
1932      <xsl:text></xsl:text> <!-- this is a newline character -->
1933  </xsl:template>
1934
1935
1936  </xsl:stylesheet>

```

---

<sup>6</sup>Why not use a random number? there should be a parameter in Tralics that inhibits this template.

## 7.16 Converting cells

This is another file. It is taken from the TEI distribution, see Copyright notice in the preceding chapter.

```

1937 <xsl:stylesheet
1938   xmlns:fotex="http://www.tug.org/fotex"
1939   xmlns:exsl="http://exslt.org/common"
1940   exclude-result-prefixes="exsl"
1941   extension-element-prefixes="exsl"
1942   xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0"
1943   xmlns:fo="http://www.w3.org/1999/XSL/Format" >
1944 <xsl:template match="cell">
1945   <fo:table-cell>
1946     <xsl:if test="@cols > 1">
1947       <xsl:attribute name="number-columns-spanned">
1948         <xsl:value-of select="@cols"/>
1949       </xsl:attribute>
1950     </xsl:if>
1951     <xsl:if test="@rows > 1">
1952       <xsl:attribute name="number-rows-spanned">
1953         <xsl:value-of select="@rows"/>
1954       </xsl:attribute>
1955     </xsl:if>
1956     <xsl:call-template name="cellProperties"/>
1957     <fo:block>
1958       <xsl:choose>
1959         <xsl:when test="@role='label' or parent::row[@role='label']">
1960           <xsl:attribute name="font-weight">bold</xsl:attribute>
1961         </xsl:when>
1962       </xsl:choose>
1963       <xsl:apply-templates/>
1964     </fo:block>
1965   </fo:table-cell>
1966 </xsl:template>

```

These are the possible cell properties. If the role is ‘hi’, we set the background color to ‘silver’. In the case where the parent table has `rend=‘frame’`, we add a frame around the cell. Only the first row has a border-before, only the last cell in the row has a border-end. Otherwise, we look at the properties of the cell, or of the row. In the new DTD, we should replace `<row>` by `<tr>`.

```

1967 <xsl:template name="cellProperties" >
1968   <xsl:if test="@role='hi'">
1969     <xsl:attribute name="background-color">silver</xsl:attribute>
1970   </xsl:if>
1971
1972   <xsl:choose>
1973     <xsl:when test="ancestor::table[1] [@rend='frame']">

```

```

1974     <xsl:if test="not(parent::row/preceding-sibling::row)">
1975         <xsl:attribute name="border-before-style">solid</xsl:attribute>
1976     </xsl:if>
1977     <xsl:attribute name="border-after-style">solid</xsl:attribute>
1978     <xsl:if test="not(following-sibling::cell)">
1979         <xsl:attribute name="border-end-style">solid</xsl:attribute>
1980     </xsl:if>
1981     <xsl:attribute name="border-start-style">solid</xsl:attribute>
1982 </xsl:when>
1983 <xsl:otherwise>
1984     <xsl:if test="@left-border='true'">
1985         <xsl:attribute name="border-start-style">solid</xsl:attribute>
1986     </xsl:if>
1987     <xsl:if test="@right-border='true'">
1988         <xsl:attribute name="border-end-style">solid</xsl:attribute>
1989     </xsl:if>
1990     <xsl:if test="ancestor::row/@top-border='true'">
1991         <xsl:attribute name="border-before-style">solid</xsl:attribute>
1992     </xsl:if>
1993     <xsl:if test="ancestor::row/@bottom-border='true'">
1994         <xsl:attribute name="border-after-style">solid</xsl:attribute>
1995     </xsl:if>
1996     <xsl:if test="ancestor::row/@bottom-border='true'">
1997         <xsl:attribute name="border-after-style">solid</xsl:attribute>
1998     </xsl:if>

2003         <xsl:attribute name="border-before-style">solid</xsl:attribute>
2004     </xsl:if>
2005 </xsl:otherwise>
2006 </xsl:choose>
```

If the table is not tight, we add some padding to the cell.

```

2007 <xsl:if test="not(ancestor::table/@rend='tight')">
2008     <xsl:attribute name="padding">
2009         <xsl:value-of select="$tableCellPadding"/>
2010     </xsl:attribute>
2011 </xsl:if>
```

In the case where the cell has an horizontal alignment property we use it. Otherwise, we look at some database, and try to extract that information. This is not used by the Raweb.

```

2012 <xsl:choose>
2013     <xsl:when test="@halign">
2014         <xsl:attribute name="text-align">
2015             <xsl:value-of select="@halign"/>
2016         </xsl:attribute>
2017     </xsl:when>
2018     <xsl:otherwise>
2019         <xsl:variable name="thiscol">
2020             <xsl:value-of select="position()"/>
2021         </xsl:variable>
```

```

2022     <xsl:variable name="tid">...</xsl:variable>
2023     <xsl:variable name="align">... </xsl:variable>
2024     <xsl:choose>
2025         <xsl:when test="$align='R'">
2026             <xsl:attribute name="text-align">right</xsl:attribute>
2027         </xsl:when>
2028         <xsl:when test="$align='L'">
2029             <xsl:attribute name="text-align">left</xsl:attribute>
2030         </xsl:when>
2031         <xsl:when test="$align='C'">
2032             <xsl:attribute name="text-align">center</xsl:attribute>
2033         </xsl:when>
2034         <xsl:otherwise>
2035             <xsl:if test="not($align=' ')">
2036                 <xsl:attribute name="text-align">
2037                     <xsl:value-of select="$align"/>
2038                 </xsl:attribute>
2039             </xsl:if>
2040         </xsl:otherwise>
2041     </xsl:choose>
2042 </xsl:otherwise>
2043 </xsl:choose>
2044 </xsl:template>
```

This is the end of the file.

```
2045 </xsl:stylesheet>
```

## 7.17 Customisation

We describe here the file raweb3-param.xsl. This is an adaptation of a file provided by the TEI. We changed the order of items, indicated which parameters are used, or unused.

```

2046 <xsl:stylesheet
2047   xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="1.0"
2048   xmlns:fo="http://www.w3.org/1999/XSL/Format">
```

Vertical space before and after a list. The \$exampleMargin is used as left and right margins for figure captions.

```

2049 <xsl:param name="listAbove-1">6pt</xsl:param>
2050 <xsl:param name="listBelow-1">6pt</xsl:param>
2051 <xsl:param name="listAbove-2">4pt</xsl:param>
2052 <xsl:param name="listBelow-2">4pt</xsl:param>
2053 <xsl:param name="listAbove-3">0pt</xsl:param>
2054 <xsl:param name="listBelow-3">0pt</xsl:param>
2055 <xsl:param name="listAbove-4">0pt</xsl:param>
2056 <xsl:param name="listBelow-4">0pt</xsl:param>
2057 <xsl:param name="exampleMargin">12pt</xsl:param>
```

Quantities use to define list markers. U+2219 is bullet operator (defined to be \ensuremath{\{ \bullet \}} in ucharacters.sty) is en dash (\textendash), U+002A is asterisk and U+002B is plus sign.

```

2058 <xsl:param name="bulletOne">\#x2219;</xsl:param>
2059 <xsl:param name="bulletTwo">\#x2013;</xsl:param>
```

```
2060 <xsl:param name="bulletThree">&#x002A;</xsl:param>
2061 <xsl:param name="bulletFour">&#x002B;</xsl:param>
```

Page dimensions and margins. The default values are used, except for the right margin (we use the same value as for the left margin). We use a single column. There is a template named `hookDefinepamasters` that does nothing. This could be redefined to do some action. Idem for `blockStartHook`.

```
2062 <xsl:param name="pageWidth">210mm</xsl:param>
2063 <xsl:param name="pageHeight">297mm</xsl:param>
2064 <xsl:param name="regionAfterExtent">12pt</xsl:param>
2065 <xsl:param name="regionBeforeExtent">12pt</xsl:param>
2066 <xsl:param name="bodyMarginBottom">24pt</xsl:param>
2067 <xsl:param name="bodyMarginTop">24pt</xsl:param>
2068 <xsl:param name="pageMarginTop">75pt</xsl:param>
2069 <xsl:param name="pageMarginBottom">100pt</xsl:param>
2070 <xsl:param name="pageMarginLeft">80pt</xsl:param>
2071 <xsl:param name="pageMarginRight">150pt</xsl:param>
2072 <xsl:param name="columnCount">1</xsl:param>
2073 <xsl:template name="hookDefinepamasters"/>
2074 <xsl:template name="blockStartHook"/>
```

Fonts. The body and the headers use Times as font family. The two other fonts are used for typesetting `<code>` and `<ident>`, bu these two elements are not created by Tralics.

```
2075 <xsl:param name="bodyFont">Times Roman</xsl:param>
2076 <xsl:param name="divFont">Times Roman</xsl:param>
2077 <xsl:param name="typewriterFont">Computer-Modern-Typewriter</xsl:param>
2078 <xsl:param name="sansFont">Helvetica</xsl:param>
```

Font sizes. The main font size is 10pt, the quantity `$footnoteSize` is used for footnotes (8pt) and `$footnotenumSize` for footnote markers (is 7pt not too small?). We define a negative indentation for the section titles: `$headingOutdent`, but a positive paragraph indentation. Note: the first paragraph in a division is not indented.

```
2079 <xsl:param name="bodyMaster">10</xsl:param>
2080 <xsl:param name="bodySize">
2081   <xsl:value-of select="$bodyMaster"/><xsl:text>pt</xsl:text>
2082 </xsl:param>
2083 <xsl:param name="footnoteSize">8pt</xsl:param>
2084 <xsl:param name="footnotenumSize">7pt</xsl:param>
2085 <xsl:param name="headingOutdent">-3em</xsl:param>
2086 <xsl:param name="parIndent">1em</xsl:param>
2087 <xsl:param name="parSkip">0pt</xsl:param>
2088 <xsl:param name="parSkipmax">12pt</xsl:param>
```

The following is used for a section title. We use a bold 18pt font. There is some space before and after: 12pt and 6pt.

```
2089 <xsl:template name="setupDiv0">
2090   <xsl:attribute name="font-size">18pt</xsl:attribute>
2091   <xsl:attribute name="text-align">left</xsl:attribute>
2092   <xsl:attribute name="font-weight">bold</xsl:attribute>
2093   <xsl:attribute name="space-after">6pt</xsl:attribute>
2094   <xsl:attribute name="space-before.optimum">12pt</xsl:attribute>
2095   <xsl:attribute name="text-indent"><xsl:value-of select="$headingOutdent"/></xsl:attribute>
2096 </xsl:template>
```

The following is used for a subsection (module) title. We use a bold 14pt font. There is some space before and after, but less than for a section: 9pt and 3pt.

```

2097 <xsl:template name="setupDiv1">
2098   <xsl:attribute name="font-size">14pt</xsl:attribute>
2099   <xsl:attribute name="text-align">left</xsl:attribute>
2100   <xsl:attribute name="font-weight">bold</xsl:attribute>
2101   <xsl:attribute name="space-after">3pt</xsl:attribute>
2102   <xsl:attribute name="space-before.optimum">9pt</xsl:attribute>
2103   <xsl:attribute name="text-indent"><xsl:value-of select="$headingOutdent"/></xsl:attribute>
2104 </xsl:template>
```

The following is used for a subsubsection title. We use a bold 12pt font. There is some space before and after, but less than for a subsection: 4pt and 2pt.

```

2105 <xsl:template name="setupDiv2">
2106   <xsl:attribute name="font-size">12pt</xsl:attribute>
2107   <xsl:attribute name="text-align">left</xsl:attribute>
2108   <xsl:attribute name="font-weight">bold</xsl:attribute>
2109   <xsl:attribute name="font-style">italic</xsl:attribute>
2110   <xsl:attribute name="space-after">2pt</xsl:attribute>
2111   <xsl:attribute name="space-before.optimum">4pt</xsl:attribute>
2112   <xsl:attribute name="text-indent"><xsl:value-of select="$headingOutdent"/></xsl:attribute>
2113 </xsl:template>
```

The following is used for a paragraph title. We use an italic 10pt font.

```

2114 <xsl:template name="setupDiv3">
2115   <xsl:attribute name="font-size">10pt</xsl:attribute>
2116   <xsl:attribute name="text-align">left</xsl:attribute>
2117   <xsl:attribute name="font-style">italic</xsl:attribute>
2118   <xsl:attribute name="space-after">0pt</xsl:attribute>
2119   <xsl:attribute name="space-before.optimum">4pt</xsl:attribute>
2120   <xsl:attribute name="text-indent"><xsl:value-of select="$headingOutdent"/></xsl:attribute>
2121 </xsl:template>
```

The following is used for a subparagraph title. We use a 10pt normal font.

```

2122 <xsl:template name="setupDiv4">
2123   <xsl:attribute name="font-size">10pt</xsl:attribute>
2124   <xsl:attribute name="space-before.optimum">4pt</xsl:attribute>
2125   <xsl:attribute name="text-indent"><xsl:value-of select="$headingOutdent"/></xsl:attribute>
2126 </xsl:template>
```

This constructs the caption of a figure. It is centered, with some indentation on both sides.

```

2127 <xsl:template name="figureCaptionstyle">
2128   <xsl:attribute name="text-align">center</xsl:attribute>
2129   <xsl:attribute name="font-style">italic</xsl:attribute>
2130   <xsl:attribute name="end-indent">
2131     <xsl:value-of select="$exampleMargin"/>
2132   </xsl:attribute>
2133   <xsl:attribute name="start-indent">
2134     <xsl:value-of select="$exampleMargin"/>
2135   </xsl:attribute>
2136 </xsl:template>
```

The template here could be used for table captions. If we compare with figures above, we see that there is some vertical space before and after the caption.

```

2137 <xsl:param name="tableCaptionAlign">center</xsl:param>
2138 <xsl:param name="spaceAroundTable">8pt</xsl:param>
2139 <xsl:param name="spaceBelowCaption">4pt</xsl:param>
```

```

2140 <xsl:param name="tableAlign">center</xsl:param>
2141 <xsl:param name="tableCellPadding">2pt</xsl:param>
2142
2143 <xsl:template name="tableCaptionstyle">
2144   <xsl:attribute name="text-align">center</xsl:attribute>
2145   <xsl:attribute name="font-style">italic</xsl:attribute>
2146   <xsl:attribute name="end-indent">
2147     <xsl:value-of select="$exampleMargin"/>
2148   </xsl:attribute>
2149   <xsl:attribute name="start-indent">
2150     <xsl:value-of select="$exampleMargin"/>
2151   </xsl:attribute>
2152     <xsl:attribute name="space-before">
2153       <xsl:value-of select="$spaceAroundTable"/>
2154     </xsl:attribute>
2155   <xsl:attribute name="space-after">
2156     <xsl:value-of select="$spaceBelowCaption"/>
2157   </xsl:attribute>
2158   <xsl:attribute name="keep-with-next">always</xsl:attribute>
2159 </xsl:template>

```

Parameters for the TOC. What is \$tocSize? the font size of the title of the toc? we use 14pt, see above. The two variables \$headingNumberSuffix and \$tocNumberSuffix explain that we should put a period-plus-space after numbers in the toc and headings. The variable \$numberHeadings says that we want something to appear in the TOC, and \$numberDepth says that we want in fact everything (in the HTML version, the TOC contains only sections and subsections, for the Pdf, we accept everything. In general it fits on a double page.)

```

2160 <xsl:param name="tocSize">16pt</xsl:param>
2161 <xsl:param name="div0Tocindent">0in</xsl:param>
2162 <xsl:param name="div1Tocindent">0.25in</xsl:param>
2163 <xsl:param name="div2Tocindent">0.5in</xsl:param>
2164 <xsl:param name="div3Tocindent">0.75in</xsl:param>
2165 <xsl:param name="div4Tocindent">1in</xsl:param>
2166 <xsl:param name="headingNumberSuffix">. </xsl:param>
2167 <xsl:param name="tocNumberSuffix">. </xsl:param>
2168 <xsl:param name="numberHeadings">true</xsl:param>
2169 <xsl:param name="numberDepth">9</xsl:param>

```

Parameters for lists.

```

2170 <xsl:param name="listRightMargin">10pt</xsl:param>
2171 <xsl:param name="listNormalIndent">15pt</xsl:param>
2172 <xsl:param name="listLeftGlossIndent">7mm</xsl:param>
2173 <xsl:param name="listLeftGlossInnerIndent">4mm</xsl:param>
2174 <xsl:param name="listLeftIndent">5pt</xsl:param>
2175 <xsl:param name="listItemsep">4pt</xsl:param>

```

Four names, useful if we decide to switch from English to another language. We use only ‘Figure’ and ‘Table’. Note the space at the end; there is no space for the other words.

```

2176 <xsl:param name="figureWord">Figure </xsl:param>
2177 <xsl:param name="tableWord">Table </xsl:param>
2178 <xsl:param name="appendixWords">Appendix</xsl:param>
2179 <xsl:param name="biblioWords">Bibliography</xsl:param>

```

Overwritten by the Raweb.

```
2180 <xsl:param name="linkColor">black</xsl:param>
2181 <xsl:param name="pdfBookmarks"></xsl:param>
```

Not used by the Raweb. The variable \$autoScaleFigures is not used: scaling must be explicit. The variable \$graphicsPrefix is not used, because we assume that images are in the current directory, and there is no need to add a prefix. The variable \$smallSize is not not used (see page 243 and following how smaller and larger fonts are used). The quantities \$authorSize, \$dateSize and \$titleSize could be used for the title page. In the case of the Raweb, the title page is created by the code on page 59, this defines fonts and size.

```
2182 <xsl:param name="autoScaleFigures"></xsl:param>
2183 <xsl:param name="graphicsPrefix"></xsl:param>
2184 <xsl:param name="smallSize">
2185   <xsl:value-of select="$bodyMaster * 0.9"/><xsl:text>pt</xsl:text>
2186 </xsl:param>
2187 <xsl:param name="authorSize">14pt</xsl:param>
2188 <xsl:param name="dateSize">14pt</xsl:param>
2189 <xsl:param name="titleSize">16pt</xsl:param>
```

The variable \$hyphenate is unused: we always hyphenate. The variable \$alignment is unused: we always justify. The \$language variable is unused.

```
2190 <xsl:param name="hyphenate">true</xsl:param>
2191 <xsl:param name="alignment">justify</xsl:param>
2192 <xsl:param name="language">US</xsl:param>
```

This defines sizes for quantities that are not used here. The quantities \$runSize and \$runFont are for running heads. We use the default font.

```
2193 <xsl:param name="runSize">9pt</xsl:param>
2194 <xsl:param name="runFont">sans-serif</xsl:param>
```

These are unused.

```
2195 <xsl:param name="flowMarginLeft"></xsl:param>
2196 <xsl:param name="giColor">orange</xsl:param>

```

## Chapter 8

# Application to other examples

We explain in this chapter how Tralics can be used to convert general documents into HTML. Two examples are considered, the Tralics documentation and the thesis of C. Roméro.

One non-trivial point of the thesis is that it contains trees: these are formed of text, connected by straight lines, or other curves, see figure 8.1. The original Pdf version of the thesis was obtained by converting a dvi file to a PostScript file, adding PostScript commands for the connections, and converting everything to Pdf; an alternate solution would be to use pdflATEX, and the pdftricks package: this package automatically extracts the trees, writes them to an external file, uses L<sup>A</sup>T<sub>E</sub>X for obtaining a dvi file, which is converted in PostScript and Pdf, as explained above, and includes each tree as an image. The same idea will be used: the document is converted to XML, trees are automatically extracted, converted to dvi, PostScript, then png, then re-inserted as images.

In the simple case, we use a shell script like the following

```
#!/bin/bash
SGML_CATALOG_FILES=./catalog
export SGML_CATALOG_FILES
FILE=$1
tralics ${FILE} -noentnames -nostraightquotes -nozerowidthspace \
    -trivialmath=7 -usequotes
xsltproc --catalogs --stringparam Main ${FILE} -o ${FILE}.html \
    ${FILE}html.xsl ${FILE}.xml
```

The idea is to convert a file, for instance `foo.tex`, that may input other source files, into `foo.xml` using Tralics (options will be explained later) and to convert this into `foo.html`, using the XML processor `xsltproc`; this second conversion depends on a style sheet, here it is `foohtml.xsl` (note how this depends on the initial file name).

Our examples do not use a configuration file, as a consequence the DTD will be ‘std’, this is a variant of the Raweb DTD, details are not important in this particular example, the `catalog` file explains where to find this DTD. In the case of the thesis, the shell script shown above can be applied (but trees are not fully rendered), but you can use a Perl script that proceeds exactly as above, but modifies the output of Tralics before converting it to HTML.

The following style sheets, that are part of the Tralics distribution, will be used and explained:

- TR1, TR2: (real name `tralics-rr1html.xsl` and `tralics-rr2html.xsl`). These two files are identical, and will be denoted by TR. They are used to convert the Tralics documentation, which is a sequence of two Inria Research Reports.
- TF, TE: (real name `thesehtml.xsl` and `thesishtml.xsl`). These two files are used to convert the thesis (original French version, and its English translation).

- TC: (real name `thesis.xsl`), common code for French and English version of the thesis.
- CLS: (real name `cls.xsl`), common code for all files shown above.

This chapter describes the following points: the modifications to L<sup>A</sup>T<sub>E</sub>X source needed by Tralics, the style sheets used for the XML to HTML conversion, and the Perl script mentioned above.

## 8.1 Modifying the source document

If you have some complex document like a PhD thesis, that compiles well with L<sup>A</sup>T<sub>E</sub>X, trying to translate it into a beautiful HTML document using Tralics will often require non trivial changes to the document (or its environment, like style files or style sheets). Let's consider first the case of the research report (the document you are reading right now).

### 8.1.1 Case of the report

The `foo.ult` file is automatically loaded by Tralics, before anything else, when you translate `foo.tex`; you can redefine some commands that come from the L<sup>A</sup>T<sub>E</sub>X kernel, or use the `\AtBeginDocument` mechanism to overwrite commands defined later. We describe here the file `tralics-rr.ult` that corresponds to the first part of the Tralics documentation, the other file being a subset of this one. This is the start of the file.

```
1 %% -- latex --
2 %%$Id: tralicsR10.tex,v 1.21 2007/01/24 18:49:07 grimm Exp $
3 %% This is the ult file for tralics-rr.tex
```

The three lines shown here define two skip registers and an environment. Our document modifies the content of the registers, this changes the page layout (Tralics ignores such parameters) and redefines the environment: we add a comment at the start of the index, that says that page numbering could be off by one, because the `\index` command of a word appearing in a verbatim block is inserted before the environment. Since Tralics does not typeset the index (i.e., the `theindex` environment produced by the `makeindex` program), this comment is lost; it can be re-inserted in the XML to HTML transformation phase.

```
4 \newskip\footskip
5 \newskip\topmargin
6 \newenvironment{theindex}{}{}
```

Here we are faced to a big problem: we want to explain that an italic Delta is not the same as a normal Delta, and we do not know how to translate the character. We found the following solution: these two lines of code provide the definitions required for the text to compile; we extracted an image of the glyphs from the dvi file, and inserted them conditionally (with a comment that explains the problem).

```
7 \def\DeclareMathSymbol#1#2#3#4{}
8 \let\itDelta\Delta
```

Same problem as above. We try to illustrate another difference between L<sup>A</sup>T<sub>E</sub>X and MathML.

```
\let\mathbbm\mathbb
\let\mathscr\mathcal
```

These redefinitions are a bit annoying. Our document gives a usage of these commands and shows the result (explaining that this cannot be translated by Tralics). It is like the italic Delta above, but concerns text fonts rather than math characters.

```
3 \def\fontencoding{\textit{\fontencoding U}}
4 \def\fontfamily{\textit{\fontfamily U}}
```

```

5 \def\fontseries{\textit{fontseries U}}
6 \def\fontshape{\textit{fontshape U}}
7 \def\fontsize{\textit{fontsize U}}
8 \def\selectfont{\textit{selectfont U}}

```

The first command shown here redefines `\item` (this is required in the case of the thesis, and since we want to avoid code duplication, it is also needed here). The third line redefines a command that is defined in a macro file, and we have to delay its evaluation. The effect is to add an attribute to the main XML element; we shall explain later how it will be used. The point is that the two parts of the report must have different values.

```

9 \let\item@\item
10 \AtBeginDocument{
11   \def\htmlprefix#1{\addattribute{document}{htmlprefix}{#1}}

```

For some reason, our document modifies the `\tabcolsep` length and the equation counter, these are quantities not managed by Tralics; a non-trivial problem is how to manage the layout of tables; currently, we use narrow tables, and sometimes add some space to widest element in each column. Note that the thesis starts with a list of tables, manually split across pages; they had to be edited, in order to improve the layout.

```

\newlength \tabcolsep
\newcounter{equation}

```

All web pages use an italic font for the Tralics name, and this document uses a sans-serif font; this explains the redefinition here. On the other hand, we prefer a normal font for the word ‘Pdf’ in the HTML version.

```

3 \def\Tralics{\textit{Tralics}}
4 \def\Pdf{Pdf}

```

We have no idea how to write the command `\cstok` that puts a box around its argument; it is used by Knuth in the T<sub>E</sub>Xbook to represent a token; we underline the argument.

```

5 \def\cstok#1{\ul{#1}}

```

Here comes the big hack. Our document uses a lot of verbatim material, and we have chosen two different colors for L<sup>A</sup>T<sub>E</sub>X and XML code. As a consequence, we have removed all occurrences to the `\verb` command, and the short hands provided by the short-verb mechanism. This means that we had to replace a simple expression like `\verb+\`e\"e+` by `\LTC{\BS verb+\BS\apos e\BS \DQ e+}` (remember that Tralics may be called with options that make single and double quote character intelligent, i.e., appropriate for text, but are no more verbatim).

A lot of commands use internally the first two commands shown here; but because of our laziness, the main text uses the shorter names that follow. The `\xmlcolor` command is used in a case where we want a non-verbatim `\xmlcode`<sup>1</sup>, it is a no-op in L<sup>A</sup>T<sub>E</sub>X. The last two lines are modifications to the verbatim environment provided by Tralics; of course we had to change the verbatim environments, as explained in the first part of this report.

```

6 \def\latexcode#1{\xbox{latexcode}{#1}}
7 \def\xmlcode#1{\xbox{xmlcode}{#1}}
8 \def\LTC#1{\xbox{latexcode}{#1}}
9 \def\XC#1{\xbox{xmlcode}{#1}}
10 \def\xmlcolor#1{\xbox{xmlcolor}{#1}}
11 \def\verbatim@hook{}
12 \def\verbatimnumberfont#1{\xbox{vbnumber}{#1}}
13 } % end of \AtBeginDocument commands

```

The following two lines appear in the main text. They are useful for conditional compilation.

---

<sup>1</sup>Normal text font, but XML-like color

```
\newif\iftralics\tralicsfalse
\ifx\tralicsversion\undefined\else\tralicstrue\fi
```

We show here the definition of the `\image` command, and an example of use: there are two L<sup>A</sup>T<sub>E</sub>X commands that produce a delta character, whose Tralics translation is identical; we conditionally include an image showing both glyphs. Note that we do not use `\includegraphics`.

```
\def\image#1#2#3{\iftralics#1\xbox{rawimage}{#2}#3\fi}
\image{This is shown in the dvi file as }{deltadelta.png}{.}
```

We had to make some further changes to the report: the document contains code, preceded by comments, and some names in the code are indexed. Thus Tralics creates an anchor; these are positioned before the verbatim text. In some pages, there is an end-of-paragraph between the comment and the code, this is invisible. However, if the `\index` command is set before the end-of-paragraph, the anchor is inside the `<p>` element (this is good), otherwise outside (this gives an invalid HTML document). We removed these spurious empty lines.

### 8.1.2 Case of the thesis

We shall explain later how the title page had to be modified. We already explained that the tables at the start of the document had to be modified. Here is one modification:

```
Langues :\par
\iftralics \else\hspace{1cm}\fi
\begin{tabular}[t]{ll}
AC\Tonly{\quad} & Anglais Contemporain \\
AE & Anglais Elisab\ethain \\
MA & Moyen-Anglais \\
VA & Vieil-Anglais \\
\end{tabular}
```

The intended purpose of the `\hspace` command is to shift the table to the right with respect to its title. But Tralics never puts tables in horizontal mode, thus inserts a `\par`, and this give a blank line. As a consequence, there is too much vertical space between the table and its title. This explains why the space is conditionally inserted. The `\Tonly` command is a no-op in L<sup>A</sup>T<sub>E</sub>X, in inserts a `\quad` in Tralics (there is not enough space between columns).

Here is another modification. The table was too big to fit on the page, and was replaced by two tables with a `\newpage` between them. The code was modified; Tralics sees a single table.

```
\begin{tabular}[t]{ll}
...
+gen & trait g\enitif \\
\iftralics\else
\end{tabular}

\newpage
\iftralics \else\hspace{1cm}\fi
\begin{tabular}[t]{ll}
\fi
+irr\eeel & trait irr\eeel \\
...
\end{tabular}
```

The thesis contains constructions like `Mod$_{Necessity}$`. One of the parameters of Tralics (shown in the shell script above) tells it to translate this as if it were `\textsubscript`; this is a non-standard L<sup>A</sup>T<sub>E</sub>X command, a variant of `\textsuperscript`; the HTML translation is obviously `Mod <sub> Necessity </sub>`. In the French version, an e with acute accent is needed, but Tralics

does nothing special if commands like `\acute{e}` appear in a Math formula. Hence, one of the modifications to the thesis was to replace such expressions by a command, that was conditionally defined:

```
\def\modneces{Mod$_{N\acute{e}cessit\'e}$}\xspace
\iftralics\def\modneces{Mod{textsubscript{N\'ecessit\'e}}}\xspace\fi
```

The thesis contains a math expression like the following (we have shown only the first two lines of the table). It is currently impossible to put anything than text in a `\mbox` in a math formula. In the case where the `\mbox{X}` is the same as `\mbox{A}` `\mbox{B}` `\mbox{C}`, math expressions are allowed. This is not the case here because the math is hidden by the font change.

```
$\left. \begin{array}{c}
\mbox{<\bf $\alpha$we>} \\
\mbox{<c\bf $\alpha$n>}
\end{array} \right. \right.$
```

We had to edit the code and replace it by:

```
$\left. \begin{array}{c}
\mbox{<}\alpha\mbox{we} \\
\mbox{<c}\alpha\mbox{n}
\end{array} \right. \right.$
```

Finally, the thesis contains the following two lines:

```
\font\vag=cmoebx10 scaled 1200
{\vag g}
```

This code compiles perfectly well. However, the intended purpose was to use the character ezh, Unicode U+292. For this reason, we modified the source, replacing the first second line by `\jgagg`, with the following definition.

```
\def\jgagg{\vag g}
```

After this change, it was possible to conditionally redefine the command, for instance like this:

```
\def\jgvag{^\^0292}
```

## 8.2 The Perl script for extracting trees

We explain here the content of a Perl script that converts a file into HTML, it replaces trees by images. This is the header of the file.

```
1 #! /usr/bin/perl
2 # -*- perl -*-
3 $empty = ""; # hack
4 #$Id="$ Id: extract-table.pl,v 2.1 2006/11/06 18:09:19 grimm Exp $empty";
5 package main;
6 use strict;
```

This software is part of the Tralics distribution and has the same license.

```
7 $::Id =~ /,v (\S*) /;
8 print "extract-table.pl $1 Copyright INRIA/APICS 2006-2007, Jos'e Grimm\n";
9 print "Licensed under the CeCILL Free Software Licensing Agreement\n";
```

We start with the some global variables. If the argument of the procedure is ‘foo’, then we create `foo.xml`, then `foo_e.xml` will contain all elements that must be converted into images, and `foo_g.xml` is the same file with elements replaced by image names. We make the assumption that

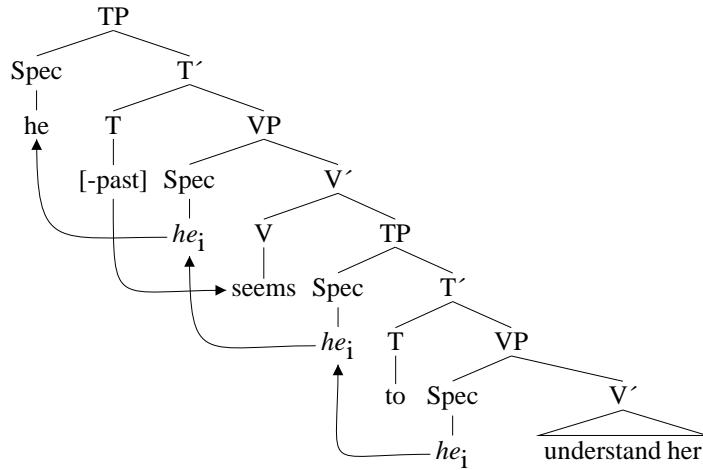

Figure 8.1: Example of a tree from the thesis of C. Roméro

the DTD is in the current directory, as well as the catalog (this explains in particular where the MathML DTD files are located).

```

10 $::name = shift;    ## argument of the script
11 $::name_o = $::name . ".xml";  ## tralics file
12 $::name_a = $::name . "_e.xml"; ## the trees
13 $::name_t = $::name . "_g.xml"; ## file to be converted to HTML
14 $::name_x = $::name . "html.xsl"; ## the style sheet
15 $::SGML_CATALOG_FILES= "./catalog";
16 $::xml_dir="../../xml";
17 $::pstoimg_cmd = "pstoimg"; ## pathname of pstoimg
18 $::use_convert = 0;  ## Use convert instead of pstoimg if non-zero
19 $::img_ctr = 0;

```

Note the arguments given to Tralics. The ‘noentnames’ option says to use character entities instead of entity names, so that an XML processor can ignore the DTD. Note that the DTD is needed for cross references. The second option tells Tralics to not use straight quotes, this is better in two cases, if the quote is used as an apostrophe, or when it is a right quote that should match a left quote. The next option tells Tralics not to use the zero-width space character, because some browsers show it as some unknown character, rather than some invisible object. We enable all math hacks. Finally, the last option tells Tralics to convert double quotes as quotations marks; said otherwise ““foo”” is interpreted in the same way as “‘‘foo’’” (giving ‘« foo »’ in French).

```

20 $::tralics_options=
21     "-noentnames -nostraightquotes -nozerowidthspace -trivialmath=7 -usequotes";

```

We should test if the script is called with at least one argument; an error is signaled if the file `foo.tex` does not exist (if no argument is given, we test for `.tex` that should not exist).

```

22 print "Working on $::name\n";
23 -f $::name . ".tex" or die ("No tex source");

```

We have a hacked version of `fotex.sty`, and we have to make sure that is found by L<sup>A</sup>T<sub>E</sub>X; this file is incompatible with the current version of `fotex.xmt`, this should be fixed, so that the old file

must be visible. The two files `fotex-add.sty` and `raweb-uni.sty` are needed so that we link them also. Finally, in order to convert an XML file via a driver named `images.tex` we must link `raweb-cfg.sty` to `images.cfg`.

```

24 sub link_files() {
25   unlink("images.cfg");
26   'ln -s $::xml_dir/raweb-cfg.sty images.cfg';
27   unlink("fotex-add.sty");
28   'ln -s $::xml_dir/fotex-add.sty';
29   unlink("fotex.sty");
30   'ln -s $::xml_dir/fotex.sty';
31   unlink("fotex.xmt");
32   'ln -s $::xml_dir/fotex.xmt';
33   unlink("raweb-uni.sty");
34   'ln -s $::xml_dir/raweb-uni.sty';
35 }
```

This creates the driver file `images.tex`. It tells L<sup>A</sup>T<sub>E</sub>X to convert `foo_e` into a `dvi` file. We also create the hack file. This is like a configuration file (but the name ‘`images.cfg`’ is already in use). The first line says that the text width should be large enough (12cm is a bit small), and the second line says that we need the `tree-dvips` package. Finally we say that the `hyperref` package should not be loaded at all.

```

36 sub prepare_for_latex {
37   open OUT,> "images.tex" || die "cannot create images.tex\n";
38   print OUT "\\def\\xmlfile{$::name_a}\n";
39   print OUT "\\def\\LastDeclaredEncoding{T1}\n";
40   print OUT "\\input{xmltex.tex}\n";
41   print OUT "\\end{document}\n";
42   close OUT;
43   open OUT,> "fotex-supp.tex" || die "cannot create fotex-supp.tex\n";
44   print OUT "\\textwidth=17cm\n";
45   print OUT "\\RequirePackage{tree-dvips}\n";
46   print OUT "\\hyperreffalse\n";
47   close OUT;
48 }
```

This is a routine that converts a file into a character string. This seems complicated, but it works, so that there is no reason why something else should be tried. The job is aborted in case where the XML file cannot be opened.

```

49 sub slurp_input {
50   my($file) = @_;
51   my(@file_string);
52   open(INPUT, "<$file") or die "File $file cannot be opened";
53   while (<INPUT>) {
54     push(@file_string, $_ );
55   };
56   close INPUT;
57   join('',@file_string);
58 }
```

This creates the XML file with only the trees. The style sheet will be explained below.

```

59 sub extract() {
60   $ENV{SGML_CATALOG_FILES}= $::SGML_CATALOG_FILES;
```

```

61   'xsltproc --catalogs -o $::name_a extract.xsl $::name_o';
62 }
```

We use a Perl script to replace `<table>` by `<img>`. You may wonder why this is not done by the style sheet. One problem is that we do not know the number associated to the image (because we cannot increment a counter like `img_ctr` in a style sheet). The second reason is that we might insert in the element attributes known only after conversion (for instance the size of the image), so that the style sheet `extract.xsl` used above cannot be used here. It is however important that the same elements are considered by both programs. The style sheet considers elements T, this is a `<table>` element that has a `<row>` child that has a `<cell>` child that has a `<node>` child. A `<preview>` element that has a T as a child is handled, and a T element is handled (unless it is the child of a preview). The function below is applied to all elements Y of name X, where X is table or preview. We replace the element if it is `<preview>`, or a table that contains a `<node>` somewhere. This works in most cases.

```

63 sub convert_table {
64   my $x = $_[0];
65   my $y = $_[1];
66   if($x eq "preview" || $y =~ /<\!/node>/) {
67     $::img_ctr++;
68     return "<img src='images/tree_image_$::img_ctr.png' alt='Tree $::img_ctr'/>";
69   } else { return $y; }
70 }
```

This functions reads the transcript file of LATEX. Processing image number N gives a line of the form ‘l2hSize :N:H:D::W’, where W, H and D are dimensions; we convert them from TeX points to PostScript points by applying the magic factor  $72\text{bp} = 72.27\text{pt}$ . These three quantities are remembered in a global table. The value of ‘align’ is not used (it is middle if H=D and bottom if D=0, but in general no such condition is true, and the value of align is ignored). One important point is ‘\$ps\_counter’, the number of images found. This has to be the same as the number of elements to be replaced.

```

71 sub read_log {
72   my ($logfile) = @_;
73   my ($name);
74   my $TeXpt = 72/72.27;
75   my $image_counter;
76   open(LOG, "<$logfile") || die "\nCannot read logfile $logfile\n";
77   while (<LOG>) {
78     if (/late2htmlSize|l2hSize/) {
79       /:([^:]*):/;
80       $name = $1;
81       ++$image_counter;
82       s/:([0-9.]*pt/$::x_height{$name} = $1*$TeXpt;'#/e;
83       s/:([0-9.]*pt/$::x_depth{$name} = $1*$TeXpt;'#/e;
84       s/:([0-9.]*pt/$::x_width{$name} = $1*$TeXpt;'#/e;
85       $::x_align{$name} = "align = 'bottom'";
86       if($::x_depth{$name}) { $::x_align{$name} = "align='middle'" };
87     }
88   }
89   print STDOUT "Processing $image_counter images \n";
90   $::ps_counter = $image_counter;
91   close(LOG);
92 }
```

This piece of code is a bit tricky. The argument is a number, say 13, and we construct `tmpdir/images013` which is the name of the PostScript file, that will be converted into a file named `tree_image_13.png` that we move into the `images` directory. For each image we have three dimensions, W, H and D. We compute H+D the total height (note how these numbers are converted into integers). The width and total height are parameters to the converter. After conversion, we use the `file` command in order to extract the size after conversion and store it in a table.

```

93 sub create_one_image {
94     my $name = $_[0];
95     my $im_name = "images";
96     if($name<100) { $im_name .= "0";}
97     if($name<10) { $im_name .= "0";}
98     $im_name .= $name;
99     my $w = $::x_width{$name};
100    my $h = $::x_height{$name};
101    my $d = $::x_depth{$name};
102    $w = int($w + 0.6);
103    $h = int($h + $d + 0.6);
104    my $size = "-geometry ${w}x$h";
105    my $cmd = "";
106    print "$name ";
107    if ($::use_convert) {
108        $cmd = $::convert_cmd;
109        $cmd .= " -crop ${w}x$h+64+44 ";
110        $cmd .= " tmpdir/$im_name tree_image_$name.png ";
111    } else {
112        $cmd = $::pstoolimg_cmd;
113        $cmd .= " -type png -tmp tmpdir";
114        $cmd .= " -discard -interlace -antialias";
115        $cmd .= " -depth 1 -scale 1.4 $size";
116        # marges 78,72 ou 72,72 ???
117        $cmd .= " -margins 62,41 -crop abls -transparent";
118        $cmd .= " -out tree_image_$name.png tmpdir/$im_name";
119    }
120    print LOG "$cmd\n";
121    print LOG '$cmd';
122
123    my $info = 'file tree_image_$name.png';
124    if($info =~ /PNG image data, (\d+) x (\d+),/) {
125        $::x_align{$name} .= " width ='$1' height ='$2'";
126    }
127    'mv tree_image_$name.png images';
128}

```

This subroutine creates the temporary directory, call `dvips` and converts all images.

```

129 sub convert_to_png {
130     'rm -rf tmpdir';
131     'mkdir tmpdir';
132     'rm -rf images';
133     'mkdir images';
134     my $DVIPSOPT="";
135     my $dvips = "dvips -S1 -i $DVIPSOPT -otmpdir/images ./images.dvi";
136     open LOG, "> pstoolimg.log";

```

```

137 print LOG '$dvips 2>&1';
138 print "dvips done\n";
139 my $i;
140 foreach $i (1 .. $::ps_counter) { create_one_image ($i); }
141 print "\n";
142 'rm -rf tmpdir';
143 close LOG;
144 }

```

This is the main routine. In case of trouble, you should first check that Tralics has correctly translated the input.

```

145 sub main() {
146 print "Working on $::name\n";
147   'tralics $::name $::tralics_options';
148   $::file = slurp_input($::name_o);
149   link_files();
150   prepare_for_latex();
151   print "Creating $::name_a\n";
152   extract;
153   print "Running tex\n";
154   system("latex", "images");
155   read_log("images.log");
156   print "Converting images\n";
157   convert_to_png;
158   $::file =~ s!<(table|preview).*?</\1>!convert_table($1,$&)!egs;
159   open OUT,> $::name_t" || die "cannot open $::name_t\n";
160   print OUT "$::file";
161   close OUT;
162   print "Seen $::img_ctr elements\n";
163   ($::ps_counter == $::img_ctr) or die "Wrong number of images";
164   print "xsltproc --catalogs --stringparam Main $::name
165         -o $::name.html $::name_x $::name_t\n";
166   'xsltproc --stringparam Main $::name --catalogs
167         -o $::name.html $::name_x $::name_t'
168 }
169 main;

```

For the thesis of C. Roméro, we have the following statistics. The runtime of Tralics and the style sheets is between one and two seconds. The time needed by L<sup>A</sup>T<sub>E</sub>X to convert the 130 images is over two minutes (nearly one second per image), and pstoimg is even slower (the total time is over five minutes). The XML file produced by Tralics has 1323K, that is reduced to 995K after replacement of tables by images. The XML file containing the images has a size of 920K, this is much more than the difference of the two sizes given above. The essential reason is that the XSLT processor reads the DTD file, and replaces missing attributes by their value. For instance, an empty cell is translated into

```
<cell halign='center' />
```

and then converted to

```
<cell halign="center" role="data" rows="1" cols="1" right-border="false"
left-border="false" top-border="false" bottom-border="false"/>
```

It should be possible to divide the size by two, hoping that the L<sup>A</sup>T<sub>E</sub>X runtime is also divided by two.

### 8.3 The style sheet for extracting trees

We give here a style sheet whose purpose is to extract some elements and convert them into images. In a first approximation, we select all `<table>` or `<preview>` elements containing a `<node>`, and handle the connectors. Details are given later.

This is the start of the file `extract.xsl`. We do not show the attributes of the style sheet elements, it is the same as for other files.

```

1  <?xml version="1.0" encoding="iso-8859-1"?>
2  <xsl:stylesheet>
3  <!--
4      Copyright INRIA/APICS 2006-2007, Jos\'e Grimm
5      Licensed under the CeCILL Free Software Licensing Agreement
6  -->
```

All connectors are in a dummy cell; if we do not take care, this cell produces a huge amount a space. The good solution would be to modify the L<sup>A</sup>T<sub>E</sub>X source, using a real element instead of this dummy cell. The temporary solution consists in ignoring spaces in cells, rows, tables.

```

7  <xsl:strip-space elements="cell row table"/>
8  <xsl:output method='xml' encoding='iso-8859-1'/>
```

In order to convert the XML file created here into dvi, it suffices to put a `<fo:block>` in a `<fo:root>`. We do something for each `<table>` and `<preview>` element.

```

9  <xsl:template match="std">
10 <fo:root>
11   <fo:block>
12     <xsl:apply-templates select ="//table | //preview "/>
13   </fo:block>
14 </fo:root>
15 </xsl:template>
```

In the case of the `<table>` element, if it contains a a `<row>` that contains a `<cell>` that contains a `<node>`, we construct a `<tree>` element, containing the table, translated via a template described below. A newline character is inserted in the XML file, to separate elements.

```

16 <xsl:template match="table">
17   <xsl:if test="row/cell/node">
18     <xsl:text>&#xA;</xsl:text>
19     <tree>
20       <xsl:call-template name="table" select=". />
21     </tree>
22   </xsl:if>
23 </xsl:template>
```

In the case of the `<preview>` element, if it contains a `<table>` that contains a `<row>` that contains a `<cell>` that contains a `<node>`, we construct a `<tree>` element, containing the `<table>` in preview mode. The important point here is that we copy the attributes.

```

24 <xsl:template match="preview">
25   <xsl:if test="table/row/cell/node">
26     <xsl:text>&#xA;</xsl:text>
27     <tree>
28       <xsl:copy-of select="@*"/>
29       <xsl:apply-templates mode="preview"/>
30     </tree>
```

```

31      </xsl:if>
32  </xsl:template>
33      If a <table> is in a <preview>, but the previous rule does not match, we do nothing.
34  <xsl:template match="preview/table">
35      Translating the table in preview mode consists of applying the common template.
36  <xsl:template match="table" mode="preview">
37      <xsl:call-template name="table" select=". />
38  </xsl:template>
39      Action is trivial: we copy the table and add the connectors. We assume that the table contains
40      only rows.
41  <xsl:template name="table">
42      <table>
43          <xsl:copy-of select="@*"/>
44          <xsl:apply-templates/>
45      </table>
46      <xsl:call-template name="extractconnectors"/>
47  </xsl:template>
48      Action is trivial: we copy the row. We assume that the row contains only cells.
49  <xsl:template match="row">
50      <row>
51          <xsl:copy-of select="@*"/>
52          <xsl:apply-templates/>
53      </row>
54  </xsl:template>
55      Action is trivial: we copy the content in copy mode.
56  <xsl:template match="cell">
57      <cell>
58          <xsl:copy-of select="@*"/>
59          <xsl:apply-templates mode="copy"/>
60      </cell>
61  </xsl:template>
62      This is a simple recursive copy of everything.
63  <xsl:template match="*|@*|text()" mode="copy">
64      <xsl:copy>
65          <xsl:apply-templates mode="copy" select="*|@*|text()"/>
66      </xsl:copy>
67  </xsl:template>
68      In fact, we copy everything but the connectors.
69  <xsl:template mode="copy"
70      match="nodeconnect|anodeconnect|barnodeconnect| abarnodeconnect
71      |nodecurve|anodecurve|nodetriangle"/>
72      Connectors are copied by this piece of code.
73  <xsl:template name="extractconnectors">
74      <xsl:for-each select="row/cell/nodeconnect| row/cell/anodeconnect
75          |row/cell/barnodeconnect| row/cell/abarnodeconnect
76          |row/cell/nodecurve| row/cell/anodecurve|row/cell/nodetriangle">
77              <xsl:copy-of select=". />
78      </xsl:for-each>
79  </xsl:template>

```

## 8.4 The title page

In the case of the thesis, we have completely changed the text of the first page. There is a first part that contains some information (place where the thesis has been defended, on two lines, the thesis type, the name of the student, the title of the thesis, the name of the supervisor, the defense date, and, for the English version, the original French title). We show here the French version:

```
\begin{metadata}
\begin{center}
\lieutthese{Université Paris III - La Sorbonne Nouvelle}
\lieutesuite{U.F.R. d'Anglais}
\typethese{Linguistique}
\doctorant{Céline}{Roméro}
\thesetitre{L'évolution syntaxique des verbes modaux dans l'histoire
de l'anglais}
\directeur{Jacqueline}{Guéron}
\datesoumission{18 novembre 2005}
\end{center}
```

There is a second part that contains the Jury.

```
\begin{jury}
\membre[Pr\'esident du Jury]{M.}{Claude}{Delmas}
\membre[Directrice de Recherche]{Mme}{Jacqueline}{Guéron}
\membre[Mme]{Annie}{Lancri}
\membre[Mme]{Jacqueline}{Lecarme}
\membre[Mme]{Susan}{Pintzuk}
\end{jury}
\end{metadata}
```

In order for these commands to work, we have defined a file `titlepage.plt`, starting like this:

```
\ProvidesPackage{titlepage}[2007/01/10 v1.1 Thesis TitlePage]
% Copyright Inria/Apics (Jos'e Grimm) 2006-2007
```

The translation of `\foo{bar}` is `<foo>bar</foo>`.

```
\newenvironment{metadata}{\begin{xmlelement*}{metadata}}{\end{xmlelement*}}
\newcommand\thesetitre[1]{\xbox{\thesetitre}{#1}}
\newcommand\titrefrancais[1]{\xbox{\titrefrancais}{#1}}
\newcommand\lieutthese[1]{\xbox{\lieutthese}{#1}}
\newcommand\typethese[1]{\xbox{\typethese}{#1}}
\newcommand\lieutesuite[1]{\xbox{\lieutesuite}{#1}}
\newcommand\datesoumission[1]{\xbox{\datesoumission}{#1}}
\newcommand\directeur[2]{\xbox{\directeur}{#1 #2}}
\newcommand\doctorant[2]{\xbox{\doctorant}{#1 #2}}
```

The command `\membre` takes three mandatory arguments plus an optional one. If arguments are A, B, C and D, the result is a `<membre>` element, with attributes `type`, `prenom`, `nom`, with values B, C, and D, and the content of the element is the optional argument A.

```
\newcommand\membre[4][]{%
\xbox{membre}{#1}%
\XMLaddatt{type}{#2}\XMLaddatt{prenom}{#3}\XMLaddatt{nom}{#4}}%
\newenvironment{jury}{\begin{xmlelement*}{jury}}{\end{xmlelement*}}
```

This command is used elsewhere. Normally, a dedication is a small text on a page. It is preceded by a `\chapter*` command.

```
\newcommand{\dedicace}[1]
{\xbox{dedicace}{#1}}
```

This is now the XML translation. As you can see, the `\chapter*` command produces a `<div0>` element, with an empty title; it will appear in the table of contents as an invisible line, so that it is better to comment it out.

```
<metadata>
<lieutthese>Université Paris III - La Sorbonne Nouvelle</lieutthese>
<lieutthesesuite>U.F.R. d'Anglais</lieutthesesuite>
<typethese>Linguistique</typethese><doctorant>Céline Roméro</doctorant>
<thesetitre>L'évolution syntaxique des verbes modaux dans l'histoire
de l'anglais</thesetitre>
<directeur>Jacqueline Guéron</directeur>
<datesoumission>18 novembre 2005</datesoumission>
<jury><membre nom='Delmas' prenom='Claude' type='M.'>Président du Jury</membre>
<membre nom='Guéron' prenom='Jacqueline' type='Mme'>
    Directrice de Recherche</membre>
<membre nom='Lancri' prenom='Annie' type='Mme' />
<membre nom='Lecarme' prenom='Jacqueline' type='Mme' />
<membre nom='Pintzuk' prenom='Susan' type='Mme' /></jury>
</metadata>
<frontmatter>
<div0 id='uid1' rend='nonumber'><head/>
<dedicace>
Text of the dedication
</dedicace></div0>
```

The research report describing Tralics starts like this:

```
\RRtitle{Tralics, un traducteur de \LaTeX\ vers XML\Partie II}
\RRtitle{Tralics, a \LaTeX\ to XML translator\Part II}
\RRauthor{José Grimm\thanks{Email: Jose.Grimm@sophia.inria.fr}}
\RRprojet{Apics}
\RRtheme{\THNum}
\RRNo{310}
\RRresume{bla bla}
\RRabstract{bla bla}
\RRdate{September 2005}
\URSophia
\motcle{xyz}
\keyword{xyz}
\RRversion{2}
\RRdater{January 2007}
```

All the commands used above are defined in the file `RR.sty`, and Tralics uses `RR.plt` instead (the content of the file has been given in the first part of this document). The effect of these commands is to memorize the arguments (`LATEX` case) or add some elements to the XML tree (Tralics case). The start of the document contains also the following two lines; the first line is ignored in Tralics mode, and the second one in `LATEX` mode, otherwise the effect is to produce the title page, or add an attribute to the document element respectively. Part one and two of the Tralics documentation have different HTML prefixes.

```
\makeRT
\htmlprefix{tdoc2}
```

The XML translation is the following.

```

<ftitle>Tralics, un traducteur de <LaTeX/> vers XML Partie II</ftitle>
<title>Tralics, a <LaTeX/> to XML translator Part II</title>
<author>José Grimm
    <note id='uid1' place='foot'>Email: Jose.Grimm@sophia.inria.fr</note>
</author>
<inria-team>Apics</inria-team>
<theme>THnum</theme>
<rrnumber>310</rrnumber>
<resume><p>bla bla</p></resume>
<abstract><p>bla bla</p></abstract>
<date>September 2005</date>
<location>Sophia Antipolis</location>
<motcle>xyz</motcle>
<keyword>xyz</keyword>
<version-number>2</version-number>
<rev-date>January 2007</rev-date>

```

This is the main template for conversion to HTML. If the document contain some text, then a table of contents then a bibliography, then an index, then footnotes, it is difficult to find the TOC, and for this reason a short TOC is included. However, if the TOC is before the main text, this is redundant; if the variable `$shorttoc` is set to false, there is no short TOC. In the case where `$split` is not false, then the main document is split, and there is no need for a short TOC.

This template allows two modes for the meta data: in the case of the thesis, the meta data are children of `<metadata>`, and the template `header` is empty; in the case of the technical report, the translation of elements like `<rev-date>` is empty, and `header` constructs the title page.

```

1  <xsl:template match="std">
2      <html>
3          <xsl:call-template name="html-meta" />
4          <body>
5              <xsl:call-template name="header"/>
6              <xsl:if test="$shorttoc='true' or
7                  ($shorttoc='maybe' and $split='false')">
8                  <xsl:call-template name="shorttoc"/>
9              </xsl:if>
10             <xsl:apply-templates/>
11             <xsl:call-template name="footnotes" />
12         </body>
13     </html>
14 </xsl:template>

```

This is how we construct the HTML meta data. Three auxiliary templates are used, since we do not know how to access to the author, title and keywords.

```

15 <xsl:template name="html-meta">
16     <head>
17         <meta http-equiv="Content-Type" content="text/html; charset=iso-8859-1" />
18         <meta name="author">
19             <xsl:attribute name="content">
20                 <xsl:call-template name="author" />
21             </xsl:attribute>
22         </meta>
23         <title> <xsl:call-template name="title" /></title>
24         <link rel="stylesheet" href="tralics.css" />
25         <meta name="keywords">

```

```

26      <xsl:attribute name="content">
27          <xsl:call-template name="keywords" />
28      </xsl:attribute>
29  </meta>
30 </head>
31 </xsl:template>
```

These three templates are used in the code above; since there are no keywords in the *TEX* source of the thesis, we invented some; for this reason the last rule exists in both French and English versions. In the case of the technical report, we select elements `<author>`, `<title>`, `<keyword>`. Note that these elements are converted in ‘text’ mode; the main idea is to omit the footnote in the author’s field.

```

32 <xsl:template name="author">
33     <xsl:apply-templates select="/std/metadata/docteur" mode="text"/>
34 </xsl:template>
35 <xsl:template name="title">
36     <xsl:apply-templates select="/std//metadata/thesetitre" mode="text"/>
37 </xsl:template>
38 <xsl:template name="keywords">
39     <xsl:text>verbe anglais histoire</xsl:text>
40 </xsl:template>
```

In the case of the thesis, the `metadata` template outputs the title in a `<h1>` heading, then all meta data in a two column table in a `<blockquote>` with non-zero margins. Each data produces a row in the table (for instance, `<lieutthese>` gives two cells, one with ‘Lieu’, and one with the value of the element. The `<jury>` command produces two cells, the second one being a table; each `<membre>` produces a row of this table. The code is obvious, the result is given here.

```

<html xmlns="http://www.w3.org/1999/xhtml">
<head>
    <meta http-equiv="Content-Type" content="text/html; charset=iso-8859-1" />
    <meta name="author" content="Céline Roméro" />
    <title>L'évolution syntaxique des verbes modaux dans l'histoire
        de l'anglais</title>
    <link rel="stylesheet" href="tralics.css" />
    <meta name="keywords" content="verbe anglais histoire" />
</head>
<body>
    <h1>L'évolution syntaxique des verbes modaux dans l'histoire
        de l'anglais</h1>
    <blockquote class="thesis-heading">
        <table>
            <tr><td>Lieu</td><td>Université Paris III - La Sorbonne Nouvelle</td></tr>
            <tr><td></td><td>U.F.R. d'Anglais</td></tr>
            <tr><td>Doctorat en</td><td>Linguistique</td></tr>
            <tr><td>Doctorant</td><td>Céline Roméro</td></tr>
            <tr><td>Thèse dirigée par</td><td>Jacqueline Guéron</td></tr>
            <tr><td>Date de soutenance</td><td>18 novembre 2005</td></tr>
            <tr><td>Jury</td><td>
                <table>
                    <tr><td>M.</td><td>Claude</td><td>Delmas</td>
                        <td>Président du Jury</td></tr>
                    <tr><td>Mme</td><td>Jacqueline</td><td>Guéron</td>
                        <td>Directrice de Recherche</td></tr>
                </table>
            </td></tr>
        </table>
    </blockquote>

```

```

<tr><td>Mme</td><td>Annie</td><td>Lancri</td><td></td></tr>
<tr><td>Mme</td><td>Jacqueline</td><td>Lecarme</td><td></td></tr>
<tr><td>Mme</td><td>Susan</td><td>Pintzuk</td><td></td></tr>
</table></td></tr>
</table></blockquote>
<hr />
```

The style sheet TF that converts the thesis contains a variable for each name used above; the style sheet TE contains the same variable, with English names.

```

33 <xsl:variable name="Bibliographyname">Bibliographie</xsl:variable>
34 <xsl:variable name="Lieuname">Lieu</xsl:variable>
35 <xsl:variable name="Frenchtitlename">Titre Français</xsl:variable>
36 <xsl:variable name="Typethesename">Doctorat en</xsl:variable>
37 <xsl:variable name="Directornname">Thèse dirigée par</xsl:variable>
38 <xsl:variable name="Doctorantname">Doctorant</xsl:variable>
39 <xsl:variable name="Datesoumissionname">Date de soutenance</xsl:variable>
40 <xsl:variable name="Juryname">Jury</xsl:variable>
```

In the case of the report, the template header selects 14 items, whose translation is otherwise empty. The code is obvious, if you compare the XML shown above and the HTML translation given here.

```

<html xmlns="http://www.w3.org/1999/xhtml">
<head><meta http-equiv="Content-Type" content="text/html; charset=iso-8859-1" />
  <meta name="author" content="José Grimm" />
  <title>Tralics, a LATEX to XML translator Part II</title>
  <link rel="stylesheet" href="tralics.css" />
  <meta name="keywords" content="xyz" />
</head>
<body>

## 8.5 The style sheets

The style sheets we use for the two examples are modifications of those explained in previous chapters; we shall explain only the differences.

### 8.5.1 Splitting the text

The default translation consists in generating a single page from the text. However, since the thesis and our reports are very long, we allow the possibility to generate a **HTML** page for each main division. Since the report uses the **report** class, a main division is associated to a **\chapter**. In the case of the thesis, the **book** class is used, and by default, the main division is **\part**; since there are no chapters, we have to use **\toplevelsection{\chapter}** in order to say that the chapter is a main division. The technical report describing Tralics has a huge index (30 **LATEX** pages in two-column mode); for this reason, we allow the possibility of a separate index. Finally, you can also ask for a separate page for the bibliography and the footnotes.

Assume that A is the main file, B, C, D, etc., the files associated to the first, second, third, chapter, etc. We shall make the following assumption: the whole document consists in an front section A1, a main part A2, and a back section A3, where the main part is essentially a sequence of chapters. More precisely, we assume that the translation of A2 is a sequence of links to pages B, C, D, and some **HTML** elements (like rules), but no text. Said otherwise, if the reader reads A1, B, C, D, A3, then he reads everything. This implies that there should be no text between chapters (because there is no end-of-chapter command in **LATEX**, this is true in general). In order to complete our notations: if a separate page is used, we shall denote it by I (for the index), F (for the footnotes) and H (for the bibliography).

We also assume that the table of contents and the bibliography appear in A (not hidden in a chapter), or use a separate page. Putting the TOC between chapter 1 and chapter 2 is strange but valid. Normally, it is at the start, after the introduction or at the end of the document. The easy case is when the document contains a **<mainmatter>** (with the chapters B, C, D, etc), and is followed by a **<backmatter>** (containing A3). We can assume that everything before the mainmatter is in a **<frontmatter>**, but this is not needed. In this case the TOC is either in the front matter or in the back matter. In the case where the document looks like a report, some care has to be taken, because, by default, the bibliography is appended to the last chapter. Our thesis ends like this:

```
\backmatter
\include{Conclusion}
\printindex
\nocite{*} \bibliographystyle{these} \bibliography{these}
```

Our technical report does not use **\printindex**, but **\inputs** the index; however the commands produced by **makeindex** are not understood by Tralics, so that the file is conditionally included. The important point here is that **\endsec** terminates the current chapter. This is the end of the report:

```
\cleardoublepage
\iftralics
  \endsec{\chapter}
\else
  \input tralics-rr2.ind
\fi
\bibliography{tralics}
\tableofcontents
```

The pages mentioned above are linked in the following way

- There is a link from A to B, C, and D (in fact, part A2 of A contains only these links).
- There is a link from B, C, and D to A (in fact, we point to the table of contents).
- There is a link from B to C to D to A3 (the last link is to the start of A3, the start of the **<backmatter>** if possible).

- There is a link from D to C to B to A1 (the last link is to the end of the front matter, this is the start of the <mainmatter> if possible).
- There is a link from A to I, H, and F (the table of contents points to the index, bibliography and footnotes in the case where these are on separate pages).
- There are links from I, H and F to A (of the form “back to main page”).
- There may be links from any of these pages to any other page (internal links).

We assume that the value \$Main contains the name A (without extension); a link to this file will be of the form A#foo, but we use the simple form #foo in the case where the file is not split (this allows you to rename the file at your leisure).

```

9  <xsl:template name="mainfile">
10 <xsl:if test="not($split='false') ">
11   <xsl:value-of select="concat($Main,'.html')" />
12 </xsl:if>
13 </xsl:template>
```

The names B, C, D, etc are computed as follows: we use a prefix, followed by the id of the chapter. This prefix is defined in the style sheet for the thesis, or in the T<sub>E</sub>X source, via the \htmlprefix command.

```

14 <xsl:template match="div0" mode="fileprefix">
15   <xsl:value-of select="concat($prefix,@id,'.html')" />
16 </xsl:template>
```

This is how we compute the names I, H and F. There are three similar templates, they depend on the variables \$separate-index, for the index, \$separate-footnote, for footnotes, and \$separate-biblio for the bibliography. The names are obtained by concatenation of the prefix and ‘uidI’, ‘uidF’ and ‘uidH’.

```

17 <xsl:template name="indexfile">
18   <xsl:choose>
19     <xsl:when test="not ($split='false') and $separate-index='true' ">
20       <xsl:value-of select="concat($prefix,'uidI','.html')" />
21     </xsl:when>
22     <xsl:otherwise>
23       <xsl:call-template name="mainfile" />
24     </xsl:otherwise>
25   </xsl:choose>
26 </xsl:template>
27
28 <xsl:template name="footnotefile"> ...
29 <xsl:template name="bibliofile"> ...
```

What precedes the first chapter is the main file; if we have a main matter, then the first chapter is the start of the main matter, so that we link to the rule that separates front and main matter.

```

30 <xsl:template name="first.page" >
31   <xsl:call-template name="mainfile" />
32   <xsl:choose>
33     <xsl:when test="//mainmatter">
34       <xsl:text>#mainmatter</xsl:text>
35     </xsl:when>
36   </xsl:choose>
37 </xsl:template>
```

What follows the last chapter is the main file; if we have a back matter, we use its anchor; if there is a non-separate bibliography we use it otherwise.

```

38 <xsl:template name="last.page" >
39   <xsl:call-template name="mainfile" />
40   <xsl:choose>
41     <xsl:when test="//backmatter">
42       <xsl:text>#backmatter</xsl:text>
43     </xsl:when>
44     <xsl:when test="//biblio and not($separate-biblio='false')">
45       <xsl:text>#bibliography</xsl:text>
46     </xsl:when>
47   </xsl:choose>
48 </xsl:template>
```

The variable `$split` can be ‘true’, ‘false’ or ‘all’. If this quantity is false, a single page is generated, if true, a **HTML** page is generated only for chapter in the main matter (child of `<mainmatter>`), otherwise for each chapter. This is controlled by the following template rule:

```

49 <xsl:template match="div0">
50   <xsl:choose>
51     <xsl:when test="$split='false'">
52       <xsl:apply-templates select='.' mode="normal"/>
53     </xsl:when>
54     <xsl:when test="$split='all'">
55       <xsl:apply-templates select='.' mode="split"/>
56     </xsl:when>
57     <xsl:when test="ancestor::mainmatter">
58       <xsl:apply-templates select='.' mode="split"/>
59     </xsl:when>
60     <xsl:otherwise>
61       <xsl:apply-templates select='.' mode="normal"/>
62     </xsl:otherwise>
63   </xsl:choose>
64 </xsl:template>
```

This template returns the filename in which a current element is located. This assumes that `<div0>` is the only element that generates a page, is defined as shown above, and the name of the page matches the previous template. Note: if we replace ‘ancestor-or-self’ by ‘ancestor’, then the link to a `<div0>` will be an anchor in the main file, this means that you have to click twice in order to see the text.

```

65 <xsl:template match="*" mode="targetfile">
66   <xsl:choose>
67     <xsl:when test="$split='false'" />
68     <xsl:when test="not(ancestor-or-self::div0)">
69       <xsl:call-template name="mainfile" />
70     </xsl:when>
71     <xsl:when test="(ancestor::mainmatter) or $split='all'">
72       <xsl:apply-templates select="ancestor-or-self::div0" mode="fileprefix" />
73     </xsl:when>
74   <xsl:otherwise>
75     <xsl:call-template name="mainfile" />
76   </xsl:otherwise>
```

```

77   </xsl:choose>
78 </xsl:template>
```

This returns the name of the previous file. The algorithm is simpler than the case of the Raweb. In particular, since this does not apply to the main page, there is a previous and a following link.

```

79 <xsl:template match="div0" mode="file-prev-prefix">
80   <xsl:choose>
81     <xsl:when test="preceding-sibling::div0">
82       <xsl:apply-templates select="preceding-sibling::div0[1]" mode="fileprefix"/>
83     </xsl:when>
84     <xsl:otherwise>
85       <xsl:call-template name="first.page" />
86     </xsl:otherwise>
87   </xsl:choose>
88 </xsl:template>
```

In the case of the last chapter, we put the link to the backmatter or the bibliography if available.

```

89 <xsl:template match="div0" mode="file-next-prefix">
90   <xsl:choose>
91     <xsl:when test="following-sibling::div0">
92       <xsl:apply-templates select="following-sibling::div0[1]" mode="fileprefix"/>
93     </xsl:when>
94     <xsl:otherwise>
95       <xsl:call-template name="last.page" />
96     </xsl:otherwise>
97   </xsl:choose>
98 </xsl:template>
```

This creates a link with a button to the previous page. The access key is P.

```

99 <xsl:template match="div0" mode="button-prev-prefix">
100   <a accesskey='P' title="previous page">
101     <xsl:attribute name='href'>
102       <xsl:apply-templates select=". " mode = "file-prev-prefix" />
103     </xsl:attribute>
104     
105   </a>
106 </xsl:template>
```

Same for the preceding page. The access key is N.

```

107 <xsl:template match="div0" mode="button-next-prefix">
108   <a accesskey='N' title="next page">
109     <xsl:attribute name='href'>
110       <xsl:apply-templates select=". " mode = "file-next-prefix" />
111     </xsl:attribute>
112     
113   </a>
114 </xsl:template>
```

This creates three buttons, that point to the previous, top, and next pages. They float to the left and right (as defined by the raweb.css file).

```

115 <xsl:template match="div0" mode="button">
116   <div class="float-left">
117     <xsl:apply-templates select=". " mode = "button-prev-prefix" />
```

```

118   </div>
119   <div class="float-left">
120     <a accesskey='T' title="table of contents" >
121       <xsl:attribute name='href'>
122         <xsl:call-template name ="mainfile" />
123         <xsl:text>#tableofcontents</xsl:text>
124     </xsl:attribute>
125     
126   </a>
127 </div>
128 <div class="float-right">
129   <xsl:apply-templates select=". ." mode ="button-next-prefix" />
130 </div>
131 </xsl:template>

```

If we have a separate page for the index, bibliography or footnotes, the previous and next buttons do not depend on the page. This creates three buttons, to the first page, the last page and the TOC.

```

132 <xsl:template name="std.buttons">
133   <div class="float-left">
134     <a accesskey='P' title="previous page">
135       <xsl:attribute name='href'>
136         <xsl:call-template name="first.page" />
137       </xsl:attribute>
138       
139     </a>
140   </div>
141   <div class="float-left">
142     <a accesskey='T' title="table of contents" >
143       <xsl:attribute name='href'>
144         <xsl:call-template name ="mainfile" />
145         <xsl:text>#tableofcontents</xsl:text>
146     </xsl:attribute>
147     
148   </a>
149 </div>
150 <div class="float-right">
151   <a accesskey='N' title="next page">
152     <xsl:attribute name='href'>
153       <xsl:call-template name="last.page" />
154     </xsl:attribute>
155     
156   </a>
157 </div>
158 </xsl:template>

```

The following template creates the page for a chapter. Note that `xsl:document` is not a XSLT1.0 command, but an extension accepted by many XSLT processors.

```

159 <xsl:template match="div0" mode ="xsplit">
160   <xsl:variable name="filename">
161     <xsl:apply-templates select=". ." mode="fileprefix" />
162   </xsl:variable>
163   <xsl:document href="{{$filename}}"
```

```

164     encoding='iso-8859-1' doctype-public='-//W3C//DTD XHTML 1.0 Strict//EN'
165     doctype-system='http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd'
166     method="xml" >

```

The HTML page created here contains the same meta data as the main page. It has the navigation buttons shown above on the top and bottom. On the top, between the navigation button, there is the title of the document, on the back, there is a link to the main file.

```

167 <html>
168   <xsl:call-template name="html-meta" />
169   <body>
170     <xsl:apply-templates select=". . ." mode="button" />
171     <div class="float-center"><xsl:call-template name="title" /></div>
172     <h1>
173       <xsl:call-template name="id"/>
174       <xsl:call-template name="calculateNumberSpace"/>
175       <xsl:apply-templates select="head" mode="caption"/>
176     </h1>
177     <xsl:apply-templates/>
178     <xsl:apply-templates select=". . ." mode="button" />
179     <xsl:call-template name="back.to.main.buttons" />
180   </body>
181 </html>
182 </xsl:document>
183 </xsl:template>

```

This is for the index. We use the same attributes for the xsl:document element, but different navigation buttons. The same rule is used for the bibliography, but `bibliofile` is used instead of `indexfile` for the name of the HTML file.

```

184 <xsl:template match="theindex" mode ="xsplit">
185   <xsl:variable name="filename">
186     <xsl:call-template name="indexfile" />
187   </xsl:variable>
188   <xsl:document ... >
189     <html>
190       <xsl:call-template name="html-meta" />
191       <body>
192         <xsl:call-template name="title.buttons" />
193         <xsl:apply-templates select=". . ." mode="ysplit" />
194         <xsl:call-template name="back.to.main.buttons" />
195       </body>
196     </html>
197   </xsl:document>
198 </xsl:template>
199
200 <xsl:template match="biblio" mode ="xsplit"> ...

```

This is for the footnotes. The idea is the same, but we have a named template, so that we cannot use modes.

```

201 <xsl:template name="footnotes-xsplit">
202   <xsl:variable name="filename">
203     <xsl:call-template name="footnotefile" />
204   </xsl:variable>
205   <xsl:document ... >

```

```

206   <html>
207     <xsl:call-template name="html-meta" />
208   <body>
209     <xsl:call-template name="title.buttons" />
210     <xsl:call-template name="footnotes-ysplit" />
211     <xsl:call-template name="back.to.main.buttons" />
212   </body>
213 </html>
214 </xsl:document>
215 </xsl:template>
```

This prints ‘Back to main page’ on the bottom of a page.

```

216 <xsl:template name="back.to.main">
217   <xsl:variable name="mainpage">
218     <xsl:call-template name="mainfile" />
219   </xsl:variable>
220   <div class="float-center">
221     <a href="${mainpage}">Back to main page</a>
222   </div>
223 </xsl:template>
```

This creates the buttons at the end of a separated page.

```

224 <xsl:template name="back.to.main.buttons">
225   <hr/>
226   <xsl:call-template name="std.buttons" />
227   <xsl:call-template name="back.to.main" />
228 </xsl:template>
```

This creates the buttons at the start of a separated page. Same buttons, but we use the title of the document.

```

229 <xsl:template name="title.buttons">
230   <xsl:call-template name="std.buttons" />
231   <div class="float-center"><xsl:call-template name="title" /></div>
232 </xsl:template>
```

This piece of code translates id = ‘foo’ into href = ‘bar#foo’, the non trivial point being how to compute the file name ‘bar’. This works only if the DTD declares the id attribute of the current element to be of type ‘ID’.

```

233 <xsl:template name="id-to-href">
234   <xsl:attribute name="href">
235     <xsl:apply-templates mode="targetfile" select="id(@id)" />
236     <xsl:text>#</xsl:text><xsl:value-of select="./@id"/>
237   </xsl:attribute>
238 </xsl:template>
```

This piece of code translates target = ‘foo’ into href = ‘bar#foo’, using the same method as above.

```

239 <xsl:template name="target-to-href">
240   <xsl:attribute name="href">
241     <xsl:apply-templates mode="targetfile" select="id(@target)" />
242     <xsl:text>#</xsl:text><xsl:value-of select="@target"/>
243   </xsl:attribute>
244 </xsl:template>
```

### 8.5.2 Footnotes

Footnotes in the Raweb are inlined, on the contrary, here, we gather them at the end of the main page, or on a separate page, using the following rule. The non-obvious point is that, if we denote by A the code created here, and by B the translation of a footnote, we have a link from A to B, and a backlink from B to A (this could be omitted, just use then ‘back’ button of your browser). Assume that this is note 25, with uid33 as ID; in this case element B will have uid33 as unique id, and element A will have note25 as identifier (this means that a link to a footnote refers to its text). In fact, A contains a rule (separating it from the previous note) and a <p> that serves as anchor, containing and a header, like ‘Note 25.’, and the text of the note; the backlink is activated by clicking on the header.

There is a non trivial question here: Are paragraphs allowed in a footnote? They are (by default) removed by Tralics; but we have to take both cases into account.

```

245 <xsl:template match='note' mode="footnote">
246   <hr/>
247   <p class='nofirst noindent'>
248     <xsl:attribute name="id">
249       <xsl:text>note</xsl:text>
250       <xsl:call-template name="calculateFootnoteNumber"/>
251     </xsl:attribute>
252     <a title="back to text">
253       <xsl:call-template name="id-to-href"/>
254       <xsl:text>Note </xsl:text>
255       <xsl:call-template name="calculateFootnoteNumber"/>
256       <xsl:text>. </xsl:text>
257     </a>
258     <xsl:if test="not(p)">
259       <xsl:apply-templates />
260     </xsl:if>
261   </p>
262   <xsl:if test="p">
263     <xsl:apply-templates />
264   </xsl:if>
265 </xsl:template>
```

Element B is an anchor, whose text is ‘(note: A)’, where A is the character U+27B3, a kind of arrow. There is also a title, formed of the start of the text.

```

266 <xsl:template match='note'>
267   <a id="{@id}">
268     <xsl:call-template name="note-to-href"/>
269     <xsl:apply-templates mode="xreftitle" select=". "/>
270     <small>(note: </small>
271     <xsl:text>&#x27B3;</xsl:text>
272     <small>)</small>
273   </a>
274 </xsl:template>
```

This removes footnotes in the meta data.

```
275 <xsl:template match='note' mode="text" />
```

This returns a unique ID for a footnote, namely its number.

```

276   <xsl:template match='note' mode="xref">
277     <xsl:call-template name="calculateFootnoteNumber"/>
278   </xsl:template>

```

In the case of a footnote, say note 25, we create a link from the current page to the page that contains the notes, with attribute href = ‘foo#note25’; the non trivial point being how to compute the file name ‘foo’.

```

279   <xsl:template name="note-to-href">
280     <xsl:attribute name="href">
281       <xsl:call-template name="footnotefile" />
282       <xsl:text>#note</xsl:text>
283       <xsl:apply-templates mode="xref" select =".."/>
284     </xsl:attribute>
285   </xsl:template>

```

This completes the translation of a footnote. The non-trivial point here is the title: we convert the note in a string, and if the string is small enough, it will be the title. Otherwise, we consider only the first one hundred characters.

```

286   <xsl:template mode="xreftitle" match="note">
287     <xsl:variable name="text" select="string(normalize-space(.))" />
288     <xsl:attribute name="title">
289       <xsl:choose>
290         <xsl:when test="string-length($text) &gt; 110">
291           <xsl:value-of select="substring($text,1,100)"/>
292           <xsl:text>...</xsl:text>
293         </xsl:when>
294         <xsl:otherwise>
295           <xsl:value-of select="$text"/>
296         </xsl:otherwise>
297       </xsl:choose>
298     </xsl:attribute>
299   </xsl:template>

```

Dispatcher template. The action depends on whether a separate page is needed.

```

300   <xsl:template name="footnotes">
301     <xsl:choose>
302       <xsl:when test="not($split='false') and $separate-footnote='true'">
303         <xsl:call-template name="footnotes-xsplit" />
304       </xsl:when>
305       <xsl:otherwise>
306         <xsl:call-template name="footnotes-ysplit" />
307       </xsl:otherwise>
308     </xsl:choose>
309   </xsl:template>

```

This is obvious. we output a title, followed by all the notes.

```

310   <xsl:template name="footnotes-ysplit">
311     <h1>Notes</h1>
312     <xsl:for-each select="//note">
313       <xsl:apply-templates select=". " mode="footnote"/>
314     </xsl:for-each>
315   </xsl:template>

```

### 8.5.3 The index

The index is created by the following trivial rule.

```
316 <xsl:template match="theindex" mode="ysplit">
317   <h1 id="index">Index</h1>
318   <xsl:apply-templates/>
319 </xsl:template>
```

The situation becomes complicated when we try to use a separate page for the index. Hence the real rule is the following.

```
320 <xsl:template match="theindex">
321   <xsl:choose>
322     <xsl:when test="not($split='false') and $separate-index='true' ">
323       <xsl:apply-templates select=". " mode="xsplit" />
324     </xsl:when>
325     <xsl:otherwise>
326       <xsl:apply-templates select=". " mode="ysplit" />
327     </xsl:otherwise>
328   </xsl:choose>
329 </xsl:template>
```

We use the same method for the bibliography, but a different variable is used.

```
330 <xsl:template match="biblio">
331   <xsl:choose>
332     <xsl:when test="not($split='false') and $separate-biblio='true' ">
333       <xsl:apply-templates select=". " mode="xsplit" />
334     </xsl:when>
335     <xsl:otherwise>
336       <xsl:apply-templates select=". " mode="ysplit" />
337     </xsl:otherwise>
338   </xsl:choose>
339 </xsl:template>
```

This is how we insert the index in the TOC.

```
340 <xsl:template match="theindex" mode="xtoc">
341   <xsl:variable name="link">
342     <xsl:call-template name="indexfile" />
343     <xsl:text>#index</xsl:text>
344   </xsl:variable>
345   <xsl:text>&#xA;</xsl:text> <br/>
346   <a href="#">Index</a>
347 </xsl:template>
```

If the source contains \index{foo!bar}, Tralics will add an anchor at the current location (unless there is already an anchor there); let's denote it by A. Moreover, an <index> element with value 'foo' (at level one) and a second <index> with value 'bar' (at level two) will be added at the end of the document, sorted in alphabetic order; let's denote these elements by B and C. Element A has an id, say D, and element C has a target attribute, which is a list of ids, and D is added to it.

The HTML translation of elements like B and C is a <div> element, with a class attribute, with value 'idx1', 'idx2', or 'idx3', depending on the level; each D in the attribute target is translated as a link to A.

```
348 <xsl:template match="index">
349   <xsl:text>&#xA;</xsl:text>
```

```

350   <div class="idx{@level}">
351     <xsl:apply-templates/>
352     <xsl:for-each select="id(@target)">
353       <xsl:if test="position()=1">: </xsl:if>
354       <a>
355         <xsl:call-template name="id-to-href"/>
356         <xsl:apply-templates mode="xref" select=". "/>
357       </a>
358       <xsl:call-template name="separateur.objet"/>
359     </xsl:for-each>
360   </div>
361 </xsl:template>
```

This what an `<anchor>` produces in the index; a character that looks like a star.

```

362 <xsl:template match="anchor" mode ='xref'>
363   <xsl:text>#273B;</xsl:text>
364 </xsl:template>
```

The following lines come from the `raweb.css` style sheet and explain how to indent the lines of the index.

```
.idx1 { text-indent:0em; margin-top:2px}
.idx2 { text-indent:2em;}
.idx3 { text-indent:4em;}
```

#### 8.5.4 Divisions

We have a template `calculateNumber` that returns the number of a section. In the case of a thesis, we restrict attention to the mainmatter (front matter and back matter contain only unnumbered chapters). The code shown here must be changed in the case of the report. There is also `calculateNumberSpace` that adds a dot and a space after the number.

```

4 <xsl:template name="calculateNumber">
5   <xsl:if test= "ancestor::mainmatter">
6     <xsl:number level="multiple" from="/mainmatter" grouping-separator=". "
7       count="div0|div1|div2|div3|div4|div5"/>
8   </xsl:if>
9 </xsl:template>
```

This is how we output a section of level three. Note that the default translation of `<head>` is empty. If the head appears in the TOC, it will be translated in mode ‘caption’, in which case anchors, footnotes, etc., are removed. Here we use full mode.

```

10 <xsl:template match="div3">
11   <h4>
12     <xsl:call-template name="id"/>
13     <xsl:call-template name="calculateNumberSpace"/>
14     <xsl:apply-templates select="head" mode="full"/>
15   </h4>
16   <xsl:apply-templates/>
17 </xsl:template>
```

The translation of `<tableofcontents>` is the TOC, it is a `<h1>` element (named ‘Table des Matières’ in the French thesis, ‘Table of contents’ in the English report) containing all divisions (the short TOC has only chapters), plus bibliography, index, and TOC (for the short TOC only), evaluated in ‘xtoc’ mode. Translation is formed of a newline character, a `<br>` element, some space, and a anchor to the section (with the number and title of the section).

```

18 <xsl:template match="div3" mode="xtoc">
19   <xsl:text>&#xA;</xsl:text>
20   <br/>
21   <xsl:apply-templates mode="prefix" select=". "/>
22   <xsl:call-template name="calculateNumberSpace"/>
23   <a>
24     <xsl:call-template name="id-to-href"/>
25     <xsl:apply-templates select="head" mode="caption"/>
26   </a>
27 </xsl:template>

```

This is how we indent the section. A `<div2>` has less `<spaces>` and a `<div4>` has more. Each template creates 5 non-break space characters.

```

28 <xsl:template match="div3" mode="prefix">
29   <xsl:call-template name="spaces"/>
30   <xsl:call-template name="spaces"/>
31   <xsl:call-template name="spaces"/>
32 </xsl:template>

```

All elements that can be referenced to have a rule in mode ‘xreftitle’, the action is generally empty; in the case of `<citation>`, we select the authors in mode ‘xref-fullauthor’; in the case of a note, we select the text of the note (see above); in the case of a division, we select the title. In all cases, the text becomes the value of the attribute `title` of the anchor. We show here only the case of a division of level 3.

```

33 <xsl:template mode="xreftitle" match="div3">
34   <xsl:attribute name="title">
35     <xsl:apply-templates select="head" mode="caption"/>
36   </xsl:attribute>
37 </xsl:template>

```

When a reference is made to an item, we evaluate it in mode ‘xref’; the result is, for instance, a section number computed by the rule given here. The case of a figure, a footnote, a table, a citation, is similar.

```

38 <xsl:template mode="xref" match="div3">
39   <xsl:call-template name="calculateNumber"/>
40 </xsl:template>

```

In the case of an `<item>`, we use the label if there is any (this is important, in the case where Tralics has calculated the number, and we do not want the style sheet to compute something different).

```

41 <xsl:template match="item" mode="xref">
42   <xsl:choose>
43     <xsl:when test="@label">
44       <xsl:value-of select="@label" />
45     </xsl:when>
46     <xsl:otherwise>
47       <xsl:call-template name="calculateItemNumber"/>
48     </xsl:otherwise>
49   </xsl:choose>
50 </xsl:template>

```

This is how we translate a `<p>` element; the result is a `<p>`, unless we are in a verbatim section, case where new lines are obeyed. If the paragraph should be centered, we add a `style` attribute, if it should not be indented, we add a `class` attribute.

```

51  <xsl:template match="p">
52      <xsl:choose>
53          <xsl:when test="parent::pre">
54              <xsl:apply-templates/>
55          </xsl:when>
56          <xsl:otherwise>
57              <p>
58                  <xsl:if test="@noindent = 'true'">
59                      <xsl:attribute name="class">nofirst noindent</xsl:attribute>
60                  </xsl:if>
61                  <xsl:if test="@rend = 'center'">
62                      <xsl:attribute name="style">text-align:center</xsl:attribute>
63                  </xsl:if>
64                  <xsl:apply-templates/>
65              </p>
66          </xsl:otherwise>
67      </xsl:choose>
68  </xsl:template>

    This is for the dedication.

69  <xsl:template match="dedicace">
70      <blockquote><p><i><xsl:apply-templates/></i></p></blockquote>
71  </xsl:template>

```

This piece of code is used for inserting a non-floating image, without caption (in the case where we want to show in the HTML file the L<sup>A</sup>T<sub>E</sub>X output, for instance).

```

72  <xsl:template match="rawimage">
73      <img>
74          <xsl:attribute name="src">
75              <xsl:apply-templates/>
76          </xsl:attribute>
77          <xsl:attribute name="alt">
78              <xsl:apply-templates/>
79          </xsl:attribute>
80      </img>
81  </xsl:template>

```

# Chapter 9

## The DTDs

### 9.1 The Raweb DTD

In this chapter we give the Raweb DTD (old and new one). The file starts like this.

```
1 <?xml version="1.0" encoding="iso-8859-1"?>
```

There is the Copyright notice of the file:

```
2 <!--
3 Copyright 2002-2004, 2005 Jose Grimm/ INRIA/ Apics Project
4 You have the right to use this file in any way, with the following
5 restriction: you cannot distribute modifications of this file under
6 its name raweb3.dtd, the name raweb.dtd,
7 nor rawebXXXX.dtd, where XXXX are four digits like 2004.
8 The name 'raweb3.dtd' is associated to the raweb DTD of YEAR 2003.
9 -->
```

We define here the & and < entities. I'm not sure that these definitions are required.

```
10 <!ENTITY amp "&#x26;#x26;" >
11 <!ENTITY lt "&#x26;#x3C;" >
```

We define here some entities. They are used to typeset things like 1<sup>st</sup>, 2<sup>nd</sup>, etc., in French.

```
12 <!ENTITY ier "<hi rend='sup'>er</hi>">
13 <!ENTITY iers "<hi rend='sup'>ers</hi>">
14 <!ENTITY iere "<hi rend='sup'>re</hi>">
15 <!ENTITY ieres "<hi rend='sup'>res</hi>">
16 <!ENTITY ieme "<hi rend='sup'>e</hi>">
17 <!ENTITY iemes "<hi rend='sup'>es</hi>">
18 <!ENTITY numero "n<hi rend='sup'>o</hi>">
19 <!ENTITY Numero "N<hi rend='sup'>o</hi>">
```

This includes the MathML DTD. Note that <ident> and <list> are defined here and in the MathML DTD, they are in a different namespace.

```
20 <!ENTITY % list.qname "m:list" >
21 <!ENTITY % ident.qname "m:ident" >
22
23 <!ENTITY % mathml PUBLIC "mathml" "mathml2.dtd">
24 %mathml;
```

### 9.1.1 General purpose elements

We list here the elements that can appear in the body of a division. There was a `<cit>` element here, it should appear only inside a `<p>`. Since version 2.5, Tralics inserts a `\leavevmode` before a `\cite`. Note that `<formula>`, `<table>` or `<figure>` can be inline or not; inline versions are refused here.

```
25  <!ENTITY % tei-aux "(p | list | note | formula | table | figure)+" >
```

We list here elements that can only appear in certain places (for instance in a title). In the case of a `<formula>`, it should be inline.

```
26  <!ENTITY % texte-restraint
```

```
27    "ident | code | hi | term | ref | xref | formula | TeX | LaTeX" >
```

This is the concatenation of the two lists, with `<cit>` added.

```
28  <!ENTITY % texte-general
```

```
29    "ident | code | hi | term | ref | xref | formula | cit | label | list |
```

```
30      note | figure | table | TeX | LaTeX" >
```

The TEI defines a lot of common attributes. Here we use only two of them. Note: the `id` is used only in the following cases: a division (including modules, and sections like ‘fondements’), an item in a list, a footnote, a table, a figure, a formula, an entry in the bibliography.

```
31  <!ENTITY % tei-common-atts
```

```
32    'id ID #IMPLIED rend CDATA #IMPLIED'>
```

Definition of `<code common-atts>text</code>`. The content of the element is assumed to be some verbatim material, hence it contains only text. Tralics does not produce directly such an element.

```
33  <!ELEMENT code (#PCDATA) >
```

```
34  <!ATTLIST code %tei-common-atts; >
```

Definition of `<ident common-atts>text</ident>`. The content of the element is assumed to be the name of an identifier, hence it contains only text. Tralics does not produce directly such an element.

```
35  <!ELEMENT ident (#PCDATA) >
```

```
36  <!ATTLIST ident %tei-common-atts; >
```

Definition of `<cit rend=A><ref></cit>`. The content of the element is a reference to the bibliography; Tralics sets the `rend` attribute to ‘foot’ in the case of `\footcite`.

```
37  <!ELEMENT cit (ref) >
```

```
38  <!ATTLIST cit rend CDATA #IMPLIED >
```

Definition of `<list type=X> body</list>`. This was simplified a lot, because we removed all references to `<anchor>`. As a result, a list can have an optional title (a `<head>`, but Tralics does not produce it), followed by a sequence of `<item>`. If the list has type gloss or description, the content is a sequence of `<label>` plus `<item>`.

```
39  <!ELEMENT list
```

```
40    ( head?, (item* | (label, item)+)) >
```

```
41  <!ATTLIST list
```

```
42    %tei-common-atts;
```

```
43    type (simple|gloss|ordered|description) "simple" >
```

Definition of `<item id=A>text</item>`. The content can be characters, paragraphs, and some general text (Tralics produces `<p>` elements in general). You can make a reference to an item; the `rend` attribute is not used.

```
44  <!ELEMENT item
```

```
45    (#PCDATA | %texte-general; | p )* >
```

```

46  <!ATTLIST item
47      id ID #IMPLIED
48      rend CDATA #IMPLIED >
49  <!ELEMENT label
50      (#PCDATA | %texte-restraint; )* >
51  <!ATTLIST label %tei-common-atts; >

```

Definition of `<label>text</label>`. The content is the label of an item; it is the optional argument of the \item command. Only simple text is accepted (in particular, if you want a bullet, you should use \textbullet rather than \bullet).

```

52  <!ENTITY % div0-textp "(div1|div2|div3|div4)+">
53  <!ENTITY % div0-texts "(div1|div2|div3|div4)*">
54  <!ENTITY % div1-textp "(div2|div3|div4)+">
55  <!ENTITY % div1-texts "(div2|div3|div4)*">
56  <!ENTITY % div2-textp "(div3|div4)+">
57  <!ENTITY % div2-texts "(div3|div4)*">
58  <!ENTITY % div3-textp "(div4)+">
59  <!ENTITY % div3-texts "(div4)*">

```

We explain here what can be put in the header of a module: participants, keywords, or moreinfo.

```

60  <!ENTITY % particip "participant|participants|participante|participantes" >
61  <!ENTITY % ramodule-header "(moreinfo|keywords|%particip;)*">

```

This describes the attributes for a division. For the Raweb, only id is used, rend and type are ignored.

```

62  <!ENTITY % tei-div-atts '
63      %tei-common-atts;
64      type CDATA #IMPLIED '>

```

This describes a `<module>`. There are some attributes: the html attribute is marked ‘required’, but it is nowadays unused, and id is preferred. The topic attribute, if present, must be a reference to a `<topic>` element (identified by its num attribute). Other attributes are unused. The content is: a `<head>` that indicates the title of the module, followed by some meta data (participants, keywords, more info), and some text (paragraphs, formulas, etc.) or divisions (`<div2>`, `<div3>`, etc.).

```

65  <!ELEMENT module
66      (head, %ramodule-header;, (%div1-textp; | (%tei-aux;, %div1-texts;))) >
67
68  <!ATTLIST module %tei-div-atts;
69      html CDATA #REQUIRED
70      topic CDATA #IMPLIED >

```

A `<figure>` element has a `rend` attribute. If this is ‘inline’, the content should be empty, and the `file` attribute should define an image. You can also specify a non-inline figure, with no attributes and a content formed uniquely of a caption (a `<head>` element), or you could specify an optional caption and a sequence of paragraphs (no `file` in this case). In the case a `file` attribute is given, this should be the name of an image; in this case, you may say `framed=true` if you want a frame around the image; you can set `width` and `height` if you want to alter the dimensions of the image, or `scale`, if you want to rescale it (you cannot give `scale` together with `height` or `depth`); you can specify `angle` if you want to turn the image.

```

108  <!ELEMENT figure

169      anchored (yes | no) "yes"
170      target IDREFS #IMPLIED >
```

The `<anchor/>` element is currently unused. We do not show the attribute list.

```
171  <!ELEMENT anchor EMPTY >
```

### 9.1.2 Elements specific to the Raweb

The main element is `<raweb>`; it is formed by a `<accueil>`, an optional `<moreinfo>`, and ten sections. All sections should be present, the mandatory ones are `<composition>` (who is in the team), `<presentation>` (a short presentation of the team), `<resultats>` (new result of the teams this year) and the bibliography. The `language` attribute indicates the language of the document (currently English), the `year` attribute indicates the year, and the `creator` holds the name of the software that created the document.

```
172  <!ELEMENT raweb (accueil, moreinfo?, composition, presentation,
173    fondements?,domaine?, logiciels?, resultats,contrats?,international?,
174    diffusion?,biblio) >
175  <!ATTLIST raweb year CDATA #IMPLIED >
176  <!ATTLIST raweb language CDATA #IMPLIED >
177  <!ATTLIST raweb creator CDATA #IMPLIED >
```

The `<composition>` element is one of the ten sections of the Raweb, as such it has some constant attributes like `titre`, `html` and `numero`. It has a possible `id` (making a reference to a section is not a good idea, because no HTML page is associated to a section; in the case without topics, a section is a continuous sequence of pages, so a link to the first page could be used; this is no more true in the case with topics). This section contain an optional `<moreinfo>` and a sequence of `<catperso>` elements.

```
178  <!ELEMENT composition (moreinfo?,catperso+)>
179  <!ATTLIST composition
180    titre CDATA #FIXED "Team"
181    html CDATA #FIXED "composition"
182    numero CDATA #FIXED "1"
183    id ID #IMPLIED>
```

The `<presentation>` section contains some `<module>` that explain briefly the main objectives of the Team.

```
184  <!ELEMENT presentation (module+)>
185  <!ATTLIST presentation
186    titre CDATA #FIXED "Overall Objectives"
187    numero CDATA #FIXED "2"
188    id ID #IMPLIED>
```

The `<fondements>` section contains some `<module>` that explain the scientific foundations of the research of the Team.

```
189  <!ELEMENT fondements (module+)>
190  <!ATTLIST fondements
191    titre CDATA #FIXED "Scientific Foundations"
192    numero CDATA #FIXED "3"
193    id ID #IMPLIED>
```

The `<domaine>` section contains some `<module>` that explain the application domains of the research of the Team.

```
194  <!ELEMENT domaine (module+)>
195  <!ATTLIST domaine
196    titre CDATA #FIXED "Application Domains"
197    numero CDATA #FIXED "4"
198    id ID #IMPLIED>
```

The <logiciels> section contains some <module> that describe the software developed in the Team.

```
199  <!ELEMENT logiciels (module+) >
200  <!ATTLIST logiciels
201      titre CDATA #FIXED "Software"
202      numero CDATA #FIXED "5"
203      id ID #IMPLIED>
```

The <resultats> section is the main section of the Raweb; it contains some <module> that explain the results of the Team for the current year.

```
204  <!ELEMENT resultats (module+) >
205  <!ATTLIST resultats
206      titre CDATA #FIXED "New Results"
207      numero CDATA #FIXED "6"
208      id ID #IMPLIED>
```

The <contrats> section contains some <module> that explain the how the team is funded (it lists the contracts with industry, etc.)

```
209  <!ELEMENT contrats (module+) >
210  <!ATTLIST contrats
211      titre CDATA #FIXED "Contracts and Grants with Industry"
212      numero CDATA #FIXED "7"
213      id ID #IMPLIED>
```

The <international> section contains some <module> that explain national, european, and international activities of the Team.

```
214  <!ELEMENT international (module+) >
215  <!ATTLIST international
216      titre CDATA #FIXED "Other Grants and Activities"
217      numero CDATA #FIXED "8"
218      id ID #IMPLIED>
```

The <diffusion> section contains some <module> that explain the how the research of the Team is diffused (teaching, etc.)

```
219  <!ELEMENT diffusion (module+) >
220  <!ATTLIST diffusion
221      titre CDATA #FIXED "Dissemination"
222      numero CDATA #FIXED "9"
223      id ID #IMPLIED>
```

The <accueil> element provides some information about the Team. The <adresse> element is obsolete, replaced by <UR>. The <typeprojet> is obsolete, replaced by the isproject attribute. The html attribute defines the name of the Team, using only ASCII characters, like ‘Miro’; the <projet> element can be more complicated, like ‘Miró’, and the <projetdeveloppe> may contain “Systèmes à objets, types et prototypes : sémantique et validation” (whenever possible, the language should be the same as in the main document).

```
224  <!ELEMENT accueil (theme,projet,projetdeveloppe,UR,topic*) >
225  <!ATTLIST accueil html CDATA #REQUIRED >
226  <!ATTLIST accueil isproject (true|false) "true">
227  <!ELEMENT typeprojet (#PCDATA)>
228  <!ELEMENT adresse (#PCDATA) >
```

The <theme> should be one of com, cog, num, bio, sym. The official list is defined in the Tralics configuration file.

```

229  <!ELEMENT theme (#PCDATA)>
230  <!ELEMENT projet (#PCDATA|hi)*>
231  <!ELEMENT projetdeveloppe (#PCDATA|hi)* >
```

The `<UR>` element contains some (at least one) references to Inria Research Units. Currently, there are six of them. This may change in a near future, in which case this file has be modified, if you want to validate the Tralics output; on the other hand, the default attribute defined here (for instance the URLs) are not used in the new DTD; so that modifications to the file are not required for construction the Raweb.

```

232  <!ELEMENT UR (URSophia|URRocquencourt|URRhoneAlpes|URRennes|URLorraine|URFuturs)+>
```

The definition of `<URRocquencourt/>` includes the full name (Rocquencourt) and a link to the official web page.

```

233  <!ELEMENT URRocquencourt EMPTY>
234  <!ATTLIST URRocquencourt
235    url CDATA #FIXED "http://www.inria.fr/inria/organigramme/fiche_ur-rocq.en.html"

```

279  <!ELEMENT TeX EMPTY>
280  <!ELEMENT LaTeX EMPTY>
```

### 9.1.3 The bibliography

These are all the possible children of a citation. The `<xref>` element is defined above, others are specific to the bibliography.

```

281  <!ENTITY % bibliostuff "bnote|bauteurs|bediteur|btitle|borganization|
282      bschool|byear|bmonth|xref|bseries|bnumber|bvolume|bedition|
283      binstitution|baddress|bpages|bhowpublished|bbooktitle
284      |bpublisher|bjournal|bchapter|btype|bdoi">
```

The <citation> contains the elements indicated above. It has five attributes. The type attribute reflects the BibTeX type. Entries that have a different type are lost by the Raweb mechanism. There are three required attributes <key>, <from>, <id>. The key is the quantity that will appear in the text, before the reference (however, a postprocessor could re-arrange the list, sort it, and recompute the key). The id identifies the reference, so that it can be referenced. The from attribute is something required by the Raweb, it is used for sorting the citations. Finally, userid is optional: this is the cite key, that appears in the BibTeX source. Useful for debug.

```

285  <!ELEMENT citation (%bibliostuff;)*>
286  <!ATTLIST citation key CDATA #REQUIRED
287          userid CDATA #IMPLIED
288          id ID #REQUIRED

      The type of a technical report (e.g. "Research Notes"). This name is used instead of the
      default "Technical Report". For the type 'phdthesis' you could use the term "Ph.D. dissertation"
      by specifying type="{Ph.D.}dissertation". Similarly, for the <inbook> and <incollection>
      entry types you can get "section 1.2" instead of the default "chapter 1.2" with chapter = "1.2",
      type="Section". Note: the <btype> field is set by Tralics; the semantics is different. Currently,
      the bname value of <bchapter> is used instead of the quantity given here. This might change in
      a future version.
322  <!ELEMENT btype (#PCDATA|hi)* >
323  <!ATTLIST btype bname CDATA #FIXED "type" >
      How something strange has been published. It can contain an external link.
324  <!ELEMENT bhowpublished (#PCDATA|xref|hi)* >
325  <!ATTLIST bhowpublished bname CDATA #FIXED "howpublished" >
      The edition of a book (e.g. "Second"). This should be an ordinal, and should have the first
      letter capitalized, as shown above; the standard styles convert to lowercase when necessary. Note.
      The Raweb leaves this currently unchanged. Thus, be careful.
326  <!ELEMENT bedition (#PCDATA) >
327  <!ATTLIST bedition bname CDATA #FIXED "edition" >
      The number of a journal, magazine, technical report, or work in a series. An issue of a journal
      or magazine is usually identified by its volume and number; a technical report normally has a
      number; and sometimes books in a named series carry numbers.
328  <!ELEMENT bnumber (#PCDATA) >
329  <!ATTLIST bnumber bname CDATA #FIXED "number" >
      The volume of a journal or multivolume book.

The work's title, typed as explained in Section 13.2.2. Note: the companion explains how BibL<sup>A</sup>T<sub>E</sub>X converts some uppercase letters into lower case ones. This does not apply here.

```
342 <!ELEMENT btitle (#PCDATA|hi|TeX|LaTeX|formula)* >
343 <!ATTLIST btitle bname CDATA #FIXED "title" >
```

#### 9.1.4 Research Reports

This DTD could also be used for other documents, like a research report. We declare here divisions of level zero and one.

```
344 <!ELEMENT div0
345   (head, (%div0-textp; | (%tei-aux;, %div0-texts;))) >
346 <!ELEMENT div1
347   (head, (%div1-textp; | (%tei-aux;, %div1-texts;))) >
```

The title page of a Research Report will contain the following items.

```
348 <!ELEMENT RRstart (UR,title, etitle, projet, theme, motcle, keyword,
349   resume, abstract, author, date, RRnumber)*>
```

The `<UR>` element is described above, it indicates in which Research Unit is located the author (since there can be more than one author, more than one UR could be given, but this is refused by L<sup>A</sup>T<sub>E</sub>X). The quantities `<projet>` and `<theme>` define the name of the Team and its theme (this can be repeated). We have then `<title>` and `<etitle>`, the title of the report, in French and English, we have `<motcle>` and `<keyword>`, the keywords in French and English. The content could be more elaborate: for instance we could allow math in the title or keywords. We have also `<resume>` and `<abstract>`, the French and English abstract (paragraphs are allowed here; the abstract should be less than half of a page in length). The element `<auth>` defines a single author, while `<author>` defines a list of authors.

```
350 <!ELEMENT title (#PCDATA|hi|LaTeX)* >
351 <!ELEMENT etitle (#PCDATA|hi|LaTeX)* >
```

```

352  <!ELEMENT resume (#PCDATA|hi|p|LaTeX)* >
353  <!ELEMENT abstract (#PCDATA|hi|p|LaTeX)* >
354  <!ELEMENT motcle (#PCDATA|hi|LaTeX)* >
355  <!ELEMENT keyword (#PCDATA|hi|LaTeX)* >
356  <!ELEMENT RRnumber (#PCDATA)* >
357  <!ELEMENT date (#PCDATA)* >
358  <!ELEMENT author (auth)* >
359  <!ELEMENT auth (#PCDATA)* >

    The could be the document element for a research report.

360  <!ELEMENT rr (RRstart,div0*)>
361  <!ATTLIST rr language CDATA #IMPLIED type CDATA #IMPLIED>

```

## 9.2 The raweb2 DTD

This is the start of the file. Current version is 1.1.2.3, dated 2004/12/16.

```

362  <?xml version="1.0" encoding="iso-8859-1"?>

    For some reason, every element has a prefix; this is currently empty.

363  <!ENTITY % prefix "">

    A name is given for the Xlink namespace.

364  <!ENTITY % XLINK xmlns "http://www.w3.org/1999/xlink" >

    The DTD starts by listing everything in alphabetic order.

365  <!ENTITY % anchor      "%prefix;anchor">

```

A decoration is either `<em>`, `<tt>`, `<i>`, `<b>`, `<big>`, `<small>`, `<sub>`, `<sup>`, or `<strong>`. This corresponds to the `<hi>` element of the old DTD. A inline object is a decoration, or a `<ressource>`, `<ref>`, `<code>`, `<anchor>`, `<formula>`, `<br>`, `<span>`, `<LaTeX>`, or `<TeX>`. A list is `<glosslist>`, `<orderedlist>`, `<simplelist>`, or a `<descriptionlist>`. A doc-block is a `<table>`, a list, or a `<p>`. Finally, a block is a doc-block, a `<footnote>` or a `<object>`.

```

428  <!ENTITY % decoration "%em; | %tt; | %i; | %b; | %big; | %small; | %sub; |
429  %sup; | %strong; "|
430  <!ENTITY % inline "%decoration; | %ressource; | %ref; | %code; | %anchor; |
431  %formula; | %br; | %span; | %LaTeX; | %TeX;" >
432  <!ENTITY % list "%glosslist; | %orderedlist; | %simplelist; | %descriptionlist;">
433  <!ENTITY % doc-block "%table; | %list; | %p;">
434  <!ENTITY % block   "%doc-block; | %footnote; | %object;">
```

We define here two entities; they say that the id attribute is required or optional. In any case it is an ID.

```

435  <!ENTITY % id      "id"          ID      "#IMPLIED">
436  <!ENTITY % id_r    "id"          ID      "#REQUIRED">
```

We define an attribute that says that the language can be French or English. We declare also some attributes used for links.

```

437  <!ENTITY % xml-lang   'xml:lang'   ( fr | en )           "en"      '>
438
439  <!ENTITY % xlink
440      'xmlns:xlink'  CDATA           #FIXED "%XLINK.xmlns;" 
441      xlink:href    CDATA           #REQUIRED
442      xlink:type   CDATA           #FIXED "simple"
443      xlink:show    ( new | replace | embed ) "replace"
444      xlink:actuate ( onLoad | onRequest ) "onRequest">
```

We declare here three files and include them. We have inlined the persons.mod file. We do not show the biblio.dtd file; it is a copy of the TEI, and is rather long.

```

445  <!ENTITY % persons-mod SYSTEM "persons.mod">
446  <!ENTITY % mathmlDTD SYSTEM "mathml2.dtd">
447  <!ENTITY % biblioDTD SYSTEM "biblio.dtd">
448  %mathmlDTD;
449  %biblioDTD;
450  %persons-mod;
```

We define here some abbreviations. A listSection defines the list of the eight standard sections: we have `<presentation>`, `<fondements>`, `<domaine>`, `<logiciels>`, `<resultats>`, `<contrats>`, `<international>`, `<diffusion>`. These are the same sections as in the old DTD. A contentSection describes what you can put in a section: an optional `<bodyTitle>` followed by some `<block>` or `<subsection>`.

```

451  <!ENTITY % listSection "(%presentation;), (%fondements;)?,
452      (%domaine;)?, (%logiciels;)?, (%resultats;), (%contrats;)?,
453      (%international;)?, (%diffusion;)?">
454  <!ENTITY % contentSection "(%bodyTitle;)?, ((%block;)* | (%subsection;)*)">
```

Here are the sections. They all have id as required attribute.

```

455  <!ELEMENT %presentation; ( %contentSection; )>
456  <!ATTLIST %presentation; %id_r;>
457
458  <!ELEMENT %fondements; ( %contentSection; )>
459  <!ATTLIST %fondements; %id_r;>
460
461  <!ELEMENT %domaine; ( %contentSection; )>
462  <!ATTLIST %domaine; %id_r;>
463
464  <!ELEMENT %logiciels; ( %contentSection; )>
465  <!ATTLIST %logiciels; %id_r;>
466
467  <!ELEMENT %resultats; ( %contentSection; )>
468  <!ATTLIST %resultats; %id_r;>
469
470  <!ELEMENT %contrats; ( %contentSection; )>
471  <!ATTLIST %contrats; %id_r;>
472
473  <!ELEMENT %international; ( %contentSection; )>
474  <!ATTLIST %international; %id_r;>
```

```

475   <!ELEMENT %diffusion; ( %contentSection; )>
476   <!ATTLIST %diffusion; %id_r;>
```

We define identSection to be the identification part of a section; this is a list of <participants>, a list of <keyword> and an optional <moreinfo>.

```

478   <!ENTITY % identSection "( (%participants;)*, (%keyword;)*, (%moreinfo;)?)">
```

A <subsection> is formed of an optional <bodyTitle>, an identSection, followed by blocks or <subsection>. It can have a topic attribute. Note: only children of a section can have a topic.

```

479   <!ELEMENT %subsection; ( (%bodyTitle;)?, (%identSection;),
480     ((%block; | (%subsection;))* ) >
481   <!ATTLIST %subsection;

      A <refperson> is a link to a <person>.
590  <!ELEMENT %refperson; EMPTY>
591  <!ATTLIST %refperson; ref IDREF #REQUIRED>
      This defines an <object> and a <ressource>. An object can be used to include a floating
      figure.
592  <!ELEMENT %object; ( (%bodyTitle;)?, (%table;)+, (%caption;)? ) >
593  <!ATTLIST %object; %id_r;>
594  <!ELEMENT %ressource; ( (%caption;)? ) >
595  <!ATTLIST %ressource;
596      %id;
597      %xlink;
598      media (WEB | PRINT ) "WEB"
599      width NMTOKEN #IMPLIED
600      height NMTOKEN #IMPLIED
601      preview CDATA #IMPLIED
602      type (inline|display) "inline"
603      framed CDATA #IMPLIED
604      scale CDATA #IMPLIED
605      angle CDATA #IMPLIED>
      Math formulas are defined like in the old DTD.
606  <!ELEMENT %formula; ( %simplemath; | %math.qname; ) >
607  <!ATTLIST %formula; %id; type (inline|display) "inline" >
608  <!ELEMENT %simplemath; (#PCDATA | %inline;)* >
609  <!ATTLIST %simplemath; %id; type (inline|display) "inline" >

```

### 9.3 The classes DTD

We use the classes DTD for converting the Tralics examples and documentation into XML and HTML. It is a modification of the raweb DTD, hence we show here only the differences. It is highly experimental.

These definitions are needed to ‘rawxml’ example.

```

1  <!ENTITY Dollar  "&#x24;" >
2  <!ENTITY Euro   "&#x20AC;" >
3  <!ENTITY Equals  "&#x3D;" >
```

The raweb does not use `<div0>` and `<div1>`. Its DTD defines the element and the content, but we forget to define the attribute list. It is however important that the style sheets sees the ‘ID’ type of the id of the element.

```

4  <!ATTLIST div0 %tei-div-atts; >
5  <!ATTLIST div1 %tei-div-atts; >
```

We added a `<div5>` element, that can be converted into a `<h6>` HTML element. What about `<div6>?`

```

6  <!ELEMENT div5  (head, %ramodule-header;, %tei-aux;) >
7  <!ATTLIST div5 %tei-div-atts; >
```

An `<index>` element has three attributes. We declare here only `target`. Our style sheet does not work without it.

```

8  <!ELEMENT index (#PCDATA | %texte-general; | p )* >
9  <!ATTLIST index target IDREFS #REQUIRED>
```

# Index

In this index, the page number of a command refers often to the start of the verbatim block where it is used or defined. In many cases, you will find the command one page after the number given in the index.
