**Abstract:** We investigate the lines tangent to four triangles in three-dimensional space. By a construction, there can be as many as 62 tangents. We show that there are at most 162 connected components of tangents, and at most 156 if the triangles are disjoint. In addition, if the triangles are in (algebraic) general position, then the number of tangents is finite and it is always even.

**Key-words:** Computational geometry, 3D visibility, line transversals, tangent lines.

## **Droites tangentes à quatre triangles en trois dimensions**

**Résumé :** Nous nous intéressons aux droites tangentes à quatre triangles en trois dimensions. Nous montrons par construction que quatre triangles peuvent admettre jusqu'à 62 tangentes communes. Nous montrons également que quatre triangles admettent au plus 162 composantes connexes de tangentes et au plus 156 si les triangles sont disjoints. De plus, si les triangles sont en position générique, alors le nombre de tangentes est fini et pair.

**Mots-clés :** Géométrie algorithmique, visibilité 3D, droites transversales, tangentes.

## Introduction

Motivated by visibility problems, we investigate lines tangent to four triangles in  $\mathbb{R}^3$ . In computer graphics and robotics, scenes are often represented as unions of not necessarily disjoint polygonal or polyhedral objects. The objects that can be seen in a particular direction from a moving viewpoint may change when the line of sight becomes tangent to one or more objects in the scene. Since this line of sight is tangent to a subset of the edges of the polygons and polyhedra representing the scene, we are also led to questions about lines tangent to segments and to polygons. Four polygons will typically have finitely many common tangents, while 5 or more will have none and 3 or fewer will have either none or infinitely many.

This paper follows a series of papers by the authors and their collaborators investigating such questions. The paper [4] investigated the lines of sight tangent to four convex polyhedra in a scene of  $k$  convex but not necessarily disjoint polyhedral objects, and proved that there could be up to but no more than  $\Theta(n^2k^2)$  connected components of such lines. The same bound for the considerably easier case of disjoint convex polyhedra in algebraic general position was proved earlier [10, 3]. The paper [6] offers a detailed study of transversals to  $n$  line segments in  $\mathbb{R}^3$  and proved that although there are at most 2 such transversals for four segments in (algebraic) general position, there are at most  $n$  such connected components of transversals in any case. Dealing with curved objects in  $\mathbb{R}^3$ , the paper [2] studies the tangent lines to four arbitrary spheres and [8] shows that there is a linear expected number of maximal non-occluded line segments tangent to four among  $n$  uniformly distributed unit balls.

Halperin and Sharir [12], and Pellegrini [13], proved that, in a polyhedral terrain, the set of free lines with  $n$  edges has near-cubic complexity. De Berg, Everett and Guibas [7] showed a  $\Omega(n^3)$  lower bound on the complexity of the set of free lines (and thus free segments) among  $n$  disjoint homothetic convex polyhedra. Recently, Agarwal et al. [1] proved that the set of free lines among  $n$  unit balls has complexity  $O(n^{3+\epsilon})$ . For related books and surveys, see [9, 11, 14, 15].

In this paper, we consider the case of four triangles in  $\mathbb{R}^3$ , and establish lower and upper bounds on the number of tangent lines.

A *triangle* in  $\mathbb{R}^3$  is the convex hull of three distinct (and non-collinear) points in  $\mathbb{R}^3$ . A line is *tangent* to a triangle if it meets an edge of the triangle. Note that a line tangent to each of four triangles forming a scene corresponds to an unoccluded line of sight in that scene. If there are  $k > 4$  triangles, then the bound  $\Theta(k^4)$  of [4] stands (as the total number of edges is  $n = 3k$  and one of the lower bound examples is made of triangles). We thus investigate the case of four triangles. Let  $n(t_1, t_2, t_3, t_4)$  be number of lines tangent to four triangles  $t_1, t_2, t_3$ , and  $t_4$  in  $\mathbb{R}^3$ . This number may be infinite if the lines supporting the edges of the different triangles are not in general position.

Our first step is to consider the algebraic relaxation of this geometric problem in which we replace each edge of a triangle by the line in  $\mathbb{C}\mathbb{P}^3$  supporting it, and then ask for the set of lines in  $\mathbb{C}\mathbb{P}^3$  which meet one supporting line from each triangle. Since there are  $3^4 = 81$  such quadruples of supporting lines, this is the disjunction of 81 instances of the classical problem of transversals to four given lines in  $\mathbb{C}\mathbb{P}^3$ . As there are two such transversals to four given lines in general position, we expect that this algebraic relaxation has 162 solutions. We say that four triangles  $t_1, t_2, t_3, t_4$  are in (algebraic) *general position* if each of the 81 quadruples of supporting lines have two transversals

Figure 1: The lines  $\ell_1$ ,  $\ell_2$  and  $\ell_3$  span a hyperbolic paraboloid  $Q$  which meets line  $\ell_4$  in two points. The two lines  $\lambda_1$  and  $\lambda_2$  are the transversals to the four lines  $\ell_1$ ,  $\ell_2$ ,  $\ell_3$ , and  $\ell_4$ .

in  $\mathbb{C}\mathbb{P}^3$  and all 162 transversals are distinct. Let  $\mathcal{T}$  be the configuration space of all quadruples of triangles in  $\mathbb{R}^3$  and  $T \subset \mathcal{T}$  consist of those quadruples which are in general position. Thus if  $(t_1, t_2, t_3, t_4) \in T$ , the number  $n(t_1, t_2, t_3, t_4)$  is finite and is at most 162.

Our primary interest is the number

$$N := \max\{n(t_1, t_2, t_3, t_4) \mid (t_1, t_2, t_3, t_4) \in T\}.$$

Our results about this number  $N$  are two-fold. First, we show that  $N \geq 62$ .

**Theorem 1** *There are four disjoint triangles in  $T$  with 62 common tangent lines.*

The idea is to perturb a configuration of four lines in  $\mathbb{R}^3$  with two real transversals, such as in Figure 1. The triangles in our construction are very ‘thin’—the smallest angle among them measures about  $10^{-11}$  degrees. We ran a computer search for ‘fatter’ triangles having many common tangents, checking the number of tangents to 5 million different quadruples of triangles. It appears that random quadruples of realistic triangles often have a fair number of common tangents. Several had as many as 40 common tangents, and quadruples that admit common tangents have 16 tangents or more with probability at least 15%. This is discussed in Section 4.

We can improve the upper bound on  $N$  when the triangles are disjoint.

**Theorem 2** *Four triangles in  $T$  admit at most 162 distinct common tangent lines. This number is at most 156 if the triangles are disjoint.*

We believe, however, that the upper bounds we give here are far from optimal. When the four triangles are not in general position, the number of tangent lines can be infinite. In this case, we

may group these tangents by connected components: two line tangents are in the same component if one may move continuously between the two lines while staying tangent to the four triangles. Each quadruple of edges may induce up to four components of tangent lines [6], giving a trivial upper bound of 324. This may be improved.

**Theorem 3** *Four triangles have at most 162 connected components of common tangents. If the triangles are disjoint, then this number is at most 156.*

We also have a congruence result.

**Theorem 4** *If  $(t_1, t_2, t_3, t_4) \in T$ , then  $n(t_1, t_2, t_3, t_4)$  is even.*

This result may not seem surprising as complex roots come in conjugate pairs. However, this usual argument does not apply because we seek tangents to triangles and not transversals to lines. Frequently, only one of two real transversals to a quadruple of supporting lines is tangent to the triangles. The main new idea behind Theorem 4 is that such tangent lines essentially come in pairs.

Theorems 1, 2, and 3 are proved in Sections 1, 2, and 3, respectively. Section 4 discusses our search for ‘fat’ triangles with many common tangents. Finally, we prove Theorem 4 in Section 5.

## 1 A construction with 62 tangents

Consider the four triangles whose vertices are given in Table 1.

$t_1$	(-10.5, 1, -10.5) (.5628568345479573470378601, 1, .5628568345479573470378601) (.56285683454726874605620706, .9999999999822994290647247, .56285683454726874605620706)
$t_2$	(-10.5, -1, 10.5) (1.394218989475, -1, -1.394218989475) (1.3942406911811439954597161, -1.0000237884694881275439271, -1.3942406911811439954597161)
$t_3$	(-9.5, -9.5, .25) (.685825, .685825, .25) (.69121730616063647303519136, .69121730616063647303519136, .26069756890079842876805653)
$t_4$	(9.5, 0, 0) (-.511, 0, 0) (-1.0873912730501133759642956, 0, -.51645811088049333541289247)

Table 1: Four triangles with 62 common tangents

**Theorem 1’.** *There are exactly 62 lines tangent to the four triangles of Table 1.*

This can be verified by a direct computation. Software is provided on this paper’s web page<sup>†</sup>. More illuminating perhaps is our construction. The idea is to perturb a configuration of four lines in  $\mathbb{R}^3$  with two transversals such as in Figure 1. The resulting triangles of Theorem 1’ are very thin. In degrees, their smallest angles are

$$t_1: 6.482 \times 10^{-12}, \quad t_2: 8.103 \times 10^{-5}, \quad t_3: 4.253 \times 10^{-2}, \quad \text{and} \quad t_4: 2.793.$$

Figure 2: Conics in the planes  $\pi_i$ 

### 1.1 A construction with 62 tangents

The lines given parametrically

$$\ell_1 : (t, 1, t), \quad \ell_2 : (t, -1, -t), \quad \ell_3 : (t, t, \frac{1}{4}), \quad \text{and} \quad \ell_4 : (t, 0, 0),$$

have two transversals

$$\lambda_1 : (\frac{1}{2}, 2t, t) \quad \text{and} \quad \lambda_2 : (-\frac{1}{2}, 2t, -t).$$

For each  $i = 1, 2, 3, 4$ , let  $Q_i$  be the hyperboloid spanned by the lines other than  $\ell_i$ . For example,  $Q_3$  has equation  $z = xy$ . The intersection of  $Q_i$  with a plane containing  $\ell_i$  will be a conic which meets  $\ell_i$  in two points (corresponding to the common transversals  $\lambda_1$  and  $\lambda_2$  at  $t = \pm \frac{1}{2}$ ). We choose the plane  $\pi_i$  so that these two points lie in the same connected component of the conic. Here is one possible choice

$$\pi_1 : x = z, \quad \pi_2 : x = -z, \quad \pi_3 : x = y, \quad \text{and} \quad \pi_4 : y = 0.$$

For each  $i$ , let  $C_i$  be the conic  $\pi_i \cap Q_i$ , shown in the plane  $\pi_i$  in Figure 2. Here, the horizontal coordinate is  $t$ , the parameter of the line  $\ell_i$ , while the vertical coordinate is  $y-1$  for  $\pi_1$ ,  $y+1$  for  $\pi_2$ ,  $z - \frac{1}{4}$  for  $\pi_3$ , and  $z$  for  $\pi_4$ .

For each  $i = 1, \dots, 4$ , rotate line  $\ell_i$  in plane  $\pi_i$  very slightly about a point that is far from the conic  $C_i$ , obtaining a new line  $k_i$  in  $\pi_i$  which also meets  $C_i$  in two points. Consider now the transversals to  $\ell_i \cup k_i$ , for  $i = 1, \dots, 4$ . Because  $k_i$  is near to  $\ell_i$  and there were two transversals to  $\ell_1, \ell_2, \ell_3, \ell_4$ , there will be 2 transversals to each of the 16 quadruples of lines obtained by choosing one of  $\ell_i$  or  $k_i$  for  $i = 1, \dots, 4$ . By our choice of the point of rotation, all of these will meet  $\ell_i$  and  $k_i$  in one of the two thin wedges they form. In this wedge, form a triangle by adding a third side so that the edges on  $\ell_i$  and  $k_i$  contain all the points where the transversals meet the lines. The resulting triangles will then have at least 32 common tangents. We claim that by carefully choosing the third side (and tuning the rotations) we are able to get 30 additional tangents.

To begin, look at Figure 3 which displays the configuration in  $\pi_4$  given by the four triangles from Table 1. Since the lines  $\ell_i$  and  $k_i$  for  $i = 1, 2$  are extremely close, the four conics given by transversals

Figure 3: Configuration in plane  $\pi_4$

to them and to  $\ell_3$  cannot be resolved in these pictures. The same is true for the four conics given by  $k_3$ , so that each of the apparent 2 conics are clusters of four nearby conics. The picture on the left is a view of this configuration in the coordinates for  $\pi_4$  of Figure 2. It includes a secant line  $m_4$  to the conics. We choose coordinates on the right so that  $m_4$  is vertical, but do not change the coordinates on  $\ell_4$ . The horizontal scale has been accentuated to separate the two clusters of conics. The three lines,  $\ell_4$ ,  $k_4$ , and  $m_4$  form the triangle  $t_4$ . Let its respective edges be  $e_4$ ,  $f_4$ , and  $g_4$ . Each edge meets each of the 8 conics in two points and these 48 points of intersection give 48 lines tangent to the four triangles.

This last assertion that the 16 lines transversal to  $m_4$  and to  $\ell_i \cup k_i$  for  $i = 1, 2, 3$  meet the edges of the triangles  $t_1$ ,  $t_2$ , and  $t_3$  needs justification. Consider for example the transversals to  $\ell_1$ ,  $\ell_2$ , and  $\ell_3$ . These form a ruling of the doubly-ruled quadric  $Q_4$  and are parameterized by their point of intersection with  $\ell_1$ . The intersection of  $Q_4$  with  $\pi_4$  is the conic  $C_4$ . Since the intersections of the conic  $C_4$  with the segment  $g_4$  supported on  $m_4$  lie between its intersections with  $\ell_4$  and  $k_4$ , the corresponding transversals to  $\ell_1$ ,  $\ell_2$ ,  $\ell_3$ , and  $g_4$  meet  $\ell_1$  between points of  $\ell_1$  met by common transversals to  $\ell_4 \cup k_4$  and  $\ell_1$ ,  $\ell_2$ , and  $\ell_3$ . The same argument for the other lines and for all 8 conics justifies the assertion.

Naively, we would expect that this same construction (the third side cutting all 8 conics in  $\pi_i$ ) could work to select each of the remaining sides of the triangles  $g_3$ ,  $g_2$ , and  $g_1$ , and that this would give four triangles having  $32 + 16 + 16 + 16 = 96$  common tangents. Unfortunately this is not the case. In the earlier conference version of this paper [5], we gave a construction that we claimed would yield 88 common tangents. Attempting that construction using Maple revealed a flaw in the argument and the current construction of four triangles with 62 common tangents is the best we can accomplish.

Figure 4: Stabbing and non-stabbing configurations

In  $\pi_4$ , the conics come in two clusters, depending upon whether or not they correspond to  $\ell_3$  or to  $k_3$ . In order for the edge  $g_4$  to cut all conics, the angle between  $\ell_4$  and  $k_4$  has to be large, in fact significantly larger than the angle between  $\ell_3$  and  $k_3$ . Thus in  $\pi_3$ , the conics corresponding to  $\ell_4$  are quite far from the conics corresponding to  $k_4$ , and the side  $g_3$  can only be drawn to cut four of the conics, giving 8 additional common tangents. Similarly,  $g_2$  can only cut two conics, and  $g_1$  only 1. In this way, we arrive at four triangles having  $32 + 16 + 8 + 4 + 2 = 62$  common tangents, which we can verify by computer. 

## 2 Upper bound for disjoint triangles in general position

Four triangles in  $T$  have at most 162 common tangents. If the triangles are disjoint, we slightly improve this upper bound to 156. Our method will be to show that not all  $81 = 3^4$  quadruples of edges can give rise to a common tangent. Our proof follows that for the upper bound on the number of tangents to four polytopes [3], limiting the number of configurations for disjoint triangles in  $\mathbb{R}^3$ . We divide the proof into two lemmas, which do not assume that the triangles lie in  $T$ .

In order for a tangent to meet an edge  $e$ , the plane it spans with  $e$  must meet one edge from each of the other triangles. A triple of edges, one from each of the other triangles, is *contributing* if there is a plane containing  $e$  which meets the three edges. We say that an edge  $e$  *stabs* a triangle  $t$  if its supporting line meets the interior of  $t$ .

**Lemma 5** *Let  $e$  be an edge of some triangle. If  $e$  stabs exactly one of the other triangles, then there are at most 26 contributing triples of edges. If  $e$  stabs no other triangle, then there are at most 25 contributing triples.*

It is not hard to see that if  $e$  stabs at least two of the other triangles, then each of the  $27 = 3^3$  triples of edges can be contributing.

*Proof.* Suppose that  $e$  is an edge of some triangle. Let  $\pi(\alpha)$  be the pencil of planes containing  $e$ . (This is parameterized by the angle  $\alpha$ .) For each edge  $f$  of another triangle  $t$ , there is an interval of angles  $\alpha$  for which  $\pi(\alpha)$  meets  $f$ . Figure 4 illustrates the two possible configurations for these intervals, which depend upon whether or not  $e$  stabs the triangle  $t$ . The intervals are labeled 1, 2, and 3 for the three edges of  $t$ . When  $e$  stabs  $t$ , these intervals cover the entire range of  $\alpha$  and the picture

Figure 5: Configurations with 26 and 25 contributing triples

is actually wrapped. Call this a *stabbing diagram*. When the supporting line of  $e$  does not meet  $t$ , these intervals do not cover the entire range of  $\alpha$ , and there are two endpoints and one *interior vertex* of the diagram. If the supporting line of  $e$  meets an edge of  $t$ , then the two endpoints of the non-stabbing diagram wrap around and coincide. Call either of these last two configurations a non-stabbing diagram.

To count contributing triples, we line up (overlay) diagrams from each of the three triangles not containing  $e$  and count how many of the 27 triples  $\{1, 2, 3\}^3$ , one from each triangle, occur at some value of  $\alpha$ . For example, Figure 5 displays a configuration with 26 contributing triples (where  $e$  stabs a single triangle) and a configuration with 25 contributing triples ( $e$  stabs no other triangles). The configuration on the left is missing the triple  $(2, 3, 3)$ , while the configuration on the right is missing the triples  $(2, 2, 3)$  and  $(3, 3, 2)$ .

These configurations are the best possible. Indeed, begin with two non-stabbing diagrams in which all 9 pairs of edges occur. (If only 8 pairs occurred, there would be at most 24 contributing triples.) The unique way to do this up to relabeling the edges is given by the lower two diagrams in either picture in Figure 5. These two diagrams divide the domain of  $\alpha$  into 6 intervals (the two at the ends are wrapped). The five pairs involving 1 occur in two intervals, but four exceptional pairs  $\{(2, 2), (2, 3), (3, 2), (3, 3)\}$  occur uniquely in different intervals.

Consider now a third diagram. An exceptional pair extends to three contributing triples only if all three sides in the third diagram meet the interval corresponding to that pair. If the third diagram is stabbing, then one of its three vertices lies in that interval—thus there is at least one triple which does not contribute. If the third diagram is non-stabbing, then either the middle vertex or else both endpoints must lie in that interval—thus there are at least two triples which do not contribute. 

**Lemma 6** *At most 78 quadruples of edges of four disjoint triangles can lead to a common tangent.*

*Proof.* First consider the maximum number of stabbing edges between two triangles. If the triangles are disjoint, then there are at most three stabbing edges; one triangle could have three edges stabbing

Figure 6: (a) Two disjoint triangles can have at most 3 stabbing lines. (b) Two intersecting triangles may have up to four.

the other. Indeed, if at least two supporting lines of a triangle  $t$  meet another triangle  $t'$  which is disjoint from  $t$ , then  $t$  lies entirely on one side of the plane supporting  $t'$ , and thus no supporting lines of  $t'$  can meet  $t$ . Figure 6(a) shows a configuration in which all three supporting lines of  $t$  stab  $t'$ .

Consider now the bipartite graph between 12 nodes representing the edges of the four triangles and 4 nodes representing the triangles. This graph has an arc between an edge  $e$  and a triangle  $t$  if the line supporting  $e$  stabs  $t$ . (We assume that  $e$  is not an edge of  $t$ .) We just showed that the edges of one triangle  $t$  can have at most 3 arcs incident on another triangle  $t'$ , and so this graph has at most 18 edges.

Let the weight of a triangle be the number of arcs emanating from its edges in this graph. As the graph has at most 18 arcs, at least one triangle has weight less than 5. We argue that there is a triangle of weight at most 3. This is immediate if the graph has 15 or fewer edges. On the other hand, this graph has more structure. If it has 18 edges, then all pairs of triangles are in the configuration of Figure 6(a), and so every triangle has weight a multiple of 3, which implies that some triangle has weight at most 3. If the graph has 17 edges, then there is exactly one pair of triangles with only two stabbing edges, and so the possible weights less than 5 are 0, 2, and 3. If the graph has 16 edges, then there is one pair with only one edge stabbing, or two pairs with 2 edges stabbing. There can be at most 2 triangles of weight 4, and again we conclude that there is triangle with weight at most 3.

If a triangle has weight at most three, either all three edges stab a unique triangle, or else one edge stabs no triangles and another edge stabs at most one other triangle. We sum the number of contributing triples over the edges of this triangle. By Lemma 5, this sum will be at most  $26+26+26=78$  if all three edges stab a unique triangle and at most  $27+26+25=78$  if not. This proves the lemma. 

**Remark 7** There exist four disjoint triangles whose bipartite graph has exactly 18 edges. Thus the previous argument cannot be improved without additional ideas. It is conceivable that further restrictions the bipartite graph may exist, leading to a smaller upper bound.

**Remark 8** This proof does not enable us to improve the bound when the triangles are not disjoint. Two intersecting triangles can induce up to four arcs (see Figure 6(b)) and thus the total number of arcs is bounded above by 24. The minimal weight of a triangle is then 6, and the edges of such a triangle could all have degree 2, which leads to no restrictions.

### 3 Upper bound on the number of components

Let  $\mathcal{F}$  and  $I$  be the sets of quadruples of edges, one from each of four triangles, whose supporting lines have finitely and infinitely, respectively, many common transversals. Let  $n_{\mathcal{F}}$  and  $n_I$  be the sum over all quadruples of edges in  $\mathcal{F}$  and  $I$ , respectively, of the numbers of connected components of common transversals to each quadruple of edges. Note that the number of quadruples in  $\mathcal{F}$  and  $I$  is  $|\mathcal{F}| + |I| = 81$ .

Consider a connected component  $c$  of common transversals to a quadruple of edges  $q \in I$ . The arguments of [6] show that  $c$  contains a line that meets a vertex of one of the four edges. That line is thus transversal to another quadruple  $q'$  of edges. Thus, the connected component  $c$  of common transversals to  $q$  is connected with a connected component  $c'$  of common transversals to  $q'$ . If  $q' \in \mathcal{F}$  we charge the component  $c \cup c'$  to  $c'$ . Otherwise  $q$  and  $q'$  are both in  $I$  and the component  $c \cup c'$  is counted twice. The number of connected components of tangents to four triangles is thus at most  $n_{\mathcal{F}} + n_I/2$ .

Since any four lines admit at most 2 or infinitely many transversals,  $n_{\mathcal{F}} \leq 2|\mathcal{F}|$ . Also, any four segments admit at most 4 connected components of common transversals [6], thus  $n_I \leq 4|I|$ . Hence, the number of connected components of tangents to four triangles is at most  $2|\mathcal{F}| + 2|I| = 162$ .

This still may overcount the number of connected components of tangents, but further analysis is very delicate. Such complicated arguments are not warranted as we have already obtained the upper bound of 162 common tangents to four triangles in  $T$ . As in Section 2, if the triangles are disjoint, then not all quadruples of edges can contribute, which lowers this bound to 156.

### 4 Random triangles

We proved Theorem 1 by exhibiting four triangles having 62 common tangents. We do not know if that is the best possible. Since the geometric problem of determining the tangents to four triangles is computationally feasible—it is the disjunction of 81 problems with algebraic degree 2 and simple inequalities on the solutions—we investigated it experimentally.

For this, we generated 5 000 000 quadruples of triangles whose vertices were points with integral coordinates chosen uniformly at random from the cube  $[-1000, 1000]^3$ . For each, we computed the number of tangents. The resulting frequencies are recorded in Table 2. This search consumed over 6 months of CPU time on 1.2GHz processors at the MSRI and a DEC Alpha machine at the University of Massachusetts in 2004. It is archived on the web page<sup>†</sup> accompanying this article.

In this search, we found four different quadruples of triangles with 40 common tangents, and none with more. The vertices of one are given in Table 3. These triangles are rather ‘fat’, in that none

Table 2: Number of triangles with a given number of tangents, out of 5 000 000 randomly constructed triangles

Triangle	Vertices		
$t_1$	$(-4, -731, -336)$	$(297, -507, 978)$	$(824, -62, -359)$
$t_2$	$(531, -631, -820)$	$(-24, -716, 713)$	$(807, 377, 177)$
$t_3$	$(586, -205, 952)$	$(861, -774, 235)$	$(-450, 758, 161)$
$t_4$	$(330, -141, -908)$	$(942, -920, 651)$	$(-226, 489, 968)$

Table 3: Four triangles with 40 common tangents

have very small angles. Contrast that to the triangles of our construction in Section 2. In Figure 7 we compare these two configurations of triangles. On the left is the configuration of triangles from Table 3, together with their 40 common tangents, while on the right is the configuration of triangles having 62 common tangents. The triangles are labeled in the second diagram, as they are hard to distinguish from the lines. As we remarked in Section 2, many of the lines are extremely close and cannot be easily distinguished; that is why one can only count 8 lines in this picture.

## 5 A congruence

We prove Theorem 4 by considering four *moving* triangles, and showing that common tangents are created and destroyed in pairs, and so the parity of  $n(t_1, t_2, t_3, t_4)$  does not change. There are two cases to consider. The first is when two real tangents which are transversal to the same four edges coalesce and become a pair of complex conjugate transversals; this is the ‘usual’ argument. The second case is when a real transversal to edges  $e_1, e_2, e_3$ , and  $e_4$  moves off of  $e_4$  and is thus no longer tangent to the four triangles. In doing so, it must pass through a vertex  $v$  of  $e_4$ . In this case, there is a real transversal to edges  $e_1, e_2, e_3$ , and some other edge  $e'_4$  meeting  $v$  which simultaneously moves off of  $e'_4$ , also passing through the vertex  $v$ . The theorem follows as there are triangles in  $T$  with no common tangents.

We study the complement  $\Sigma$  of  $T$  in the set  $\mathcal{T}$  of quadruples of all triangles. The reason is that the number  $n(t_1, t_2, t_3, t_4)$  of common tangents is constant in each connected component of  $T$  and so

Figure 7: Triangles with many common tangents

we must pass through  $\Sigma$  to connect quadruples in  $T$ . This is called ‘crossing a wall’. Since the set of smooth points of  $\Sigma$  is open and dense in  $\Sigma$ , a path may be found which meets  $\Sigma$  only in its smooth points. Since a smooth point lies on a unique algebraic component, each crossing involves only one algebraic component of  $\Sigma$ , and so we must also describe the different algebraic components of  $\Sigma$ . This amounts to describing what happens near a smooth point of  $\Sigma$ . Note that  $\Sigma$  is also called the discriminant hypersurface of  $\mathcal{T}$ .

Recall that a quadruple  $(t_1, t_2, t_3, t_4)$  lies in  $T$  only if

- (A) There are two lines in  $\mathbb{CP}^3$  transversal to each quadruple  $\ell_1, \ell_2, \ell_3, \ell_4$  of lines supporting one edge from each triangle, and
- (B) the 162 such lines are distinct.

**Lemma 9** *Each complex algebraic component of  $\Sigma$  contains an open dense set on which exactly one of (a) or (b)(i) or (b)(ii) occurs.*

- (a) *There is a unique transversal  $\lambda$  in  $\mathbb{CP}^3$  to one quadruple of supporting lines.*
- (b) *One of the lines  $\lambda$  meeting one quadruple of supporting lines  $\ell_1, \ell_2, \ell_3, \ell_4$  meets one other supporting line  $\ell'$ . There are two ways for this to occur. Either*
  - (i)  *$\lambda$  meets a vertex of the triangle having  $\ell'$  as a supporting line, or*
  - (ii)  *$\lambda$  lies in the plane of the triangle having  $\ell'$  as a supporting line.*

In each case, the distinguished line  $\lambda$  is real.

*Proof.* We consider what happens when one of the conditions (A) or (B) fails, but the rest of the configuration remains generic. For (A), if there is a quadruple  $\ell_1, \ell_2, \ell_3, \ell_4$  of supporting lines without two common transversals, then either there is only one transversal or there are infinitely many. Since we are considering generic such configurations, we may assume that  $\ell_1, \ell_2$ , and  $\ell_3$  are in general position in that they span a quadric  $Q$  as in Figure 1, and ask what happens as  $\ell_4$  moves out of general position. If  $\ell_4$  meets one of  $\ell_1, \ell_2$ , or  $\ell_3$ , there still will be two lines, but if  $\ell_4$  becomes tangent to  $Q$ , then there will only be one, as the two lines  $\lambda_1$  and  $\lambda_2$  coalesce. Further degeneration is required for there to be infinitely many lines, since  $\ell_4$  has then to become contained in  $Q$ . Thus (a) describes what happens generically when (A) fails for a single quadruple of supporting lines.

For (B), we may assume that each quadruple of supporting lines has two transversals, but there are two quadruples with a common transversal. The generic way for this to occur is described in (b). That is,  $\ell_1, \ell_2$ , and  $\ell_3$  are in general position and a line  $\lambda$  meeting all three also meets both  $\ell_4$  and  $\ell'$ , and also  $\ell_4$  and  $\ell'$  are lines supporting edges from the same triangle,  $t_4$ . Since  $\ell_4$  and  $\ell'$  meet in a vertex  $v$  of  $t_4$  and also span the plane  $\pi_4$  of  $t_4$ , either  $\lambda$  meets  $v$  or else  $\lambda$  lies in  $\pi_4$ , and these are the two cases (b)(i) and (b)(ii). As we consider configurations which are otherwise general, exactly one of these two possibilities occurs.

To see that it is possible for exactly one of (a) or (b)(i) or (b)(ii) to occur, begin with a configuration of four triangles in  $T$ , and allow exactly one supporting line of one triangle to rotate about one vertex, remaining in the plane of the triangle. Perturbing the plane of this last triangle if necessary, we see that only the configurations described in (a) or (b)(i) or (b)(ii) can occur, each will occur finitely many times, and they will occur for distinct angles of rotation. This shows that each different possibility describes different algebraic components of the discriminant, and that each component has an open dense set in which exactly one of these possibilities occurs.

Since the lines and vertices defining the special line  $\lambda$  are all real and  $\lambda$  is unique, it will also be real. 

*Proof of Theorem 4.* Suppose now that we have two quadruples of triangles in  $T$ . A consequence of Lemma 9 is that there exists a path  $\gamma$  in  $\mathcal{T}$  connecting them such that each time  $\gamma$  meets the discriminant hypersurface  $\Sigma$ , exactly one of (a) or (b)(i) or (b)(ii) occurs. We need only show that the parity of the number of tangents does not change as we move along  $\gamma$  and one of (a) or (b)(i) or (b)(ii) occurs.

If (a) occurs, the number of tangents changes only if the double line  $\lambda$  is tangent to the triangles. Approaching this configuration along the curve  $\gamma$ , either two real lines or two complex lines coalesce into  $\lambda$ . Thus the parity of  $n(t_1, t_2, t_3, t_4)$  does not change when crossing  $\Sigma$  in a component of type (a).

For (b)(i), we suppose that  $\ell' = \ell'_4$  is the line supporting an edge of the fourth triangle,  $t_4$ . Let  $C_4$  be the conic which is the intersection of the hyperboloid spanned by  $\ell_1, \ell_2$ , and  $\ell_3$  with the plane  $\pi_4$  spanned by  $t_4$ . Through every point of  $C_4$  there is a unique line meeting  $\ell_1, \ell_2$ , and  $\ell_3$ . In particular, the line  $\lambda$  corresponds to the vertex  $v$  of  $t_4$  where  $\ell_4$  meets  $\ell'_4$ . Figure 8 illustrates the two possibilities for the configuration of  $C_4$  and  $t_4$ : Either (1)  $C_4$  meets the interior of  $t_4$  or (2) it does not. Moving along the curve  $\gamma$  perturbs the configuration. Topologically, this corresponds to moving  $C_4$  off the vertex  $v$ , which is suggested by the arrows in Figure 8. In (1), there will be one line near to  $\lambda$  meeting

Figure 8: Configuration in plane  $\pi_4$

$\ell_1, \ell_2$ , and  $\ell_3$ , and  $t_4$  both before and after the conic  $C_4$  meets the vertex  $v$  (but these lines will meet different edges of  $t_4$ ). In case (2), two lines which meet the supporting lines outside of  $t_4$  coalesce into  $\lambda$ , and then become two lines meeting  $t_4$ .

For (b)(ii), we also suppose that  $\ell' = \ell'_4$  is the line supporting an edge of the fourth triangle,  $t_4$ , and that  $\pi_4$  is the plane of the triangle  $t_4$ . Then the three points  $\ell_i \cap \pi_4$  for  $i = 1, 2, 3$  are collinear and span the line  $\lambda$  which meets  $t_4$ . We may assume that  $\lambda$  does not meet any vertex of the triangle  $t_4$ . But then  $\lambda$  meets the interiors of the edges of  $t_4$  supported by  $\ell_4$  and  $\ell'_4$ , but not the third edge. If we perturb  $\ell_1, \ell_2$ , and  $\ell_3$  to  $\ell'_1, \ell'_2$ , and  $\ell'_3$ , then there is a line  $\mu$  meeting this perturbed triple and  $\ell_4$  which is close to  $\lambda$ . Similarly, there is a line  $\mu'$  meeting this perturbed triple and  $\ell'_4$  which is close to  $\lambda$ . If the points of intersection of  $\ell'_1, \ell'_2$ , and  $\ell'_3$  with  $\pi_4$  are not collinear, then  $\mu \neq \mu'$ . Thus there is no change in the number of common tangents to the four triangles when crossing a wall of this type.

Thus the parity of the number of lines tangent to the four triangles does not change when crossing  $\Sigma$ , which completes the proof of Theorem 4. 

## Acknowledgments

This research was initiated at the Second McGill-INRIA Workshop on Computational Geometry in Computer Graphics, February 7–14, 2003, co-organized by H. Everett, S. Lazard, and S. Whitesides, and held at the Bellairs Research Institute of McGill University. We would like to thank the other participants of the workshop for useful discussions.
