#### Abstract

This paper presents a dynamic algorithm for the construction of the Euclidean Voronoi diagram of a set of convex objects in the plane. We consider first the Voronoi diagram of smooth convex objects forming pseudo-circles set. A pseudo-circles set is a set of bounded objects such that the boundaries of any two objects intersect at most twice. Our algorithm is a randomized dynamic algorithm. It does not use a conflict graph or any sophisticated data structure to perform conflict detection. This feature allows us to handle deletions in a relatively easy way. In the case where objects do not intersect, the randomized complexity of an insertion or deletion can be shown to be respectively $O\left(\log ^{2} n\right)$ and $O\left(\log ^{3} n\right)$. Our algorithm can easily be adapted to the case of pseudocircles sets formed by piecewise smooth convex objects. Finally, given any set of convex objects in the plane, we show how to compute the restriction of the Voronoi diagram in the complement of the objects' union.

## Diagrammes de Voronoï d'Objets Convexes en Dimension 2

Résumé : Ce rapport présente un algorithme dynamique pour construire le diagramme de Voronoi Euclidien d'un ensemble d'objets convexes en dimension 2. Nous considérons tout d'abord la cas d'objets lisses et convexes constituant un ensemble de pseudo-circles. Un ensemble de pseudo-circles est un ensemble d'objets bornés tels que les frontières de deux objets quelconques de l'ensemble ont au plus deux points d'intersection. Notre algorithme est randomisé et dynamique. Il n'utilise ni graphes de conflits ni structures sophistiquée pour détecter les conflits. De ce fait, il est relativement facile de gérer les suppressions. Si les objets sont disjoints, le coût randommisé d'une insertion et $O\left(\log ^{2} n\right)$ et celui d'une suppresssion est $O\left(\log ^{3} n\right)$ Cet algorithme peut être adaptée aux ensembles de pseudo-circles formés d'objets convexes lisses par morceaux. Pour finir, il permet aussi de calculer, pour tout ensemble d'objets convexes, la restriction de leur diagramme de Voronoï au complémentaire de leur union.

Mots-clés : diagramme de Voronoï; triangulation de Delaunay; distance euclidienne; diagramme de Voronoï abstrait; algorithme randomisés, algorithme dynamique

## 1 Introduction

Given a set of sites and a distance function from a point to a site, a Voronoi diagram can be roughly described as the partition of the space into cells that are the locus of points closer to a given site than to any other site. Voronoi diagrams have proven to be useful structures in various fields such as astronomy, crystallography, biology etc. Voronoi diagrams have been extensively studied. See for example the survey by Aurenhammer [2] or the more recent one by Aurenhammer and Klein [3] or the book by Okabe, Boots, Sugihara and Chiu [12]. The early studies were mainly concerned with point sites and the Euclidean distance. Subsequent studies considered extended sites such has segments, lines, convex polytopes and various distances such as $L_{1}$ or $L_{\infty}$ or any distance defined by a convex polytope as unit ball. While the complexity and the related algorithmic issues of Voronoi diagrams for extended sites in higher dimensions is still not completely understood, as witnessed in the recent works by Koltun and Sharir [9, 10], the planar cases are now rather well mastered, at least for linear objects. The rising need for handling curved objects triggered further works for the planar cases. Klein et al. [7, 8] set up a general framework of abstract Voronoi diagrams which covers a large class of planar Voronoi diagrams. They provided a randomized incremental algorithm to construct diagrams of this class. Alt and Schwarzkopf [1] handled the case of generic planar curves and described an incremental randomized algorithm for this case too. Since they handle curves, they cannot handle objects with non-empty interior, which is our focus. Their algorithm is incremental but does not work in-line (it requires the construction of a Delaunay triangulation with one point on each curve before the curve segments are really treated). Another closely related work is that by McAllister, Kirkpatrick and Snoeyink [11], which deals with the Voronoi diagrams of disjoint convex polygons. The algorithm presented treats the convex polygons as objects, rather than as collections of segments; it follows the sweep-line paradigm, thus it is not dynamic. Moreover, the case of intersecting convex polygons is not considered. The present papers deals with the Euclidean Voronoi diagram of planar convex objects and generalizes a previous work of the same authors on the Voronoi diagram of circles [6].

Let $p$ be a point and $A$ be a bounded convex object in the Euclidean plane $\mathbb{E}^{2}$. We define the distance $\delta(p, A)$ from $p$ to $A$ to be:

$$
\delta(p, A)= \begin{cases}\min _{x \in \partial A}\|p-x\|, & x \notin A \\ -\min _{x \in \partial A}\|p-x\|, & x \in A\end{cases}
$$

where $\partial A$ denotes the boundary of $A$ and $\|\cdot\|$ denotes the Euclidean norm.
Given the distance $\delta(\cdot, \cdot)$ and a set of convex objects $\mathcal{A}=\left\{A_{1}, \ldots, A_{n}\right\}$, the Voronoi diagram $\mathcal{V}(\mathcal{A})$ is the planar partition into cells, edges and vertices defined as follows. The Voronoi cell of an object $A_{i}$ is the set of points which are closer to $A_{i}$ than to any other object in $\mathcal{A}$. Voronoi edges are maximal connected sets of points equidistant to two objects in $\mathcal{A}$ and closer to these objects than to any other in $\mathcal{A}$. Voronoi vertices are points equidistant to at least three objects of $\mathcal{A}$ and closer to these objects than to any other object in $\mathcal{A}$.

We first consider Voronoi diagrams for special collections of smooth convex objects called pseudo-circles sets. A pseudo-circles set is a set of bounded objects such that the boundaries of any two objects in the set have at most two intersection points. In the sequel, unless specified oth-

Figure 1: Various configurations for two convex objects. (a)-(e): an sc-pseudo-circles set in general position; (f)-(g): an sc-pseudo-circles set in degenerate position; (h)-(j): a pseudo-circles set of piecewise smooth convex objects; (k)-(l): not a pseudo-circles set.
erwise, we consider pseudo-circles sets formed by smooth convex objects, and we call them smooth convex pseudo-circles sets, or sc-pseudo-circles sets for short.

Let $A$ be a convex object. A line $L$ is a supporting line of $A$ if and only if $A$ is included in one of the closed half-planes bounded by $L$, and $\partial A \cap L$ is not empty. Given two convex objects $A_{i}$ and $A_{j}$, a line $L$ is a (common) supporting line of $A_{i}$ and $A_{j}$ if and only if $L$ is a supporting line of $A_{i}$ and $A_{j}$, such that $A_{i}$ and $A_{j}$ are both included in the same half-plane bounded by $L$.

In this paper, we first deal with smooth bounded convex objects forming pseudo-circles sets (cf. Fig. 1). Any two objects in such a set set have at most two common supporting lines (cf. Fig. 1). Two convex objects have no common supporting line if one is included in the other. They have two common supporting lines if they are either disjoint or properly intersecting at two points (a proper intersection point is a point where the boundaries are not only meeting but also crossing each other) or externally tangent (which means that their interiors are disjoint and their boundaries share a common tangent point). Two objects forming a pseudo-circles set may also be internally tangent, meaning that one is included in the other and their boundaries share one or two common points.

Then they have, respectively, one or two common supporting lines. A pseudo-circles set is said to be in general position if there is no pair of tangent objects. In fact, tangent objects which are properly intersecting at their common tangent point or externally tangent objects do not harm our algorithm and we shall say that a pseudo-circles set is in general position when there is no pair of internally tangent objects.

The algorithm that we propose for the construction of the Voronoi diagram of sc-pseudo-circles sets in general position is a dynamic one. It is a variant of the incremental randomized algorithm proposed by Klein et al. [8]. The data structures used are simple, which allows us perform not only insertions but also deletions of sites in a relatively easy way. When input sites are allowed to intersect each other, it is possible for a site to have an empty Voronoi cell. Such a site is called a hidden site, while a site with non-empty cell is said to be visible. Our algorithm handles hidden sites. The detection of the first conflict or the detection of a hidden site is performed through closest site queries. Such a query can be done by either a simple walk in the Voronoi diagram or using a hierarchy of Voronoi diagrams, i.e., a data structure inspired from the Delaunay hierarchy of Devillers [5].

To analyze the complexity of the algorithm, we assume that each object has constant complexity, which implies that each operation involving a constant number of object is performed in constant time (e.g., finding a circle tangent to three objects). We show that if sites do not intersect, the randomized complexity of updating a Voronoi diagram with $n$ sites is $O\left(\log ^{2} n\right)$ for an insertion and $O\left(\log ^{3} n\right)$ for a deletion. The complexities of insertions and deletions are more involved when sites intersect.

We then extend our results by firstly dropping the hypothesis of general position and secondly by dealing with pseudo-circles sets formed by convex objects whose boundaries are only piecewise smooth. Using this extension, we can then build the Voronoi diagram of any set $\mathcal{A}$ of convex objects in the complement of the objects' union (i.e., in free space). This done by constructing a new set of objects $\mathcal{A}^{\prime}$, which is a pseudo-circles set of piecewise smooth convex objects and such that the Voronoi diagrams $\mathcal{V}(\mathcal{A})$ and $\mathcal{V}\left(\mathcal{A}^{\prime}\right)$ coincide in free space.

The rest of the paper is structured as follows. In Section 2 we study the properties of the Euclidean Voronoi diagram of sc-pseudo-circles sets in general position. In particular we show that such a diagram belongs to the class of abstract Voronoi diagrams described by Klein et al. [8]. In Section 3 we present the dynamic algorithm for the construction of the Voronoi diagram of sc-pseudo-circles sets in general position. Section 4 describes closest site queries, whereas Section 5 deals with the complexity analysis of insertions and deletions. Finally, in Section 6 we show how our approach can be extended to handle sc-pseudo-circles sets with degeneracies, pseudo-circles sets of convex objects with piecewise smooth boundaries and eventually any set of convex objects in the plane.

## 2 The Voronoi diagram of sc-pseudo-circles sets

In this section we present the main properties of the Voronoi diagram of sc-pseudo-circles sets in general position. Let us first make precise a few definitions and notations. Here and in the following, we consider any bounded convex object $A_{i}$ as closed and we note $\partial A_{i}$ and $A_{i}^{\circ}$, respectively, the boundary and the interior of $A_{i}$.

Let $\mathcal{A}=\left\{A_{1}, \ldots, A_{n}\right\}$ be an sc-pseudo-circles set. The Voronoi cell of an object $A$ is denoted as $V(A)$ and is considered a closed set. The interior and boundary of $V(A)$ are denoted by $V^{\circ}(A)$ and $\partial V(A)$, respectively. We are going to consider maximal disks either included in a given object $A_{i}$ or disjoint from $A_{i}^{\circ}$, where the term maximal refers to the inclusion relation. For any point $x$, we denote by $C_{i}(x)$ the closed disk centered at $x$ with radius $\left|\delta\left(x, A_{i}\right)\right|$. If $x \notin A_{i}, C_{i}(x)$ is the maximal disk centered at $x$ and disjoint from $A_{i}^{\circ}$. If $x \in A_{i}, C_{i}(x)$ is the maximal disk centered at $x$ and included in $A_{i}$. In the latter case these is a unique maximal disk inside $A_{i}$ containing $C_{i}(x)$, which we denote by $M_{i}(x)$. Finally, the medial axis $S\left(A_{i}\right)$ of a bounded convex object $A_{i}$ is defined as the locus of points that are centers of maximal disks included in $A_{i}$.

Let $A_{i}$ and $A_{j}$ be two smooth bounded convex objects. The set of points $p \in \mathbb{E}^{2}$ that are at equal distance from $A_{i}$ and $A_{j}$ is called the bisector $\pi_{i j}$ of $A_{i}$ and $A_{j}$. Theorem 2 ensures that $\pi_{i j}$ is an one-dimensional set if the two objects $A_{i}$ and $A_{j}$ form an sc-pseudo-circles set in general position and justifies the definition of Voronoi edges given above.

Let us begin with a technical lemma.
Lemma 1 Let $A_{i}$ and $A_{j}$ be two bounded convex objects.

1. If $x \in A_{i}, \delta\left(x, A_{i}\right)<\delta\left(x, A_{j}\right)$ if and only if $C_{i}(x)$ is not included in $A_{j}$ and $\delta\left(x, A_{i}\right)=$ $\delta\left(x, A_{j}\right)$ if and only if $C_{i}(x)$ is internally tangent to $A_{j}$.
2. If $x \notin A_{i}, \delta\left(x, A_{i}\right)<\delta\left(x, A_{j}\right)$ if and only if $C_{i}(x)$ does not intersect $A_{j}$, and $\delta\left(x, A_{i}\right)=$ $\delta\left(x, A_{j}\right)$ if and only if $C_{i}(x)$ is externally tangent to $A_{j}$.

Proof. Follows trivially from the definition of the distance.

Theorem 2 Let $A_{i}$ and $A_{j}$ be two convex objects forming a pseudo-circles set in general position and let $\pi_{i j}$ be the bisector of $A_{i}, A_{j}$ with respect to the Euclidean distance $\delta(\cdot, \cdot)$. Then :

1. If $A_{i}$ and $A_{j}$ have no supporting line, then $\pi_{i j}=\emptyset$.
2. If $A_{i}$ and $A_{j}$ have two supporting lines, then $\pi_{i j}$ is a single curve homeomorphic to the open interval $(0,1)$.

## Proof.

1. Suppose that $A_{i}$ and $A_{j}$ have no common supporting line. This implies that either $A_{i} \subset A_{j}^{\circ}$ or $A_{j} \subset A_{i}^{\circ}$. Let us assume that $A_{j} \subset A_{i}^{\circ}$. Let $x \in \mathbb{E}^{2}$. We consider the following cases for $x$ :
(a) $x \notin A_{i}$. Any disk centered in $x$ that does not intersect $A_{i}^{\circ}$ does not intersect $A_{j}$. This is in particular true for $C_{i}(x)$ which implies that $\delta\left(x, A_{i}\right)<\delta\left(x, A_{j}\right)$.
(b) $x \in A_{i} \backslash A_{j}$. Then $\delta\left(p, A_{i}\right) \leq 0<\delta\left(p, A_{j}\right)$.
(c) $x \in A_{j}$. The maximum disk $C_{i}(x)$ is tangent to $\partial A_{i}$ at at least one point and therefore cannot be included in $A_{j}$. Thus, $\delta\left(p, A_{i}\right)<\delta\left(p, A_{j}\right)$.

Figure 2: The set of rays $\ell_{i}(y), y \in \partial A_{i}$, covers the entire plane. The ray $\ell_{i}(p)$ and the bisector $\pi_{i j}$ intersect in at most one point. Left: the case $A_{i} \cap A_{j}=\emptyset$. Right: the case $A_{i} \cap A_{j} \neq \emptyset$.

Thus any point $x$ is closer to $A_{i}$ than $A_{j}$, and $\pi_{i j}=\emptyset$.
2. Suppose now that $A_{i}, A_{j}$ have two common supporting lines. For a point $p \in \partial A_{i}$, let $\sigma_{i}(p)$ be the point of the medial axis $S\left(A_{i}\right)$ which is the center of the maximal disk included in $A_{i}$ and tangent to $\partial A_{i}$ at $p$. We denote by $\ell_{i}(p)$ the half-line issued from $\sigma_{i}(p)$ and perpendicular to $\partial A_{i}$ at $p$. The set of rays $\ell_{i}(p)$ covers the whole plane and two such rays do not intersect except if they share the same origin on the medial axis. (See Fig. 2). We first show that the bisector $\pi_{i j}$ intersects each ray $\ell_{i}(p)$ in at most one point.

For any point $x$ on $\ell_{i}(p)$, we consider as before the disk $C_{i}(x)$ centered at $x$ with radius $\left|\delta\left(x, A_{i}\right)\right| . C_{i}(x)$ is tangent to $\partial A_{i}$ at $p$. When $x$ moves from $\sigma_{i}(p)$ to $p$ along $\ell_{i}(p), C_{i}(x)$ decreases from the maximal disk $M_{i}(\sigma(p))$ to the disk $C_{i}(p)$ which is reduced to the point $p$. Then, when $x$ moves beyond $p$ on $\ell_{i}(p)$, the disk $C_{i}(x)$ increase from $p$ to the closed halfplane $H_{i}(p)$ limited by the line tangent to $\partial A_{i}$ at $p$ and not containing $A_{i}$.
We denote by $p_{i}, q_{i}$ the contact points of object $A_{i}$ with the common supporting lines of $A_{i}$ and $A_{j}$, and $p_{j}, q_{j}$ the contact points of object $A_{j}$ with those lines. We assume that the contact points $p_{i}, q_{i}, p_{j}$ and $q_{j}$ are labeled in such a way that they are encountered in that order along a counterclockwise traversal of the boundary of the convex hull $C H\left(A_{i} \cup A_{j}\right)$. Let $\alpha_{i}$ be the open arc between $q_{i}$ and $p_{i}$ along a counterclockwise traversal of $\partial A_{i}$, i.e. $\alpha_{i}$ is the part of $\partial A_{i}$ which does not appear on $\partial C H\left(A_{i} \cup A_{j}\right)$.
We will first assume that the contact points of $A_{i}$ and $A_{j}$ with their supporting lines are distinct, i.e., $p_{i} \neq q_{j}$ and $q_{i} \neq p_{j}$.
If $p \notin \alpha_{i}$, then first of all $p \notin A_{j}$ (this would contradict the fact that $p$ lies on $\partial C H\left(A_{i} \cup A_{j}\right)$ ). We then claim that any point $x \in \ell_{i}(p)$ is closer to $A_{i}$ and $\ell_{i}(p) \cap \pi_{i j}=\emptyset$. Indeed, for any
point $x \in \sigma_{i}(p) p$, the disk $C_{i}(x)$ includes $p$ and thus it is not included in $A_{j}$ and for any point $x$ on $\ell_{i}(p)$ beyond $p, C_{i}(x)$ is included in the halfplane $H_{i}(p)$ which does not intersect $A_{j}$.

If $p \in \alpha_{i}$ but $p \notin A_{j}, \pi_{i j}$ intersects $\ell_{i}(p)$ at a single point. Indeed, any point $x \in \sigma_{i}(p) p$ is closer to $A_{i}$, for the same reason as above. Let us consider now the points of $\ell_{i}(p)$ beyond $p$. When $x$ moves beyond $p, C_{i}(x)$ increases from $C_{i}(p)=\{p\}$ which does not intersect $A_{j}$ to the halfplane $H_{i}(p)$ which does. There is a unique point $x(p)$ beyond $p$ on $\ell_{i}(p)$ for which $C_{i}(x(p))$ is externally tangent to $A_{j}$. This point is at equal distance from $A_{i}$ and $A_{j}$, and thus belongs to $\pi_{i j}$. Note that the uniqueness of $x(p)$ stems from the fact that $C_{i}(y) \subseteq C_{i}\left(y^{\prime}\right)$ if $\|y-p\| \leq\left\|y^{\prime}-p\right\|$.
At last, when $A_{i}$ and $A_{j}$ intersect there are points $p$ in $\alpha_{i} \cap A_{j}$. For such a point $p, \ell_{i}(p) \cap \pi_{i j}$ can be either empty or a single point. Indeed any point $x$ beyond $p$ on $\ell_{i}(p)$ is closer to $A_{j}$, because the disk $C_{i}(x)$ includes $p$ and thus intersects $A_{j}$. Consider now points $x$ on $\sigma_{i}(p) p$. Assume first that $M_{i}\left(\sigma_{i}(p)\right)$ is included in $A_{j}$. Then, for any $x \in \sigma_{i}(p) p, C_{i}(x)$ is included in $A_{j}, x$ is closer to $A_{j}$ and $\ell_{i}(p) \cap \pi_{i j}$ is empty. Assume now that $M_{i}\left(\sigma_{i}(p)\right)$ is not included in $A_{j}$. When $x$ moves from $\sigma_{i}(p)$ to $p, C_{i}(x)$ decreases from $M_{i}\left(\sigma_{i}(p)\right)$, which is not included in $A_{j}$, to $\{p\}$ which is included in $A_{j}$. There exists a unique point $x(p) \in \sigma_{i}(p) p$ such that $C_{i}(x(p))$ is tangent to $\partial A_{j}$. This point is at equal distance from $A_{i}$ and $A_{j}$ and thus belongs to $\pi_{i j}$. Again we can argue the uniqueness of $x(p)$ using an arguments similar to the one above.

Thus if $A_{i}$ and $A_{j}$ are disjoint, then for any point $p \in \alpha_{i}$, there is a unique point $x(p)$ in $\ell_{i}(p) \cap \pi_{i j}$. Reciprocally, any point $y$ in $\pi_{i j}$ is the center of a disk tangent to both $A_{i}$ and $A_{j}$. This disk touches $\partial A_{i}$ in a point $p$ of $\alpha_{i}$ such that $y=x(p)$. Thus the mapping from $\alpha_{i}$ to $\pi_{i j}$, which maps $p \in \alpha_{i}$ to the point $x(p)=\ell_{i}(p) \cap \pi_{i j}$ is an one-to-one and onto mapping. The reverse mapping is well known to be continuous and therefore $\pi_{i j}$ is a single curve homeomorphic to the open $\operatorname{arc} \alpha_{i}$, i.e., to the open interval $(0,1)$.

Assume now that $A_{i}$ and $A_{j}$ are not disjoint. From the pseudo-circles property $\partial A_{i}$ and $\partial A_{j}$ intersect in two points $a$ and $b$. Assume that $q_{i}, b, a$ and $p_{i}$ are encountered in that order on the counterclockwise traversal of the $\operatorname{arc} \alpha_{i}$. Let $\alpha_{i}^{1}$ be the subarc of $\alpha_{i}$ joining $q_{i}$ to $b$. Any point $p$ on $\alpha_{i}^{1}$ is on $\alpha_{i} \backslash A_{j}$ and therefore the ray $\ell_{i}(p)$ intersects the bisector $\pi_{i j}$ at a unique point $x(p)$. As above the mapping from $p$ to $x(p)$ is one-to-one and continuous and therefore the bisector $\pi_{i j}$ includes an unbounded simple arc $\pi_{i j}^{1}$ homeomorphic to $\alpha_{i}^{1}$, (i.e., homeomorphic to the interval $(0,1])$, and joining $b=\pi_{i j}(b)$ with the image of $q_{i}$ which is the infinite point of the ray $\ell_{i}\left(q_{i}\right)$. In the same way, if $\alpha_{i}^{3}$ is the subarc of $\alpha_{i}$ joining $a$ to $p_{i}$, the bisector $\pi_{i j}$ includes an unbounded simple arc $\pi_{i j}^{3}$ homeomorphic to $\alpha_{i}^{3}$ (i.e., homeomorphic to the interval $[0,1)$ ), and joining $a=\pi_{i j}(a)$ to the image of $p_{i}$ which is the infinite point of the ray $\ell_{i}\left(p_{i}\right)$. These two arcs are disjoint, they are included in the complement of $A_{i} \cup A_{j}$ and are the only components of the bisector in that region. Obviously $\pi_{i j}$ has no component in $A_{i} \backslash A_{j}$ and $A_{j} \backslash A_{i}$. Let us show now that $\pi_{i j} \cap A_{i} \cap A_{j}$ is a simple connected curve joining $a$ to $b$. First let us notice that $\pi_{i j}$ has to include a connected component in $A_{i} \cap A_{j}$ joining $a$ to $b$. Indeed consider the continuous function $f(x)=\delta\left(x, A_{i}\right)-\delta\left(x, A_{j}\right)$. Let $x_{i}$ be a point of $\partial A_{i} \cap A_{j}$ and $x_{j}$ a point of $\partial A_{j} \cap A_{i}$. Assume that $x_{i}$ and $x_{j}$ are distinct from $a$ and $b$. Then we have $f\left(x_{i}\right)>0, f\left(x_{j}\right)<0$. Thus there exists at least one point where $f(x)=0$, i.e. a point of
$\pi_{i j}$ on any path joining $x_{i}$ to $x_{j}$ in $A_{i} \cap A_{j}$. Then we remark that any point in $\pi_{i j} \cap A_{i} \cap A_{j}$ belongs to the medial axis of the convex body $A_{i} \cap A_{j}$. The medial axis of this object is a tree and has a single path joining $a$ to $b$. This proves that $\pi_{i j} \cap A_{i} \cap A_{j}$ is the path of the medial axis joining $a$ to $b$. Finally the concatenation of the three $\operatorname{arcs} \pi_{i j}^{1}, \pi_{i j}^{3}$ and $\pi_{i j}^{2}=\pi_{i j} \cap A_{i} \cap A_{j}$ yields a curve homeomorphic to $(0,1)$.
To finish the proof we need to consider the case where the points of contact of the supporting lines coincide. For convenience we will assume that both $p_{i} \equiv q_{j}$ and $q_{i} \equiv p_{j}$. The remaining cases are just combinations of what we describe below and the arguments made above.
Note that in this case the common points of contact are also the points of intersection of the boundaries $\partial A_{i}$ and $\partial A_{j}$. Moreover, the arc $\alpha_{i}^{1}$ (resp. $\alpha_{i}^{3}$ ) is now a ray starting from $b$ (resp. $a$ ), with direction perpendicular to $\partial A_{i}$ and $\partial A_{j}$, that is contained in the closed halfspace $H_{i}(b)$ (resp. $\left.H_{i}(a)\right)$. As far as the portion of the bisector inside $A_{i} \cap A_{j}$ is concerned we can no longer claim that is it the portion of the medial axis $S\left(A_{i} \cap A_{j}\right)$ connecting $b$ with $a$; this is due to the fact that the points $a$ and $b$ are no longer points of discontinuity on the boundary $\partial\left(A_{i} \cap A_{j}\right)$ of $A_{i} \cap A_{j}$ and thus they are not necessarily points on $S\left(A_{i} \cap A_{j}\right)$. However, the same argument works with minor modifications. Let $a^{\prime}$ and $b^{\prime}$ be the points on the medial axis $S\left(A_{i} \cap A_{j}\right)$ corresponding to $a$ and $b$, respectively. Clearly, there is a unique path $\Pi$ from $a^{\prime}$ to $b^{\prime}$ in $S\left(A_{i} \cap A_{j}\right)$ (recall that the medial axis $S\left(A_{i} \cap A_{j}\right)$ is a tree, since $A_{i} \cap A_{j}$ is a convex object). Now consider the path $b b^{\prime} \cup \Pi \cup a^{\prime} a$. This path connects $b$ to $a$ and all its points are at equal distance from the two arcs $\partial A_{i} \cap A_{j}$ and $\partial A_{j} \cap A_{i}$ on the boundary of $A_{i} \cap A_{j}$. The union of this path along with the two rays emanating from $a$ and $b$ constitute the bisector $\pi_{i j}$ of $A_{i}$ and $A_{j}$. Clearly, $\pi_{i j}$ is homeomorphic to the interval $(0,1)$.

Theorem 4 ensures that each cell in the Euclidean Voronoi diagram of an sc-pseudo-circles set in general position is simply connected. We begin by a technical lemma which generalizes Lemma 1.

Lemma 3 Let $\mathcal{A}=\left\{A_{1}, \ldots, A_{n}\right\}$ be an sc-pseudo-circles set.

1. If $x \in A_{i}$, then $x$ belongs to the Voronoi cell $V\left(A_{i}\right)$ of $A_{i}$ if and only if $C_{i}(x)$ is not contained in the interior $A_{j}^{\circ}$ of any object $A_{j}$ in $\mathcal{A} \backslash\left\{A_{i}\right\}$.
2. If $x \in A_{i}$, then $x$ belongs to the interior $V^{\circ}\left(A_{i}\right)$ of the Voronoi cell $V\left(A_{i}\right)$ of $A_{i}$ if and only if $C_{i}(x)$ is not contained in any object $A_{j}$ in $\mathcal{A} \backslash\left\{A_{i}\right\}$.
3. If $x \notin A_{i}$, then $x$ belongs to the Voronoi cell $V\left(A_{i}\right)$ of $A_{i}$ if and only if $C_{i}(x)$ does not intersect the interior $A_{j}^{\circ}$ of any object $A_{j}$ in $\mathcal{A} \backslash\left\{A_{i}\right\}$.
4. If $x \notin A_{i}$, then $x$ belongs to the interior $V^{\circ}\left(A_{i}\right)$ of the Voronoi cell $V\left(A_{i}\right)$ of $A_{i}$ if and only if $C_{i}(x)$ does not intersect any object $A_{j}$ in $\mathcal{A} \backslash\left\{A_{i}\right\}$.

Proof. The proof follows trivially from Lemma 1.

Theorem 4 Let $\mathcal{A}=\left\{A_{1}, \ldots, A_{n}\right\}$ be an sc-pseudo-circles set in general position. For each object $A_{i}$, we denote by $N\left(A_{i}\right)$ the locus of the centers of maximal disks included in $A_{i}$ that are not included in the interior of any object in $\mathcal{A} \backslash\left\{A_{i}\right\}$, and by $N^{\circ}\left(A_{i}\right)$ the locus of the centers of maximal disks included in $A_{i}$ that are not included in any object in $\mathcal{A} \backslash\left\{A_{i}\right\}$. Then:

1. $N\left(A_{i}\right)=S\left(A_{i}\right) \cap V\left(A_{i}\right)$ and $N^{\circ}\left(A_{i}\right)=S\left(A_{i}\right) \cap V^{\circ}\left(A_{i}\right)$.
2. $N\left(A_{i}\right)$ and $N^{\circ}\left(A_{i}\right)$ are simply connected sets.
3. The Voronoi cell $V\left(A_{i}\right)$ is weakly star-shaped with respect to $N\left(A_{i}\right)$, which means that any point of $V\left(A_{i}\right)$ can be connected to a point in $N\left(A_{i}\right)$ by a segment included in $V\left(A_{i}\right)$. Analogously, $V^{\circ}\left(A_{i}\right)$ is weakly star-shaped with respect to $N^{\circ}\left(A_{i}\right)$.
4. $V\left(A_{i}\right)=\emptyset$ if and only if $N\left(A_{i}\right)=\emptyset$ and $V^{\circ}\left(A_{i}\right)=\emptyset$ if and only if $N^{\circ}\left(A_{i}\right)=\emptyset$.

Proof. For any point $x \in \mathbb{E}^{2}$, we note as before $C_{i}(x)$ the disk centered at $x$ with radius $\left|\delta\left(x, A_{i}\right)\right|$ and by $p_{i}(x)$ the point where $C_{i}(x)$ touches $\partial A_{i}$. If $x \in A_{i}$ the disk $C_{i}(x)$ is included in a unique maximal disk inside $A_{i}$ which is called $M_{i}(x)$. If $x \notin A_{i}$, we still denote by $M_{i}(x)$ the maximal disk included in $A_{i}$ and tangent to $\partial A_{i}$ at $p_{i}(x)$. In any case, we note $\sigma_{i}(x)$ the center of $M_{i}(x)$.

1. Let $y \in N\left(A_{i}\right)$. By definition $y \in S\left(A_{i}\right)$. Consider the circle $C_{i}(y)=M_{i}(y)$. Since it is not contained in the interior $A_{j}^{\circ}$ of any object in $\mathcal{A} \backslash\left\{A_{i}\right\}$, we have by Lemma 3, Case 2, that $y \in V\left(A_{i}\right)$. Conversely, if $y \in S\left(A_{i}\right) \cap V\left(A_{i}\right)$, then we have by Lemma 3, Case 2, that $M_{i}(y)$ is not contained in the interior of some other object $A_{j}$ in $\mathcal{A}$. Hence $y \in N\left(A_{i}\right)$. The proof of the other assertion is analog.
2. Let $u^{\prime}$ and $v^{\prime}$ be two points in $N\left(A_{i}\right)$. Because $S\left(A_{i}\right)$ is a tree, there is a unique path $\mathcal{P}$ in $S\left(A_{i}\right)$ connecting $u^{\prime}$ to $v^{\prime}$. Suppose that there exists a point $w \in \mathcal{P}$ such that $w \notin N\left(A_{i}\right)$. This implies that $M_{i}(w)$ is contained in the interior $A_{j}^{\circ}$ of some other object in $\mathcal{A}$. Consider the subpath of $\mathcal{P}$ from $w$ to $u^{\prime}$. Since $M_{i}(w)$ is contained in $A_{j}^{\circ}$ while $M_{i}\left(u^{\prime}\right)$ is not, there must be a first point $u$ on this subpath (from $w$ to $u^{\prime}$ ) such that $M_{i}(u)$ is tangent to $A_{j}$. Similarly, there exists a first point $v$ in the subpath of $\mathcal{P}$ from $w$ to $v^{\prime}$ such that $M_{i}(v)$ is tangent to $A_{j}$. The end of the proof amounts to show that this situation enforces the existence of more than two intersection points between $\partial A_{i}$ and $\partial A_{j}$, which contradicts with the fact $A_{i}$ and $A_{j}$ belong to a pseudo-circles set.
Let $p_{u}$ and $q_{u}$ (resp. $p_{v}$ and $q_{v}$ ) be the contact points between $M_{i}(u)$ (resp $M_{i}(v)$ ) and $\partial A_{i}$ and let $r_{u}$ (resp. $r_{v}$ ) be the contact point of $M_{i}(u)\left(\right.$ resp $\left.M_{i}(v)\right)$ with $\partial A_{j}$. (See Fig. 3). Assume $p_{u}, q_{u}, p_{v}, q_{v}$ are labeled in such a way that they are encountered in that order along a counterclockwise traversal of the boundary of the convex hull $C H\left(M_{i}(u) \cup M_{i}(v)\right)$. Because any maximal ball in $A_{i}$ centered between $u$ and $v$ on $\mathcal{P}$ is included in $A_{j}^{\circ}, r_{u}$ (resp. $r_{v}$ ) is encountered between $p_{u}$ and $q_{u}$ (resp. between $p_{v}$ and $q_{v}$ ) on $\partial C H\left(M_{i}(u) \cup M_{i}(v)\right)$. Let $\gamma$ be the simple closed path which counterclockwisely follows $\partial C H\left(M_{i}(u) \cup M_{i}(v)\right)$ from $r_{u}$ to $r_{v}$ and $\partial A_{j}$ from $r_{v}$ to $r_{u}$. Except if $A_{i}$ and $A_{j}$ are internally tangent, which contradicts the general position assumption, $r_{u}$ and $r_{v}$ are in $A_{i}^{\circ}$ and on $\partial A_{j}$ while $p_{u}, q_{u}, p_{v}, q_{v}$ are in

Figure 3: The boundaries of $A_{i}$ and $A_{j}$ have at least four intersection points.
$A_{j}^{\circ}$ and on $\partial A_{i}$. Thus $\gamma$ which passes through $r_{u}, q_{u}, p_{v}, r_{v}$ and encloses $q_{v}$ and $p_{u}$ has to intersect $\partial A_{i}$ at least twice. This implies that the arc of $\partial A_{j}$ joining counterclockwisely $r_{v}$ to $r_{u}$ intersects twice $\partial A_{i}$. In the same way the arc of $\partial A_{j}$ joining counterclockwisely $r_{u}$ to $r_{v}$ intersects twice $\partial A_{i}$. Since the two arcs on $\partial A_{j}$ are disjoint (except for $r_{u}$ and $r_{v}$, of course), we must have at least four intersection points between $\partial A_{j}$ and $\partial A_{i}$, which contradicts the fact that $\mathcal{A}$ is a pseudo-circle sets.
3. Consider a point $x \in V\left(A_{i}\right)$. We will show that $\sigma_{i}(x) \in N\left(A_{i}\right)$ and that any point $y$ of the segment $x \sigma_{i}(x)$ belongs to $V\left(A_{i}\right)$. If $x \in A_{i}$, we grow a circle tangent to $\partial A_{i}$ at $p_{i}(x)$ from $C_{i}(x)$ to $M_{i}(x)$. Any point $y$ in $x \sigma_{i}(x)$ is the center of a circle $C_{i}(y)$ tangent to $\partial A_{i}$ at $p_{i}(x)$ and such that $C_{i}(x) \subseteq C_{i}(y) \subseteq M_{i}(x)$. Because $x \in V\left(A_{i}\right), C_{i}(x)$ is not contained in the interior $A_{j}^{\circ}$ of any other object of $\mathcal{A}$, hence $C_{i}(y)$ and $M_{i}(x)$ are not included in the interior $A_{j}^{\circ}$ of any other object $A_{j}$, which proves that $y \in V\left(A_{i}\right)$ and $\sigma_{i}(x) \in N\left(A_{i}\right)$. If $x \notin A_{i}$, we first shrink a circle tangent to $\partial A_{i}$ at $p_{i}(x)$, from $C_{i}(x)$ to the point $p_{i}(x)$, then grow a circle tangent to $\partial A_{i}$ at $p_{i}(x)$ from the point $p_{i}(x)$ to $M_{i}(x)$. Any point $y$ in the subsegment $x p_{i}(x)$ is the center of a circle $C_{i}(y)$ tangent to $\partial A_{i}$ at $p_{i}(x)$ and such that $C_{i}(y) \subseteq C_{i}(x)$. Because $x \in V\left(A_{i}\right), C_{i}(x)$ does not intersect the interior $A_{j}^{\circ}$ of any other object of $\mathcal{A}$, thus neither does $C_{i}(y)$ and $y \in V\left(A_{i}\right)$. Any point $y$ in subsegment $p_{i}(x) \sigma_{i}(x)$ is the center of a circle $C_{i}(y)$ tangent to $\partial A_{i}$ at $p_{i}(x)$ and such that $p_{i}(x) \subseteq C_{i}(y) \subseteq M_{i}(x)$. Because $p_{i}(x) \in V\left(A_{i}\right)$, $p_{i}(x)$ is not contained in the interior $A_{j}^{\circ}$ of any other object $A_{j}$ of $\mathcal{A}$, and thus neither does $C_{i}(y)$ nor $M_{i}(x)$. Thus $y \in V\left(A_{i}\right)$ and $\sigma_{i}(x) \in N\left(A_{i}\right)$.
We can apply an analogous argument to show that if $x \in V^{\circ}\left(A_{i}\right)$, then any point $y$ in $x \sigma_{i}(x)$ belongs to $V^{\circ}\left(A_{i}\right)$.
4. Claim 4 is follows immediately from the proofs of the previous claims.

In the sequel we say that an object $A$ is hidden if $N^{\circ}(A)=\emptyset$.

In the framework of abstract Voronoi diagrams introduced by Klein [7], the diagram is defined by a set of bisecting curves $B_{i, j}$. In this framework, a set of bisectors is set to be admissible if:

1. Each bisector is homeomorphic to a line.
2. The closures of the Voronoi regions covers the entire plane.
3. Regions are path connected.
4. Two bisectors intersect in at most a finite number of connected components.

Let us consider the Euclidean Voronoi diagrams of an sc-pseudo-circles set in general position such that any pair of objects has exactly two supporting lines. Theorems 2 and 4 ensure, respectively, that Conditions 1 and 3 are fulfilled. Condition 2 is granted for any diagram induced by a distance. Condition 4 is a technical condition that we have not explicitly proved. In our case this results indeed from the assumption that the objects have constant complexity (note that Condition 4 is used in the theory of abstract Voronoi diagrams to prove that Voronoi cells are simply connected, which in our case is directly ensured by Theorem 4). The converse is also true: if we have a set of convex objects in general position, then their bisectors form an admissible system only if every pair of objects has exactly two supporting lines. Indeed, if this is not the case, one of the following holds: (1) the bisector is empty (e.g., if one object is contained in the interior of another; cf. Fig. 1(e)); (2) there exist Voronoi cells that consist of more than one connected components (e.g., if two the boundaries of two objects have four points of intersection; cf. Fig. 1(k)).

Theorem 5 Let $A=\left\{A_{1}, \ldots, A_{n}\right\}$ be a set of smooth convex objects of constant complexity and in general position. Then the set of bisectors $\pi_{i j}$ is an admissible system of bisectors if and only if every pair of objects has exactly two supporting lines.

## 3 The dynamic algorithm

The algorithm that we propose is a variant of the randomized incremental algorithm for abstract Voronoi diagrams proposed by Klein and al. [8]. Our algorithm is fully dynamic and maintains the Voronoi diagram when a site is either added to the current set or deleted from it. To facilitate the presentation of the algorithm we first define the compactified version of the diagram and introduce the notion of conflict region.
The compactified diagram. We call 1-skeleton of the Voronoi diagram, the union of the Voronoi vertices and Voronoi edges. The 1 -skeleton of the Voronoi diagram of an sc-pseudo-circles set $\mathcal{A}$ may consist of more than one connected components. However, we can define a compactified version of the diagram by adding to $\mathcal{A}$ a spurious site, $A_{\infty}$ called the infinite site. The bisector of $A_{\infty}$ and $A_{i} \in \mathcal{A}$ is a closed curve at infinity, intersecting any unbounded edge of the original diagram (see for example [7]). In the sequel we consider such a compactified version of the diagram, in which case the 1 -skeleton is connected.

The conflict region. Each point $x$ on a Voronoi edge incident to $V\left(A_{i}\right)$ and $V\left(A_{j}\right)$ is the center of a disk $C_{i j}(x)$ tangent to the boundaries $\partial A_{i}$ and $\partial A_{j}$. This disk is called a Voronoi bitangent disk, and
more precisely an interior Voronoi bitangent disk if it is included in $A_{i} \cap A_{j}$, or an exterior Voronoi bitangent disk if it lies in the complement of $A_{i}^{\circ} \cup A_{j}^{\circ}$. Similarly, a Voronoi vertex that belongs to the cells $V\left(A_{i}\right), V\left(A_{j}\right)$ and $V\left(A_{k}\right)$ is the center of a disk $C_{i j k}(x)$ tangent to the boundaries of $A_{i}$, $A_{j}$ and $A_{k}$. Such a disk is called a Voronoi tritangent disk, and more precisely an interior Voronoi tritangent disk if it is included in $A_{i} \cap A_{j} \cap A_{k}$, or an exterior Voronoi tritangent disk if it is lies in the complement of $A_{i}^{\circ} \cup A_{j}^{\circ} \cup A_{k}^{\circ}$.

Suppose we want to add a new object $A \notin \mathcal{A}$ and update the Voronoi diagram from $\mathcal{V}(\mathcal{A})$ to $\mathcal{V}\left(\mathcal{A}^{+}\right)$where $\mathcal{A}^{+}=\mathcal{A} \cup\{A\}$. We assume that $\mathcal{A}^{+}$is also an sc-pseudo-circles set. The object $A$ is said to be in conflict with a point $x$ on the 1 -skeleton of the current diagram if the Voronoi disk associated to $x$ is either an internal Voronoi disk included in $A^{\circ}$ or an exterior Voronoi disk intersecting $A^{\circ}$. We call conflict region the subset of the 1 -skeleton of $\mathcal{V}(\mathcal{A})$ that is in conflict with the new object $A$. A Voronoi edge of $\mathcal{V}(\mathcal{A})$ is said to be in conflict with $A$ if some part of this edge is in conflict with $A$.

Our dynamic algorithm relies on the two following theorems, which can be proved as in [8].
Theorem 6 Let $\mathcal{A}^{+}=\mathcal{A} \cup\{A\}$ be an sc-pseudo-circles set such that $A \notin \mathcal{A}$. The conflict region of $A$ with respect to $\mathcal{V}(\mathcal{A})$ is a connected subset of the 1 -skeleton of $\mathcal{V}(\mathcal{A})$.

Theorem 7 Let $\left\{A_{i}, A_{j}, A_{k}\right\}$ be an sc-pseudo-circles set in general position. Then the Voronoi diagram of $A_{i}, A_{j}$ and $A_{k}$ has at most two Voronoi vertices.

This theorem is equivalent to saying that two bisecting curves $\pi_{i j}$ and $\pi_{i k}$ relative to the same object $A_{i}$ have at most two points of intersection. In particular, it implies that the conflict region of a new object $A$ contains at most two connected subsets of each edge of $\mathcal{V}(\mathcal{A})$.

The data structures. The Voronoi diagram $\mathcal{V}(\mathcal{A})$ of the current set of objects is maintained through its dual graph $\mathcal{D}(\mathcal{A})$.

When a deletion is performed, a hidden site can reappear as visible. Therefore, we have to keep track of hidden sites. This is done through an additional data structure that we call the covering graph $\mathcal{K}(\mathcal{A})$. For each hidden object $A_{i}$, we call covering set of $A_{i}$ a set $K\left(A_{i}\right)$ of objects such that any maximal disk included in $A_{i}$ is included in the interior of at least one object of $K\left(A_{i}\right)$. In other words, in the Voronoi diagram $\mathcal{V}\left(K\left(A_{i}\right) \cup\left\{A_{i}\right\}\right)$ the Voronoi cell $V\left(A_{i}\right)$ of $A_{i}$ is empty. The covering graph is a directed acyclic graph with a node for each object. A node associated to a visible object is a root. The parents of a hidden object $A_{i}$ are objects that form a covering set of $A_{i}$. The parents of a hidden object may be hidden or visible objects.

Note that if we perform only insertions or if it is known in advance that all sites will have nonempty Voronoi cells (e.g., this is the case for disjoint objects), it is not necessary to maintain a covering graph.

The algorithm needs to perform closest site queries. Such a query takes a point $x$ as input and asks for the object in the current set $\mathcal{A}$ that is closest to $x$. The algorithm maintains a location data structure to perform efficiently those queries. The location data structure that we present here is called a Voronoi hierarchy and is described below in Section 4.

### 3.1 The insertion procedure

The insertion of a new object $A$ in the current Voronoi diagram $\mathcal{V}(\mathcal{A})$ involves the following steps:

1. Find a first conflict between an edge of $\mathcal{V}(\mathcal{A})$ and $A$ or detect that $A$ is hidden in $\mathcal{A}^{+}$.
2. Find the whole conflict region of $A$.
3. Repair the dual graph.
4. Update the covering graph.
5. Update the location data structure if any.

Steps 1, 4 and 5 are discussed below. Steps 2 and 3 are performed exactly as in [6] for the case of disks. Briefly, in Step 2 we perform a depth-first search on the 1 -skeleton of $\mathcal{V}(\mathcal{A})$ starting from the first conflict found in Step 1. The boundary points of the conflict region of $A$ with respect to $\mathcal{V}(\mathcal{A})$ are the Voronoi vertices of the Voronoi cell of $A$ in $\mathcal{V}\left(\mathcal{A}^{+}\right)$. Once we have found the conflict region of $A$, we can construct the Voronoi cell of $A$ in $\mathcal{V}\left(\mathcal{A}^{+}\right)$by connecting these boundary points in the correct order. In the dual, Step 2 corresponds to finding the boundary of the star of $A$ in $\mathcal{D}\left(\mathcal{A}^{+}\right)$. This boundary represents a hole in $\mathcal{D}(\mathcal{A})$, i.e., a sequence of edges of $\mathcal{D}(\mathcal{A})$ forming a topological circle. Step 3 simply amounts to "staring" this hole from $A$, that is to connect the vertex in $\mathcal{D}\left(\mathcal{A}^{+}\right)$ associated with $A$ to every vertex on the hole boundary.
Finding the first conflict or detecting a hidden object. The first crucial operation to perform when inserting a new object is to determine if the inserted object is hidden or not. If the object is hidden we need to find a covering set for this object. If the object is not hidden we need to find an edge of the current diagram in conflict with the inserted object.

The detection of the first conflict is based on closest site queries. Such a query takes a point $x$ as input and asks for the object in the current set $\mathcal{A}$ that is closest to $x$. If we don't have any location data structure, then we perform the following simple walk on the Voronoi diagram to find the object in $\mathcal{A}$ closest to $x$. The walk starts from any object $A_{i} \in \mathcal{A}$ and compares the distance $\delta\left(x, A_{i}\right)$ with the distances $\delta(x, A)$ to the neighbors $A$ of $A_{i}$ in the Voronoi diagram $\mathcal{V}(\mathcal{A})$. Here and in the following, two objects are said to be neighbors in the Voronoi diagram if their Voronoi cells are adjacent through an edge. If some neighbor $A_{j}$ of $A_{i}$ is found closer to $x$ than $A_{i}$, the walk proceeds to $A_{j}$. If there is no neighbor of $A_{i}$ that is closer to $x$ than $A_{i}$, then $A_{i}$ is the object closest to $x$ among all objects in $\mathcal{A}$. It is easy to see that this walk can take linear time. We postpone until the next section the description of the location data structure and the way these queries can be answered more efficiently.

Let us consider first the case of disjoint objects. In this case there are no hidden objects and each object is included in its own cell. We perform a closest site query for any point $p$ of the object $A$ to be inserted. Let $A_{i}$ be the object of $\mathcal{A}$ closest to $p$. The cell of $A_{i}$ will shrink in the Voronoi diagram $\mathcal{V}\left(\mathcal{A}^{+}\right)$and at least one edge of $\partial V\left(A_{i}\right)$ is in conflict with $A$. Hence, we only have to look at the edges of $\partial V\left(A_{i}\right)$ until we find one in conflict with $A$.

When objects do intersect, we perform an operation called location of the medial axis, which either provides an edge of $\mathcal{V}(\mathcal{A})$ that is in conflict with $A$, or returns a covering set of $A$. To explain
how this operation is performed, let us say that a point $p$ of the medial axis $S(A)$ of $A$ is covered by $A_{i}$ if the disk $M(p)$, which is the maximal disk in $A$ centered at $p$, is included in the interior $A_{i}^{\circ}$ of some object $A_{i} \in \mathcal{A}$. Let us recall that the medial axis $S(A)$ of $A$ is a tree embedded in the plane and that, from the proof of Theorem 4, we know that the part of $S(A)$ which is not covered by any subset of objects in $\mathcal{A}$ is connected. Roughly, the method consists in pruning recursively the parts of $S(A)$ covered by objects in $\mathcal{A}$ until either: (1) the remaining part of $S(A)$ is empty or (2) we have found a point $p$ of $S(A)$ whose maximal disk $M(p)$ is not covered by the object $A_{i}$ of $\mathcal{A}$ which is closest to $p$ (if $p$ is not covered by $A_{i}$ it will not be covered by any other object in $\mathcal{A} \backslash\left\{A_{i}\right\}$ ). In the first case, $A$ is hidden and the objects in $\mathcal{A}$ which have been used to prune $S(A)$ form a covering of $A$. In the second case, the point $p$ is in the cell of $A_{i}$ and at least one edge of $\partial V\left(A_{i}\right)$ is in conflict with $A$.

Let us explain more precisely, how we select the objects in $\mathcal{A}$ covering parts of $S(A)$ or detect an uncovered point of $S(A)$. We start from a leaf vertex $p$ of the medial axis $S(A)$ and issue a closest site query to find the object $A_{i}$ closest to $p$. If the maximal disk $M(p)$ is not covered by $A_{i}$ we are done. Otherwise we prune the part of $S(A)$ covered by $A_{i}$ and start again with a new leaf point $p^{\prime}$, on the boundary of the pruned part of $S(A)$. There is no need to issue a new closest site query for point $p^{\prime}$ or subsequent considered leaf points on $S(A)$. Indeed because $p^{\prime}$ is an endpoint of the part of $S(A)$ covered by $A_{i}$, the maximal circle $M\left(p^{\prime}\right)$ of $A$ centered at $p^{\prime}$ is also internally tangent to $A_{i}$. therefore we just need to scan the neighbors of $A_{i}$ in the Voronoi diagram $\mathcal{V}(\mathcal{A})$ searching for a neighbor covering $M\left(p^{\prime}\right)$. If one is found, it becomes the next object $A_{j}$ used to prune $S(A)$. If none is found, we know that $A_{i}$ is closest to $p^{\prime}$ among all objects in $\mathcal{A}$ and that one of the edge of $\partial V\left(A_{i}\right)$ is in conflict with $A$.
Updating the covering graph. We now describe how Step 4 of the insertion procedure is performed. We start by creating a node for $A$ in the covering graph.

If $A$ is hidden, the location of its medial axis yields a covering set $K(A)$ of $A$. In the covering graph we simply assign the objects in $K(A)$ as parents of $A$.

If the inserted object $A$ is visible, some objects in $\mathcal{A}$ can become hidden due to the insertion of $A$. The set of objects that become hidden because of $A$ are provided by Step 2 of the insertion procedure. They correspond to cycles in the conflict region of $A$. The next lemma ensures that the covering graph can be updated by looking at the neighbors of $A$ in the new Voronoi diagram.

Lemma 8 Let $\mathcal{A}$ be an sc-pseudo-circles set. Let $A \notin \mathcal{A}$ be an object such that $\mathcal{A}^{+}=\mathcal{A} \cup\{A\}$ is also an sc-pseudo-circles set and $A$ is visible in $\mathcal{V}\left(\mathcal{A}^{+}\right)$. If an object $A_{i} \in \mathcal{A}$ becomes hidden upon the insertion of $A$, then the neighbors of $A$ in $\mathcal{V}\left(\mathcal{A}^{+}\right)$along with $A$ is a covering set of $A_{i}$.

Proof. Let $N\left(A_{i}\right)$ and $N^{\circ}\left(A_{i}\right)$ be the parts of the medial axis $S\left(A_{i}\right)$ relative to the diagram $\mathcal{V}(\mathcal{A})$ as defined in Theorem 4. Since $A_{i}$ becomes hidden in $\mathcal{A}^{+}$, for every $y \in N^{\circ}\left(A_{i}\right), M_{i}(y)$ is contained in $A$. Let $x$ be a point on the boundary $\partial N\left(A_{i}\right)=N\left(A_{i}\right) \backslash N^{\circ}\left(A_{i}\right)$ of $N\left(A_{i}\right)$. Then $M_{i}(x)$ is tangent to some neighbor $A_{j}$ of $A_{i}$ in $\mathcal{V}(\mathcal{A})$ and included in $A_{j}$. Moreover, we know from the proof of Theorem 4 that if $x^{\prime}$ belongs to the same connected component of $S\left(A_{i}\right) \backslash N\left(A_{i}\right)$ as $x$, then $M_{i}\left(x^{\prime}\right)$ is also contained in $A_{j}$. Hence the neighbors of $A_{i}$ in $\mathcal{V}(\mathcal{A})$ along with $A$ form a covering set of $A_{i}$. A neighbor $A_{j}$ of $A_{i}$ in $\mathcal{V}(\mathcal{A})$ is either a neighbor of $A$ in $\mathcal{V}\left(\mathcal{A}^{+}\right)$or it becomes hidden in
this diagram. Therefore the set of neighbors of $A$ in $\mathcal{V}\left(\mathcal{A}^{+}\right)$, plus $A$ is a covering set for any object $A_{i}$ that becomes hidden upon the insertion of $A$.

Let $A_{i}$ be an object that becomes hidden upon the insertion of $A$. By Lemma 8 the set of neighbors of $A$ in $\mathcal{V}\left(\mathcal{A}^{+}\right)$along with $A$ is a covering set $K\left(A_{i}\right)$ of $A_{i}$. The only modification we have to do in the covering graph is to assign all objects in $K\left(A_{i}\right)$ as parents of $A_{i}$.

Updating the location data structure. The location data structure, if any, is updated as follows. Let $A$ be the object inserted. If $A$ is hidden we do nothing. If $A$ is not hidden, we insert $A$ in the location data structure, and delete from it all objects than become hidden because of the insertion of $A$.

### 3.2 The deletion procedure

Let $A_{i}$ be the object to be deleted and let $K_{p}\left(A_{i}\right)$ be the set of all objects in the covering graph $\mathcal{K}(\mathcal{A})$ that have $A_{i}$ as parent. The deletion of $A_{i}$ involves the following steps:

1. Remove $A_{i}$ from the dual graph.
2. Remove $A_{i}$ from the covering graph.
3. Remove $A_{i}$ from location data structure.
4. Reinsert the objects in $K_{p}\left(A_{i}\right)$.

Step 1 requires no action if $A_{i}$ is hidden. If $A_{i}$ is visible, we first build an annex Voronoi diagram for the neighbors of $A_{i}$ in $\mathcal{V}(\mathcal{A})$ and use this annex Voronoi diagram to fill in the cell of $A_{i}$ (see [6]). In Step 2, we simply delete all edges of $\mathcal{K}(\mathcal{A})$ to and from $A_{i}$, as well as the node corresponding to $A_{i}$. In Step 3, we simply delete $A_{i}$ from the location data structure. Finally, in Step 4 we apply the insertion procedure to all objects in $K_{p}\left(A_{i}\right)$. Note, that if $A_{i}$ is hidden, this last step amounts to finding a new covering set for all objects in $K_{p}\left(A_{i}\right)$.

## 4 Closest site queries

The location data structure is used to answer closest site queries. A closest site query takes as input a point $x$ and asks for the object in the current set $\mathcal{A}$ that is closest to $x$. Such queries can be answered through a simple walk in the Voronoi diagram (as described in the previous section) or using a hierarchical data structure called the Voronoi hierarchy.

The Voronoi hierarchy. The hierarchical data structure used here, denoted by $\mathcal{H}(\mathcal{A})$, is inspired from the Delaunay hierarchy proposed by Devillers [5].

The data structure consists in a sequence of Voronoi diagrams $\mathcal{V}\left(\mathcal{A}_{\ell}\right), \ell=0, \ldots, L$, built for subsets of $\mathcal{A}$ forming a hierarchy, i.e, $\mathcal{A}=\mathcal{A}_{0} \supseteq \mathcal{A}_{1} \supseteq \ldots \supseteq \mathcal{A}_{L}$.

The hierarchy $\mathcal{H}(\mathcal{A})$ is built together with the Voronoi diagram $\mathcal{V}(\mathcal{A})$ according to the following rules. Any object of $\mathcal{A}$ is inserted in $\mathcal{V}\left(\mathcal{A}_{0}\right)=\mathcal{V}(\mathcal{A})$. If $A$ has been inserted in $\mathcal{V}\left(\mathcal{A}_{\ell}\right)$ and is visible,
it is inserted in $\mathcal{V}\left(\mathcal{A}_{\ell+1}\right)$ with probability $\beta$. If, upon the insertion of $A$ in $\mathcal{V}(\mathcal{A})$, an object becomes hidden it is deleted from all diagrams $\mathcal{V}(\mathcal{A} \ell), \ell>0$, in which it has been inserted. Finally, when an object $A_{i}$ is deleted from the Voronoi diagram $\mathcal{V}(\mathcal{A})$, we delete $A_{i}$ from all diagrams $\mathcal{V}\left(\mathcal{A}_{\ell}\right), \ell \geq 0$, in which it has been inserted. Note that all diagrams $\mathcal{V}\left(\mathcal{A}_{\ell}\right), \ell>0$, do not contain any hidden objects and that if $A \in \mathcal{A}_{\ell}$, then $A \in \mathcal{A}_{\ell^{\prime}}$, for all $\ell^{\prime}<\ell$.

The closest site query for a point $x$ is performed as follows. The query is first performed in the top-most diagram $\mathcal{V}\left(\mathcal{A}_{L}\right)$ using the simple walk. Then, for $\ell=L-1, \ldots, 0$ a simple walk is performed in $\mathcal{V}\left(A_{\ell}\right)$ from $A_{\ell+1}$ to $A_{\ell}$ where $A_{\ell+1}\left(\right.$ resp. $\left.A_{\ell}\right)$ is the object of $\mathcal{A}_{\ell+1}$ (resp. of $\mathcal{A}_{\ell}$ ) closest to $x$.

It easy to show that the expected size of $\mathcal{H}(\mathcal{A})$ is $O\left(\frac{1}{1-\beta} n\right)$, and that the expected number of levels in $\mathcal{H}(\mathcal{A})$ is $O\left(\log _{1 / \beta} n\right)$. Moreover, the following lemma, proves that the expected number of steps performed by the walk at each level is constant.

Lemma 9 Let $x$ be a point in $\mathbb{E}^{2}$. Let $A_{\ell}\left(\right.$ resp. $\left.A_{\ell+1}\right)$ be the object closest to $x$ in $\mathcal{A}_{\ell}\left(\right.$ resp. $\left.\mathcal{A}_{\ell+1}\right)$. Then the expected number of Voronoi cells (objects) visited during the walk in $\mathcal{V}\left(\mathcal{A}_{\ell}\right)$ from $A_{\ell+1}$ to $A_{\ell}$ is $O(1 / \beta)$.

Proof. The objects visited at level $\ell$ are closer to $x$ than $A_{\ell+1}$ and their distances to $x$ are monotonically decreasing. Consequently, if $A_{\ell+1}$ is, among the objects of $\mathcal{A}_{\ell}$, the $k$-th closest to $x$, the walk at level $\ell$ performs at most $k$ steps. The probability for $A_{\ell+1}$ to be, among the objects of $\mathcal{A}_{\ell}$, the $k$-th closest to $x$ is just $\beta(1-\beta)^{k-1}$ and therefore the expected number $N_{\ell}$ of objects visited at level $\ell$ is bounded as follows:

$$
N_{\ell} \leq \sum_{k=1}^{n_{\ell}} k(1-\beta)^{k-1} \beta<\beta \sum_{k=1}^{\infty} k(1-\beta)^{k-1}=\frac{1}{\beta}
$$

where $n_{\ell}$ denotes the cardinality of $\mathcal{A}_{\ell}$.
We still have to bound the time spent in each one of the visited cells. Let $A_{i}$ be the site of a visited cell in $\mathcal{V}\left(\mathcal{A}_{\ell}\right)$. Since the complexity of all cells in the Voronoi diagram $V\left(\mathcal{A}_{\ell}\right)$ is only $O\left(n_{\ell}\right)$, where $n_{\ell}$ is the number of sites in $\mathcal{A}_{\ell}$, it is not efficient to simply compare the distances $\delta\left(x, A_{i}\right)$ and $\delta(x, A)$ for each neighbor $A$ of $A_{i}$ in $\mathcal{V}\left(\mathcal{A}_{\ell}\right)$. This would only imply that the time spent at each level $\ell$ of the hierarchy is $O\left(n_{\ell}\right)=O(n)$, yielding a total of $O(n)$ time per insertion.

To remedy this we attach an additional balanced binary tree to each cell of each Voronoi diagram in the hierarchy. The tree attached to the cell $V_{\ell}\left(A_{i}\right)$ of $A_{i}$ in the diagram $\mathcal{V}\left(\mathcal{A}_{\ell}\right)$ includes, for each Voronoi vertex $v$ of $V_{\ell}\left(A_{i}\right)$, the ray $\rho_{i}\left(p_{v}\right)$ where $p_{v}$ is the point on $\partial A_{i}$ closest to $v$, and $\rho_{i}\left(p_{v}\right)$ is defined as the ray starting from the center of the maximal disk $M_{i}\left(p_{v}\right)$ and passing through $p_{v}$. The rays are sorted according to the (counter-clockwise) order of the points $p_{v}$ on $\partial A_{i}$. When $V_{\ell}\left(A_{i}\right)$ is visited, the ray $\rho_{i}\left(p_{x}\right)$ corresponding to the query point $x$ is localized using the tree; here $p_{x}$ denotes the point of tangency of the disk $C_{i}(x)$ with the boundary $\partial A_{i}$ of $A_{i}$. Suppose that $\rho_{i}\left(p_{x}\right)$ is found to be between the rays of two vertices $v_{1}$ and $v_{2}$. Then it suffices to compare $\delta\left(x, A_{i}\right)$ and $\delta\left(x, A_{j}\right)$, where $A_{j}$ is the neighbor of $A_{i}$ in $\mathcal{V}\left(\mathcal{A}_{\ell}\right)$ sharing the vertices $v_{1}$ and $v_{2}$. Thus the time spend in each visited cell of $\mathcal{V}\left(\mathcal{A}_{\ell}\right)$ is $O\left(\log n_{\ell}\right)=O(\log n)$, which (together with with the expected number of visited nodes) yields the following lemma

Lemma 10 Using a hierarchy of Voronoi diagrams with additional binary trees for each cell, a closest site query can be answered in time $O\left(\frac{1}{\beta \log (1 / \beta)} \log ^{2} n\right)$.

## 5 Complexity analysis

In this section we deal with the cost of the basic operations of our dynamic algorithm. We consider three scenarios. The first one assumes that objects do not intersect. In the second scenario objects may intersect but it is assumed that there are no hidden objects. The third scenario is the general case where we allow intersecting and hidden objects.

In each of the above three cases, we consider the expected cost of the basic operations, namely insertion and deletion. The expectation refers to the insertion order, that is, all possible insertion orders are considered to be equally likely and each deletion is considered to deal equally likely with any object in the current set.

Our results are summarized in the table below.

|  | Disjoint <br> objects | No hidden <br> objects | General <br> case |
| :---: | :---: | :---: | :---: |
| Insertion | $O\left(\log ^{2} n\right)$ | $O(n)$ | $O(n)$ |
| Deletion | $O\left(\log ^{3} n\right)$ | $O(n)$ | $O\left(n^{2}\right)$ |

Disjoint objects. If the objects are disjoint, there are no hidden objects and therefore there is no need to maintain a covering graph. In this case we use a Voronoi hierarchy as location data structure and therefore we have to take into account the cost for maintaining this structure. Note that the Voronoi hierarchy introduce another source of randomization, which is independent from the randomization in the order of insertion.

Let us first analyze the cost of an insertion.

- Using the Voronoi hierarchy a closest site query can be performed in $O\left(\log ^{2} n\right)$ time. Knowing the object $A_{i}$ closest to a point $p$ of the inserted object, the tree corresponding to cell $V\left(A_{i}\right)$ in the first level of the hierarchy can be used to find the first edge of $\mathcal{V}(\mathcal{A})$ in conflict with $A$ in time $O(\log n)$.
- Finding the whole conflict region at level $\ell$ of the hierarchy and updating the Voronoi diagram $\mathcal{V}\left(\mathcal{A}_{\ell}\right)$ can be performed in time $O\left(k_{\ell}\right)$ where $k_{\ell}$ is the number of changes occurring in the diagram. The update of additional trees at level $\ell$ of the hierarchy can be performed in time $O\left(k_{\ell} \log n_{\ell}\right)$, where $n_{\ell}$ is the number of sites in $\mathcal{V}\left(\mathcal{A}_{\ell}\right)$.

At each level $\ell$, we have $\log n_{\ell}=O(\log n)$, and the expected value for $k_{\ell}$ is constant. Because the expected number of levels is $O(\log n)$, the expected cost for updating the diagram and the hierarchy upon an insertion is $O\left(\log ^{2} n\right)$.

Let us now analyze the cost of a deletion.

- Updating the Voronoi diagram at level $\ell$ involves computing a secondary Voronoi diagram involving only the $k_{\ell}$ neighbors of the deleted site in the diagram $V\left(\mathcal{A}_{\ell}\right)$. The neighbors are
inserted in random order in the secondary diagram. From what precedes, the expected cost for building this diagram is $O\left(k_{\ell} \log ^{2} n_{\ell}\right)$, with the expectation here referring to the random insertion order of the neighbors.
- The cost for updating the additional trees of the location data structure at level $\ell$ is still $O\left(k_{\ell} \log n_{\ell}\right)$.

As above, the expected value of $k_{\ell}, \ell \geq 0$, is $O(1)$. Moreover, for all levels $\ell, \log n_{\ell}=O(\log n)$ and the expected number of levels is $O(\log n)$. Therefore the expected cost for a deletion is $O\left(\log ^{3} n\right)$.
No hidden objects. Assume now that the objects may intersect but that there are no hidden objects. In this case, we maintain neither a covering graph nor a location data structure. Indeed, to find a first conflict we need to perform a location of the medial axis operation. Because this operation has a linear complexity with respect to the number of sites, there is no reason to maintain a location data structure for fast closest site queries.

Then, the analysis of an insertion operation is as above except that finding the first conflict now costs $O(n)$ and, clearly, there is no cost associated with updating the location data structure. Therefore, the expected cost of an insertion is $O(n)$.

The cost of a deletion reduces to the expected cost of building the secondary Voronoi diagram involving the $k$ neighbors of the deleted site. In view of the insertion analysis, it takes $O\left(k^{2}\right)$ expected time to create this secondary Voronoi diagram, with the expectation referring to the random insertion order of the neighbors of the site to be deleted. Taking into account that $k=O(n)$ and that the expected value of $k$ is $O(1)$, we conclude that the expected cost of a deletion is $O(n)$.

General case. In the general case, objects may intersect and/or may be hidden. We maintain a covering graph but no location data structure graph.

Let us analyze the cost of an insertion.

- If the inserted object is hidden, the location of the medial axis provides a covering set for this object, and updating the covering graph has a complexity proportional to the size of the covering set, which is $O(n)$.
- If the inserted object is not hidden, it may induce the hiding of other objects. Objects hidden on an insertion are detected while finding the whole conflict zone. In this case, the analysis of the insertion cost is just as above except that we need to add the cost for updating the conflict graph. This cost is $O\left(h k^{\prime}\right)$, where $h$ is the number of objects that become hidden and $k^{\prime}$ the number of neighbors of the newly inserted object in the updated Voronoi diagram. Because, $h=O(n)$ and $k^{\prime}$ has a constant expected value, the expected cost to update the conflict graph is $O(n)$.

Thus, in both cases, the expected cost of an insertion is $O(n)$.
Let us come to the analysis of a deletion.

- Because the expected cost of an insertion is linear, the cost of Step 1 (removal of the deleted object from the dual graph) is still $O\left(k^{2}\right)$, where $k$ is the number of neighbors of the deleted site. As above, this gives an expected contribution of $O(n)$.
- Step 2 (removal of the deleted object from the conflict graph) is obviously performed in no more than $O(n)$ time.
- Step 3 induces no cost since we do not maintain a location data structure.
- The cost of Step 4 is $O\left(n h^{\prime}\right)$, where $h^{\prime}$ is the number of sites covered (at least partially) by the deleted site. Obviously, randomization cannot help here to bound the expected number of neighbors of these covered sites and the cost of Step 4 can only be bounded by $O\left(n^{2}\right)$.

Hence, the overall expected cost of a deletion is $O\left(n^{2}\right)$.

## 6 Extensions

In this section we consider several extensions of the problem discussed in the preceding sections.
Degenerate configurations. Degenerate configurations occur when the set contains pairs of internally tangent objects (cf. Figs. 1(f) and $1(\mathrm{~g})$ ). Let $\left\{A_{i}, A_{j}\right\}$ be an sc-pseudo-circles set with $A_{i}$ and $A_{j}$ internally tangent and $A_{i} \subseteq A_{j}$. The bisector $\pi_{i j}$ is homeomorphic to a ray, if $A_{i}$ and $A_{j}$ have a single tangent point, or two, in general disconnected, rays, if $A_{i}$ and $A_{j}$ have two tangent points. In any case, the interior $V^{\circ}\left(A_{i}\right)$ of the Voronoi region of $A_{i}$ in $\mathcal{V}\left(\left\{A_{i}, A_{j}\right\}\right)$ is empty and we consider the object $A_{i}$ as hidden. This point of view is consistent with the definition we gave for hidden sites, which is that an object $A$ is hidden if $N^{\circ}(A)=\emptyset$.

Let us discuss the algorithmic consequences of allowing degenerate configurations. When the object $A$ is inserted in the diagram, the case where $A$ is internally tangent to a visible object $A_{i} \in \mathcal{A}$ is detected at Step 1, during the location the medial axis of $A$. The case of an object $A_{j} \in \mathcal{A}$ is internally tangent to $A$ is detected during Step 2, when the entire conflict region is searched. In the first case $A$ is hidden and its covering set is $\left\{A_{i}\right\}$. In the second case $A_{i}$ becomes hidden and its covering set is $\{A\}$. The complexity of insertions and deletions is not affected by allowing these degenerate configurations.

Pseudo-circles sets of piecewise smooth convex objects. In the sections above we assumed that all convex objects have smooth boundaries, i.e., their boundaries are at least $C^{1}$-continuous. In fact we can handle quite easily the case of objects whose boundaries are only piecewise $C^{1}$-continuous. Let us call vertices the points on the boundary of an object where there is no $C^{1}$-continuity. The main problem of piecewise $C^{1}$-continuous objects is that they can yield two-dimensional bisectors when two objects share the same vertex (cf. Figs. 1(i) and 1(j)). The remedy is similar to the commonly used approach for the Voronoi diagram of segments (e.g., cf. [4]): we consider the vertices on the boundary of the objects as objects by themselves and slightly change the distance so that a point whose closest point on object $A_{i}$ is a vertex of $A_{i}$ is considered to be closer to that vertex. All two-dimensional bisectors, if any, then become the Voronoi cells of these vertices.

As far as our basic operations are concerned, we proceed as follows. Let $A$ be the object to be inserted or deleted. We denote by $A_{v}$ the set of vertices of $A$ and $\hat{A}$ the object $A$ minus the points in $A_{v}$. When we want to insert $A$ in the current Voronoi diagram we at first insert all points in $A_{v}$ and then $\hat{A}$. When we want to delete $A$ we at first delete $\hat{A}$ and then all points in $A_{v}$. During the latter

Figure 4: The sets $\mathcal{A}$ (left) and $\mathcal{A}^{\prime}$ (right). $\mathcal{A}^{\prime}$ is a generalized pseudo-circles set.
step we have to make sure that points in $A_{v}$ are not vertices of other objects as well. This can be done easily by looking at the neighbors in the Voronoi diagram of each point in $A_{v}$.
Generic convex objects. In the case of smooth convex objects which do not form pseudo-circles sets we can compute the Voronoi diagram in the complement of their union (free space). The basic idea is that the Voronoi diagram in free space depends only on the arcs appearing on the boundary of the union of the objects.

More precisely, let $\mathcal{A}$ be a set of convex objects and let $C$ be a connected component of the union of the objects in $\mathcal{A}$. Along the boundary $\partial C$ of $C$, there exists a sequence of points $\left\{p_{1}, \ldots, p_{m}\right\}$, which are points of intersection of objects in $\mathcal{A}$. An arc $\alpha_{i}$ on $\partial C$ joining $p_{i}$ to $p_{i+1}$ belongs to a single object $A \in \mathcal{A}$. We form the piecewise smooth convex object $A_{\alpha_{i}}$, whose boundary is $\alpha_{i} \cup p_{i} p_{i+1}$, where $p_{i} p_{i+1}$ is the segment joining the points $p_{i}$ and $p_{i+1}$. Consider the set $\mathcal{A}^{\prime}$ consisting of all such objects $A_{\alpha_{i}} . \mathcal{A}^{\prime}$ is a pseudo-circles set (consisting of disjoint piecewise smooth convex objects) and the Voronoi diagrams $\mathcal{V}(\mathcal{A})$ and $\mathcal{V}\left(\mathcal{A}^{\prime}\right)$ coincide in free space.

The set $\mathcal{A}^{\prime}$ can be computed by performing a line-sweep on the set $\mathcal{A}$ and keeping track of the boundary of the connected components of the union of the objects in $\mathcal{A}$. This can be done in time $O(n \log n+k)$, where $k=O\left(n^{2}\right)$ is the complexity of the boundary of the afore-mentioned union. Since the objects in $\mathcal{A}^{\prime}$ are disjoint, we can then compute the Voronoi diagram in free space in total expected time $O\left((n+k) \log ^{2} n\right)$.

## 7 Conclusion

We presented a dynamic algorithm for the construction of the euclidean Voronoi diagram in the plane for various classes of convex objects. In particular, we considered pseudo-circles sets of piecewise smooth convex objects, as well as generic smooth convex objects, in which case we can compute the

Voronoi diagram in free space. Our algorithm uses fairly simple data structures and enables us to perform deletions easily.

We are currently working on extending the above results to non-convex objects, as well as understanding the relationship between the euclidean Voronoi diagram of such objects and abstract Voronoi diagrams. We conjecture that, given a pseudo-circles set (of possibly non-convex objects) in general position, such that any pair of objects has exactly two supporting lines, the corresponding set of bisectors is an admissible system of bisectors.
