# The PERT Problem with Alternatives: Modelisation and Optimisation

Fabrice CHAUVET\* and Jean-Marie PROTH\* and \*\*

## ABSTRACT

Management of projects often requires decisions concerning the choice of alternative activities. The completion time of the whole project (i.e. the makespan) is computed subsequently. In this paper, we aim at selecting the activities and computing the makespan simultaneously. This problem is referred to as PERT Problem with Alternatives (PPA). The corresponding model is similar to a conventional PERT graph, except that two types of nodes are introduced to represent either the choice between activities, or the fact that a set of activities should be completed before starting a subsequent set of activities. In this paper, we analyse the PPA and we propose a pseudo-polynomial algorithm to solve it.

# Problème PERT avec Alternatives : Modélisation et Optimisation

Fabrice CHAUVET\* et Jean-Marie PROTH\* et \*\*

## RESUME

La gestion de projet demande souvent que soient choisies les activités à exécuter dans un ensemble d'activités équivalentes. La durée requise pour exécuter le projet, c'est-à-dire le "makespan", est calculée à partir de ce choix. Dans cet article, nous cherchons à sélectionner les activités et à calculer le makespan simultanément. Nous appelons ce problème Problème PERT avec Alternatives (PPA). Le modèle correspondant à ce problème est similaire au graphe PERT conventionnel, excepté que deux types de nœuds sont utilisés pour représenter soit le choix entre plusieurs activités alternatives, soit le fait qu'un ensemble d'activités doit être terminé avant qu'un autre ensemble d'activités puisse commencer. Dans cet article, nous analysons le PPA et proposons un algorithme pseudo-polynomial pour le résoudre.

## 1. INTRODUCTION

In this paper we introduce and analyze PERT networks modeling projects with alternative operations. Recall that any PERT network is a finite directed graph  $G$  in which arcs represent *activities*, or *operations*, and nodes represent *events*, that is, starting and ending points of activities.  $j$  and  $i$  denote respectively the origin and the ending node of arc  $(j,i)$ . The length of each arc is given; it is assumed to be either a positive or negative rational number, or zero.

In the traditional PERT models (see, for instance, [8, 9, 12, 13]), all activities are assumed to be of the *and*-type when the goal is to find the longest path. An arc  $(j,i)$  represents an *and*-type activity if *all* the activities represented by an arc  $(j',i)$  (whose ending node is  $i$ ) must be completed before any activity represented by an arc  $(i,k)$  (whose starting node is  $i$ ) can begin. However, in many practical cases, a project may include, along with the *and*-type activities, another type of activities known as *alternatives*, or *or*-type activities. An arc  $(j,i)$  represents an *or*-type activity if *at least one* activity represented by an arc  $(j',i)$  (whose ending node is  $i$ ) must be completed before any activity represented by an arc  $(i,k)$  (whose starting node is  $i$ ) can begin. There are many real-life applications in manufacturing, communication and logistic that are modeled by means of networks with alternative operations (see, for example, [1, 4-7, 10-11]).

The type of project management problem presented in this paper is referred to as *PERT Problem with Alternatives (PPA)*. Given a project containing both *and*-type and *or*-type activities, with two fixed nodes denoted respectively by  $s$  (*start*) and  $f$  (*final*), the problem is to find the earliest starting time of each one of the activities so that the completion time (i.e. the makespan) of the entire project is minimum. The mathematical model of this problem is a combination of the classical PERT (longest path) problem and the routing (shortest path) problem.

Not much have been done to date for efficiently solving scheduling problems with alternative activities. Dinic [4] described a polynomial-time algorithm for solving the PERT Problem with Alternatives (PPA) on a bipartite graph with arcs of (strictly) positive lengths. This algorithm has been extended (see [2]) to find the minimum makespan for any graph (not necessary bipartite) with (strictly) positive arc lengths. In [2], several well-solvable cases of the problem and a powerful decomposition algorithm running in polynomial time are presented. This algorithm is applicable for solving many real-life problems. Other approaches as integer-programming, heuristic and branch-and-bound have been studied to treat alternative activities in network systems. Kusiak and Finke [7] were apparently the first who studied a problem with alternative process plans. They proposed an integer mathematical programming model to measure the total cost. Nasr and Elsayed [10] considered the problem of minimizing the mean flow time in a machining system with alternative routings and developed a decomposition method for solving the mixed integer formulation of the problem. Wilhelm and Shin [15]

effectively applied a linear programming model and examined the influence of alternative operations on the performance of flexible manufacturing systems. Ahn, He and Kusiak [1] and Gere [5] demonstrated that scheduling manufacturing systems taking into account simultaneously alternative process plans and alternative operations permit to increase the throughput rate by a better utilization of scarce resources; these authors developed heuristic algorithms for scheduling alternative operations and studied the effect of alternative operations on the performance of schedules generated by different heuristic rules. Iwata, Murotsu and Oba [6] proposed a branch-and-bound technique to determine a minimum total production time in a flexible system with alternative operations. A branch-and-bound algorithm was developed also by Pan and Chen [11] to minimize the makespan in a two-machine flowshop with alternative operations. In an early paper by Stecke and Solberg [14], a simulation experiment is conducted for the real-time control of an FMS with alternative operations.

The present paper is devoted to PERT Problem with Alternatives (PPA) represented by graphs whose *arc lengths are rational and of any sign*. We will focus on the analysis of its properties. Notice that the optimal solution is neither defined by the longest path (as in the PERT/CPM models with *and*-type activities) nor by the shortest one (as in the routing problem), but rather recursively as a combination of paths of the both types.

We introduce the formalisation of the problem in Section 2. Some basic definitions are given in Section 3. In Section 4, we describe the properties of a feasible solution and an algorithm to obtain such a feasible solution. In Section 5, we give a necessary and sufficient condition for a solution to be optimal and derive an algorithm to obtain the optimal solution. Section 6 is the conclusion.

## 2. PROBLEM FORMULATION

### *Notations*

Let  $G=(V, E)$  be a PERT network, that is, a finite directed graph, where  $V$  is the set of nodes and  $E$  the set of arcs. The network describes a project in which arcs represent activities and nodes represent events (i.e. starting and ending points of the project activities). Without loss of generality, we assume that graph  $G$  is connected (otherwise, we could process each one of its connected component independently). The lengths  $l(e)$  of arcs  $e \in E$  are given. Each arc length is assumed to be a rational constant (positive, negative or zero). A positive arc length denotes the duration of the activity corresponding to the arc. An arc of positive (respectively negative) length  $l(j,i)$  ending with an *and*-node  $i$  (respectively *or*-node  $i$ ) means that event  $i$  will occur not sooner than  $l(j,i)$  units of time after event  $j$  occurs. Notice that events  $i$  and  $j$  may belong to different activities. An arc of positive (respectively negative) length  $l(j,i)$  ending with an *or*-node  $i$  (respectively *and*-node  $i$ ) means that event  $i$  must occur at most  $l(j,i)$  units of time after event  $j$ .

As mentioned in introduction, we consider PERT networks with two types of activities, that is *or*- and *and*-activities. Corresponding to these two types of activities, two kinds of nodes are introduced in the corresponding network model. In the remainder of this paper, the ending nodes of *or*-type activities are called *or*-nodes, and the ending nodes of *and*-type activities, *and*-nodes (see Figure 1).

(a) Since  $T_a$  and  $T_b$  are *or*-activities, at least one of the activities  $T_a$  or  $T_b$  must be completed before  $T_c$  and  $T_d$  start. The ending node of  $T_a$  and  $T_b$  is an *or*-node.

$t_a$ ,  $t_b$ ,  $t_c$  and  $t_d$  being the starting times of activities  $T_a$ ,  $T_b$ ,  $T_c$  and  $T_d$  respectively, the following inequalities must be satisfied:

$$t_c \geq \min\{t_a + l(T_a); t_b + l(T_b)\}, \text{ and} \\ t_d \geq \min\{t_a + l(T_a); t_b + l(T_b)\}.$$

(b) Since  $T_a$  and  $T_b$  are *and*-activities, both activities  $T_a$  and  $T_b$  must be completed before  $T_c$  and  $T_d$  start. The ending node of  $T_a$  and  $T_b$  is an *and*-node.

$t_a$ ,  $t_b$ ,  $t_c$  and  $t_d$  being the starting times of activities  $T_a$ ,  $T_b$ ,  $T_c$  and  $T_d$  respectively, the following inequalities must be satisfied:

$$t_c \geq \max\{t_a + l(T_a); t_b + l(T_b)\}, \text{ and} \\ t_d \geq \max\{t_a + l(T_a); t_b + l(T_b)\}.$$

Figure 1. An *or*-node and an *and*-node.

We assume that there is only one node without predecessors, called the *start* node of the project and denoted by  $s$ . (Notice that if there are several nodes having no predecessor, it is always possible to add one *new\_start* node and connect this node with the nodes having no predecessors with arcs of zero length). Using a similar argument, we assume that there is only one node without successors, called the *final* node of the project and denoted by  $f$ . Node  $s$  represents the beginning of the project while node  $f$  represents its end. We also assume that there exists a (directed) path from node  $s$  to any node in the graph.

The set of *or*-nodes (respectively *and*-nodes) is denoted by  $R$  (respectively  $A$ );  $V = \{s\} \cup R \cup A$ . Notice that node  $f$  belongs to either  $R$  or  $A$ . Let us denote by  $Pred(i)$  the set of predecessors of node  $i$ , where  $i \in R \cup A$ :  $Pred(i) = \{j / j \in V, (j, i) \in E\}$ . If there are several arcs starting from the same node and ending at an *or*-node (respectively an *and*-node), the arc of the lowest (respectively greatest) value is the only one which will be considered. Finally, we can assume, without loss of generality, that there exists at most one arc between any two nodes.

A parameter  $t_i$  is associated with each node  $i$ . If  $i$  is an *and*-node,  $t_i$  is an upper bound of the completion times of *all* the activities represented by arcs whose ending node is  $i$ . If  $i$  is an *or*-

node,  $t_i$  is an upper bound of the completion time of *at least one* activity represented by arcs whose ending node is  $i$ . Without loss of generality, we assume that the project starts no sooner than time 0, i.e.  $t_s \geq 0$ .

### Modelisation

Our goal is to find, for each node  $i$ , the times  $t_i$  such that:

$$\begin{cases} t_i \geq \min_{j \in \text{Pred}(i)} \{t_j + l(j, i)\} & \text{if } i \in R \\ t_i \geq \max_{j \in \text{Pred}(i)} \{t_j + l(j, i)\} & \text{if } i \in A \end{cases}$$

and such that the completion time of the entire project (i.e. the time  $t_f$  assigned to node  $f$ ) is minimum. This optimal solution is provided (see [2]) by solving the following problem  $P_{\text{INEQ}}$ :

Problem  $P_{\text{INEQ}}$  : minimize  $\sum_{i \in V} t_i$

subject to

$$\begin{cases} t_i \geq 0 & \text{if } i = s \\ t_i \geq \min_{j \in \text{Pred}(i)} \{t_j + l(j, i)\} & \text{if } i \in R \\ t_i \geq \max_{j \in \text{Pred}(i)} \{t_j + l(j, i)\} & \text{if } i \in A \end{cases} \quad (S_{\text{INEQ}})$$

A set  $\{t_i\}_{i \in V}$  which satisfies  $(S_{\text{INEQ}})$  is a feasible solution of  $P_{\text{INEQ}}$ . The optimal solution of  $P_{\text{INEQ}}$ , called *earliest times* solution, is unique (see [2]) and is also the unique optimal solution of the associated problem  $P_{\text{EQ}}$  defined as follows:

Problem  $P_{\text{EQ}}$  : minimize  $\sum_{i \in V} t_i$

subject to

$$\begin{cases} t_i = 0 & \text{if } i = s \\ t_i = \min_{j \in \text{Pred}(i)} \{t_j + l(j, i)\} & \text{if } i \in R \\ t_i = \max_{j \in \text{Pred}(i)} \{t_j + l(j, i)\} & \text{if } i \in A \end{cases} \quad (S_{\text{EQ}})$$

Since the two problems  $P_{\text{INEQ}}$  and  $P_{\text{EQ}}$  have the same optimal solutions if one of them has an optimal solution, we focus on  $P_{\text{EQ}}$  and we present the proprieties of the feasible and the optimal solutions of  $P_{\text{EQ}}$  and some algorithms to obtain these solutions.

At the end of the computation of the optimal solutions, some arcs ending with an *or*-node can be deleted since they represent an activity which will not be performed. For example, assume that  $\{t_i\}_{i \in V}$  is the optimal solution of problems  $P_{\text{INEQ}}$  and  $P_{\text{EQ}}$ . In this case, if node  $f$  is

an *and*-node then all the operations  $(i, f)$  ending with  $f$  must be performed. Otherwise,  $f$  is an *or*-node and at least one operation  $(j, f)$  such that  $t_f = \min_{j \in \text{Pred}(f)} \{t_j + l(j, f)\}$  must be performed.

### 3. SATURATED ARCS, NODES AND CIRCUITS

#### Definitions 1

Recall that a (directed) path is a sequence of different arcs  $\{e_1, e_2, \dots, e_q\}$  of  $E$  such that the end node of  $e_k$  is the origin node of  $e_{k+1}$  for each  $k=1, 2, \dots, q-1$ . A path is a *circuit* if it begins and ends with the same node (i.e. the end node of  $e_q$  is the origin node of  $e_1$ ).

Since there exists only one arc between two nodes, it is possible to define a path (resp. a circuit) either by a sequence of arcs, or by a sequence of nodes. A circuit whose length is equal to zero, is called a *null-circuit*. A circuit whose length is strictly positive (resp. strictly negative) is called a *positive circuit* (resp. *negative circuit*).

An arc  $(j_0, i_0)$ , where  $j_0$  and  $i_0$  denote respectively the origin and the ending node of the arc, is called *saturated* by a solution  $\{t_i\}_{i \in V}$

$$\text{if } t_{i_0} = t_{j_0} + l(j_0, i_0) \text{ and if } \begin{cases} t_{i_0} = \min_{j \in \text{Pred}(i_0)} \{t_j + l(j, i_0)\} & \text{if } i_0 \in R \\ t_{i_0} = \max_{j \in \text{Pred}(i_0)} \{t_j + l(j, i_0)\} & \text{if } i_0 \in A. \end{cases}$$

A node is called *saturated* by a solution  $\{t_i\}_{i \in V}$  if there exists a saturated arc which ends with this node. A solution feasible to  $P_{\text{EQ}}$  saturates all the nodes of the graph.

A path is called *saturated* if all the arcs belonging to this path are saturated.

By adding sequentially the latter equations along the path, we obtain the following property: for any path  $P_{i_1 \rightarrow i_{q+1}} = \{(i_1, i_2); (i_2, i_3); \dots; (i_q, i_{q+1})\}$  saturated by a solution  $\{t_i\}_{i \in V}$ , we have

$t_{i_{q+1}} - t_{i_1} = \sum_{k=1}^q l(i_k, i_{k+1})$ . If the saturated path is a circuit, the length of a such saturated circuit must be equal to zero since, in this case,  $t_{i_{q+1}} - t_{i_1} = t_{i_1} - t_{i_1} = 0$ .

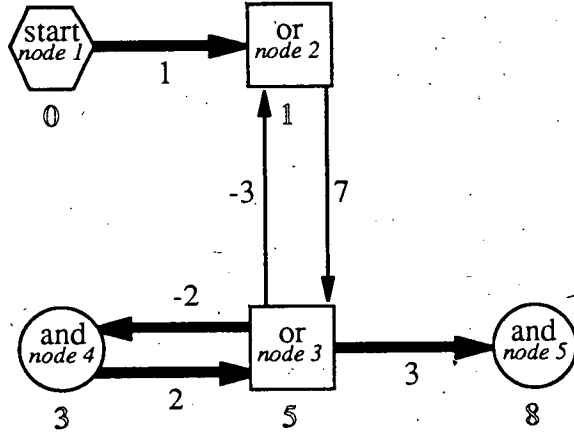

#### Lemma 1

If there exists a feasible solution of  $P_{\text{EQ}}$  such that there is no saturated path from node  $s$  to some other nodes, then there exists a saturated null-circuit in  $G$ .

#### Proof

Let  $\{t_i\}_{i \in V}$  be a feasible solution of  $P_{\text{EQ}}$ , for which there is no saturated path from node  $s$  to some other nodes. Let us denote by  $I \subset V$  the set of all such nodes. Since  $\{t_i\}_{i \in V}$  is a feasible solution of  $P_{\text{EQ}}$ , for any node  $i$  of  $V$ , there exists a node  $j \in \text{Pred}(i)$  such that the arc  $(j, i)$  is saturated. Since there is no path saturated by solution  $\{t_i\}_{i \in V}$  from node  $s$  to any node of  $I$ , there is no saturated arc from a node of  $V \setminus I$  to a node of  $I$ . Thus, for any node  $i$  of  $I$ , there

exists  $j \in \text{Pred}(i) \cap I$  such that the arc  $(j, i)$  is saturated. Beginning with node  $i_1 \in I$ , and scanning the nodes of  $I$  one after another in this way, we obtain a saturated path whose nodes belong to  $I$ , say  $\{(i_p, i_{p-1}); (i_{p-1}, i_{p-2}); \dots; (i_{q+1}, i_q); \dots; (i_2, i_1)\}$  in which  $i_q = i_p$ , because the set  $I$  is finite. The sequence  $\mathcal{C} = \{(i_p, i_{p-1}); (i_{p-1}, i_{p-2}); \dots; (i_{q+1}, i_q)\}$  is a circuit in which all arcs are saturated. Thus, the length of this saturated circuit is equal to zero (see above). QED

The lengths are indicated near the corresponding arcs and the saturated arcs are thick-lined. A feasible solution is given by the numbers located under the nodes. For the given feasible solution of  $P_{EQ}$ , there is no saturated path from node  $s$  to nodes 3, 4 and 5, while two nodes, 3 and 4 constitute a null-circuit.

Figure 2. Illustration of Lemma 1.

**Theorem 1 (Importance of null-circuit)**

If there exists a feasible solution of  $P_{EQ}$  which does not saturate any null-circuit in  $G$ , then:

- (i) this feasible solution is the unique feasible solution of  $P_{EQ}$ ,
- (ii) it is optimal for  $P_{EQ}$  and  $P_{INEQ}$ , and
- (iii) there exists a path, saturated by this solution, from node  $s$  to any other node of  $G$ .

Remind that the length of any saturated path from node  $s$  to node  $f$  is equal to the makespan.

**Proof**

(i) To prove that a feasible solution of  $P_{EQ}$  which does not saturate any null-circuit in  $G$  is the unique feasible solution of  $P_{EQ}$ , we assume that two different solutions  $\{t_i\}_{i \in V}$  and  $\{x_i\}_{i \in V}$ , feasible to  $P_{EQ}$ , exist. Thus, there exists  $i_0 \in V$  such that  $x_{i_0} \neq t_{i_0}$ . We assume that:

$$x_{i_0} > t_{i_0} \quad (1)$$

(if not, it is always possible to rename the two solutions so that  $x_{i_0} > t_{i_0}$ ). We then construct backward a directed path whose ending node is  $i_0$ . For  $k=0, -1, -2, \dots$ , we select  $i_{k-1}$  such that:

$$t_{i_k} = t_{i_{k-1}} + l(i_{k-1}, i_k) \text{ if } i_k \text{ is an or-node, and} \quad (2)$$

$$x_{i_k} = x_{i_{k-1}} + l(i_{k-1}, i_k) \text{ if } i_k \text{ is an and-node.} \quad (3)$$

Since  $\{t_i\}_{i \in V}$  and  $\{x_i\}_{i \in V}$  are feasible solutions of  $P_{EQ}$ , all the nodes are saturated and  $i_{k-1}$  always exists.

The properties of this path are the following:

- We have  $x_{i_k} > t_{i_k}$  for any  $k \leq 0$ . (4)

- The difference  $x_{i_k} - t_{i_k}$  increases as  $k$  decreases, (5)

that is  $x_{i_{k-1}} - t_{i_{k-1}} \geq x_{i_k} - t_{i_k}$  for any  $k \leq 0$ .

These properties are proved hereafter. For  $k=0$ , we have  $x_{i_0} > t_{i_0}$ . Assume that property (4) holds for  $k \leq 0$ . We prove that, in this case, property (4) also holds for  $k-1$  and  $x_{i_{k-1}} - t_{i_{k-1}} \geq x_{i_k} - t_{i_k}$ .

If  $i_k$  is an *or*-node, then:

$$t_{i_k} = \min_{j \in \text{Pred}(i_k)} \{t_j + l(j, i_k)\} = t_{i_{k-1}} + l(i_{k-1}, i_k) \text{ (see relation (2))}, \text{ and}$$

$$x_{i_k} = \min_{j \in \text{Pred}(i_k)} \{x_j + l(j, i_k)\} \leq x_{i_{k-1}} + l(i_{k-1}, i_k) \text{ (since } \{x_i\}_{i \in V} \text{ is feasible for } P_{\text{EQ}}).$$

Thus, since  $x_{i_k} > t_{i_k}$ , we have  $x_{i_{k-1}} > t_{i_{k-1}}$  and  $x_{i_{k-1}} - t_{i_{k-1}} \geq x_{i_k} - t_{i_k}$ .

If  $i_k$  is an *and*-node, then:

$$x_{i_k} = \max_{j \in \text{Pred}(i_k)} \{x_j + l(j, i_k)\} = x_{i_{k-1}} + l(i_{k-1}, i_k) \text{ (see relation (3))}, \text{ and}$$

$$t_{i_k} = \max_{j \in \text{Pred}(i_k)} \{t_j + l(j, i_k)\} \geq t_{i_{k-1}} + l(i_{k-1}, i_k) \text{ (since } \{t_i\}_{i \in V} \text{ is feasible for } P_{\text{EQ}}).$$

Thus, since  $x_{i_k} > t_{i_k}$ , we have  $x_{i_{k-1}} > t_{i_{k-1}}$  and  $x_{i_{k-1}} - t_{i_{k-1}} \geq x_{i_k} - t_{i_k}$ .

Finally, properties (4) and (5) hold, whatever the type of node  $i_k$ , for  $k \leq 0$ . Hereafter, we use the above properties to derive the existence of at least one null-circuit which is saturated by both solutions.

The path under consideration is constructed on the finite set of nodes  $V$ . As a consequence, there exist two indexes  $k_2 < k_1 \leq 0$  such that  $i_{k_1} = i_{k_2}$ . In other words, the backward construction of the path leads out onto a circuit. In this circuit, according to property (5), we have:  $0 < x_{i_{k_1}} - t_{i_{k_1}} \leq x_{i_{k_1-1}} - t_{i_{k_1-1}} \leq \dots \leq x_{i_{k_2+1}} - t_{i_{k_2+1}} \leq x_{i_{k_2}} - t_{i_{k_2}} = x_{i_{k_1}} - t_{i_{k_1}}$ . As a consequence, these differences are equal to each other, and:

$$0 < x_{i_{k_1}} - t_{i_{k_1}} = x_{i_{k_1-1}} - t_{i_{k_1-1}} = \dots = x_{i_{k_2+1}} - t_{i_{k_2+1}} = x_{i_{k_2}} - t_{i_{k_2}} = \Delta. \quad (6)$$

In other words, the restriction of the solutions to the nodes of the circuit are derived from each other by adding the same value to each component of the solution.

Let us consider two consecutive nodes of the circuit, say  $i_{k-1}$  and  $i_k$ . We have just proved that:  $x_{i_{k-1}} - t_{i_{k-1}} = x_{i_k} - t_{i_k}$ . This leads to:  $t_{i_k} - t_{i_{k-1}} = x_{i_k} - x_{i_{k-1}}$ .

If  $i_k$  is an *or*-node, then:  $t_{i_k} - t_{i_{k-1}} = l(i_{k-1}, i_k)$  (see relation (2)) and thus  $x_{i_k} - x_{i_{k-1}} = l(i_{k-1}, i_k)$ .

If  $i_k$  is an *and*-node, then:  $x_{i_k} - x_{i_{k-1}} = l(i_{k-1}, i_k)$  (see relation (3)) and thus  $t_{i_k} - t_{i_{k-1}} = l(i_{k-1}, i_k)$ .

In both cases, the arc  $(i_{k-1}, i_k)$  is saturated by both solutions. Such a saturated circuit is a null-circuit.

Thus, this null-circuit is saturated by both solutions. (7)

This contradicts the hypothesis of the Theorem and (i) is proved: if a feasible solution of  $P_{EQ}$  does not saturate any null-circuit, then this solution is unique.

(ii) According to our premise, graph  $G$  does not contain any saturated null-circuit, and the feasible solution of  $P_{EQ}$  is unique. Thus, it is optimal to  $P_{EQ}$ . It is also optimal to  $P_{INEQ}$  as shown in [2].

(iii) According to Lemma 1, there exists a saturated path in graph  $G$  from node  $s$  to any other node. QED

As a consequence of Theorem 1, if the graph does not contain any null-circuit, a feasible solution of  $P_{EQ}$  is the unique feasible solution of  $P_{EQ}$  and is optimal for  $P_{EQ}$  and  $P_{INEQ}$ .

### Definition 2

There exists a saturated path from the node  $s$  to each node. This set of saturated paths from node  $s$  is called a *saturated arborescence*. This concept generalizes the concept of the shortest path tree for the shortest path problem [3].

The solution (indicated by the numbers located under the nodes) is feasible to  $P_{EQ}$ . No null-circuit are saturated by this solution. According to Theorem 1, it is optimal.

Figure 3. Illustration of Theorem 1.

### Corollary 1

If there exists two feasible solutions  $\{t_i\}_{i \in V}$  and  $\{x_i\}_{i \in V}$  of  $P_{EQ}$ , then:

- (i) the graph  $G$  contains at least one null-circuit  $\mathcal{C}_0$  saturated by the two solutions, and
- (ii) there exists  $\Delta_{\mathcal{C}_0} > 0$  such that any node  $i$  of  $\mathcal{C}_0$  satisfies the condition  $|x_i - t_i| = \Delta_{\mathcal{C}_0}$ .

### Proof

Point (i) is mentioned in (7) while point (ii) is obtained by inequality (5) completed by (6).

QED

- (a) The solution  $\{0;1;8;6;11\}$  given by the numbers located under the nodes is feasible for  $P_{EQ}$ .  
 (b) The solution  $\{0;0;3;1;6\}$  given by the numbers located under the nodes is feasible for  $P_{EQ}$ .

The two solutions (a) and (b) are different. According to Corollary 1, there exists a null-circuit saturated by the two solutions. This circuit is the one made with nodes 3 and 4.

Figure 4. Illustration of Corollary 1.

#### 4. PROPERTIES OF THE FEASIBLE SOLUTION OF $P_{EQ}$

The goal of this section is to establish properties which lead to:

- a characterization of a feasible solution of  $P_{EQ}$ ,
- an algorithm to reach a feasible solution in the most general cases.

##### **Theorem 2** (Characterization of a feasible solution)

Assume that one of the two following conditions is satisfied:

- There exists a set of negative circuits  $C^- = \{C_1^-, C_2^-, \dots, C_q^-\}$  in the graph such that any arcs  $(j,i)$  which ends with an *and*-node  $i$  of one circuit of  $C^-$ , belongs to a circuit of  $C^-$ ,
- There exists a set of positive circuits  $C^+ = \{C_1^+, C_2^+, \dots, C_p^+\}$  in the graph such that any arcs  $(j,i)$  which ends with an *or*-node  $i$  of one circuit of  $C^+$ , belongs to a circuit of  $C^+$ .

In this case, the problem  $P_{EQ}$  has no feasible solution.

##### **Proof**

(i) Assume that condition (i) is satisfied and that there exists a feasible solution  $\{t_i\}_{i \in V}$  to problem  $P_{EQ}$ . Thus, for any *and*-node  $i$  of one circuit of  $C^-$ , there exists  $j \in \text{Pred}(i)$  such that the arc  $(j,i)$  is saturated by  $\{t_i\}_{i \in V}$  and  $(j,i)$  belongs to a circuit of  $C^-$ . As a consequence, we can select backward a circuit  $C_r^- \in C^-$  such that, if  $C_r^- = \{i_0, i_1, \dots, i_n = i_0\}$  then, for any  $k \in \{1, 2, \dots, n\}$ :

$$t_{i_k} = t_{i_{k-1}} + l(i_{k-1}, i_k) \text{ if } i_k \text{ is an and-node (see condition (i)), and}$$

$$t_{i_k} \leq t_{i_{k-1}} + l(i_{k-1}, i_k) \text{ if } i_k \text{ is an or-node (by definition of } P_{EQ}).$$

By summing left-hand sides and right-hand sides of these equalities and inequalities for the

nodes of  $\mathcal{C}_r^-$ , we obtain:

$$t_{i_0} = t_{i_n} \leq t_{i_0} + \sum_{k=1}^n l(i_{k-1}, i_k) \text{ which is impossible since the length of } \mathcal{C}_r^- \text{ is strictly negative.}$$

(ii) Using the same arguments as in (i), we can show that (ii) holds. QED

### Remarks

Algorithm 1 which is presented at the end of this section, ends either by finding a feasible solution of  $P_{EQ}$ , or by finding a set of circuits for which at least one of the conditions of the Theorem 2 is satisfied. It follows that if the problem  $P_{EQ}$  has no feasible solution, at least one of the conditions of the Theorem 2 is satisfied.

These two conditions are the generalisation of the existence of negative circuit in routing problems (which included only *or*-nodes), and of the existence of positive circuit in the PERT/CPM models (which included only *and*-nodes).

Consider  $\mathcal{C}_1^-$  the negative circuit made with nodes 2, 4, 6 and 3, and  $\mathcal{C}_2^-$  the negative circuit made with nodes 3 and 6. Arcs (3, 6) and (4, 6) are the only arcs ending with an *and*-node belonging to  $\mathcal{C}_1^-$  and  $\mathcal{C}_2^-$ . Both of these arcs belong to one of the circuits  $\mathcal{C}_1^-$  and  $\mathcal{C}_2^-$ . According to Theorem 2, the problem  $P_{EQ}$  has no feasible solution.

The solution (indicated by the numbers located under the nodes) is not feasible to  $P_{EQ}$  since node 3 is a non-saturated node (because of the dotted arc).

Figure 5. Illustration of Theorem 2.

### Construction of an initial solution

We denote by  $G=(V,E')$ , the subgraph composed with the set of arcs  $E' \subseteq E$ , but which contains all the nodes of the initial graph  $G=(V,E)$ .

Let  $E_0$  be a subset of  $E$  such that  $G=(V,E_0)$  does not contain any directed cycle, and such that there exists a (directed) path from node  $s$  to any node in  $G(V,E_0)$ . Such a subset of  $E$  exists since we assumed that there exists a (directed) path from node  $s$  to any node in  $G(V,E)$ .

To obtain the optimal solution of problems  $P_{EQ}$  associated with  $G(V,E_0)$ , it is possible to use the breadth first search (BFS) which marks the nodes of the network progressively step by step (see [3]). Nodes are labelled using relations  $(S_{EQ})$ . Since the lengths of arcs are rational, all the

components of  $\{t_i^0\}_{i \in V}$  are rational. Let  $q$  be the greatest common divisor of the lengths of arcs. Then,  $q$  is also a common divisor of the components of  $\{t_i^0\}_{i \in V}$ . The optimal solution  $\{t_i^0\}_{i \in V}$  of problems  $P_{EQ}$  associated with  $G(V, E_0)$  is not necessary feasible to  $P_{EQ}$  associated with  $G(V, E)$ . This solution  $\{t_i^0\}_{i \in V}$  is feasible to the following problem  $P_{INEQ2}$ :

$$\begin{aligned} \text{Problem } P_{INEQ2} : & \text{minimize } \left[ \sum_{i \in R} \left( t_i - \min_{j \in \text{Pred}(i)} \{t_j + l(j, i)\} \right) + \sum_{i \in A} \left( \max_{j \in \text{Pred}(i)} \{t_j + l(j, i)\} - t_i \right) \right] \\ & \text{subject to} \\ & \begin{cases} t_i = 0 & \text{if } i = s \\ t_i \geq \min_{j \in \text{Pred}(i)} \{t_j + l(j, i)\} & \text{if } i \in R \\ t_i \leq \max_{j \in \text{Pred}(i)} \{t_j + l(j, i)\} & \text{if } i \in A \end{cases} \end{aligned} \quad (S_{INEQ2})$$

Algorithm 1, which will be presented at the end of this section, consists in reducing the value of the *or*-nodes  $i$  for which  $t_i^0 > \min_{j \in \text{Pred}(i)} \{t_j^0 + l(j, i)\}$  and increasing the value of the *and*-nodes  $i$  for which  $t_i^0 < \max_{j \in \text{Pred}(i)} \{t_j^0 + l(j, i)\}$ . These values are modified step by step and, at each step, the solution obtained still satisfies  $(S_{INEQ2})$ . Lemma 2 describes some specific properties of a subset of nodes  $K \subset V$  and of a solution satisfying  $S_{INEQ2}$ . These properties allow us to improve the solution under consideration.

### Lemma 2

We consider a rational solution  $\{t_i\}_{i \in V}$  satisfying  $S_{INEQ2}$  and we assume that there exists  $K \subset V$  ( $K$  is strictly included in  $V$ ) such that:

- (i) for any saturated *or*-node  $i \in K$ , there exists a node  $j \in K$  such that the arc  $(j, i)$  is saturated, i.e.  $t_i = \min_{j \in \text{Pred}(i)} \{t_j + l(j, i)\}$ ,
- (ii) for any saturated *and*-node  $i \in K$ , it does not exist a node  $j \in V/K$  such that the arc  $(j, i)$  is saturated, i.e.  $t_i > \max_{j \in \text{Pred}(i)} \{t_j + l(j, i)\}$ ,
- (iii) for any saturated *or*-node  $i \in V/K$ , it does not exist a node  $j \in K$  such that the arc  $(j, i)$  is saturated, i.e.  $t_i < \min_{j \in \text{Pred}(i)} \{t_j + l(j, i)\}$ , and
- (iv) for any saturated *and*-node  $i \in V/K$ , there exists a node  $j \in V/K$  such that the arc  $(j, i)$  is saturated, i.e.  $t_i = \max_{j \in \text{Pred}(i)} \{t_j + l(j, i)\}$ .

If these conditions are satisfied, then there exist an infinite number of rational solutions satisfying  $S_{INEQ2}$  which saturate all the nodes saturated by  $\{t_i\}_{i \in V}$ .

All non-saturated arcs are optional for the definition of  $K$  and are not represented in the figure. Properties (i) to (iv) can be summarized as follows:

- any saturated node is the end point of a saturated arc whose origin is in the same subset,
- the only saturated arcs which cross the boundaries of  $K$  are those which either ends in  $K$  with an *or*-node, or ends in  $V/K$  with an *and*-node (these saturated arcs are optional).

Figure 6. Definition of the subset  $K$ .

### Proof

Let  $\{t_i\}_{i \in V}$  the solution under consideration which satisfies  $S_{\text{INEQ2}}$ . The basic idea behind the proof presented hereafter is to use the relative independence between the restriction of the solution to the nodes belonging to  $K$ , and the restriction of the solution to the nodes belonging to  $V/K$ . We denote by:

$A_S$  (respectively  $R_S$ ) the set of the saturated *and*-nodes (respectively *or*-nodes) and  $A_{NS}$  (respectively  $R_{NS}$ ) the set of the non-saturated *and*-nodes (respectively *or*-nodes).

We consider:

$$\Delta_{A_S \cap K} = \begin{cases} +\infty & \text{if } A_S \cap K = \emptyset \text{ or } \text{Pred}(i \text{ s.t. } i \in A_S \cap K) / K = \emptyset \\ \min \left\{ \max_{j \in \text{Pred}(i) / K} \{t_i - t_j - l(j, i)\} \right\} & \text{otherwise.} \end{cases}$$

According to property (ii), we have:  $t_j + l(j, i) < t_i \quad \forall i \in A_S \cap K, \quad \forall j \in \text{Pred}(i) / K$ .

Thus,  $\Delta_{A_S \cap K} > 0$ .

We also consider:

$$\Delta_{R_S / K} = \begin{cases} +\infty & \text{if } R_S / K = \emptyset \text{ or } \text{Pred}(i \text{ s.t. } i \in R_S / K) \cap K = \emptyset \\ \min \left\{ \min_{j \in \text{Pred}(i) \cap K} \{t_j + l(j, i) - t_i\} \right\} & \text{otherwise.} \end{cases}$$

According to property (iii), we have:  $t_j + l(j, i) > t_i \quad \forall i \in R_S / K, \quad \forall j \in \text{Pred}(i) \cap K$ .

Thus,  $\Delta_{R_S/K} > 0$ .

We then consider:

$$\Delta_{R_{NS} \cap K} = \begin{cases} +\infty & \text{if } \exists j \in K \text{ s.t. } t_i > t_j + l(j, i) \\ \min_{i \in R_{NS} \cap K} \left\{ \min_{j \in \text{Pred}(i)} \{t_i - t_j - l(j, i)\} \right\} & \text{otherwise.} \end{cases}$$

By definition of the non-saturated *or*-nodes, we have:  $\Delta_{R_{NS} \cap K} > 0$ .

Finally, we consider:

$$\Delta_{A_{NS}/K} = \begin{cases} +\infty & \text{if } \exists j \in V/K \text{ s.t. } t_i < t_j + l(j, i) \\ \min_{i \in A_{NS}/K} \left\{ \max_{j \in \text{Pred}(i)} \{t_j + l(j, i) - t_i\} \right\} & \text{otherwise.} \end{cases}$$

By definition of the non-saturated *and*-nodes, we have:  $\Delta_{A_{NS}/K} > 0$ .

We set  $\Delta = \min\{\Delta_{A_S \cap K}, \Delta_{R_S/K}, \Delta_{R_{NS} \cap K}, \Delta_{A_{NS}/K}\} > 0$ .  $\Delta$  is rational since the components of  $\{t_i\}_{i \in V}$  and the lengths of arcs are rational.

If  $s \in V/K$ , we claim that, for any rational  $\alpha \in ]0; \Delta]$  and  $\alpha \neq +\infty$ , the solution  $\{t_i(\alpha)\}_{i \in V}$ , defined as follows, satisfies  $S_{\text{INEQ2}}$  and saturates all the nodes saturated by  $\{t_i\}_{i \in V}$ :

$$\begin{cases} t_i(\alpha) = t_i - \alpha & \text{if } i \in K \\ t_i(\alpha) = t_i & \text{if } i \in V/K. \end{cases}$$

The explanation is straightforward.

Similarly, if  $s \in K$ , we claim that, for any rational  $\beta \in ]0; \Delta]$  and  $\beta \neq +\infty$ , the solution  $\{t_i(\beta)\}_{i \in V}$ , defined as follows, satisfies  $S_{\text{INEQ2}}$  and saturates all the nodes saturated by  $\{t_i\}_{i \in V}$ :

$$\begin{cases} t_i(\beta) = t_i & \text{if } i \in K \\ t_i(\beta) = t_i + \beta & \text{if } i \in V/K. \end{cases}$$

QED

### Remark

As a consequence of the Lemma 2, if there exists  $\{t_i\}_{i \in V}$ , feasible solution of  $P_{\text{EQ}}$ , and a set of nodes  $K \subset V$  such that properties (i) to (iv) hold, then  $P_{\text{EQ}}$  has an infinite number of feasible solutions. Moreover, according to the definitions of  $\Delta$  and  $\{t_i(\alpha)\}_{i \in V}$  given in the proof, if  $s \notin K$ , then  $\{t_i\}_{i \in V}$  is not optimal to  $P_{\text{EQ}}$  since the solution  $\{t_i(\alpha)\}_{i \in V}$  is better. Furthermore, if  $\Delta = +\infty$  then there is no optimal solution of  $P_{\text{EQ}}$  since it is possible to decrease  $\{t_i\}_{i \in K}$  to  $-\infty$ .

If  $q$ , the greatest common divisor of the lengths of arcs, is a common divisor of the components of  $\{t_i\}_{i \in V}$ , then it is also a common divisor of  $\Delta$  and of the components of the solutions  $\{t_i(\alpha=\Delta)\}_{i \in V}$  and  $\{t_i(\beta=\Delta)\}_{i \in V}$ .

Assume that  $\{t_i\}_{i \in V}$  is a solution satisfying  $S_{\text{INEQ2}}$ . If we want to reduce (resp. increase) the

values  $\{t_i\}_{i \in L}$  of the nodes of a set  $L \subset V$  in order to obtain another solution satisfying  $S_{INEQ2}$  which saturate all the nodes already saturated by  $\{t_i\}_{i \in V}$ , we will show that we must reduce (resp. increase) the values of all the nodes of a larger set, called  $L_1$  (resp.  $L_2$ ). These new sets are introduced hereafter.

### Definitions 3

For any set of nodes  $L$ , we define  $L_1$  as the smallest set such that:

- (a1) If  $i \in L$ , then  $i \in L_1$ , i.e.  $L_1 \supseteq L$ .
- (b1) If  $i \in R$  and if the starting node  $j$  of *at least one* saturated arc  $(j, i)$  belongs to  $L_1$ , then  $i \in L_1$ .
- (c1) If  $i \in A$  and if the starting node  $j$  of *all the* saturated arcs  $(j, i)$  belong to  $L_1$ , then  $i \in L_1$ .

For a set of nodes  $L$ , we define  $L_2$  as the smallest set such that:

- (a2) If  $i \in V/L$ , then  $i \in L_2$ , i.e.  $L_2 \supseteq V/L$ .
- (b2) If  $i \in R$  and if the starting node  $j$  of *all the* saturated arcs  $(j, i)$  belong to  $L_2$ , then  $i \in L_2$ .
- (c2) If  $i \in A$  and if the starting node  $j$  of *at least one* saturated arc  $(j, i)$  belongs to  $L_2$ , then  $i \in L_2$ .

We can obtain  $L_1$  (resp.  $L_2$ ) from  $L$  (resp.  $V/L$ ), using a breadth first search (BFS) on the subgraph composed with the saturated arcs of  $E$ , knowing the feasible solution at hand. Starting from  $L$  (resp.  $V/L$ ), the nodes satisfying conditions (b1) and (c1) (resp. (b2) and (c2)) are added one after the other until no more node can be added. The resulting subset is  $L_1$  (resp.  $L_2$ ). Lemma 3 precises the properties that a set  $L$  must satisfy in order to be able to modify the values of the nodes of  $L_1$  (or  $L_2$ ) derived from  $L$ .

### Lemma 3

Assume that there exists a solution  $\{t_i\}_{i \in V}$  satisfying  $S_{INEQ2}$ .

- (a) If  $L$  is a set of nodes satisfying properties (i) and (ii) of Lemma 2 by replacing  $K$  by  $L$ , then  $L_1$  (where  $L_1$  is defined by (a1), (b1), (c1)) satisfies properties (i) to (iv) of Lemma 2 by replacing  $K$  by  $L_1$ .
- (b) If  $V/L$  is a set of nodes satisfying properties (iii) and (iv) of Lemma 2 by replacing  $V/K$  by  $V/L$ , then  $V/L_2$  (where  $L_2$  is defined by (a2), (b2), (c2)) satisfies properties (i) to (iv) of Lemma 2 by replacing  $K$  by  $V/L_2$ .

As a consequence, if  $V/L_1 \neq \emptyset$  or  $L_2 \neq \emptyset$ , then there exist an infinite number of solutions satisfying  $S_{INEQ2}$  which saturate all the nodes saturated by  $\{t_i\}_{i \in V}$  (see Lemma 2).

### Proof

(a) Let  $L$  be a set satisfying properties (i) to (ii) of Lemma 2 and  $L_1$  the subset derived from  $L$ .

If an *or*-node  $i \notin L_1$  is such that the starting node  $j$  of a saturated arc  $(j, i)$  belongs to  $L_1$ , node  $i$  would be added to  $L_1$  according to (b1) of Definitions 3. Thus, the nodes of  $L_1$  satisfy property (iii) of Lemma 2.

Moreover, if an *and*-node  $i \notin L_1$  is such that the starting node  $j$  of any saturated arc  $(j, i)$  belongs to  $L_1$ , node  $i$  would be added to  $L_1$  according to (c1) of Definitions 3. Thus, the nodes of  $L_1$  satisfy property (iv) of Lemma 2. By construction (see (b1) and (c1)), the nodes of  $L_1/L$  satisfy properties (i) and (ii) of Lemma 2. Finally, the nodes of  $L_1 = L \cup L_1/L$  satisfy properties (i) to (iv) of Lemma 2.

(b) Using the same arguments as in (a), we can show that (b) holds. QED

### Remark

If  $L_1 = V$  (or  $L_2 = V$ ), we cannot apply Lemma 2 since  $L_1$  (resp.  $L_2$ ) should be strictly included in  $V$  for Lemma 2 to apply.

The solution (indicated by the numbers located under the nodes) satisfies  $(S_{\text{INEQ2}})$ . Node 2 is non-saturated because of arc (1, 2).

The set of nodes  $L = \{2\}$  satisfies the two first properties of Lemma 2. The set of nodes  $L_1 = K = \{2, 3, 5\}$  derived from  $L$ , satisfies the four properties of Lemma 2. Thus, for any  $\alpha \in [-1; 0]$ , the solutions  $\{t_i(\alpha)\}_{i=1, \dots, 5}$  defined by  $\{t_1=0; t_2=2+\alpha; t_3=3+\alpha; t_4=1; t_5=4+\alpha\}$  satisfies  $(S_{\text{INEQ2}})$  and saturates all the nodes saturated by  $\{t_i\}_{i=1, \dots, 5}$ .

Figure 7. Illustration of Lemma 2 and 3.

### Definitions

We consider a solution  $\{t_i\}_{i \in V}$  satisfying  $S_{\text{INEQ2}}$ . Let  $R_{NS}$  (respectively  $R_S$ ) be the set of non-saturated (respectively saturated) *or*-nodes. Let  $R_{NS,1}$  be the set derived from  $R_{NS}$  by applying (a1) to (c1) of Definitions 3.

Since  $R_{NS}$  satisfies properties (i) and (ii) of Lemma 2,  $R_{NS,1}$  satisfies properties (i) to (iv) of

Lemma 2 (see Lemma 3). Furthermore,  $s \notin R_{NS}$ . As a consequence of the definition of  $R_{NS,1}$  and since node  $s$  has no predecessor,  $s \notin R_{NS,1}$ . Thus, we can apply Lemma 2 to decrease the values of the nodes belonging to  $R_{NS,1}$  using the solution  $\{t_i(\alpha=\Delta)\}_{i \in V}$  (see proof of Lemma 2).

Let  $A_{NS}$  (respectively  $A_S$ ) be the set of non-saturated (respectively saturated) *and*-nodes non-saturated. Let  $A_{NS,2}$  be the set derived from  $A_{NS}$  by applying (a2) to (c2) of Definitions 3.

Since  $A_{NS}$  satisfies properties (i) and (ii) of Lemma 2,  $A_{NS,2}$  satisfies properties (i) to (iv) of Lemma 2 (see Lemma 3). Furthermore,  $s \notin A_{NS,2}$ . As a consequence of the definition of  $A_{NS,2}$  and since node  $s$  has no predecessor,  $s \notin A_{NS,2}$ . Thus, we can apply Lemma 2 to increase the values of the nodes belonging to  $A_{NS,2}$  using the solution  $\{t_i(\beta=\Delta)\}_{i \in V}$  (see proof of Lemma 2).

Lemma 4 shows that if applying Lemma 2 to  $R_{NS,1}$  (respectively  $A_{NS,2}$ ) we obtain  $\Delta = +\infty$ , then the problem  $P_{EQ}$  under consideration has no feasible solution.

#### Lemma 4

Assume that there exists a solution  $\{t_i\}_{i \in V}$  satisfying  $S_{INEQ2}$ .

(a) If there exists a set  $R_{NS,1}$  derived from  $R_{NS}$  satisfying the following properties:

- no arc  $(j,i)$  starts from  $j \notin R_{NS,1}$  and ends with *and*-node  $i \in R_{NS,1}$ ,
  - for any  $i \in R_{NS}$ , there exists  $(j,i)$  starting from  $j \in R_{NS,1}$  such that  $t_i > t_j + l(j,i)$ ,
- then there exists in  $R_{NS,1}$  a set of negative circuits  $C^- = \{C_1^-, C_2^-, \dots, C_q^-\}$  such that any arcs  $(j,i)$  which ends with an *and*-node  $i$  of one circuit of  $C^-$ , belongs to a circuit of  $C^-$ .

(b) If there exists a set  $A_{NS,2}$  derived from  $A_{NS}$  satisfying the following properties:

- no arc  $(j,i)$  starts from  $j \in A_{NS,2}$  and ends with *and*-node  $i \notin A_{NS,2}$ ,
  - for any  $i \in A_{NS}$ , there exists  $(j,i)$  starting from  $j \in A_{NS,2}$  such that  $t_i < t_j + l(j,i)$ ,
- then there exists a set of positive circuits  $C^+ = \{C_1^+, C_2^+, \dots, C_p^+\}$  in the graph such that any arcs  $(j,i)$  which ends with an *or*-node  $i$  of one circuit of  $C^+$ , belongs to a circuit of  $C^+$ .

In both cases, according to Theorem 2, the problem  $P_{EQ}$  has no feasible solution.

#### Proof

(a) Assume that there exists  $\{t_i\}_{i \in V}$  satisfying  $S_{INEQ2}$  and a set  $R_{NS,1}$  derived from  $R_{NS}$  satisfying the two properties (a) of Lemma 4.

Let  $R_{NS}^1, R_{NS}^2, \dots, R_{NS}^n$  be the smallest disjoint subsets of  $R_{NS}$  such that  $R_{NS} = R_{NS}^1 \cup R_{NS}^2 \cup \dots \cup R_{NS}^n$  and that, for any  $1 \leq r \leq n$  and any  $i \in R_{NS}^r$ , there exists  $(j,i)$  starting from  $j \in R_{NS,1}^r$  which satisfies  $t_i > t_j + l(j,i)$ , where  $R_{NS,1}^r$  is derived from  $R_{NS}^r$ . According to the second condition of (a), we know that this partition is possible.

Consider a subset  $R_{NS}^r$ . For any  $i \in R_{NS}^r$ , there exists  $(j,i)$  starting from  $j \in R_{NS,1}^r$  such that  $t_i > t_j + l(j,i)$ . By construction of  $R_{NS,1}^r$ , there exists in  $R_{NS,1}^r$  a saturated path from a node of  $R_{NS}^r$  to

$j \in R'_{NS,1}$ . Thus, there exists, in  $R'_{NS,1}$ , a circuit which includes arcs saturated by  $\{t_i\}_{i \in V}$ , and at least one arc  $(j,i)$  satisfying  $t_i > t_j + l(j,i)$ . Let  $\mathcal{C}'$  be such a circuit. For any arc  $(j,i)$  of this circuit  $\mathcal{C}'$ , we have  $t_j - t_i \leq l(j,i)$  and there exists at least one arc for which  $t_j - t_i < l(j,i)$ . It follows that  $R'_{NS,1}$  contains a negative circuit  $\mathcal{C}'$  which includes an arc  $(j,i)$  satisfying  $t_i > t_j + l(j,i)$ . Moreover, there exists a path  $P_{\rightarrow k}$  from  $\mathcal{C}'$  to any *or*-node  $k \in R'_{NS}$  which includes either arcs  $(j,i)$  satisfying  $t_i > t_j + l(j,i)$ , or saturated arcs.

Two cases are possible:

*First case.* There exists  $R'_{NS,1}$  such that the predecessors of any *and*-node  $i$  of the negative circuit  $\mathcal{C}'$ , belong to  $R'_{NS,1}$ . Let  $C^*$  be the set of the negative circuits in  $R'_{NS,1}$  intersecting  $\mathcal{C}'$ . In this case, for any predecessor  $j$  of an *and*-node  $i$  of a circuit  $\mathcal{C}'$  in  $C^*$ , there exists a saturated path  $P_{k \rightarrow j}$  from  $k \in R'_{NS}$  to  $j$ . Thus, arc  $(j,i)$  belongs to a negative circuit in  $C^*$  made with paths  $P_{\rightarrow k}$  and  $P_{k \rightarrow j}$ , arc  $(j,i)$ , and a path included in  $\mathcal{C}'$ .

*Second case.* For any subset  $R'_{NS,1}$ , there exists a predecessor  $j_q \notin R'_{NS,1}$  of an *and*-node  $i_r$  ( $r \neq q$ ) of the negative circuit  $\mathcal{C}'$ . In this case, there exists a negative circuit made with arcs similar to  $(j_q, i_r)$  and paths included in  $\mathcal{C}'$  and joining  $i_r$  to  $j_r$ . Finally, it is possible to obtain in  $R_{NS,1}$  a set of negative circuits  $C^*$  such that any arcs  $(j,i)$  which ends with an *and*-node  $i$  of one circuit of  $C^*$ , belongs to a circuit of  $C^*$ .

(b) Using the same arguments as in (a), we can claim that (b) holds. QED

### Construction of a feasible solution of $P_{EQ}$

**First step.** We start building the solution  $\{t_i\}_{i \in V}$  optimal to the problem  $P_{EQ}$  associated with  $G(V, E_0)$ , where  $E_0$  is a subset of  $E$  such that  $G = (V, E_0)$  does not contain any directed cycle, and such that there exists a (directed) path from node  $s$  to any node in  $G(V, E_0)$ . The solution  $\{t_i\}_{i \in V}$  satisfies  $(S_{INEQ2})$ . Then, the algorithm proceeds in two other steps.

**Second step.** The algorithm modifies the solution  $\{t_i\}_{i \in V}$  in order to saturate the non-saturated *or*-nodes. The idea of the algorithm is to decrease the values  $\{t_i\}$  of the nodes  $i$  which belong to  $R_{NS,1}$  derived from  $R_{NS}$ , and to adjust  $R_{NS,1}$  by adding or removing nodes adequately.

If  $R_{NS} = \emptyset$  then all the *or*-nodes are saturated by the solution. Otherwise, since  $R_{NS}$  satisfies the properties (i) and (ii) of Lemma 2,  $R_{NS,1}$  satisfies the properties (i) to (iv) of Lemma 2 (see Lemma 3). Furthermore,  $s \notin R_{NS}$ . As a consequence of the definition of  $R_{NS,1}$  and since node  $s$  has no predecessor,  $s \notin R_{NS,1}$ . As in the proof of Lemma 2, we define  $\Delta$  and, for  $\alpha \in ]0; \Delta]$ ,  $\{t_i(\alpha)\}_{i \in V}$ . According Lemma 4, if  $\Delta = +\infty$  then there is no feasible solution to  $P_{EQ}$ .

If  $\Delta \neq +\infty$ , by definition of  $\Delta$ , the solution  $\{t_i(\alpha = \Delta)\}_{i \in V}$  saturates one arc  $(j,i)$  which was not saturated by solution  $\{t_i\}_{i \in V}$ . Four cases are possible to adjust  $R_{NS,1}$ , according to its definition:

- this arc  $(j,i)$  starts from  $j \notin R_{NS,1}$  and ends with *and*-node  $i \in R_{NS,1}$ : this *and*-node  $i$  must be removed from  $R_{NS,1}$ ,
- this arc  $(j,i)$  starts from  $j \in R_{NS,1}$  and ends with *or*-node  $i \notin R_{NS}$ : this *or*-node  $i$  must be added

to  $R_{NS,I}$ ,

- this arc  $(j,i)$  starts from  $j \notin R_{NS,I}$  and ends with  $i \in R_{NS}$ : this *or*-node  $i$  must be removed from  $R_{NS}$  and  $R_{NS,I}$ , or
- this arc  $(j,i)$  starts from  $j \in R_{NS,I}$  and ends with  $i \notin A_{NS}$ : this *and*-node  $i$  must be added to  $R_{NS,I}$  (and removed from  $A_{NS}$ ).

In both cases, we derive a new set  $R_{NS,I}$  from  $R_{NS}$  by applying (a1) to (c1) of Definitions 3 taking into account the arcs saturated by solution  $\{t_i(\alpha=\Delta)\}_{i \in V}$ .

For each set  $R_{NS,I}$ , we define a solution  $\{t_i\}_{i \in V}$ . Since the number of non-saturated *or*-nodes decreases and since the value  $\sum_{i \in R_{NS}} \min_{j \in \text{Pred}(i)} \{t_i - t_j - l(j,i)\}$  strictly decreases at each modification of

the solution, the algorithm converges to a feasible solution of  $P_{EQ}$ , if any.

Since all the non-saturated *or*-nodes belong to  $R_{NS} \subseteq R_{NS,I}$  and since all the *and*-nodes of  $R_{NS,I}$  are saturated, we have:  $A_S \cap R_{NS,I} = A \cap R_{NS,I}$ ,  $R_S/R_{NS,I} = R/R_{NS,I}$ ,  $R_{NS} \cap R_{NS,I} = R_{NS}$  and  $A_{NS}/R_{NS,I} = A_{NS}$ . These simplifications will be used in the notations of steps 2.4 to 2.8 in Algorithm 1.

**Third step.** The algorithm modifies the solution in order to saturate all the *and*-nodes. The idea is to increase the values  $\{t_i\}$  of the nodes  $i$  which belong to  $A_{NS,2}$  (where  $A_{NS,2}$  is derived from  $A_{NS}$  by applying (a2) to (c2), to the set of the non-saturated *and*-nodes). Then,  $A_{NS,2}$  is adjusted by adding or removing nodes adequately, similarly as in the second step.

### Algorithm 1 - Construction of a feasible solution of $P_{EQ}$

#### Input data:

$G=(V,E)$  is the graph under consideration.

#### Output data:

$\{t_i\}_{i \in V}$ , is a feasible solution to  $P_{EQ}$ , if any.

#### 1. Construction of an initial solution satisfying ( $S_{INEQ2}$ )

- 1.1. Select  $E_0$ , a subset of  $E$ , such that  $G=(V,E_0)$  does not contain any directed cycle, and such that there exists a (directed) path from node  $s$  to any node in  $G(V,E_0)$ .
- 1.2. Compute  $\{t_i\}_{i \in V}$ , the optimal solution of problems  $P_{EQ}$  associated with  $G(V,E_0)$ , using a breadth first search.

#### 2. Saturation of the *or*-nodes

- 2.1. Let  $R_{NS}$  be the set of the *or*-nodes which are not saturated by  $\{t_i\}_{i \in V}$ .
- 2.2. If  $R_{NS} = \emptyset$  then goto step 3.
- 2.3. Derive  $R_{NS,I}$  from  $R_{NS}$  by applying:
  - (a1) If  $i \in R_{NS}$ , then  $i \in R_{NS,I}$ .
  - (b1) If  $i \in R$  and if the starting node  $j$  of at least one saturated arc  $(j,i)$  belongs to  $R_{NS,I}$ , then  $i \in R_{NS,I}$ .

(c1) If  $i \in A$  and if the starting node  $j$  of *all the* saturated arcs  $(j,i)$  belong to  $R_{NS,1}$ , then

$$i \in R_{NS,1}.$$

$$2.4. \text{ Set } \Delta_{A \cap R_{NS,1}} = \begin{cases} +\infty & \text{if } A \cap R_{NS,1} = \emptyset \text{ or } \text{Pred}(i \text{ s.t. } i \in A \cap R_{NS,1}) / R_{NS,1} = \emptyset \\ \min_{i \in A \cap R_{NS,1}} \left\{ \max_{j \in \text{Pred}(i) / R_{NS,1}} \{t_i - t_j - l(j,i)\} \right\} & \text{otherwise.} \end{cases}$$

$$2.5. \text{ Set } \Delta_{R / R_{NS,1}} = \begin{cases} +\infty & \text{if } R / R_{NS,1} = \emptyset \text{ or } \text{Pred}(i \text{ s.t. } i \in R / R_{NS,1}) \cap R_{NS,1} = \emptyset \\ \min_{i \in R / R_{NS,1}} \left\{ \min_{j \in \text{Pred}(i) \cap R_{NS,1}} \{t_j + l(j,i) - t_i\} \right\} & \text{otherwise.} \end{cases}$$

$$2.6. \text{ Set } \Delta_{R_{NS}} = \begin{cases} +\infty & \text{if } \exists j \in R_{NS,1} \text{ s.t. } t_i > t_j + l(j,i) \\ \min_{i \in R_{NS}} \left\{ \min_{j \in \text{Pred}(i)} \{t_i - t_j - l(j,i)\} \right\} & \text{otherwise.} \end{cases}$$

$$2.7. \text{ Set } \Delta_{A_{NS}} = \begin{cases} +\infty & \text{if } \exists j \in V / R_{NS,1} \text{ s.t. } t_i < t_j + l(j,i) \\ \min_{i \in A_{NS}} \left\{ \max_{j \in \text{Pred}(i)} \{t_j + l(j,i) - t_i\} \right\} & \text{otherwise.} \end{cases}$$

$$2.8. \text{ Set } \Delta = \min\{\Delta_{A \cap R_{NS,1}}; \Delta_{R / R_{NS,1}}; \Delta_{R_{NS}}; \Delta_{A_{NS}}\} > 0.$$

2.9. If  $\Delta = +\infty$  then there is no feasible solution of  $P_{EQ}$ . End.

2.10. Set  $t_i = t_i - \Delta$  for  $i \in R_{NS,1}$ .

2.11. Goto step 2.

### 3. Saturation of the *and*-nodes

3.1. Let  $A_{NS}$  be the set of the *and*-nodes which are not saturated by  $\{t_i\}_{i \in V}$ .

3.2. If  $A_{NS} = \emptyset$  then  $\{t_i\}_{i \in V}$  is feasible to  $P_{EQ}$ . End.

3.3. Derive  $A_{NS,2}$  from  $A_{NS}$  by applying:

(a2) If  $i \in A_{NS}$ , then  $i \in A_{NS,2}$ .

(b2) If  $i \in R$  and if the starting node  $j$  of *all the* saturated arcs  $(j,i)$  belong to  $A_{NS,2}$ , then

$$i \in A_{NS,2}.$$

(c2) If  $i \in A$  and if the starting node  $j$  of *at least one* saturated arc  $(j,i)$  belongs to  $A_{NS,2}$ , then  $i \in A_{NS,2}$ .

$$3.4. \text{ Set } \Delta_{A / A_{NS,2}} = \begin{cases} +\infty & \text{if } A / A_{NS,2} = \emptyset \text{ or } \text{Pred}(i \text{ s.t. } i \in A / A_{NS,2}) \cap A_{NS,2} = \emptyset \\ \min_{i \in A / A_{NS,2}} \left\{ \max_{j \in \text{Pred}(i) \cap A_{NS,2}} \{t_i - t_j - l(j,i)\} \right\} & \text{otherwise.} \end{cases}$$

$$3.5. \text{ Set } \Delta_{R \cap A_{NS,2}} = \begin{cases} +\infty & \text{if } R \cap A_{NS,2} = \emptyset \text{ or } \text{Pred}(i \text{ s.t. } i \in R \cap A_{NS,2}) / A_{NS,2} = \emptyset \\ \min_{i \in R \cap A_{NS,2}} \left\{ \min_{j \in \text{Pred}(i) / A_{NS,2}} \{t_j + l(j,i) - t_i\} \right\} & \text{otherwise.} \end{cases}$$

$$3.6. \text{ Set } \Delta_{R_{NS}} = \begin{cases} +\infty & \text{if } \exists j \notin A_{NS,2} \text{ s.t. } t_i > t_j + l(j,i) \\ \min_{i \in R_{NS}} \left\{ \min_{j \in \text{Pred}(i)} \{t_i - t_j - l(j,i)\} \right\} & \text{otherwise.} \end{cases}$$

$$3.7. \text{ Set } \Delta_{A_{NS}} = \begin{cases} +\infty & \text{if } \exists j \in A_{NS,2} \text{ s.t. } t_i < t_j + l(j,i) \\ \min_{i \in A_{NS}} \left\{ \max_{j \in \text{Pred}(i)} \{t_j + l(j,i) - t_i\} \right\} & \text{otherwise.} \end{cases}$$

$$3.8. \text{ Set } \Delta = \min\{\Delta_{A / A_{NS,2}}; \Delta_{R \cap A_{NS,2}}; \Delta_{R_{NS}}; \Delta_{A_{NS}}\} > 0.$$

3.9. If  $\Delta = +\infty$  then there is no feasible solution of  $P_{EQ}$ . End.

3.10. Set  $t_i = t_i + \Delta$  for  $i \in A_{NS,2}$ .

3.11. Goto step 3.

### Proposition

The complexity of the previous algorithm is  $O((|V| + |E|) |V| Lq)$ , where  $|V|$  and  $|E|$  represent respectively the number of nodes and arcs,  $q$  is the greatest common divisor of the lengths of arcs and  $L = \sum_{i_0 \in V} \sum_{j_0 \in \text{Pred}(i_0)} |l(j_0, i_0)|$  is equal to the sum of the lengths of the arcs.

### Proof

Using a breadth first search (BFS), it is possible to find a subset  $E_0$  of  $E$  such that it does not contain any directed cycle, and such that there exists a (directed) path from node  $s$  to any node. Thus, step 1.1 is computed in  $O(|V| + |E|)$ .

The breadth first search (BFS) marks the nodes of the network step by step (see [3]). Nodes are labelled using the relations  $(S_{EQ})$ . Thus, step 1.2 is computed in  $O(|V| + |E_0|) \leq O(|V| + |E|)$ .

It is possible to find the non-saturated nodes by looking at all the arcs. Thus, steps 2.1 and 3.1 are computed in  $O(|V| + |E|)$ .

Steps 2.2 and 3.2 are computed in  $O(1)$ .

Applying (a1) to (c1) to the subgraph limited to the saturated arcs, we derive  $R_{NS,1}$  from  $R_{NS}$ . Applying (a2) to (c2) to the subgraph limited to the saturated arcs, we derive  $A_{NS,2}$  from  $A_{NS}$ . Thus, steps 2.3 and 3.3 are computed in  $O(|V| + |E|)$ .

Steps 2.4 to 2.7, and 3.4 to 3.7 are computed in  $O(|V| + |E|)$ , since it is sufficient to look at the arcs one end of which belongs to  $R_{NS,1}$  or  $A_{NS,2}$ .

Steps 2.8 to 2.9, and 3.8 to 3.9 are computed in  $O(1)$ .

Steps 2.10 and 3.10 are computed in  $O(|R_{NS,1}|) + O(|A_{NS,2}|) \leq O(|V|)$ .

Let  $q$  be the greatest common divisor of the lengths of arcs.  $q$  is a common divisor of the components of the initial solution  $\{t_i\}_{i \in V}$ , computed at step 1.2, and is also a common divisor of the components of all the new solutions  $\{t_i\}_{i \in V}$  computed at steps 2.10 and 3.10 (see Lemma 2).

Since the criterium of  $P_{INEQ2}$ , which is  $\sum_{i \in R} \left( t_i - \min_{j \in \text{Pred}(i)} \{t_j + l(j, i)\} \right) + \sum_{i \in A} \left( \max_{j \in \text{Pred}(i)} \{t_j + l(j, i)\} - t_i \right)$ ,

strictly decreases, it decreases by a value greater or equal to  $1/q$ , at each step. If there exists a feasible solution to  $P_{EQ}$ , the criterium is lower bounded by 0. Thus, steps 2.11 and 3.11 are performed at most  $O(Zq)$ -times, where  $Z$  is the value of the criterium for the initial solution computed at step 1.2.

Since each component  $t_i$  of the initial solution is equal to the length of a path from  $s$  to node  $i$ , we have for any  $(j, i) \in E$ ,  $|t_i - t_j - l(j, i)| \leq 2 \sum_{i_0 \in V} \sum_{j_0 \in \text{Pred}(i_0)} |l(j_0, i_0)|$  and

$Z \leq 2|V| \sum_{i_0 \in V} \sum_{j_0 \in \text{Pred}(i_0)} |l(j_0, i_0)|$ . It follows that steps 2.11 and 3.11 are performed at most

$O(|V| Lq)$ -times, where  $L$  is equal to the sum of the lengths of the arcs of  $G$ .

Finally, the algorithm requires  $O((|V| + |E|) |V| Lq)$  operations.

QED

**Remark**

According to Theorem 1, if there is no null-circuit in the graph, the feasible solution to  $P_{EQ}$  provided by Algorithm 1 is optimal.

**5. PROPERTIES OF THE OPTIMAL SOLUTION**

The goal of this section is to establish properties which lead to:

- a characterization of the optimal solution,
- an algorithm to reach the optimal solution in the most general cases.

**Definition 4**

A null-circuit  $\mathcal{C}$  is said to be **and-saturated** if  $\mathcal{C}$  is saturated and if there exists a saturated path ending with an *and*-node of  $\mathcal{C}$  which do not contain arcs belonging to a saturated null-circuit and which starts from either node  $s$ , or a node of another *and*-saturated null-circuit.

The set of *and*-saturated null-circuits can be obtained iteratively from the above definition.

Note that there exists a saturated path from node  $s$  to any node of an *and*-saturated null-circuit.

**Theorem 3 (Necessary and sufficient conditions for optimality)**

A feasible solution of  $P_{EQ}$  is optimal if and only if the following conditions are satisfied:

- (i) there is a saturated path from node  $s$  to any node of  $G$ , and
- (ii) any saturated null-circuit is *and*-saturated.

**Proof**

(a) A feasible solution of  $P_{EQ}$  is not optimal if one of the two conditions (i) and (ii) is not satisfied.

Assume that there exists a feasible solution of  $P_{EQ}$  for which condition (i) and/or (ii) is not satisfied. Let  $N$  be the set nodes such that it does not exist a saturated path either from node  $s$  or from a node belonging to an *and*-saturated null-circuit, to such a node. By definition of  $N$ , the only saturated arcs  $(j,i)$  such that  $j \in V/N$  and  $i \in N$ , end with an *or*-node  $i$  which belongs to a null-circuit. According to the definition of  $P_{EQ}$  (see Section 2), whatever  $i \in N$ , there exists  $j \in N$  such that  $(j,i)$  is saturated. As a consequence,  $N$  satisfies the properties (i) and (ii) of Lemma 2. Thus, if  $N_1$  is derived from  $N$  by applying (a1) to (c1) of Definitions 3,  $N_1$  satisfies the properties (i) to (iv) of Lemma 2 (see Lemma 3). Furthermore,  $s \notin N$ . As a consequence of the definition of  $N_1$  and since node  $s$  has no predecessor,  $s \notin N_1$ . According to Lemma 2, we conclude that a feasible solution of  $P_{EQ}$  for which condition (i) and/or (ii) of Theorem 1 is not satisfied is not optimal.

(b) If a feasible solution of  $P_{EQ}$  satisfies the two conditions (i) and (ii), it is optimal.

Assume that there exists a feasible solution  $\{t_i\}_{i \in V}$  of  $P_{EQ}$  for which the two conditions (i) and (ii) are satisfied. According to condition (ii), we can number the  $p$  null-circuits saturated by this solution from 1 to  $p$  such that:

for any saturated null-circuit  $\mathcal{C}_n$  ( $1 \leq n \leq p$ ), there exists a saturated path  $\mathcal{P}_n$  ending with an *and*-node of  $\mathcal{C}_n$  which does not contain arcs from another saturated null-circuit and which starts from either node  $s$ , or from a node of *and*-saturated null-circuit belonging to  $\mathcal{C}_m$ , where  $1 \leq m < n$ .

We set  $O_0 = \{s\}$ . The solution  $\{t_s = 0\} = \{t_i\}_{i \in O_0}$  is equal to the optimal solution to problem  $P_{EQ}$  restricted to the set  $O_0$ . Let also  $O_n$  be  $O_n = O_{n-1} \cup \mathcal{P}_n \cup \mathcal{C}_n$ , for  $1 \leq n \leq p$ .

Assume that the solution  $\{t_i\}_{i \in O_{n-1}}$  is equal to the optimal solution to problem  $P_{EQ}$  restricted to  $O_{n-1}$ . Another solution to the restriction of problem  $P_{EQ}$  to  $O_n$ , better than  $\{t_i\}_{i \in O_{n-1}}$ , will saturate a null-circuit  $\mathcal{C}$ , according to Corollary 1. If we consider the restriction of this new solution to  $\mathcal{C}$ , it will be obtained by decreasing the values  $\{t_i\}_{i \in \mathcal{C}}$  by  $\Delta_{\mathcal{C}} > 0$  (see Corollary 1). Since the solution  $\{t_i\}_{i \in O_{n-1}}$  cannot be decreased and since the only null-circuit which appears in  $O_n/O_{n-1}$  is  $\mathcal{C}_n$ , the values  $\{t_i\}_{i \in \mathcal{C}_n}$  of the nodes of  $\mathcal{C}_n$  would be decreased by  $\Delta_{\mathcal{C}_n} > 0$ . It is the case in particular for the value of the *and*-node belonging to  $\mathcal{C}_n$  at which the saturated path  $\mathcal{P}_n$  ends. It follows that the values  $\{t_i\}_{i \in \mathcal{P}_n}$  of all the nodes of the saturated path  $\mathcal{P}_n$  would be decreased by a positive value. Since the first node of the path  $\mathcal{P}_n$  belongs to  $O_{n-1}$  and since we assume that  $\{t_i\}_{i \in O_{n-1}}$  is the optimal solution to problem  $P_{EQ}$  restricted to  $O_{n-1}$ , it is impossible to decrease its value. Hence, the solution  $\{t_i\}_{i \in O_n}$  is equal to the optimal solution to problem  $P_{EQ}$  restricted to  $O_n$ .

Thus, recursively, we prove that the solution  $\{t_i\}_{i \in O_n}$  is equal to the optimal solution to problem  $P_{EQ}$  restricted to  $O_n$ , for  $1 \leq n \leq p$ . Since there is no null-circuit which belongs to  $G(V/O_p)$  and since there is a saturated path from  $s$  to any node of  $V/O_p$  (see condition (i)), according to Theorem 1, the solution  $\{t_i\}_{i \in V}$  is equal to the optimal solution to problem  $P_{EQ}$ .

### Remarks

As a consequence of the Theorem 3, if there is no path in the graph from node  $s$  to some nodes in  $G$ , there is no optimal solution to  $P_{EQ}$ . This condition is assumed in this paper.

In the optimal solution, the length of the saturated path between node  $s$  to node  $f$  is equal to the makespan.

The feasible solution (indicated by the numbers located under the nodes) of  $P_{EQ}$  is optimal, according to Theorem 3.

Figure 8. Illustration of Theorem 3.

**Construction of the optimal solution of  $P_{EQ}$  starting from a feasible solution**

Assume that  $\{t_i\}_{i \in V}$  is a feasible solution of  $P_{EQ}$ . It can be obtained by applying Algorithm 1. Let  $N$  be the set of nodes such that it does not exist a saturated path from either node  $s$  or a node belonging to an *and*-saturated null-circuit, to any node of  $N$ . Let  $N_1$  be the set derived from  $N$  by applying (a1) to (c1) of Definitions 3 taking into account the arcs saturated by solution  $\{t_i\}_{i \in V}$ . Let  $N_2 = V/N_1$ . The idea of the algorithm is to decrease the values  $\{t_i\}$  of the nodes  $i$  which belong to  $N_1$  and to adjust  $N_1$  by adding or removing nodes adequately.

If  $N_1 = \emptyset$  then  $N = \emptyset$  and, according to Theorem 3,  $\{t_i\}_{i \in V}$  is the optimal solution to  $P_{EQ}$  and also to  $P_{INEQ}$ . Otherwise, as seen in the proof of Theorem 3,  $N_1$  satisfies the properties (i) to (iv) of Lemma 2 and  $s \notin N_1$ . We define both  $\Delta$  and, for  $\alpha \in ]0; \Delta]$ ,  $\{t_i(\alpha)\}_{i \in V}$ , as in the proof of Lemma 2. Any of these solutions is better than  $\{t_i\}_{i \in V}$  regarding problem  $P_{EQ}$ . Moreover, if  $\Delta = +\infty$  then there is no optimal solution.

If  $\Delta \neq +\infty$ , by definition of  $\Delta$ , the solution  $\{t_i(\alpha=\Delta)\}_{i \in V}$  saturates one arc which was not saturated by solution  $\{t_i\}_{i \in V}$ . This arc either starts from a node of  $N_1$  and ends with an *or*-node of  $V/N_1$ , or starts from a node of  $V/N_1$  and ends with an *and*-node of  $N_1$ . In the first case, we derive a new set  $N_1$  from  $N$  by applying (a1) to (c1) of Definitions 3 taking into account the arcs saturated by solution  $\{t_i(\alpha=\Delta)\}_{i \in V}$ . In the second case, for at least one *and*-node of  $N_1$ , there exists a saturated path starting either from node  $s$  or from a node belonging to an *and*-saturated null-circuit, and ending with this *and*-node. These *and*-nodes can be removed from  $N_1$ . Moreover, the set of nodes obtained by applying (a2) to (c2) of Definitions 3, on the set  $V/N_1$  taking into account the arcs saturated by solution  $\{t_i(\alpha=\Delta)\}_{i \in V}$  can be removed from  $N_1$ .

For each set  $N_1$  obtained along the algorithm, we consider the previous solution  $\{t_i(\alpha=\Delta)\}_{i \in V}$  as the new initial solution  $\{t_i\}_{i \in V}$ . Since the solution is strictly better at each modification of the set  $N_1$ , the algorithm converges to the optimal solution, if any.

Since all the nodes are saturated, we have:  $A_{N_1} = \emptyset$  and  $A_s \cap N_1 = A \cap N_1$ . We have also

$R_{NS}=\emptyset$  and  $R_S/N_1=R/N_1$ . These simplifications will be used in the notations of steps 4 to 6 in Algorithm 2.

**Algorithm 2 - Construction of the optimal solution of  $P_{EQ}$**

**Input data:**

$G=(V,E)$  is the graph under consideration

$\{t_i\}_{i \in V}$  is a feasible solution of  $P_{EQ}$ , obtained by applying Algorithm 1.

**Output data:**

$\{t_i\}_{i \in V}$  is the optimal solution of  $P_{EQ}$ , if any.

1. Let  $N$  be the set nodes such that it does not exist a saturated path from either node  $s$  or a node belonging to an *and*-saturated null-circuit, to such a node.

2. If  $N=\emptyset$  then  $\{t_i\}_{i \in V}$  is optimal for  $P_{EQ}$  and also to  $P_{INEQ}$ . End.

3. Derive  $N_1$  from  $N$  by applying:

(a1) If  $i \in N$ , then  $i \in N_1$ , i.e.  $N_1 \supseteq N$ .

(b1) If  $i \in R$  and if the starting node  $j$  of *at least one* saturated arc  $(j,i)$  belongs to  $N_1$ , then  $i \in N_1$ .

(c1) If  $i \in A$  and if the starting node  $j$  of *all the* saturated arcs  $(j,i)$  belong to  $N_1$ , then  $i \in N_1$ .

3. If  $N_1=\emptyset$  then  $\{t_i\}_{i \in V}$  is optimal for  $P_{EQ}$  and also to  $P_{INEQ}$ . End.

4. Set  $\Delta_{A \cap N_1} = \begin{cases} +\infty & \text{if } A \cap N_1 \text{ or } \text{Pred}(i \text{ s.t. } i \in A \cap N_1) / N_1 \text{ is empty} \\ \min_{i \in A \cap N_1} \left\{ \max_{j \in \text{Pred}(i) \cap N_1} \{t_i - t_j - l(j,i)\} \right\} & \text{otherwise.} \end{cases}$

5. Set  $\Delta_{R/N_1} = \begin{cases} +\infty & \text{if } R/N_1 \text{ or } \text{Pred}(i \text{ s.t. } i \in R/N_1) \cap N_1 \text{ is empty} \\ \min_{i \in R/N_1} \left\{ \min_{j \in \text{Pred}(i) \cap N_1} \{t_j + l(j,i) - t_i\} \right\} & \text{otherwise.} \end{cases}$

6. Set  $\Delta = \min\{\Delta_{A \cap N_1}; \Delta_{R/N_1}\} > 0$ .

7. If  $\Delta = +\infty$  then there is no optimal solution. End.

8. Set  $t_i = t_i - \Delta$  for  $i \in N_1$ .

9. Goto step 1.

**Proposition**

The complexity of the previous algorithm is  $O[(|V| + |E|) |V| . Lq]$ , where  $|V|$  and  $|E|$  represent respectively the number of nodes and arcs,  $q$  is the greatest common divisor of the lengths of arcs and  $L = \sum_{i_0 \in V} \sum_{j_0 \in \text{Pred}(i_0)} |l(j_0, i_0)|$  is equal to the sum of the lengths of the arcs.

**Proof**

It is possible to find in  $O(|V| + |E|)$  the fully connected components of the subgraph limited to the saturated arcs (see [3]). Each component corresponds to either an unique node which

does not belong to a saturated null-circuit, or a set of nodes which belong to a saturated null-circuit. Using a breadth first search (BFS) from node  $s$  (see [3]) in the subgraph restricted to the saturated arcs, we find the set  $V/N$  of nodes such that it exists a saturated path from either node  $s$  or a node belonging to an *and*-saturated null-circuit, to such a node. Note that if a saturated path, starting from either node  $s$  or a node belonging to an *and*-saturated null-circuit, ends with an *and*-node  $i$ , any saturated null-circuit which contains  $i$  is *and*-saturated. Thus, step 1 is computed in  $O(|V| + |E|)$ .

Steps 2 to 5 of Algorithm 2 are similar to steps 2.2 to 2.5 of Algorithm 1. Steps 6 to 8 of Algorithm 2 are similar to steps 2.8 to 2.10 of Algorithm 1. Thus, steps 2 to 8 of Algorithm 2 can be computed in  $O(|V| + |E|)$ .

Let us denote by  $q$  the greatest common divisor of the lengths of arcs.  $q$  is a common divisor of the components of the feasible solution  $\{t_i\}_{i \in V}$  computed by Algorithm 1, and is also a common divisor of the components of all the new solutions  $\{t_i\}_{i \in V}$  computed at step 8 (see Lemma 2). The criterium of  $P_{EQ}$ , which is  $\sum_{i \in V} t_i$ , strictly decreases by a value greater or equal to  $1/q$  at each change of the solution. Thus, step 9 is performed at most  $O[(Z_0 - \underline{Z})q]$ -times, where  $Z_0$  is the value of the criterium for the solution at the beginning of Algorithm 2 and  $\underline{Z}$  is the value of the criterium for the optimal solution, if any. Since each component  $t_i$  of a solution computed by Algorithm 2 is equal to the length of a path from  $s$  to node  $i$ , we have for any  $i \in V$ ,  $|t_i| \leq \sum_{j_0 \in V} \sum_{j_0 \in \text{Pred}(i_0)} |l(j_0, i_0)|$  and  $(Z_0 - \underline{Z}) \leq 2|V| \sum_{i_0 \in V} \sum_{j_0 \in \text{Pred}(i_0)} |l(j_0, i_0)|$ . It follows that step 9 is performed at most  $O(|V| Lq)$ -times, where  $L$  is equal to the sum of the lengths of the arcs of  $G$ .

Finally, the algorithm requires  $O[(|V| + |E|) |V| Lq]$  operations. QED

## 6. CONCLUSION

In this paper, we proposed a new type of graphs to handle project management where a new type of activities have to be taken into account, that is alternative activities. We showed that a possible approach consists in finding a feasible solution which is then improved step by step until the optimal solution (if any) is reached.

The most important aspect of this paper, in terms of research, is that it provides results which permits to handle graphs including arcs of any rational value, and null-circuits. Further research will consist in working on the complexity, the goal being to define if a strongly polynomial algorithm exists for this problem.
