#### Abstract

We present a new algorithm for testing language inclusion $L(A) \subseteq L(B)$ between tree automata in time $O(|A| *|B|)$ where $B$ is deterministic. We extend this algorithm for testing inclusion between automata for unranked trees $A$ and deterministic DTDs $D$ in time $O(|A| *$ $|\Sigma| *|D|)$. No previous algorithms with these complexities exist.

## 1 Introduction

Language inclusion for tree automata is a basic decision problem that is closely related to universality and equivalence [5,14,15]. Tree automata algorithms are generally relevant for XML document processing [11,17,7,13]. Regarding inclusion checking, a typical application is inverse type checking for tree transducers [10]. Another one is schema-guided query induction [4], the motivation for the present study. There, candidate queries produced by the learning process are to be checked for consistency with deterministic DTDs, such as for HTML.

We investigate language inclusion $L(A) \subseteq L(B)$ for tree automata $A$ and $B$ under the assumption that $B$ is (bottom up) deterministic, not necessarily $A$. Without this assumption the problem becomes DEXPTIME complete [15]. Deterministic language inclusion still subsumes universality of deterministic tree automata $L(B)=T_{\Sigma}$ up to a linear time reduction, as well as equivalence of two deterministic automata $L(A)=L(B)$. The converse might be false, i.e., we cannot rely on polynomial time equivalence tests, as for instance, by comparing number of solutions [14] or minimal deterministic tree automata.

In the case of standard tree automata for ranked trees, the well-known naive algorithm for inclusion goes through complementation. It first computes an automaton $B^{c}$ that recognizes the complement of the language of $B$, and then checks whether the intersection automaton for $B^{c}$ and $A$ has a nonempty language. The problematic step is to complete $B$ before complementing its final states, since completion might require to add rules for all possible left-hand sides. The overall running time may thus become $O\left(|A| *|\Sigma| *|B|^{n}\right)$, which is exponential in the maximal rank $n$ of function symbols in the signature $\Sigma$.

It seems folklore that one can bound the maximal arity of a signature to 2 . This can be done by transforming ranked trees into binary trees, and then converting automata for ranked trees into automata for binary trees correspondingly. The problem is to preserve determinism in such a construction, while the size of
automata should grow at most linearly. We show how to obtain such a transformation by stepwise tree automata [3,5]. Thereby we obtain an inclusion test in time $O\left(|A| *|\Sigma| *|B|^{2}\right)$. This is still too much in practice with DTDs, where $A$ and $B$ may be of size 500 and $\Sigma$ of size 100 .

Our first contribution is a more efficient algorithm for standard tree automata on binary trees that verifies inclusion in time $O(|A| *|B|)$ if $B$ is deterministic. This bound is independent of the size of the signature, even though $\Sigma$ is not fixed. As a second contribution, we show how to test inclusion between automata $A$ for unranked trees and deterministic DTDs $D$ in time $O(|A| *|\Sigma| *|D|)$. Determinism is required by the XML standards. Our algorithm first computes the Glushkov automata of all regular expressions of $D$ in time $O(|\Sigma| *|D|)$, which is possible for deterministic DTDs [2]. The second step is more tedious. We would like to transform the collection of Glushkov automata to a deterministic stepwise tree automaton of the same size. Unfortunately, this seems difficult to achieve, since the usual construction of [9] eliminates $\epsilon$-rules on the fly, which may lead to a quadratic blowup of the number of rules (not the number of states). We solve this problem by introducing factorized tree automata, which use $\epsilon$-transitions for representing deterministic automata more compactly. We show how to adapt our inclusion test to factorized tree automata and thus to DTDs.
Related Work and Outline. Heuristic algorithms for inclusion between nondeterministic schemas that avoid the high worst-case complexity were proposed in [16]. The complexity of inclusion for various fragments of DTDs and extended DTDs was studied in [8]. The algorithms presented there assume the same types of regular expressions on both sides of the inclusion test. When applied to deterministic DTDs, the same complexity results may be obtainable. Our algorithm permits richer left-hand sides.

We reduce inclusion for the ranked case to the binary case in Section 2. The efficient algorithm for binary tree automata is given in Section 3. In Section 4, we introduce deterministic factorized tree automata and lift the algorithm for inclusion testing to them. Finally in Section 5, we apply them to testing inclusion of automata for unranked trees in deterministic DTDs.

## 2 Standard Tree Automata for Ranked Trees

We reduce the inclusion problem of tree automata for ranked trees [5] to the case of binary trees with a single binary function symbol.

A ranked signature $\Sigma$ is a finite set of function symbols $f \in \Sigma$, each of which has an arity $n \geq 0$. A constant $a \in \Sigma$ is a function symbol of arity 0 . A tree $t \in T_{\Sigma}$ is either a constant $a \in \Sigma$ or a tuple $f\left(t_{1}, \ldots, t_{n}\right)$ consisting of a function symbol $f$ of arity $n$ and $n$ trees $t_{1}, \ldots, t_{n} \in T_{\Sigma}$.

A tree automaton (possibly with $\epsilon$-rules) $A$ over $\Sigma$ consists of a finite set states $(A)$ of states, a subset final $(A) \subseteq \operatorname{states}(A)$ of final states, and a set rules $(A)$ of rules of the form $f\left(p_{1}, \ldots, p_{n}\right) \rightarrow p$ or $p^{\prime} \xrightarrow{\epsilon} p$ where $f \in \Sigma$ has arity $n$ and $p_{1}, \ldots, p_{n}, p, p^{\prime} \in \operatorname{states}(A)$. We write $p^{\prime} \xrightarrow{\epsilon}_{A} p$ iff $p^{\prime} \xrightarrow{\epsilon} p \in \operatorname{rules}(A),{\xrightarrow{\epsilon}{ }_{A}^{*} \text { for the }}$
reflexive transitive closure of $\xrightarrow{\epsilon}$, and $\xrightarrow{\epsilon}{ }_{A}^{\leq 1}$ for the union of $\xrightarrow{\epsilon} A$ and the identity relation on states $(A)$.

The size $|A|$ of $A$ is the sum of the cardinality of states $(A)$ and the number of symbols in rules $(A)$, i.e., $\sum_{f\left(p_{1}, \ldots, p_{n}\right) \rightarrow p \in \operatorname{rules}(A)}(n+2)$. The cardinality of the signature can be ignored, since our algorithms will not take unused function symbols into account. Every tree automaton $A$ defines an evaluator $\operatorname{eval}_{A}: T_{\Sigma \cup \operatorname{states}(A)} \rightarrow 2^{\text {states }(A)}$ such that $\operatorname{eval}_{A}\left(f\left(t_{1}, \ldots, t_{n}\right)\right)=\left\{p \mid p_{1} \in\right.$ $\left.\operatorname{eval}_{A}\left(t_{1}\right), \ldots, p_{n} \in \operatorname{eval}_{A}\left(t_{n}\right), f\left(p_{1}, \ldots, p_{n}\right) \rightarrow p^{\prime} \in \operatorname{rules}(A), p^{\prime} \xrightarrow{\epsilon}_{A}^{*} p\right\}$ and $\operatorname{eval}_{A}(p)=\{p\}$. A tree $t \in T_{\Sigma}$ is accepted by $A$ if final $(A) \cap \operatorname{eval}_{A}(t) \neq \emptyset$. The language $L(A)$ is the set of trees accepted by $A$.

A tree automaton is (bottom-up) deterministic if it has no $\epsilon$-rules, and if no two rules have the same left-hand side. It is complete if there are rules for all potential left-hand sides. It is well-known that deterministic complete tree automata can be complemented in linear time, by switching the final states.

We will study the inclusion problem for tree automata, whose input consists of a ranked signature $\Sigma$, tree automata $A$ with $\epsilon$-rules and deterministic $B$, both over $\Sigma$. Its output is the truth value of $L(A) \subseteq L(B)$. We can deal with this problem by restriction to so-called stepwise signatures $\Sigma_{@}$, consisting of a single binary function symbol @ and a finite set of constants $a \in \Sigma$. A stepwise tree automaton [3] is a tree automaton over a stepwise signature.

Proposition 1. The above inclusion problem for ranked trees can be reduced in linear time to the corresponding inclusion problem for stepwise tree automata over binary trees.

We first encode ranked trees into binary trees via Currying. Given a ranked signature $\Sigma$ we define the corresponding signature $\Sigma_{@}=\{@\} \uplus \Sigma$ whereby all symbols of $\Sigma$ become constants. Currying is defined by a function curry: $T_{\Sigma} \rightarrow$ $T_{\Sigma_{\varrho}}$ which for all trees $t_{1}, \ldots, t_{n} \in T_{\Sigma}$ and $f \in \Sigma$ satisfies:

$$
\operatorname{curry}\left(f\left(t_{1}, \ldots, t_{n}\right)\right)=f @ \operatorname{curry}\left(t_{1}\right) @ \ldots \text { curry }\left(t_{n}\right)
$$

For instance, $f(a, g(a, b), c)$ is mapped to $f @ a @(g @ a @ b) @ c$ which is infix notation with left-most parenthesis for the tree @ $(@(@), a), @(@(g, a), b)), c)$. Now we encode tree automata $A$ over $\Sigma$ into stepwise tree automata $\operatorname{step}(A)$ over $\Sigma_{@}$, such that the language is preserved up to Currying, i.e., such that $L(\operatorname{step}(A))=$ curry $(L(A))$. The states of $\operatorname{step}(A)$ are the prefixes of left-hand sides of rules in $A$, i.e., words in $\Sigma(\operatorname{states}(A))^{*}$ :

```
\(\operatorname{states}(\operatorname{step}(A))=\left\{f q_{1} \ldots q_{i} \mid f\left(q_{1}, \ldots, q_{n}\right) \rightarrow q \in \operatorname{rules}(A), 0 \leq i \leq n\right\} \uplus \operatorname{states}(A)\)
```

Its rules extend prefixes step by step by states $q_{i}$ according to the rule of $A$. Since constants do not need to be extended, we distinguish two cases in Fig. 1.
Lemma 1. The encoding of tree automata $A$ over $\Sigma$ into stepwise tree automata $\operatorname{step}(A)$ over $\Sigma_{@}$ preserves determinism, the tree language modulo Currying, and the automata size up to a constant factor of 3 .
As a consequence, $L(A) \subseteq L(B)$ is equivalent to $L(\operatorname{step}(A)) \subseteq L(\operatorname{step}(B))$, and can be tested in this way modulo a linear time transformation. Most importantly, the determinism of $B$ carries over to step $(B)$.

```
\(f\left(q_{1}, \ldots, q_{n}\right) \rightarrow q \in \operatorname{rules}(A) \quad 1 \leq i<n\)
\(f \rightarrow f \in \operatorname{rules}(\operatorname{step}(A))\)
\(f q_{1} \ldots q_{i-1} @ q_{i} \rightarrow f q_{1} \ldots q_{i} \in \operatorname{rules}(\operatorname{step}(A))\)\(\quad \frac{a \rightarrow q \in \operatorname{rules}(A)}{a \rightarrow q \in \operatorname{rules}(\operatorname{step}(A))}\)
    \(f q_{1} \ldots q_{n-1} @ q_{n} \rightarrow q \in \operatorname{rules}(\operatorname{step}(A))\)
```

## 3 Stepwise Tree Automata for Binary Trees

We present a new inclusion test that applies to stepwise tree automata over binary trees. We first characterize inclusion into deterministic tree automata, second, express the characterization in Datalog [6] and third, turn it into an efficient algorithm. While the two first steps are easy, the last step is nontrivial.

Characterization of Inclusion. We call a state $p \in \operatorname{states}(A)$ accessible if there exists a tree $t$ such that $p \in \operatorname{eval}_{A}(t)$. We call $p$ co-accessible if there exists a tree $t \in T_{\Sigma \cup\{p\}}$ with a unique occurrence of $p$ such that $\operatorname{eval}_{A}(t) \cap$ final $(A) \neq \emptyset$. A tree automaton is productive if all its states are accessible and co-accessible. We denote the product of two automata $A$ and $B$ with the same signature by $A \times B$. The state set of $A \times B$ is states $(A) \times \operatorname{states}(B)$. For inferring its rules, we assume that $B$ does not have $\epsilon$-rules:

$$
\begin{aligned}
& a \rightarrow p \in \operatorname{rules}(A) \\
& \frac{a \rightarrow q \in \operatorname{rules}(B)}{a \rightarrow(p, q)}
\end{aligned} \quad \begin{gathered}
p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A) \\
q_{1} @ q_{2} \rightarrow q \in \operatorname{rules}(B) \\
\left(p_{1}, q_{1}\right) @\left(p_{2}, q_{2}\right) \rightarrow(p, q)
\end{gathered} \quad \begin{aligned}
& p^{\prime} \xrightarrow{\epsilon} p \in \operatorname{rules}(A) \\
& \frac{q \in \operatorname{states}(B)}{\left(p^{\prime}, q\right) \xrightarrow{\epsilon}(p, q)}
\end{aligned}
$$

We do not care about final states of $A \times B$ since these are useless in our characterization of inclusion.

Proposition 2. Inclusion $L(A) \subseteq L(B)$ for a productive stepwise tree automaton $A$ with $\epsilon$-rules and a deterministic stepwise tree automaton $B$ fails iff:
fail $l_{0}$ : there exists a rule $a \rightarrow p \in \operatorname{rules}(A)$ but no state $q \in \operatorname{states}(B)$ such that $a \rightarrow q \in \operatorname{rules}(B)$, or
fail $l_{1}$ there exist accessible states $\left(p_{1}, q_{1}\right)$ and $\left(p_{2}, q_{2}\right)$ of $A \times B$ and a rule $p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A)$ but no state $q \in \operatorname{states}(B)$ such that $q_{1} @ q_{2} \rightarrow q \in$ rules $(B)$, or
fail $_{2}$ : some accessible state $(p, q)$ of $A \times B$ satisfies $p \in$ final $(A)$ but $q \notin \operatorname{final}(B)$.
Proof. If one of the failure conditions holds, then failure of inclusion follows from the hypotheses that $A$ is productive and $B$ deterministic.

For the converse, let us consider a tree $t$ such that $t \in L(A)$ and $t \notin L(B)$. There are two cases to be considered, depending on eval ${ }_{B}(t)$.
(i) Assume eval ${ }_{B}(t)=\emptyset$. There exists a minimal subtree $t^{\prime}$ of $t$ such that $\operatorname{eval}_{B}\left(t^{\prime}\right)=\emptyset$, too. If $t^{\prime}=a$ is a leaf then $\operatorname{eval}_{A}(a) \neq \emptyset$, since $t \in L(A)$, and $\operatorname{eval}_{B}(a)=\emptyset$, thus fail ${ }_{0}$ holds. If $t^{\prime}=t_{1} @ t_{2}$, then there exist $p_{1} \in \operatorname{eval}_{A}\left(t_{1}\right)$, $p_{2} \in \operatorname{eval}_{A}\left(t_{2}\right)$ and $p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A)$, since $t \in L(A)$. Since $t^{\prime}$ is defined as a

$$
\begin{aligned}
& \left(\operatorname{acc}_{/ 1}\right) \frac{a \rightarrow p \in \operatorname{rules}(A) \quad a \rightarrow q \in \operatorname{rules}(B)}{\operatorname{acc}(p, q) .} \quad\left(\operatorname{acc}_{/ 2}\right) \frac{p^{\prime} \xrightarrow{\epsilon}_{\rightarrow} A p \in q \in \operatorname{states}(B)}{\operatorname{acc}(p, q):-\operatorname{acc}\left(p^{\prime}, q\right) .} \\
& \left(\operatorname{acc}_{/ 3}\right) \frac{p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A) \quad q_{1} @ q_{2} \rightarrow q \in \operatorname{rules}(B)}{\operatorname{acc}(p, q):-\operatorname{acc}\left(p_{1}, q_{1}\right), \operatorname{acc}\left(p_{2}, q_{2}\right) .} \\
& \left(\operatorname{frb)} \frac{p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A) \quad \nexists q \cdot q_{1} @ q_{2} \rightarrow q \in \operatorname{rules}(B)}{\operatorname{frb}\left(p_{2}, q_{2}\right):-\operatorname{acc}\left(p_{1}, q_{1}\right) .}\right. \\
& \operatorname{frb}\left(p_{1}, q_{1}\right):-\operatorname{acc}\left(p_{2}, q_{2}\right) . \\
& \left(\operatorname{fail}_{1}\right) \frac{p \in \operatorname{states}(A) \quad q \in \operatorname{states}(B)}{\operatorname{fail}:-\operatorname{acc}(p, q), \operatorname{frb}(p, q) .} \quad\left(\operatorname{fail}_{2}\right) \frac{p \in \operatorname{final}(A) \quad q \notin \operatorname{final}(B)}{\operatorname{fail} l_{2}:-\operatorname{acc}(p, q) .}
\end{aligned}
$$

Fig. 2. Transforming tree automata $A$ and $B$ into a Datalog program $D_{1}(A, B)$.
minimal subtree and $B$ is deterministic, eval ${ }_{B}\left(t_{1}\right)=\left\{q_{1}\right\}$, eval $_{B}\left(t_{2}\right)=\left\{q_{2}\right\}$, and since eval ${ }_{B}\left(t^{\prime}\right)=\emptyset$, there is no rule $q_{1} @ q_{2} \rightarrow q \in \operatorname{rules}(B)$. This leads to fail ${ }_{1}$.
(ii) If eval ${ }_{B}(t) \neq \emptyset$ then there exists $q \in \operatorname{eval}_{B}(t) ; B$ being deterministic this $q$ is necessarily unique. Since $t \notin L(B), q \notin$ final $(B)$. Moreover, since $t \in L(A)$, there exists $p \in \operatorname{eval}_{A}(t) \cap \operatorname{final}(A)$. This leads to $\mathrm{fail}_{2}$.

Testing the Characterization. The following efficiency theorem for ground Datalog will be fundamental to all what follows. Given a Datalog program $P$ (without negation), we write $\operatorname{Ifp}(P)$ for its least fixed point semantics.

Theorem 1 (Efficiency of Ground Datalog [6]). For every ground Datalog program $P$, the least fixed point semantics $\operatorname{lfp}(P)$ can be computed in linear time $O(|P|)$ where the size $|P|$ is the number of symbols in $P$.

This result holds even without any bound on the arity of the relation symbols of $P$, which will be very useful later on. If relation symbols of higher arities are used, the number of their arguments is accounted for by the size of $P$.

Fig. 2 presents a Datalog program $D_{1}(A, B)$ that verifies the characterization of $L(A) \subseteq L(B)$ in Proposition 2. Transformation rules $\left(\right.$ acc $\left._{/ 1}\right)$, (acc/2), and (acc/3) define clauses for accessibility in $A \times B$ through predicate acc. The clauses produced by transformation rule (frb) define forbidden states of $A \times B$ through predicate frb. These are states that lead to $\mathrm{fail}_{1}$ when accessed. Transformation rules $\left(\right.$ fail $\left._{0}\right),\left(\right.$ fail $\left._{1}\right)$, and (fail $\left.{ }_{2}\right)$ define clauses for failures. The characterization of inclusion from Proposition 2 is captured in the following sense:

Proposition 3. Let $A$ and $B$ be stepwise tree automata for binary trees. If $A$ is productive and $B$ deterministic then:

$$
L(A) \subseteq L(B) \Leftrightarrow \operatorname{Ifp}\left(D_{1}(A, B)\right) \cap\left\{\mathrm{fail}_{0}, \mathrm{fail}_{1}, \mathrm{fail}_{2}\right\}=\emptyset
$$

$$
\begin{array}{ll}
\left(\mathrm{frb}_{/ 2}^{c}\right) \frac{p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A)}{} \quad q_{1} \in \operatorname{states}(B) \quad Q_{2}=\left\{q_{2} \mid q_{1} @ q_{2} \rightarrow q \in \operatorname{rules}(B)\right\} \\
\operatorname{frb}^{c}\left(p_{2}, Q_{2}\right):-\operatorname{acc}\left(p_{1}, q_{1}\right) . \\
\left(\operatorname{frb}_{/ 1}^{c}\right) \frac{p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A)}{} q_{2} \in \operatorname{states}(B) \quad Q_{1}=\left\{q_{1} \mid q_{1} @ q_{2} \rightarrow q \in \operatorname{rules}(B)\right\} \\
\operatorname{frb}^{c}\left(p_{1}, Q_{1}\right):-\operatorname{acc}\left(p_{2}, q_{2}\right) .
\end{array}
$$

Fig. 3. Grouping (frb) transformations.

The sum of the sizes of the clauses defined by transformation rules $\left(\mathrm{acc}_{/ 1}\right)$, $\left(\mathrm{acc}_{/ 2}\right),\left(\mathrm{acc}_{/ 3}\right),\left(\right.$ fail $\left._{0}\right)$, $\left(\right.$ fail $\left._{1}\right)$, and $\left(\right.$ fail $\left._{2}\right)$ is $O(|A| *|B|)$. The sizes of the clauses defined by transformation rule (frb) sum up to $O\left(|A| *|\operatorname{states}(B)|^{2}\right)$. The overall size of the ground Datalog program $D_{1}(A, B)$ is $O\left(|A| *\left(|B|+|\operatorname{states}(B)|^{2}\right)\right)$, which may be $O\left(|A| *|B|^{2}\right)$ in the worst case. Therefore, using Theorem 1, inclusion can be decided in time $O\left(|A| *|B|^{2}\right)$.

Efficient Algorithm. This running time is not better than that of the naive algorithm. The square factor is due to the computation of forbidden states for capturing fail ${ }_{1}$. Since (frb) rules cannot be inferred efficiently enough with a Datalog program, we introduce a new predicate frb ${ }^{c}$ that will group (frb) rules. Using an appropriate data structure, the frb predicates can be induced efficiently from $\mathrm{frb}^{c}$. The semantics of the latter is given below:

$$
A, B \models \operatorname{frb}^{c}(p, Q) \Leftrightarrow \forall q \in(\operatorname{states}(B) \backslash Q), A, B \models \operatorname{frb}(p, q)
$$

Formally, we impose an order $<$ on states $(B)$ and consider $\operatorname{frb}^{c}\left(p,\left\{q_{1}, \ldots, q_{n}\right\}\right)$ as $(n+1)$-ary literals $\operatorname{frb}^{c}\left(p, q_{i_{1}}, \ldots, q_{i_{n}}\right)$ such that $\left\{q_{i_{1}}, \ldots, q_{i_{n}}\right\}=\left\{q_{1}, \ldots, q_{n}\right\}$ and $q_{i_{1}}<\ldots<q_{i_{n}}$.

In Fig. 3, we propose two transformations ( $\mathrm{frb}^{c}{ }_{11}$ ) and ( $\mathrm{frb}^{c}{ }^{c}$ ) for inferring $\mathrm{frb}^{c}$ clauses, both of which group (frb) transformations. Note that for every state $p$, there may be several sets $Q$ such that $\operatorname{frb}^{c}(p, Q)$ gets inferred. Therefore, we will have to test efficiently whether a state belongs to the union of complements of those state sets. This will be further detailed.

Let us consider the transformation of tree automata $A$ and $B$ into a ground Datalog program $D_{2}(A, B)$ defined by transformation rules ( $\mathrm{acc}_{/ 1}$ ), ( $\mathrm{acc}_{/ 2}$ ), $\left(\mathrm{acc}_{/ 3}\right),\left(\mathrm{frb}_{/ 1}^{c}\right),\left(\mathrm{frb}_{/ 2}^{c}\right),\left(\right.$ fail $\left._{0}\right)$, and (fail $)^{2}$. The clauses producing acc, fail ${ }_{0}$, and fail ${ }_{2}$ of $D_{1}(A, B)$ and $D_{2}(A, B)$ are identical and their number is in $O(|A| *|B|)$. The number of $\mathrm{frb}^{c}$ clauses introduced by rule $\left(\mathrm{frb}^{c}{ }^{c}\right)$ is in $O(|A| *|\operatorname{states}(B)|)$ but the size of each such clause is $n+1$ which in the worst case could be $\mid$ states $(B) \mid+1$, and symmetrically for $\left(\operatorname{frb}^{c}\right.$ ) $)$. The overall size of all frb ${ }^{c}$ clauses, however, is bounded by the overall number of acc clauses, which in turn is bounded by $O(|A| *|B|)$, too! To see this, we can rewrite ( $\mathrm{frb}^{c}{ }^{c}$ ) as shown in Fig. 4, such that the corresponding ( $\mathrm{acc}_{/ 3}$ ) clauses are inferred simultaneously (and these don't overlap). Therefore the overall size of $D_{2}(A, B)$ is in $O(|A| *|B|)$.
$\left.\begin{array}{c}q_{1} @ q_{2}^{1} \rightarrow q^{1} \in \operatorname{rules}(B) \\ \vdots \\ p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A) \\ q_{1} @ q_{2}^{n} \rightarrow q^{n} \in \operatorname{rules}(B)\end{array}\right\}$ all the rules for $q_{1}$

Fig. 4. Rewriting grouping rules for complexity analysis of ( $\mathrm{frb}_{/ 2}^{c}$ ) clauses.

Inclusion Test. First it computes $\operatorname{lfp}\left(D_{2}(A, B)\right)$ in time $O(|A| *|B|)$. If fail ${ }_{0}$ or fail ${ }_{2}$ belong to $\operatorname{Ifp}\left(D_{2}(A, B)\right)$ then inclusion does not hold, so false is returned. Otherwise, we test for fail $l_{1}$ in a second step, by checking for all states $\operatorname{acc}(p, q) \in \operatorname{Ifp}\left(D_{2}(A, B)\right)$ whether there is a $\operatorname{frb}^{c}(p, Q) \in \operatorname{Ifp}\left(D_{2}(A, B)\right)$ such that $q \in(\operatorname{states}(B) \backslash Q)$. If so, false is returned, otherwise true.

We have to prove that the second step can be done in time $O(|A| *|B|)$. For every state $p \in \operatorname{states}(A)$, there are some state sets $Q_{1}, \ldots, Q_{m}$ such that for $1 \leq j \leq m$, $\operatorname{frb}^{c}\left(p, Q_{j}\right) \in \operatorname{Ifp}\left(D_{2}(A, B)\right)$ and we have to check efficiently whether some state $q$ is in $\bigcup_{j=1}^{j=m}\left(\operatorname{states}(B) \backslash Q_{j}\right)$. For this, we define a data structure bad_states $(p)$ as an array $T$ of size $|\operatorname{states}(B)|+1$. Counters are indexed by elements in $\operatorname{states}(B)$ and one counter is indexed by 0 . All counter values are set to 0 initially. The initialization of all bad_states $(p)$ can be done in $O(|\operatorname{states}(A)| *|\operatorname{states}(B)|)$. For every $p$ and

$$
\begin{array}{c|c|c|c|c|c|c|c|} 
& 0 & q_{1} & q_{2} & q_{3} & q_{4} & q_{5} & \ldots \\
\hline p & 2 & 0 & 1 & 2 & 1 & 0 & \ldots
\end{array}
$$

Fig. 5. Data structure bad_state. Here, it has been set up $\operatorname{frb}^{c}\left(p,\left\{q_{2}, q_{3}\right\}\right)$ and $\operatorname{frb}^{c}\left(p,\left\{q_{3}, q_{4}\right\}\right)$. When $\operatorname{frb}^{c}\left(p,\left\{q_{2}, q_{3}\right\}\right)$ is set up, bad_state $(p)(0)$, bad_state $(p)\left(q_{2}\right)$ and bad_state $(p)\left(q_{3}\right)$ are incremented. We have for instance $\operatorname{frb}\left(p, q_{4}\right)$ since bad_state $(p)\left(q_{4}\right)=1$ is lower than bad_state $(p)(0)=2$. In fact, the only not forbidden state is $\left(p, q_{3}\right)$ because $q_{3}$ belongs to the intersection of $\left\{q_{2}, q_{3}\right\}$ and $\left\{q_{3}, q_{4}\right\}$. every $Q_{j}$ such that $\operatorname{frb}^{c}\left(p, Q_{j}\right) \in \operatorname{Ifp}\left(D_{2}(A, B)\right)$, counter $T[0]$ is incremented by 1 and counter $T[q]$ is incremented by 1 for all $q \in Q_{j}$, which can be done in time $O\left(\left|Q_{j}\right|\right)$. As the overall size of frb $^{c}$ clauses in $\operatorname{lfp}\left(D_{2}(A, B)\right)$ is in $O(|A| *|B|)$, the computation of all bad_states $(p)$ can be done in time $O(|A| *|B|)$.

It remains to test for all states $\operatorname{acc}(p, q) \in \operatorname{lfp}\left(D_{2}(A, B)\right)$ whether there exists a $\operatorname{frb}^{c}(p, Q) \in \operatorname{Ifp}\left(D_{2}(A, B)\right)$ such that $q \in(\operatorname{states}(B) \backslash Q)$. This is done by checking whether $T[q]<T[0]$ in bad_states $(p)$ (see, e.g., Fig. 5). Indeed, if $\{Q \mid$ $\left.\operatorname{frb}^{c}(p, Q) \in \operatorname{Ifp}\left(D_{2}(A, B)\right)\right\}=\left\{Q_{1}, \ldots, Q_{m}\right\}$ then bad_states $(p)$ is defined such that $T[q]=T[0]$ iff $q \in \bigcap_{j=1}^{j=m} Q_{j}$, thus $T[q]<T[0]$ iff $q \in \bigcup_{j=1}^{j=m}\left(\operatorname{states}(B) \backslash Q_{j}\right)$. Each such test costs $O(1)$ so the overall time is bounded by $O(|A| *|B|)$.

This concludes the inclusion test for stepwise tree automata, for productive $A$ and deterministic $B$. Every tree automaton can be made productive in linear time. Higher arities can be reduced to 2 by Proposition 1. This yields:

Theorem 2. Let $A$ and $B$ be standard tree automata for ranked trees of some signature $\Sigma$ possibly with $\epsilon$-rules. If $B$ is deterministic, inclusion $L(A) \subseteq L(B)$ can be decided in time $O(|A| *|B|)$ independently of the size of $\Sigma$.

## 4 Factorized Tree Automata

We next relax the determinism assumption on $B$ in a controlled manner, that will be crucial to deal with DTDs. We replace $B$ by deterministic factorized automata, that we introduce. These are automata with $\epsilon$-rules, that represent deterministic automata in a compact manner.
Definition 1. $A$ factorized tree automaton $F$ over a stepwise signature $\Sigma$ is $a$ stepwise tree automaton with $\epsilon$-rules and a sorting $\mathrm{s}(F)$ : states $(F) \rightarrow\{1,2\}$, such that if $q_{1} @ q_{2} \rightarrow q$ in rules $(F)$ then $\mathbf{s}(F)\left(q_{1}\right)=1$ and $\mathbf{s}(F)\left(q_{2}\right)=2$.

The sort determines which states may be used in the first, resp. second, positions of binary symbol @ in rules of $F$.

Every factorized automaton $F$ defines a tree automaton $\operatorname{ta}(F)$ without $\epsilon$-rules that recognizes the same language. Both automata have the same signature and states; the rules of $\operatorname{ta}(F)$ are inferred as follows from those of $F$ :

$$
\left(\mathrm{E}_{1}\right) \frac{a \rightarrow q \in \operatorname{rules}(F)}{a \rightarrow q \in \operatorname{rules}(\operatorname{ta}(F))} \quad\left(\mathrm{E}_{2}\right) \frac{q_{1} \stackrel{\epsilon}{\rightarrow}_{F}^{*} r_{1} \quad q_{2} \stackrel{\epsilon}{\rightarrow}_{F}^{*} r_{2} \quad r_{1} @ r_{2} \rightarrow q \in \operatorname{rules}(F)}{q_{1} @ q_{2} \rightarrow q \in \operatorname{rules}(\operatorname{ta}(F))}
$$

For every set $R \subseteq \operatorname{rules}(F)$, we define $R^{\iota^{*}}=\left\{q \mid q \xrightarrow{\epsilon}_{F}^{*} r, r \in R\right\}$. In par-
 $O\left(|\operatorname{rules}(F)| *|\operatorname{states}(F)|^{2}\right)$ which is cubic in that of $F$ in the worst case. Besides their succinctness, the truly interesting bit about factorized tree automata is their notion of determinism.

Definition 2. A factorized tree automaton $F$ is (bottom-up) deterministic if:
$\mathrm{d}_{0}$ : the $\epsilon$-free part of $F$ is (bottom-up) deterministic;
$\mathrm{d}_{1}$ : for all $q \in \operatorname{states}(F)$ and sorts $i \in\{1,2\}$, there is at most one state $r$ of sort $i$ such that $q \xrightarrow{\epsilon_{F}^{*}} r$.
Nonredundant $\epsilon$-rules must change the sort: if $q \xrightarrow{\epsilon}_{F} r$ for two states of the same sort then $r=q$ by d $d_{1}$ and $q \xrightarrow{\epsilon_{F}^{*}} q$. A similar argument shows that all proper chains of $\epsilon$-rules are redundant so that $\xrightarrow{\epsilon}_{F}^{*}$ is equal to $\xrightarrow{\epsilon} \leq 1$.
Proposition 4. The tree automaton $\mathrm{ta}(F)$ represented by a deterministic factorized tree automaton $F$ is deterministic.

Proof. Let $B=\operatorname{ta}(F)$ which by construction is free of $\epsilon$-rules. For every constant $a \in \Sigma$, the uniqueness of $q$ such that $a \rightarrow q \in \operatorname{rules}(B)$ follows from $\mathrm{d}_{0}$. For every $q_{1} @ q_{2} \rightarrow q$ in rules $(B)$ we have to show that $q$ is uniquely determined by $q_{1}$ and $q_{2}$. By did there is at most one state $r_{1}$ of sort 1 such that $q_{1} \xrightarrow{\epsilon_{F}^{*}} r_{1}$ at most one $r_{2}$ of sort 2 such that $q_{2} \xrightarrow{\epsilon_{F}^{*}} r_{2}$. Condition $\mathrm{d}_{0}$ implies that there exists at most one state $q$ such that $r_{1} @ r_{2} \rightarrow q \in \operatorname{rules}(F)$.

$$
\begin{aligned}
& \left(\operatorname{acc}_{/ 3 a}\right) \frac{p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A) \quad q_{1} @ q_{2} \rightarrow q \in \operatorname{rules}(F)}{\operatorname{acc}(p, q):-\mathrm{f} . \operatorname{acc}\left(p_{1}, q_{1}\right), \mathrm{f} . \operatorname{acc}\left(p_{2}, q_{2}\right) .} \quad \text { (f.acc) } \frac{p \in \operatorname{states}(A) \quad q \rightarrow \underset{F}{\leq 1} r}{\mathrm{f} . \operatorname{acc}(p, r):-\operatorname{acc}(p, q) .} \\
& \left(\text { f.frb }{ }_{2}^{c}\right) \frac{p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A) \quad q_{1} \in \operatorname{states}(F)}{\text { f.frb }} \quad\left(\text { f.frb }_{1}^{c}\right) \frac{\left.p_{1} @ p_{2}, Q_{2}^{F}\left(q_{1}\right)\right):-\mathrm{f} . \operatorname{acc}\left(p_{1}, q_{1}\right) .}{\text { f.frb }} 1
\end{aligned}
$$

$$
\begin{aligned}
& \left(\operatorname{frb}_{1}^{c}\right) \frac{p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A) \quad q_{2} \in \operatorname{states}(F) \quad Q=\left\{q \mid q \xrightarrow{\epsilon} \leq 1_{\leq_{F}} r \text { and } \mathbf{s}(F)(r)=1\right\}}{\operatorname{frb}_{1}^{c}\left(p_{1}, Q\right):-\operatorname{acc}\left(p_{2}, q_{2}\right) .} \\
& \left(\operatorname{fail}_{2 a}\right) \frac{p \in \operatorname{final}(A) \quad q \notin \operatorname{final}(F)}{\mathrm{fail} \mathrm{I}_{2}:-\mathrm{f} . \operatorname{acc}(p, q) .}
\end{aligned}
$$

We use $Q_{2}^{F}\left(q_{1}\right)=\left\{q^{\prime} \mid q_{1} @ q^{\prime} \rightarrow q^{\prime \prime} \in \operatorname{rules}(F)\right\}$ and $Q_{1}^{F}\left(q_{2}\right)$ defined symmetrically. The clauses from $\left(\mathrm{acc}_{/ 1}\right),\left(\mathrm{acc}_{/ 2}\right)$ and (fail $)$ in $D_{2}(A, F)$ belong to $D_{3}(A, F)$, too.

Fig. 6. Inferring clauses of Datalog program $D_{3}(A, F)$ simulating $D_{2}(A, \operatorname{ta}(F))$.

We fix a stepwise tree automaton $A$ and a deterministic factorized tree automaton $F$, and let us $B=\operatorname{ta}(F)$. We now show how to test language inclusion $L(A) \subseteq L(B)$ from $A$ and $F$ without computing $B$. This is done by the ground Datalog program $D_{3}(A, F)$ of Fig. 6.

We need new predicates for properties of $F$ in order to infer corresponding properties of $B$. The accessibility predicate f .acc for $F$ subsumes the accessibility predicate acc for $B$. Subsumption may by proper as stated by the rule (f.acc) of $D_{3}(A, F)$. Vice versa, we infer accessibility in $F$ from accessibility in $B$ according to the rule $\left(\mathrm{acc}_{/ 3 a}\right)$. Rules $\left(\mathrm{acc}_{/ 1}\right)$ and $\left(\mathrm{acc}_{/ 2}\right)$ of $D_{2}(A, F)$ remain valid for accessibility in $B$, too.

Lemma 2. $\quad \operatorname{acc}(p, q) \in \operatorname{Ifp}\left(D_{3}(A, F)\right)$ iff $\operatorname{acc}(p, q) \in \operatorname{Ifp}\left(D_{2}(A, B)\right)$
We need to refine predicate frb into predicates $\mathrm{frb}_{1}$ and $\mathrm{frb}_{2}$ that take sorts into account, and corresponding predicates f.frb ${ }_{1}$ and f.frb ${ }_{2}$ in the factorized case. Their semantics can be defined as follows, where $A, B$ are tree automata and $F$ is a factorized tree automaton.
$A, B \models \operatorname{frb}_{2}\left(p_{2}, q_{2}\right) \Leftrightarrow \exists p, p_{1}, q_{1} . A, B \models \operatorname{acc}\left(p_{1}, q_{1}\right), p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A), q_{2} \notin Q_{2}^{B}\left(q_{1}\right)$
$A, F \models \mathrm{f} . \mathrm{frb}_{2}\left(p_{2}, r_{2}\right) \Leftrightarrow \exists p, p_{1}, r_{1} . A, F \models \mathrm{f} . \operatorname{acc}\left(p_{1}, r_{1}\right), p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A), r_{2} \notin Q_{2}^{F}\left(r_{1}\right)$
The semantics of $\mathrm{frb}_{1}$ and $\mathrm{f} . \mathrm{frb}_{1}$ are symmetric. The relation to the previous predicate frb is that $A, B \models \mathrm{frb}(p, q)$ if and only if $A, B \models \operatorname{frb}_{1}(p, q) \vee \mathrm{frb}_{2}(p, q)$.

The Datalog program $D_{3}(A, F)$ infers for sorts $i \in\{1,2\}$ literals with predicates f.frb ${ }_{i}^{c}$ that are to be understood by grouping of f.frb ${ }_{i}$ literals, and similarly $\mathrm{frb}_{i}^{c}$ by grouping of $\mathrm{frb}_{i}$. These grouping mechanisms account for sorts, since complementation is with respect to sorts.

$$
\begin{gathered}
A, F \models \mathrm{f} . \operatorname{frb}_{i}^{c}(p, Q) \Leftrightarrow \forall q \notin Q . \mathrm{s}(F)(q)=i \Rightarrow A, F \models \mathrm{f}^{\prime} \mathrm{frb}_{i}(p, q) \\
A, F \models \operatorname{frb}_{i}^{c}(p, Q) \Leftrightarrow \forall q \notin Q . \mathrm{s}(F)(q)=i \Rightarrow A, F \models \operatorname{frb}_{i}(p, q)
\end{gathered}
$$

The clauses produced by $\left(\mathrm{f} . \mathrm{frb}_{i}^{c}\right)$ and $\left(\mathrm{frb}_{i}^{c}\right)$ are sound with respect to this semantics for deterministic $F$ 's. This is easier to see for $\left(\mathrm{f} . \mathrm{frb}_{i}^{c}\right)$ than for $\left(\mathrm{frb}_{i}^{c}\right)$. We prove it by the next lemma. For states $p, q, r$ and sorts $i \in\{1,2\}$ we define:
$A, B \vdash \operatorname{frb}_{i}(p, q) \quad$ iff exists $Q \subseteq(\operatorname{states}(B) \backslash\{q\}) . \operatorname{frb}^{c}(p, Q) \in \operatorname{lfp}\left(D_{2}(A, B)\right)$ via $\left(\operatorname{frb}_{/ i}^{c}\right)$
$A, F \vdash \mathrm{f} . \mathrm{frb}_{i}(p, r)$ iff exists $R \subseteq(\operatorname{states}(F) \backslash\{r\})$. f.frb ${ }_{i}^{c}(p, R) \in \operatorname{lfp}\left(D_{3}(A, F)\right)$
$A, F \vdash \operatorname{frb}_{i}(p, r) \quad$ iff exists $R \subseteq(\operatorname{states}(F) \backslash\{r\}) . \operatorname{frb}_{i}^{c}(p, R) \in \operatorname{Ifp}\left(D_{3}(A, F)\right)$
Lemma 3 (Core). $A, B \vdash \operatorname{frb}_{i}(p, q)$ iff $A, F \vdash \operatorname{frb}_{i}(p, q)$ or the unique state $r$ of sort $i$ with $q \xrightarrow{\epsilon} \leq 1$

Since the size of $D_{3}(A, F)$ is in $O(|A| *|F|)$ we can compute the set of all f. $\mathrm{frb}_{1}^{c}(p, R)$ and $\mathrm{f} . \mathrm{frb}_{2}^{c}(p, R)$ literals in $\operatorname{Ifp}\left(D_{3}(A, F)\right)$ in time $O(|A| *|F|)$. It remains to infer the induced literals f.frb ${ }_{i}(p, r)$ literals in an efficient manner. Computing all $A, F \vdash \mathrm{f}$. $\mathrm{frb}_{i}(p, r)$ from $\operatorname{Ifp}\left(D_{3}(A, F)\right)$ can be done by the same clever algorithm as before for deducing all $A, B \vdash \operatorname{frb}(p, q)$ given $\operatorname{lfp}\left(D_{2}(A, B)\right)$. Note, however, that we now need two different data structures for the two sorts.

Theorem 3. For a stepwise tree automaton with $\epsilon$-rules $A$ and a deterministic factorized tree automaton $F$ over the same signature, inclusion $L(A) \subseteq L(F)$ can be decided in time $O(|A| *|F|)$.

## 5 Automata for Unranked Trees and DTDs

We lift our results to deterministic tree automata for unranked trees possibly with factorization, so that they become applicable to deterministic DTDs.

An unranked signature $\Sigma$ is a finite set of symbols (without arity restrictions). The set $T_{\Sigma}^{u}$ of unranked trees over $\Sigma$ is the least set that contains all pairs $a\left(t_{1}, \ldots, t_{n}\right)$ where $a \in \Sigma$ and $\left(t_{1}, \ldots, t_{n}\right)$ is a possibly empty sequence of unranked trees in $T_{\Sigma}^{u}$. Currying carries over literally from ranked to unranked trees. This yields a bijection curry : $T_{\Sigma}^{u} \rightarrow T_{\Sigma_{\varrho}}$. Thus, we can reuse stepwise tree automata to recognize languages of unranked trees, and as before, we can factorize them. So, as a corollary of Theorem 3 we have:

Corollary 2. For a stepwise tree automaton for unranked trees $A$ and a deterministic factorized tree automaton for unranked trees $F$ over the same signature $\Sigma, L(A) \subseteq L(F)$ can be decided in time $O(|A| *|F|)$ independently of $|\Sigma|$.

Note that hedge automata [5] can be translated in linear time to stepwise tree automata with $\epsilon$-rules [9]. The automata of [12] support factorization, too. We finally show how to convert deterministic DTDs $D$ to deterministic factorized tree automata in time $O(|\Sigma| *|D|)$, so that we can reuse our algorithm for testing inclusion in deterministic DTDs. Factorization avoids the quadratic blowup from translating hedge to stepwise automata [9].

Fig. 7. An example DTD and the corresponding Glushkov automata.

A DTD $D$ with elements in a set $\Sigma$ is a function mapping letters $a \in \Sigma$ to regular expressions $e$ over $\Sigma$, what we write $a \rightarrow_{D} e$ in this case. One of these elements is the distinguished start symbol. The language $L_{a}(D) \subseteq T_{\Sigma}^{u}$ of elements $a$ of a DTD $D$ is the smallest set of unranked trees such that:

$$
L_{a}(D)=\left\{a\left(t_{1}, \ldots, t_{n}\right) \mid a \rightarrow_{D} e, a_{1} \ldots a_{n} \in L(e), t_{i} \in L_{a_{i}}(D) \text { for } 1 \leq i \leq n\right\}
$$

The language of a DTD $D$ is $L(D)=L_{a}(D)$ where $a$ is the start symbol of $D$. The size of $D$ is the total number of symbols in the regular expressions of $D$. An example in XML syntax is given in Fig. 7. The set of elements of $D$ is $\Sigma=\{$ doc, block, text, link $\}$, of which the element doc is the start symbol. The regular expression for \#PCDATA recognizes only the empty word.

A DTD is deterministic if all its regular expressions are one-unambiguous [2]. This is equivalent to say that all corresponding Glushkov automata are deterministic, which is a requirement by the W3C. See Fig. 7 for the example.

Theorem 4 (Brüggemann-Klein [1]). The collection of Glushkov automata for a deterministic DTD D over $\Sigma$ can be computed in time $O(|\Sigma| *|D|)$.

We transform a collection of Glushkov automata for a deterministic DTD $D$ into a single factorized tree automaton $F$ as follows. The set of states of sort 1 of $F$ is the disjoint union of the states of the Glushkov automata. The states of sort 2 of $F$ are the elements of $D$. For every element $a$, we connect all final states $q$ of its Glushkov automaton to the state $a$, i.e., $q \xrightarrow{\epsilon} a \in \operatorname{rules}(F)$. The only final state of $F$ is the start symbol of the DTD $D$. The result is a finite automaton, that represents a

Fig. 8. The deterministic factorized tree automaton for the DTD in Fig. 7. factorized tree automaton, as for instance in Fig. 8. This needs time of at most $O(|\Sigma| *|D|)$. Note that the size of the example automaton would grow quadratically, when eliminating $\epsilon$-edges. For every $a \in \Sigma$, there is $a \rightarrow q \in \operatorname{rules}(F)$ for
the unique initial state $q$ of the Glushkov automaton of $a$. For every transition $q \xrightarrow{a} q^{\prime}$ of one of the Glushkov automata, we add a rule $q @ a \rightarrow q^{\prime} \in \operatorname{rules}(F)$.

Note that $F$ is deterministic as a factorized automaton. The $\epsilon$-free part of $F$ is deterministic since all Glushkov automata are: $\mathrm{d}_{0}$. Let $q$ be a state of the Glushkov automaton for some letter $a$. The only state of sort $1 q$ can reach by $\epsilon$-edges is $a$ and the only state of sort 2 is $q$ itself. All other states of $F$ are elements of $a \in \Sigma$, which have no outgoing $\epsilon$-edges: $\mathrm{d}_{1}$.

Theorem 5. Deterministic DTDs $D$ over $\Sigma$ can be translated to deterministic factorized tree automata that recognize the same language in time $O(|\Sigma| *|D|)$.

Corollary 3. Language inclusion of hedge automata $A$ over $\Sigma$ in deterministic DTDs $D$ with elements in $\Sigma$ can be decided in time $O(|A| *|\Sigma| *|D|)$.

## A Proof of Proposition 2 on Characterizing Inclusion

We complete the proof of Proposition 2, which characterizes noninclusion in terms of failure conditions. It remains to show the following implication.

Lemma 4. If one of the failure condition holds for a productive tree automaton $A$ and a deterministic tree automaton $B$ then inclusion fails, i.e., there exists a tree $t \in L(A) \backslash L(B)$.

Proof. First, assume fail $_{0}$. By definition we have $a \rightarrow p \in \operatorname{rules}(A)$. Since $A$ is productive there exists a term $C[p] \in T_{\Sigma \cup s t a t e s(A)}$ with a single occurence of $p$ (i.e., a context with hole marker $p$ ) such that $\operatorname{eval}_{A}(C[p]) \cap$ final $(A) \neq \emptyset$. For every term $s \in T_{\Sigma}$ let $C[s] \in T_{\Sigma}$ be the term obtained by replacing the unique occurence of $p$ in $C[p]$ by $s$. Then $C[a] \in L(A)$. We also have $\nexists q . a \rightarrow q \in \operatorname{rules}(B)$ and then $C[a] \notin L(B)$. Hence $C[a] \in L(A)$ and $C[a] \notin L(B)$.

Second, assume fail ${ }_{1}$. We get that there exists $t_{1}$ such that $\left(p_{1}, q_{1}\right) \in$ eval ${ }_{A \times B}\left(t_{1}\right)$ by accessibility of $\left(p_{1}, q_{1}\right)$ and that there exists $t_{2}$ such that $\left(p_{2}, q_{2}\right) \in$ eval ${ }_{A \times B}\left(t_{2}\right)$ by accessibility of $\left(p_{2}, q_{2}\right)$. Since $p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A)$ we also get $p \in \operatorname{eval}_{A}\left(t_{1} @ t_{2}\right)$ by definition of eval ${ }_{A}$. Furthermore since $A$ is productive there exists term $C[p] \in T_{\Sigma \cup \operatorname{states}(A)}$ with a single occurence $p$ such that $C\left[t_{1} @ t_{2}\right] \in$ $L(A)$, and $B$ being deterministic, $q_{1} \in \operatorname{eval}_{B}\left(t_{1}\right)$ and $q_{2} \in \operatorname{eval}_{B}\left(t_{2}\right)$ are unique and by hypothesis $\nexists q \cdot q_{1} @ q_{2} \rightarrow q \in \operatorname{rules}(B)$ then we have $C\left[t_{1} @ t_{2}\right] \notin L(B)$.

Third, assume $\mathrm{fail}_{2}$. By definition we have $p \in$ final $(A)$ and $q \notin$ final $(B)$, and $(p, q)$ is accessible. From the latter we get that there exists $t$ such that $(p, q) \in$ eval ${ }_{A \times B}(t)$. The state $p$ is final in $A$ then $t \in L(A)$. Since $B$ is deterministic $q \in \operatorname{eval}_{B}(t)$ is unique but $q$ not final in $B$ implies $t \notin L(B)$.

## B Proofs of Lemmas on Factorized Tree Automata

We fix a stepwise tree automaton $A$ and a deterministic factorized tree automaton $F$, and let us $B=\operatorname{ta}(F)$. We now show how to test language inclusion $L(A) \subseteq L(B)$ from $A$ and $F$ without computing $B$. This is done by the ground Datalog program $D_{3}(A, F)$ of Fig. 6.

We need new predicates for properties of $F$ in order to infer corresponding properties of $B$. The accessibility predicate f.acc for $F$ subsumes the accessibility predicate acc for $B$. Subsumption may by proper as stated by the rule (f.acc) of $D_{3}(A, F)$. Vice versa, we infer accessibility in $F$ from accessibility in $B$ according to the rule $\left(\mathrm{acc}_{/ 3 a}\right)$. Rules $\left(\mathrm{acc}_{/ 1}\right)$ and $\left(\mathrm{acc}_{/ 2}\right)$ of $D_{2}(A, F)$ remain valid for accessibility in $B$, too.

Lemma 2. $\quad \operatorname{acc}(p, q) \in \operatorname{Ifp}\left(D_{3}(A, F)\right)$ iff $\operatorname{acc}(p, q) \in \operatorname{Ifp}\left(D_{2}(A, B)\right)$
Proof. We prove both inclusions independently by induction over the construction of least fixed points. We first prove the inclusion from right to left, and then do the other way.

To each step of the computation of acc in $\operatorname{Ifp}\left(D_{2}(A, B)\right)$ corresponds some steps for computing acc in $\operatorname{Ifp}\left(D_{3}(A, F)\right)$. Let us assume that we are adding $\operatorname{acc}(p, q)$ to $\operatorname{lfp}\left(D_{2}(A, B)\right)$. One uses $\left(\operatorname{acc}_{/ 1}\right),\left(\operatorname{acc}_{/ 2}\right)$ or $\left(\operatorname{acc}_{/ 3}\right)$ :
$\left(\operatorname{acc}_{/ 1}\right)$ Membership of $\operatorname{acc}(p, q)$ in $\operatorname{Ifp}\left(D_{2}(A, B)\right)$ is proved by a fact of $D_{2}(A, B)$ inferred as follows:

$$
\frac{a \rightarrow p \in \operatorname{rules}(A) \quad a \rightarrow q \in \operatorname{rules}(B)}{\operatorname{acc}(p, q) .}
$$

By $\left(\mathrm{E}_{1}\right)$ it holds that $a \rightarrow q \in \operatorname{rules}(F)$, then we can apply the corresponding rule of $D_{3}(A, F)$ in order to show $\operatorname{acc}(p, q) \in \operatorname{Ifp}\left(D_{3}(A, F)\right)$ :

$$
\frac{a \rightarrow p \in \operatorname{rules}(A) \quad a \rightarrow q \in \operatorname{rules}(F)}{\operatorname{acc}(p, q) .}
$$

$\left(\operatorname{acc}_{/ 2}\right)$ Membership of $\operatorname{acc}(p, q)$ in $\operatorname{Ifp}\left(D_{2}(A, B)\right)$ is proved by a clause of $D_{2}(A, B)$ inferred from $\epsilon$-rules of $A$ :

$$
\frac{p^{\prime} \stackrel{\epsilon}{\rightarrow}_{A} p \quad q \in \operatorname{states}(B)}{\operatorname{acc}(p, q):-\operatorname{acc}\left(p^{\prime}, q\right) .}
$$

Since $B$ and $F$ have the same states, $\operatorname{acc}(p, q) \in \operatorname{Ifp}\left(D_{3}(A, F)\right)$, too.
$\left(\operatorname{acc}_{/ 3}\right)$ Membership of $\operatorname{acc}(p, q)$ in $\operatorname{Ifp}\left(D_{2}(A, B)\right)$ is contributed by applying a clause of $D_{2}(A, B)$ inferred as follows, under the assumption that $\operatorname{acc}\left(p_{1}, q_{1}\right)$, $\operatorname{acc}\left(p_{2}, q_{2}\right) \in \operatorname{Ifp}\left(D_{2}(A, B)\right)$.

$$
\frac{p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A) \quad q_{1} @ q_{2} \rightarrow q \in \operatorname{rules}(B)}{\operatorname{acc}(p, q):-\operatorname{acc}\left(p_{1}, q_{1}\right), \operatorname{acc}\left(p_{2}, q_{2}\right) .}
$$

From $\left(\mathrm{E}_{2}\right)$ and $q_{1} @ q_{2} \rightarrow q \in \operatorname{rules}(B)$ it follows that there are $r_{1}, r_{2}$ such that $r_{1} @ r_{2} \rightarrow q \in \operatorname{rules}(F), q_{1} \xrightarrow{\epsilon_{F}^{*}} r_{1}$ and $q_{2} \xrightarrow{\epsilon^{*}} r_{2}$. Thus:

$$
\frac{p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A) \quad r_{1} @ r_{2} \rightarrow q \in \operatorname{rules}(F) \quad q_{1} \stackrel{\epsilon}{\rightarrow}_{F}^{*} r_{1} \quad q_{2} \stackrel{\epsilon}{\rightarrow}_{F}^{*} r_{2}}{\operatorname{acc}(p, q):-\operatorname{acc}\left(p_{1}, q_{1}\right), \operatorname{acc}\left(p_{2}, q_{2}\right) .}
$$

Since $F$ is deterministic, $q_{1} \xrightarrow{\epsilon_{F}^{*}} r_{1}$ is equivalent to $q_{1} \xrightarrow{\epsilon} \stackrel{\leq 1}{F} r_{1}$ and $q_{2} \xrightarrow{\epsilon *}{ }_{F}^{*} r_{2}$ to $q_{2} \xrightarrow{\epsilon} \stackrel{\leq 1}{F} r_{2}$. Thus:

Transformation rule (acc $/ 3 a$ ) provides the following Datalog clause of $D_{3}(A, F)$ :

$$
\frac{p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A) \quad r_{1} @ r_{2} \rightarrow q \in \operatorname{rules}(F)}{\operatorname{acc}(p, q):-\operatorname{f.acc}\left(p_{1}, r_{1}\right), \mathrm{f} . \operatorname{acc}\left(p_{2}, r_{2}\right) .}
$$

The induction hypothesis yields $\operatorname{acc}\left(p_{1}, q_{1}\right), \operatorname{acc}\left(p_{2}, q_{2}\right) \in \operatorname{Ifp}\left(D_{3}(A, F)\right)$. Transformation rule (f.acc) provides clauses which prove f.acc $\left(p_{1}, r_{1}\right), \mathrm{f} . \operatorname{acc}\left(p_{2}, r_{2}\right) \in$ Ifp $\left(D_{3}(A, F)\right)$. In combination with the above clause of $D_{3}(A, F)$ this shows that $\operatorname{acc}(p, q) \in \operatorname{Ifp}\left(D_{3}(A, F)\right)$.

Conversely we prove that each step of the computation of acc in $D_{3}(A, F)$ corresponds to some steps for computing acc in $\operatorname{Ifp}\left(D_{2}(A, B)\right)$. Assume we are adding $\operatorname{acc}(p, q)$ to $\operatorname{Ifp}\left(D_{3}(A, F)\right)$. One now uses $\left(\operatorname{acc}_{/ 1}\right),\left(\operatorname{acc}_{/ 2}\right)$ or $\left(\operatorname{acc}_{/ 3 a}\right)$ :
$\left(\operatorname{acc}_{/ 1}\right)$ Membership of $\operatorname{acc}(p, q)$ in $\operatorname{Ifp}\left(D_{3}(A, F)\right)$ is proved by a fact of $D_{3}(A, F)$ inferred as follows:

$$
\frac{a \rightarrow p \in \operatorname{rules}(A) \quad a \rightarrow q \in \operatorname{rules}(F)}{\operatorname{acc}(p, q) .}
$$

By $\left(\mathrm{E}_{1}\right)$ it holds that $a \rightarrow q \in \operatorname{rules}(B)$, then we can apply the corresponding rule of $D_{2}(A, B)$ in order to show $\operatorname{acc}(p, q) \in \operatorname{Ifp}\left(D_{2}(A, B)\right)$ :

$$
\frac{a \rightarrow p \in \operatorname{rules}(A) \quad a \rightarrow q \in \operatorname{rules}(B)}{\operatorname{acc}(p, q) .}
$$

$\left(\operatorname{acc}_{/ 2}\right)$ Membership of $\operatorname{acc}(p, q)$ in $\operatorname{Ifp}\left(D_{3}(A, F)\right)$ is proved by a clause of $D_{3}(A, F)$ inferred from $\epsilon$-rules of $A$ :

$$
\frac{p^{\prime} \stackrel{\epsilon}{\rightarrow}_{A} p \quad q \in \operatorname{states}(F)}{\operatorname{acc}(p, q):-\operatorname{acc}\left(p^{\prime}, q\right) .}
$$

Since $F$ and $B$ have the same states, $\operatorname{acc}(p, q) \in D_{2}(A, B)$, too.
$\left(\operatorname{acc}_{/ 3 a}\right)$ Membership of $\operatorname{acc}(p, q)$ in $\operatorname{Ifp}\left(D_{3}(A, F)\right)$ is contributed by a clause of $D_{3}(A, F)$ :

$$
\frac{p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A) \quad q_{1} @ q_{2} \rightarrow q \in \operatorname{rules}(F)}{\operatorname{acc}(p, q):-\operatorname{f.acc}\left(p_{1}, q_{1}\right), \operatorname{f.acc}\left(p_{2}, q_{2}\right) .}
$$

This implies that there are $r_{1}, r_{2}$ such that $r_{1} \xrightarrow{\epsilon} \stackrel{\leq 1}{F} q_{1}$ and $r_{2} \xrightarrow{\epsilon} \stackrel{\leq 1}{F} q_{2}$, and also that $\operatorname{acc}\left(p_{1}, r_{1}\right)$ and $\operatorname{acc}\left(p_{2}, r_{2}\right)$ belong to $\operatorname{Ifp}\left(D_{3}(A, F)\right)$, because memberships of $\operatorname{f} \cdot \operatorname{acc}\left(p_{1}, q_{1}\right)$ and $\mathrm{f} \cdot \operatorname{acc}\left(p_{2}, q_{2}\right)$ in $\operatorname{Ifp}\left(D_{3}(A, F)\right)$ can only be obtained using:

$$
\frac{p_{1} \in \operatorname{states}(A) \quad r_{1} \xrightarrow[\rightarrow]{\leq 1} q_{1}}{\text { f.acc }\left(p_{1}, q_{1}\right):-\operatorname{acc}\left(p_{1}, r_{1}\right) .} \text { and } \frac{p_{2} \in \operatorname{states}(A) \quad r_{2} \xrightarrow[\rightarrow]{\epsilon}{ }_{F}^{\leq 1} q_{2}}{\text { f.acc }\left(p_{2}, q_{2}\right):-\operatorname{acc}\left(p_{2}, r_{2}\right) .}
$$

From $\left(\mathrm{E}_{2}\right)$ and all what precedes, it follows that $r_{1} @ r_{2} \rightarrow q \in \operatorname{rules}(B)$ and thus:

$$
\frac{p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A) \quad r_{1} @ r_{2} \rightarrow q \in \operatorname{rules}(B)}{\operatorname{acc}(p, q):-\operatorname{acc}\left(p_{1}, r_{1}\right), \operatorname{acc}\left(p_{2}, r_{2}\right) .}
$$

By induction hypothesis $\operatorname{acc}\left(p_{1}, r_{1}\right)$ and $\operatorname{acc}\left(p_{2}, r_{2}\right)$ belong to $\operatorname{Ifp}\left(D_{2}(A, B)\right)$, and then the rule $\left(\mathrm{acc}_{/ 3}\right)$ can be applied to get $\operatorname{acc}(p, q) \in \operatorname{Ifp}\left(D_{2}(A, B)\right)$.

We need to refine predicate frb into predicates $\mathrm{frb}_{1}$ and $\mathrm{frb}_{2}$ that take sorts into account, and corresponding predicates $f . \mathrm{frb}_{1}$ and $\mathrm{f} . \mathrm{frb}_{2}$ in the factorized case. Their semantics can be defined as follows, where $A, B$ are tree automata and $F$ is a factorized tree automaton.
$A, B \models \operatorname{frb}_{2}\left(p_{2}, q_{2}\right) \Leftrightarrow \exists p, p_{1}, q_{1} . A, B \models \operatorname{acc}\left(p_{1}, q_{1}\right), p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A), q_{2} \notin Q_{2}^{B}\left(q_{1}\right)$
$A, F \models \mathrm{f} . \mathrm{frb}_{2}\left(p_{2}, r_{2}\right) \Leftrightarrow \exists p, p_{1}, r_{1} . A, F \models \mathrm{f} . \operatorname{acc}\left(p_{1}, r_{1}\right), p_{1} @ p_{2} \rightarrow p \in \operatorname{rules}(A), r_{2} \notin Q_{2}^{F}\left(r_{1}\right)$

The semantics of $\mathrm{frb}_{1}$ and $\mathrm{f} . \mathrm{frb}_{1}$ are symmetric. The relation to the previous predicate frb is that $A, B \models \operatorname{frb}(p, q)$ if and only if $A, B \models \operatorname{frb}_{1}(p, q) \vee \operatorname{frb}_{2}(p, q)$.

The Datalog program $D_{3}(A, F)$ infers for sorts $i \in\{1,2\}$ literals with predicates $\mathrm{f} . \mathrm{frb}_{i}^{c}$ that are to be understood by grouping of $\mathrm{f} . \mathrm{frb}_{i}$ literals, and similarly $\mathrm{frb}_{i}^{c}$ by grouping of $\mathrm{frb}_{i}$. These grouping mechanisms account for sorts, since complementation is with respect to sorts.

$$
\begin{gathered}
A, F \models \mathrm{f} . \operatorname{frb}_{i}^{c}(p, Q) \Leftrightarrow \forall q \notin Q . \mathrm{s}(F)(q)=i \Rightarrow A, F \models \mathrm{f}^{\prime} \mathrm{frb}_{i}(p, q) \\
A, F \models \operatorname{frb}_{i}^{c}(p, Q) \Leftrightarrow \forall q \notin Q . \mathrm{s}(F)(q)=i \Rightarrow A, F \models \operatorname{frb}_{i}(p, q)
\end{gathered}
$$

The clauses produced by $\left(f . \mathrm{frb}_{i}^{c}\right)$ and $\left(\mathrm{frb}_{i}^{c}\right)$ are sound with respect to this semantics for deterministic $F$ 's. This is easier to see for $\left(\mathrm{f} . \mathrm{frb}_{i}^{c}\right)$ than for $\left(\mathrm{frb}_{i}^{c}\right)$. We prove it by the next lemma. For states $p, q, r$ and sorts $i \in\{1,2\}$ we define:
$A, B \vdash \operatorname{frb}_{i}(p, q) \quad$ iff exists $Q \subseteq(\operatorname{states}(B) \backslash\{q\}) . \operatorname{frb}^{c}(p, Q) \in \operatorname{Ifp}\left(D_{2}(A, B)\right)$ via $\left(\operatorname{frb}_{/ i}^{c}\right)$
$A, F \vdash \mathrm{f} . \mathrm{frb}_{i}(p, r)$ iff exists $R \subseteq(\operatorname{states}(F) \backslash\{r\})$. f.frb ${ }_{i}^{c}(p, R) \in \operatorname{lfp}\left(D_{3}(A, F)\right)$
$A, F \vdash \operatorname{frb}_{i}(p, r) \quad$ iff exists $R \subseteq(\operatorname{states}(F) \backslash\{r\}) . \operatorname{frb}_{i}^{c}(p, R) \in \operatorname{Ifp}\left(D_{3}(A, F)\right)$
Lemma 3 (Core). $A, B \vdash \operatorname{frb}_{i}(p, q)$ iff $A, F \vdash \operatorname{frb}_{i}(p, q)$ or the unique state $r$ of sort $i$ with $q \xrightarrow{\epsilon}{ }_{F}^{\leq 1} r$ exists and satisfies $A, F \vdash \mathrm{f}^{\prime} \mathrm{frb}_{i}(p, r)$.

Proof. By symmmetry it is sufficient to consider the case $i=1$. We show that $A, B \vdash \operatorname{frb}_{1}\left(p_{1}, q_{1}\right)$ iff $A, F \vdash \operatorname{frb}_{1}\left(p_{1}, q_{1}\right)$ or the unique state $r_{1}$ of sort 1 with $q_{1} \xrightarrow{\epsilon} \leq 1$ to be proved.
" $\Leftarrow$ " We distinguish the two cases of the disjunction.

1. Case $A, F \vdash \operatorname{frb}_{1}\left(p_{1}, q_{1}\right)$. There exists literal $\operatorname{frb}_{1}^{c}\left(p_{1}, Q\right)$ in $\operatorname{Ifp}\left(D_{3}(A, F)\right)$ such that $q_{1} \notin Q$. This literal is derived by a clause from rule $\left(\mathrm{frb}_{1}^{c}\right)$. Hence, there exists a rule $p_{1} @ p_{2} \rightarrow p$ of $A$ and a state $q_{2}$ such that $\operatorname{acc}\left(p_{2}, q_{2}\right) \in \operatorname{Ifp}\left(D_{3}(A, F)\right)$, and $Q=\{q \mid q \xrightarrow{\epsilon} \underset{F}{\leq 1} r$ and $r$ of sort 1$\}$. Membership of $\operatorname{acc}\left(p_{2}, q_{2}\right)$ in $\operatorname{Ifp}\left(D_{2}(A, B)\right)$ is proved by Lemma 2. Since $q_{1} \notin Q$, there is no $r \in \operatorname{states}(F)$ of sort 1 such that $q_{1} \xrightarrow{\epsilon}{ }_{F}^{\leq 1} r$. Thus, there is no rule $q_{1} @ q_{2} \rightarrow q$ in $B$, i.e., $q_{1} \notin Q$ where $Q=\left\{q^{\prime} \mid q^{\prime} @ q_{2} \rightarrow q \in\right.$ rules $(B)\}$. We use a clause from rule $\left(\mathrm{frb}_{/ 1}^{c}\right)$ in order to prove membership of $\operatorname{frb}^{c}\left(p_{1}, Q\right)$ in $\operatorname{Ifp}\left(D_{2}(A, B)\right)$, and thus $A, B \vdash \operatorname{frb}_{1}\left(p_{1}, q_{1}\right)$.
2. Case where the unique state $r_{1}$ of sort 1 with $q_{1} \xrightarrow{\epsilon \leq 1} r_{1}$ exists and satisfies $A, F \vdash \mathrm{f} . \mathrm{frb}_{1}\left(p_{1}, r_{1}\right)$. There exists $R$ such that $\mathrm{f} . \mathrm{frb}_{1}^{c}\left(p_{1}, R\right)$ belongs to $\operatorname{lfp}\left(D_{3}(A, F)\right)$ and $r_{1} \notin R$. According to rule (f.frb ${ }_{1}^{c}$ ) there exist a rule $p_{1} @ p_{2} \rightarrow p$ of $A$ and a state $r_{2}$ of $F$ such that $R=\left\{r^{\prime} \mid\right.$ $\left.r^{\prime} @ r_{2} \rightarrow r^{\prime \prime} \in \operatorname{rules}(F)\right\}$ and $\operatorname{f.acc}\left(p_{2}, r_{2}\right)$ belongs to $\operatorname{Ifp}\left(D_{3}(A, F)\right)$. By rule (f.acc) there exists $q_{2}$ such that $q_{2} \xrightarrow{\epsilon}{ }_{F}^{\leq 1} r_{2}$ and $\operatorname{acc}\left(p_{2}, q_{2}\right)$ belongs to $\operatorname{Ifp}\left(D_{3}(A, F)\right)$. By Lemma $2, \operatorname{acc}\left(p_{2}, q_{2}\right)$ also belongs to Ifp $\left(D_{2}(A, B)\right)$. Let $Q=\left\{q^{\prime} \mid q^{\prime} @ q_{2} \rightarrow q^{\prime \prime} \in \operatorname{rules}(B)\right\}$. Since $r_{1} \notin R$ it follows that $q_{1} \notin Q$. Furthermore, we have that $\operatorname{frb}^{c}\left(p_{1}, Q\right)$ in $\operatorname{Ifp}\left(D_{2}(A, B)\right)$ via $\left(\operatorname{frb}_{/ 1}^{c}\right)$. This proves $A, B \vdash \operatorname{frb}_{1}\left(p_{1}, q_{1}\right)$.
" $\Rightarrow$ " Assume $A, B \vdash \operatorname{frb}_{1}\left(p_{1}, q_{1}\right)$ so that there exists $Q \subseteq \operatorname{states}(B)$ with $q_{1} \notin$ $Q$ such that $\operatorname{frb}^{c}\left(p_{1}, Q\right) \in \operatorname{Ifp}\left(D_{2}(A, B)\right)$ has been deduced by a clause of $\left(\operatorname{frb}_{/ 1}^{c}\right)$. Thus, there exist a rule $p_{1} @ p_{2} \rightarrow p$ of $A$ and $q_{2} \in \operatorname{states}(B)$ such that $\operatorname{acc}\left(p_{2}, q_{2}\right) \in \operatorname{Ifp}\left(D_{2}(A, B)\right)$ and $Q=\left\{q^{\prime} \mid q^{\prime} @ q_{2} \rightarrow q^{\prime \prime} \in \operatorname{rules}(B)\right\}$. Membership of $\operatorname{acc}\left(p_{2}, q_{2}\right)$ in $\operatorname{Ifp}\left(D_{3}(A, F)\right)$ is induced by Lemma 2 . We have to distinguish whether or not there exists $r_{1} \in \operatorname{states}(F)$ with $\mathbf{s}(F)\left(r_{1}\right)=1$ such that $q_{1} \xrightarrow{\epsilon} \leq 1$
3. Case where no $r_{1}$ of sort 1 exists such that $q_{1} \xrightarrow{\epsilon} \stackrel{\leq 1}{F} r_{1}$. By rule (frb ${ }_{1}^{c}$ ), it follows that $\operatorname{frb}_{1}^{c}\left(p_{1}, Q\right) \in \operatorname{Ifp}\left(D_{3}(A, F)\right)$, where $Q=\left\{q^{\prime} \mid q^{\prime} \xrightarrow{\epsilon} \underset{F}{\leq 1}\right.$ $r, r$ of sort 1$\}$ by ( $\mathrm{E}_{2}$ ). Since $q_{1} \notin Q$ this yields $A, F \vdash \operatorname{frb}_{1}\left(p_{1}, q_{1}\right)$.
4. Case where there exists $r_{1}$ of sort 1 such that $q_{1} \xrightarrow{\epsilon} \underset{F}{\leq 1} r_{1}$. We also have to consider whether or not there exists $r_{2} \in \operatorname{states}(F)$ with $\mathbf{s}(F)\left(r_{2}\right)=2$ such that $q_{2} \xrightarrow{\epsilon} \underset{F}{\leq 1} r_{2}$.
(a) Subcase where exists $r_{2}$ of sort 2 such that $q_{2} \xrightarrow[\rightarrow]{\epsilon} \stackrel{\leq}{F} r_{2}$. A clause by rule (f.acc) shows that $\mathrm{f} . \operatorname{acc}\left(p_{2}, r_{2}\right) \in \operatorname{Ifp}\left(D_{3}(A, F)\right)$. Let $R=$ $\left\{r^{\prime} \mid r^{\prime} @ r_{2} \rightarrow r^{\prime \prime} \in \operatorname{rules}(F)\right\}$, i.e., $R=Q_{1}^{F}\left(r_{2}\right)$. Since $q_{1} \notin Q$ if follows that $r_{1} \notin R$. Furthermore, (f.frb ${ }_{1}^{c}$ ) yields f.frb ${ }_{1}^{c}\left(p_{1}, R\right)$ in $\operatorname{Ifp}\left(D_{3}(A, F)\right)$, and thus $A, F \vdash \mathrm{f} . \mathrm{frb}_{1}\left(p_{1}, r_{1}\right)$ where $q_{1} \xrightarrow{\epsilon}{ }_{F}^{\leq 1} r_{1}$ and $r_{1}$ is of sort 1 .
(b) Subcase where no $r_{2}$ of sort 2 exists such that $q_{2} \xrightarrow{\epsilon} \underset{F}{\leq 1} r_{2}$. In this case, the sort of $q_{2}$ is 1 and $\operatorname{f.acc}\left(p_{2}, q_{2}\right)$ belongs to $\operatorname{lfp}\left(D_{3}(A, F)\right)$. Let $R=\left\{r^{\prime} \mid r^{\prime} @ q_{2} \rightarrow r^{\prime \prime} \in \operatorname{rules}(F)\right\}$. Since $q_{2}$ is of sort 1 , it follows that $R=\emptyset$ and thus, $r_{1} \notin R$. Furthermore, we can infer f.frb ${ }_{1}^{c}\left(p_{1}, R\right)$ by rule (f.frb ${ }_{1}^{c}$ ). Thus $A, F \vdash \mathrm{f}$.frb ${ }_{1}\left(p_{1}, r_{1}\right)$ where $q_{1} \xrightarrow{\epsilon} \underset{F}{\leq 1} r_{1}$ and $r_{1}$ is of sort 1 .

Since the size of $D_{3}(A, F)$ is in $O(|A| *|F|)$ we can compute the set of all $\mathrm{f} . \mathrm{frb}_{1}^{c}(p, R)$ and $\mathrm{f} . \mathrm{frb}_{2}^{c}(p, R)$ literals in $\operatorname{Ifp}\left(D_{3}(A, F)\right)$ in time $O(|A| *|F|)$. It remains to infer the induced literals $\mathrm{f} . \mathrm{frb}_{i}(p, r)$ literals in an efficient manner. Computing all $A, F \vdash \mathrm{f} . \mathrm{frb}_{i}(p, r)$ from $\operatorname{Ifp}\left(D_{3}(A, F)\right)$ can be done by the same clever algorithm as before for deducing all $A, B \vdash \operatorname{frb}(p, q)$ given $\operatorname{Ifp}\left(D_{2}(A, B)\right)$. Note, however, that we now need two different data structures for the two sorts.

Theorem 3. For a stepwise tree automaton with $\epsilon$-rules $A$ and a deterministic factorized tree automaton $F$ over the same signature, inclusion $L(A) \subseteq L(F)$ can be decided in time $O(|A| *|F|)$.
