ABSTRACT
Introducing priorities on rules in rewriting increases their expressive power and helps to limit computations. Priority rewriting is used in rule-based programming as well as in functional programming. Termination of priority rewriting is then important to guarantee that programs give a result. We describe in this paper an inductive proof method for termination of priority rewriting, relying on an explicit induction on the termination property. It works by generating proof trees, modeling the rewriting relation by using abstraction and narrowing. As it specifically handles priorities on the rules, our technique allows proving termination of term rewrite systems that would diverge without priorities.

1. INTRODUCTION
In [3, 4], priority rewriting systems (PRS’s in short) have been introduced. A PRS is a term rewrite system (TRS in short) with a partial ordering on rules, determining a priority between some of them. Considering priorities on the rewrite rules to be used can be very useful for an implementation purpose, to reduce the non-determinism of computations or to enable divergent systems to terminate, and for a semantical purpose, to increase the expressive power of rules. Priority rewriting is enabled in rule-based languages like ASF+SDF [23] or Maude [15]. It is also used as a computation model for functional programming [18], and is underlying in the functional strategy, used for example in Lazy ML [1], Clean [5], or Haskell [13]. Let us also cite recent works on specification and correctness of security policies using rewriting with priorities [7, 8].

But priority rewriting is delicate to handle. First, the priority rewriting relation is not always decidable, because a term rewrites with a given rule only if in the redex, there is no reduction leading to another redex, reducible with a rule of higher priority. A way to overcome the undecidability can be to force evaluation of the terms in reducing subterms to strong head normal form via some strategy [18], or to use the innermost strategy [16]. But in these cases, normalization can lead to non-termination.

Second, the semantics of a PRS is not always clearly defined. In [3], a semantics is proposed, relying on a notion of unique sound and complete set of closed instances of the rules of the PRS, and it is showed that bounded -the bounded property is weaker than termination- PRS’s have a semantics. In [21], a fixed point based technique is proposed to compute the semantics of a PRS. It is also proved that for a bounded PRS with finitely many rules, the set of successors of any ground term is finite and computable. In [16], a logical semantics of PRS’s, based on equational logic is given. A particular class of PRS’s is proved sound and complete with respect to the initial algebra, provided every priority rewriting sequence from every ground term terminates.

Then the termination problem of the priority rewriting relation naturally arises, either to guarantee that it has a semantics, or to ensure that rewriting computations always give a result. Surprisingly, it seems not to have been much investigated until now. Let us cite [19], discussing a normalizing strategy of PRSs i.e., a strategy giving only finite derivations for terms having a normal form with usual rewriting, and [22], where it is proved that termination of innermost rewriting implies termination of generalized innermost rewriting with ordered rules. But to our knowledge,
the problem of finding a specific termination proof technique has only been specifically addressed in [16], where the use of reduction orderings is extended with an instantiation condition on rules linked with the priority order.

Our purpose here is to consider termination of priority rewriting from an operational point of view, with the concern of guaranteeing a result for every computation. So it seems interesting to focus on the innermost priority rewriting of [16], because it is decidable, easy to manipulate, and the innermost strategy is often used in programming contexts where priorities on rules are considered. The security policies given in [7] have indeed been executed in TOM [17] with an innermost evaluation mechanism.

Obviously, a PRS is terminating if the underlying TRS is. So usual rewriting termination proof techniques can be used for priority rewriting. Here, we propose to be finer in considering non (innermost) terminating TRS’s, that become terminating using priorities on rules.

We use an inductive method, whose principle has already been applied for proving termination of rewriting (without priorities) under strategies [12]. The idea is to prove on the ground term algebra that every derivation starting from a term terminates, supposing that it is true for terms smaller than the starting terms and for an induction ordering.

Priority rewriting is defined in Section 2. In Section 3, we present the inductive proof principle of our approach. Section 4 develops the basic concepts of the inductive proof mechanism relying on abstraction and narrowing, and the involved constraints. Section 5 presents the proof procedure and the related correctness and completeness theorem. Section 6 describes a variant of the previous procedure, dealing with the unsatisfiability of the involved constraints. We conclude in Section 7.

2. PRIORITY REWRITING

2.1 The background

We assume that the reader is familiar with the basic definitions and notations of term rewriting given for instance in [2, 9, 20]. $\mathcal{T}(\mathcal{F}, \mathcal{X})$ is the set of terms built from a given finite set $\mathcal{F}$ of function symbols $f$ having arity $n \in \mathbb{N}$, and a set $\mathcal{X}$ of variables denoted by $x, y, \ldots$. $\mathcal{T}(\mathcal{F})$ is the set of ground terms (without variables). The terms reduced to a symbol of arity 0 are called constants. Positions in a term are represented as sequences of integers. The empty sequence $\epsilon$ denotes the top position. Let $p$ and $p'$ be two positions. The position $p'$ is said to be a (strict) suffix position of $p$ if $p' = \sigma \cdot p$, where $\sigma$ is a (non-empty) sequence of integers. For a position $p$ of a term $t$, we denote by $t[p]$ the subterm of $t$ at position $p$, and by $t[s]_p$ the term obtained by replacing with $s$ the subterm at position $p$ in $t$.

A substitution is an assignment from $\mathcal{X}$ to $\mathcal{T}(\mathcal{F}, \mathcal{X})$, written $\sigma = (x = t, \ldots, y = u)$. It uniquely extends to an endomorphism of $\mathcal{T}(\mathcal{F}, \mathcal{X})$. The result of applying $\sigma$ to a term $t$ in $\mathcal{T}(\mathcal{F}, \mathcal{X})$ is written $\sigma(t)$ or $\sigma t$. The domain of $\sigma$, denoted by $\text{Dom}(\sigma)$ is the finite subset of $\mathcal{X}$ such that $\sigma x \neq x$. The range of $\sigma$, denoted by $\text{Ran}(\sigma)$, is defined by $\text{Ran}(\sigma) = \bigcup_{V \in \text{Dom}(\sigma)} \text{Var}(\sigma V)$. An instantiation or ground substitution is an assignment from $\mathcal{X}$ to $\mathcal{T}(\mathcal{F})$. $\text{Id}$ denotes the identity substitution. The composition of substitutions $\sigma_1$ followed by $\sigma_2$ is denoted by $\sigma_2 \sigma_1$. Given a subset $\mathcal{X}_1$ of $\mathcal{X}$, we write $\sigma|_{\mathcal{X}_1}$ for the restriction of $\sigma$ to the variables of $\mathcal{X}_1$ i.e., the substitution such that $\text{Dom}(\sigma|_{\mathcal{X}_1}) \subseteq \mathcal{X}_1$ and $\forall x \in \text{Dom}(\sigma|_{\mathcal{X}_1}) : \sigma|_{\mathcal{X}_1} x = \sigma x$.

A set $\mathcal{R}$ of (term) rewrite rules or term rewrite system on $\mathcal{T}(\mathcal{F}, \mathcal{X})$ is a set of pairs of terms of $\mathcal{T}(\mathcal{F}, \mathcal{X})$, denoted by $l \rightarrow r$, such that $l \not \in \mathcal{X}$ and $\text{Var}(r) \subseteq \text{Var}(l)$. Given a term rewrite system $\mathcal{R}$, a function symbol in $\mathcal{F}$ is called a constructor iff it does not occur in $\mathcal{R}$ at the top position of a left-hand side of rule, and is called a defined function symbol otherwise.

A priority term rewrite system (PRS in short) is a pair $(\mathcal{R}, \triangleright)$ where priorities on rules are considered. The security of guaranteeing a result for every computation. So it seems interesting to focus on the innermost priority rewriting of [16], because it is decidable, easy to manipulate, and the innermost strategy is often used in programming contexts where priorities on rules are considered. The security policies given in [7] have indeed been executed in TOM [17] with an innermost evaluation mechanism.

Obviously, a PRS is terminating if the underlying TRS is. So usual rewriting termination proof techniques can be used for priority rewriting. Here, we propose to be finer in considering non (innermost) terminating TRS’s, that become terminating using priorities on rules.

We use an inductive method, whose principle has already been applied for proving termination of rewriting (without priorities) under strategies [12]. The idea is to prove on the ground term algebra that every derivation starting from a term terminates, supposing that it is true for terms smaller than the starting terms for an induction ordering.

Priority rewriting is defined in Section 2. In Section 3, we present the inductive proof principle of our approach. Section 4 develops the basic concepts of the inductive proof mechanism relying on abstraction and narrowing, and the involved constraints. Section 5 presents the proof procedure and the related correctness and completeness theorem. Section 6 describes a variant of the previous procedure, dealing with the unsatisfiability of the involved constraints. We conclude in Section 7.

2.2 Priority rewriting

A priority term rewrite system (PRS in short) is a pair $(\mathcal{R}, \triangleright)$ of an underlying rewrite system $\mathcal{R}$ (always considered as finite in this paper) and a partial ordering $\triangleright$ on the rules of $\mathcal{R}$. A rule $r_1$ has a higher priority than a rule $r_2$ if $r_1 \triangleright r_2$, which is also written $r_1 \triangleright_\mathcal{R} r_2$.

Definition 1. [16] Let $\mathcal{R}$ be a PRS on $\mathcal{T}(\mathcal{F}, \mathcal{X})$. A term $t$ is $\mathcal{R}$-reducible (and $\mathcal{R}$-) rewrites to $t'$ at position $p$ with the rule $l \rightarrow r$, and the substitution $\sigma$ which is written $t \rightarrow^p_{\mathcal{R}, l \rightarrow r, \sigma} t'$ iff:

- $s \rightarrow^p_{\mathcal{R}, l \rightarrow r, \sigma} t$
- No proper subterm of the reduct $s|_p$ is $\mathcal{R}$-reducible
- $s|_p$ is not $\mathcal{R}$-reducible by any rule in $\mathcal{R}$ of higher priority than $l \rightarrow r$.

Example: With the rewrite system

- $f(g(x)) \rightarrow b$ (1)
- $g(a) \rightarrow c$ (2)
- $\downarrow g(a) \rightarrow d$ (3)
on the term \( f(g(a)) \), Rule (1) should apply, but this would not be an innermost rewriting step. So Rule (2) applies, but Rule (3) does not, because (2) ➀ (3).

A PRS \( R \) is \( IP \)-terminates if and only if every \( IP \)-derivation of the rewriting relation induced by \( R \) is finite. If \( t \overset{R}{\longrightarrow}_{IP} t' \) with \( t' \) \( IP \)-irreducible, then \( t' \) is called a(n) (\( IP \)-) normal form of \( t \) and denoted by \( t \downarrow \). Note that given \( t, t \downarrow \) may be not unique.

3. **INDUCTIVELY PROVING TERMINATION OF IP-REWRITING**

We prove termination of \( IP \)-rewriting by induction on the ground terms. Working on ground terms is appropriate, since most of the time, the algebraic semantics of rule-based languages is initial. Moreover, in [16], to guarantee stability by substitution of the innermost rewriting relation, the rules without highest priority only can reduce ground terms. Finally, there are TRS’s which are non-innermost terminating on \( T(F, X) \) and innermost terminating on \( T(F) \). A termination proof method working on \( T(F, X) \) could not handle them.

For proving that a priority term rewrite system on \( T(F) \) \( IP \)-terminates, we reason with a local notion of termination on terms: a term \( t \) of \( T(F) \) is said to be \( IP \)-terminating for a PRS \( R \) if every \( IP \)-rewriting chain (or derivation) starting from \( t \) is finite.

For proving that a term \( t \) of \( T(F) \) is \( IP \)-terminating, we proceed by induction on \( T(F) \) with a noetherian ordering \( \succ \), assuming the property for every \( t' \) such that \( t \succ t' \). To guarantee non emptiness of \( T(F) \), we assume that \( F \) contains at least one constructor constant. The main intuition is to observe rewriting derivations starting from a ground term \( t \in T(F) \) which is any instance of a pattern \( g(x_1, \ldots, x_m) \in T(F, X) \), for some defined function symbol \( g \in \mathcal{D} \), and variables \( x_1, \ldots, x_m \). Proving the property of \( IP \)-termination on ground terms amounts to proving that every ground instance of the patterns \( g(x_1, \ldots, x_m) \), for all \( g \in \mathcal{D} \), is terminating.

Rewriting derivations are simulated, using a lifting mechanism, by a proof tree developed from \( g(x_1, \ldots, x_m) \) on \( T(F, X) \), for every \( g \in \mathcal{D} \), by alternatively using narrowing and an abstraction mechanism. Narrowing schematizes the rewriting possibilities of terms, abstraction simulates the reduction of subterms in the derivations until these subterms become normal forms. It expresses the application of the induction hypothesis on these subterms, for which, as they are supposed to be \( IP \)-terminating, a normal form exists.

The nodes of the developed proof trees are composed of a current term of \( T(F, X) \), and a constraint composed of two kinds of formulas: ordering constraints, set to guarantee the validity of the inductive steps, and abstraction constraints combined to narrowing substitutions. Each node in a proof tree schematizes the set of ground instances of the current term, which are solutions of the abstraction constraint.

For a term \( t \) of \( T(F, X) \) occurring in a proof tree issued from an initial pattern \( t_{ref} = g(x_1, \ldots, x_m) \),

- first, some subterms \( \theta | t_j \) of \( \theta \) are supposed to be \( IP \)-terminating for every \( \theta \) solution of the constraint associated to \( t \), by the induction hypothesis, if \( \theta | t_{ref} \succ \theta | t_j \) for the induction ordering \( \succ \). So the \( t_j \) are replaced in \( t \) by abstraction variables \( X_j \) representing respectively any of their normal forms. Reasoning by induction allows us to only suppose the existence of the normal forms without explicitly computing them. If the ground instances of the resulting term are \( IP \)-terminating (either if the induction hypothesis can be applied to them, or if they can be proved \( IP \)-by other means, which we will present later), then the ground instances of the initial term are \( IP \)-terminating.
- the resulting term \( u = t_i[X_j]{i_1, \ldots, i_p} \) (where \( i_1, \ldots, i_p \) are the abstraction positions in \( t \)) is narrowed in all possible ways into terms \( v \), with an appropriate narrowing relation corresponding to \( IP \)-rewriting \( u \) according to the possible instances of the \( X_j \).

Then \( IP \)-termination of the ground instances of \( t \) is reduced to \( IP \)-termination of the ground instances of the terms \( v \). Now, if \( \theta | t_{ref} \succ \theta | v \) for every ground substitution \( \theta \) that is a solution of the constraint associated to \( v \), by the induction hypothesis, \( \theta | v \) is supposed to be \( IP \)-terminating. Otherwise, the process is iterated on \( v \), until we get a term \( t' \) such that either \( \theta | t_{ref} \succ \theta | t' \), or \( \theta | t' \) can be proved \( IP \)-terminating.

This technique was inspired from the one we proposed for proving the innermost termination of classical rewrite systems in [12]. We now give the concepts needed to formalize and automate it.

4. **ABSTRACTION, NARROWING, CONSTRAINTS**

The induction ordering is constrained along the proof by inequalities between terms that must be comparable, each time the induction hypothesis is used in the abstraction mechanism.

This ordering is not defined a priori, but just has to verify inequalities of the form \( t > u_1, \ldots, u_m \), accumulated along the proof, and which are called ordering constraints. Thus, for establishing the inductive termination proof, it is sufficient to decide whether ordering constraints are satisfiable.

**DEFINITION 2 (ORDERING CONSTRAINT).** An ordering constraint is a pair of terms of \( T(F, X) \) denoted by \((t \succ t')\). It is said to be satisfiable if there is an ordering \( \succ \), such that for every instantiation \( \theta \) whose domain contains \( \forall \var(t) \) or \( \forall \var(t') \), we have \( \theta | t \succ \theta | t' \). We say that \( \succ \) satisfies \((t \succ t')\).

A conjunction \( C \) of ordering constraints is satisfiable if there is an ordering satisfying all conjuncts. The empty conjunction, always satisfied, is denoted by \( \top \).

Satisfiability of a constraint conjunction \( C \) of this form is undecidable. But a sufficient condition for an ordering \( \succ_P \) on \( T(F, X) \) to satisfy \( C \) is that \( t \succ_P t' \) for every constraint \( t \succ t' \) of \( C \), and \( \succ_P \) is stable under substitution.

Simplification orderings fulfill such a condition. So, in practice, it is sufficient to find a simplification ordering \( \succ_P \) such that \( t \succ_P t' \) for every constraint \( t \succ t' \) of \( C \).

The ordering \( \succ_P \), defined on \( T(F, X) \), can than be seen as an extension of the induction ordering \( \succ \) on \( T(F) \). For convenience sake, \( \succ_P \) will also be written \( \succ \).

Solving ordering constraints in finding simplification orderings is a well-known problem. The simplest way and an automatable way to proceed is to test simple existing orderings like the subterm ordering, the Recursive Path Ordering,
or the Lexicographic Path Ordering. This is often sufficient for the constraints considered here: thanks to the power of induction, they are often simpler than for termination methods directly using ordering for orienting rewrite rules.

If these simple orderings are not powerful enough, automatic constraint solvers like Cime \(^1\) can provide adequate polynomial orderings.

### 4.1 Abstraction

Let us define the abstraction variables more formally.

#### Definition 3. Let \(N\) be a set of variables disjoint from \(X\). Symbols of \(N\) are called abstraction variables. Substitutions and instantiations are extended to \(T(F, X \cup N)\) in the following way: for any substitution \(\sigma\) (resp. instantiation \(\theta\)) such that Dom(\(\sigma\)) (resp. Dom(\(\theta\))) contains a variable \(X \in N\), \(\sigma X\) (resp. \(\theta X\)) is in IP-normal form.

#### Definition 4 (term abstraction). The term \(t(X_j) \in (t_1, \ldots, t_p)\) is said to be abstracted into the term \(u\) (called abstraction of \(t\)) at positions \(i_1, \ldots, i_p\) iff:

\[
\begin{align*}
\forall j \in \{i_1, \ldots, i_p\}, \quad &X_j \text{ are fresh distinct abstraction variables.}
\end{align*}
\]

IP-termination on \(T(F)\) is in fact proved by reasoning on terms with abstraction variables i.e., on terms of \(T(F, X \cup N)\). Ordering constraints are extended to pairs of terms of \(T(F, X \cup N)\). When subterms \(t_j\) are abstracted by \(X_j\), we state constraints on abstraction variables, called abstraction constraints to express that their instances can only be normal forms of the corresponding instances of \(t_j\). Initially, they are of the form \(t_j = X\) where \(t \in T(F, X \cup N)\), and \(X \in N\), but we will see later how they are combined with the substitutions used for the narrowing process.

### 4.2 Narrowing

After abstracting the current term \(t\) into \(t(X_j) \in (t_1, \ldots, t_p)\), we test whether the possible ground instances of \((t(X_j)) \in (t_1, \ldots, t_p)\) are reducible, according to the possible values of the instances of \(X_j\). This is achieved by innermost narrowing \((t(X_j)) \in (t_1, \ldots, t_p)\), with the priority rewrite system.

In a first time, to schematize innermost rewriting on ground terms, we need to refine the usual notion of narrowing. In fact, with the usual innermost narrowing relation, if a position \(p\) in a term \(t\) is a narrowing position, no suffix position of \(p\) can be a narrowing position as well. However, if we consider ground instances of \(t\), we can have rewriting positions \(p\) for some instances, and \(p'\) for other instances, such that \(p'\) is a suffix position of \(p\). So, when using the narrowing relation to schematize innermost rewriting of ground instances of \(t\), the narrowing positions \(p\) to consider depend on a set of ground instances of \(t\), which is defined by excluding the ground instances of \(t\) that would be narrowable at some suffix position of \(p\). For instance, with the TRS \(R = \{g(a) \rightarrow a, f(g(x)) \rightarrow b\}\), the innermost narrowing positions of the term \(f(g(X))\) are 1 with the narrowing substitution \(\sigma = (X = a)\), and \(\epsilon\) with any \(\sigma\) such that \(\sigma X \neq a\). This leads us to introduce constrained substitutions.

Let \(\sigma\) be a substitution on \(T(F, X \cup N)\). In the following, we identify \(\sigma = (x_1 = t_1, \ldots, x_n = t_n)\) with the equality formula \(\bigwedge_i (x_i = t_i)\), with \(x_i \in X \cup N\), \(t_i \in T(F, X \cup N)\). Similarly, we call negation \(\sigma\) of the substitution \(\sigma\) the formula \(\bigvee_i (x_i \neq t_i)\). The negation of Id means that no substitution can then be applied.

#### Definition 5. A substitution \(\sigma\) is said to satisfy a constraint \(\bigwedge_j \bigvee_i (x_i \neq t_i)\), if for every ground instantiation \(\theta\), \(\bigwedge_j \bigvee_i (\theta x_i \neq \theta t_i)\). A constrained substitution \(\sigma\) is a formula \(\sigma_0 \land \bigwedge_j \bigvee_i (x_i \neq t_i)\), where \(\sigma_0\) is a substitution, and \(\bigwedge_j \bigvee_i (x_i \neq t_i)\) the constraint to be satisfied by \(\sigma_0\).

#### Definition 6 (Innermost Narrowing) [12]. A term \(t\) \(\in T(F, X \cup N)\) innermost narrows into a term \(t'\) at the non-variable position \(p\) of \(t\), using the rule \(l \rightarrow r \in R\) with the constrained substitution \(\sigma = \sigma_0 \land \bigwedge_{j \in [1..k]} \sigma_j\), which is written

\[
\begin{align*}
&\quad t \sim_{\sigma_0 \land \bigwedge_{j \in [1..k]} \sigma_j} \quad &t' \quad &\text{iff} \quad &t' = \sigma_0(t[r_p]),
&\text{where } \sigma_0 \text{ is the most general unifier of } t|_p \quad &\text{and } \sigma_j, j \in [1..k] \text{ are all most general unifiers of } \sigma|_l \omega_j. \quad &\text{and a left-hand side } l' \text{ of a rule of } R, \text{ for all suffix position } p' \text{ of } p \text{ in } t.
\end{align*}
\]

Notice that we are interested in the narrowing substitution applied to the current term \(t\), but not in its definition on the variables of the left-hand side of the rule. So, the narrowing substitutions we consider are restricted to the variables of the narrowed term \(t\).

Now, we have to see how to simulate the IP-rewriting steps of a given term following the possible instances of its variables, by narrowing it with the rules, considering their priority. Unlike for simulating rewriting without priorities, where the narrowing process only depends on the term to be rewritten and of the rules considered, simulating IP-rewriting of ground instances of a term with a given rule requires to consider the narrowing steps with the rules having a higher priority. This also requires to use negations of substitutions. Let us consider the following example:

\[
\begin{align*}
&f(g(x), y) \rightarrow a \\
&f(x, h(y)) \rightarrow b \\
&f(x, y) \rightarrow c.
\end{align*}
\]

The term \(f(x, y)\) innermost narrows into \(a\) with the first rule and the most general unifier \((x = g(x'))\), into \(b\) with the second rule, the most general unifier \((y = h(y'))\) and the constraint \(x \neq g(x')\), and finally into \(c\) with the third rule, the most general unifier equal to \(Id\) and the constraint \(x \neq g(x') \land y \neq h(y')\). So, applying the rules one after the other, with the current narrowing most general unifier we have to accumulate the negation of the most general unifiers of the previous constrained substitutions, ignoring their constraint part.

If the narrowing substitutions \(\sigma_0 \land \bigwedge_{j \in [1..k]} \sigma_j\) of the previous rules have a constraint part coming from the innermost mechanism of Definition 6, this constraint part is also ignored by the priority mechanism. Indeed, the constraint part is defined from \(\sigma_0\), and has no meaning for the negation of \(\sigma_0\). With the PRS:

\[
\begin{align*}
&f(g(h(x))) \rightarrow a \\
&h(a) \rightarrow b \\
&f(g(x)) \rightarrow c.
\end{align*}
\]

---

\(^1\)Available at http://cime.iri.fr/
the term $f(x)$ innermost narrows with the first rule and $\sigma_1 = (x = g(h(x')) \land x' \neq a)$, the second rule does not apply, and the third rule applies with $\sigma_3 = (x = g(h(x')) \land x \neq g(h(x')))$. Also, if the constraint part of a substitution is due to the priority mechanism, the negation of this substitution by the innermost mechanism also considers the most general unifier of the substitution. With the PRS:

\[
\begin{align*}
\text{f}(g(h(x,y)), z) &\rightarrow a \\
\text{f}(x, y) &\rightarrow b \\
h(a, x) &\rightarrow a \\
h(b, x) &\rightarrow b
\end{align*}
\]

the term $f(x, y)$ innermost narrows into $a$ with the first rule and the constrained substitution $(x = g(h(x'), y')) \land x' \neq a \land y' \neq b)$, because $h(x', y')$ narrows with the third rule and the substitution $(x' = a)$, and with the fourth rule and the substitution $(y' = b \land x' \neq a)$.

The term $f(x, y)$ also innermost narrows into $b$ with the second rule and the substitution $(Id \land x \neq g(h(x', y')))$.

Definition 7 (Inner. Prior. Narrowing). Let $R$ be a priority term rewrite system. A term $t \in T(F, X \cup N)$ IP-narrows into $t' \in T(F, X \cup N)$ at the non-variable position $p$ of $t$, using the rule $l \rightarrow r \in R$ with the constrained substitution $\sigma = \sigma_0 \land \bigwedge_{j \in \{1, \ldots, p\}} \sigma_j \land \bigwedge_{j \in \{1, \ldots, p\}} \sigma_0$, which is written $t \sim_{IP}^{p, l \rightarrow r, \sigma} t'$ if $t = \sigma_0(t[x])$, where $\sigma_0$ is the most general unifier of $t[\sigma]$, and $l, \sigma_j, j \in \{1, \ldots, p\}$ are all most general unifiers of $\sigma_0 t[p']$ and a left-hand side $l'$ of a rule of $R$, for all suffix position $p'$ of $p$ in $t$, and $\sigma_0, \ldots, \sigma_p$ are the most general unifiers of $t[p']$ with the left-hand sides of the rules having a greater priority than $l \rightarrow r$.

4.3 Accumulating constraints

Abstraction constraints have to be combined with the narrowing substitutions to characterize the ground terms instantiated by the current term $t$ in the proof tree. Indeed, a narrowing step on the current term $u$ with narrowing substitution $\sigma$ represents a rewriting step for any ground instance of $\sigma u$. So, when narrowing, $\sigma$, considered as the narrowing constraint attached to the narrowing step, is added to the abstraction constraint. Note that if $\sigma$ does not satisfy the abstraction constraint, the narrowing step is meaningless: it does not correspond to any rewriting step of the considered ground instances. This leads to the introduction of abstraction constraint formulas.

Definition 8. An abstraction constraint formula (ACF in short) is a formula $\bigwedge_i (t_i = t'_i) \land \bigwedge_j (x_j = u_j)$, where $x_j \in X \cup N$, $t_i, t'_i, u_j \in T(F, X \cup N)$.

Definition 9. An abstraction constraint formula $A = \bigwedge_i (t_i = t'_i) \land \bigwedge_j (x_j = u_j)$ is satisfiable iff there is at least one instantiation $\theta$ such that $\bigwedge_i (\theta(t_i) = \theta(t'_i)) \land \bigwedge_j (\theta(x_j) = \theta(u_j))$. The instantiation $\theta$ is then said to satisfy the ACF $A$ and is called solution of $A$.

An ACF $A$ is attached to each term $u$ in the proof trees; the ground substitutions solutions of $A$ define the instances of the current term $u$, for which we are observing IP-termination. When $A$ has no solution, the current node of the proof tree represents no ground term. Such nodes are then irrelevant for the proof. Detecting and suppressing them during a narrowing step allows us to control the narrowing mechanism, well known to easily diverge. So, we have the choice between generating only the relevant nodes of the proof tree, by testing the satisfiability of $A$ at each step, or stopping the proof on a branch on an irrelevant node, by testing the unsatisfiability of $A$. The satisfiability of $A$ is in general undecidable, but it is often easy in practice to exhibit an instantiation satisfying it: most of the time, solutions built on constructor terms can be synthesized in an automatic way. Other automatable sufficient conditions, relying in particular on the characterization of normal forms, are also under study. The unsatisfiability of $A$ is also undecidable in general, but here also, simple automatable sufficient conditions can be used [12], as to test whether $A$ contains equalities $\ell = u$, where $u$ is reducible. In the following section, we present the procedure exactly simulating the rewriting trees i.e., dealing with the satisfiability of $A$. In the next section, we present the alternative approach dealing with the unsatisfiability.

5. THE IP-TERMINATION PROCEDURE

We are now ready to describe the inference rules defining our proof mechanism. They transform a set $T$ of 3-tuples $(U, A, C)$ where $U = \{t\}$ or $\emptyset$, $t$ is the current term whose ground instances have to be proved IP-terminating, $A$ is an abstraction constraint formula, $C$ is a conjunction of ordering constraints.

- The first rule abstracts the current term $t$ at given positions $t_1, \ldots, t_p$ into $t_j \in \{t_1, \ldots, t_p\}$. The constraint $\bigwedge_{i \in \{1, \ldots, p\}} \ell_0 > t_j$ is set in $C$. The abstraction constraint $\bigwedge_{i \in \{1, \ldots, p\}} \ell_0 \succ t_j$ is added to the ACF $C$. We call this rule Abstract.

The abstraction positions are chosen so that the abstraction mechanism captures the greatest possible number of rewriting steps: then we abstract all of the greatest possible subterms of $t = f(t_1, \ldots, t_m)$. More concretely, we try to abstract $t_1, \ldots, t_m$ and, for each $t_i = g(t_{i_1}, \ldots, t_{i_p})$ that cannot be abstracted, because $C \land \bigwedge_{j \in \{1, \ldots, p\}} \ell_0 > t_j$ cannot be proved satisfiable, we try to abstract $t'_1, \ldots, t'_p$, and so on. In the worst case, we are driven to abstract leaves of the term, which are either variables, or constants.

Note also that it is not useful to abstract non-narrowable subterms of $T(F, X \cup N)$. Indeed, by Definition 3, every ground instance of such subterms is in IP-normal form.

- The second rule narrows the resulting term $u$ in all possible ways in one step, with all possible rewrite rules of the rewrite system $R$, and all possible substitutions, into terms $v_1, \ldots, v_\theta$, according to Definition 7. This step is a branching step, creating as many states as there are narrowing possibilities. The substitution $\sigma$ is integrated to $A$. If $A \land \sigma$ is not satisfiable, the narrowing step with $\sigma$ is meaningless: it does not represent any rewriting step for the ground instances of $u$. So it can be discarded. This is the Narrow rule.

- We finally have a Stop rule halting the proof process on the current branch of the proof tree, when the
Abstract: \{u\}, A \land \bigwedge_{j \in \{i_1, \ldots, i_p\}} t_j \Downarrow = X_j, C \land \bigwedge_{j \in \{i_1, \ldots, i_p\}} H_C(t_j)

where \(t\) is abstracted into \(u\) at positions \(i_1, \ldots, i_p\) if \(C \land H_C(t_{i_1}) \ldots H_C(t_{i_p})\) is satisfiable

\[H_A(t) = \begin{cases} \top & \text{if } t \in T(F, N) \\ t \Downarrow = X & \text{otherwise.} \end{cases}\]

\[H_C(t) = \begin{cases} \top & \text{if } IPT(t) \\ t_{ref} > t & \text{otherwise.} \end{cases}\]

The first application of Abstract generates \(A = (\bigwedge_i x_i \Downarrow = X_i)\), always satisfied by the constructor constant supposed to exist in \(F\). Thus, with strategy \(S\), it is useless to prove the satisfiability of \(A\) in the Abstract and Stop rules.

The process may not terminate if there is an infinite number of applications of Abstract and Narrow on the same branch of a proof tree. It may stop on the rule Abstract when the ordering constraints cannot be proved satisfiable, on the rule Narrow when the abstraction constraints cannot be proved satisfiable. Nothing can be said in these cases about IP-termination.

Theorem 1. Let \(R\) be a priority term rewrite system on \(T(F, X)\) having at least one constructor constant. Every term of \(T(F)\) is IP-terminating if there is a noetherian ordering \(\triangleright\) such that for each symbol \(g \in D\), we have Succ-Cess \((g, \triangleright)\).

Note that because it is the induction relation, the ordering \(\triangleright\) has to be the same for all proof trees.

Example: Let us consider thePRS

\[
\begin{align*}
  f(g(h(x))) & \rightarrow a \\
  h(a) & \rightarrow g(a) \\
  f(g(x)) & \rightarrow f(g(h(x)))
\end{align*}
\]

whose underlying TRS is neither terminating, nor innermost terminating. Theorem 1 is applied to prove that it is IP-terminating.

For a better readability of the proof, whenever we have \(A \land \sigma\), we propagate \(\sigma\) into \(A\), by applying the substitution part of \(\sigma\) to \(A\). Moreover, the sets \(A\) and \(C\) are not repeated on a branch, when they do not change. The proof tree of \(f\) is given in Figure 1.
Abstract applies on $f(x)$ because the ordering constraint $f(x) > x$ is satisfiable by any noetherian ordering having the subterm property. Then, Narrow applies on $f(X)$ using the first and third rules, according to Definition 7.

On the second branch, the term $f(g(h(X'')))$ narrows into $f(g(g(a)))$ with the second rule, and $\sigma = (X'' = a)$, into a with the first rule and $\sigma = (Id \land X'' \neq a)$, but does not narrow with the third rule: the negation of $Id$ does not exist.

The set $A$ after the Abstract step is trivially satisfied by the instantiation $\theta = (x = X = a)$. One can take $\theta = (x = g(h(g(a))), X' = g(a))$ for the next set $A$ on the first branch, $\theta = (x = g(a), X = X' = X'' = a)$ for the next set $A$ on the second branch, and $\theta = (x = g(a), X = X'' = a)$ for the last set $A$ on the second branch.

In the proof tree of $h$, we just have an Abstract, a Narrow and a Stop step. The ordering constraints are satisfied by the same noetherian ordering than above. Applying Theorem 1, we conclude that the PRS is IP-terminating.

Example: Consider now the following IP-terminating specification of the $or$ operator, whose underlying RS is also neither terminating nor innermost terminating, because of the commutativity rule:

$$
\begin{align*}
or(0, y) & \rightarrow y \quad (1) \\
or(x, 1) & \rightarrow 1 \quad (2) \\
or(x, y) & \rightarrow or(y, x) \quad (3)
\end{align*}
$$

The proof tree of $or$ is given in Figure 2. The Stop rule applies on $Y \in N$ because, by definition of an abstraction variable, we have $IPT(Y)$. Stop applies on $or(Y, X)$ because the term would only be narrowable with the substitution $\sigma = (Id \land Y \neq 0 \land X \neq 1)$. But $A \land \sigma = (x = X = Y', Y' \land X \neq 0 \land Y \neq 0 \land X \neq 1)$ would be unsatisfiable. $X$ and $Y$ could only be of the form $or(X', Y')$, which is impossible since $or(X', Y')$ is always reducible.

The set $A$ after the Abstract step is trivially satisfied by the instantiation $\theta = (x = X = Y = Y)$. One can take $\theta = (x = y = Y = 0)$ for the next set $A$ on the first branch, $\theta = (x = X = y = 1)$ for the set $A$ on the second branch, and $\theta = (x = X = 1, y = Y = 0)$ for the set $A$ on the third branch.

Note that in the two examples above, the irreducible constants of the algebra, and more generally the constructors, can be used in an automatic way to find a solution of $A$.

6. DEALING WITH THE UNSATISFIABILITY OF A

We present in this section an alternative approach to our procedure, dealing with the unsatisfiability of $A$ instead of the satisfiability. As said in Section 4.3, instead of testing whether each node generated in the proof tree is relevant i.e., whether $A$ is satisfiable, we test whether we have generated irrelevant nodes.

As explained in Section 5, the satisfiability test of $A$ in the inference rules of our procedure (see Table 1) is given in the condition of Narrow. The unsatisfiability test only localizes in the condition of Stop, because the underlying idea is to stop the proof process on a branch whose current node is detected to be irrelevant. It is given as an alternative to the initial condition of Stop. The new conditions of the inference rules are given in Table 2.
The following automatonic sufficient conditions for the unsatisfiability of an abstraction constraint $t_i \parallel t'$ are often applicable in practice.

**Case 1:** $t_i \parallel t'$, with $t'$ reducible. Indeed, in this case, any ground instance of $t'$ is reducible, and hence cannot be a normal form.

**Case 2:** $t_i \parallel t' \wedge \cdots \wedge t'_i = t''$, with $t'$ and $t''$ not unifiable. Indeed, any ground substitution $\theta$ satisfying the above conjunction is such that (1) $\theta t_i = \theta t'$ and (2) $\theta t'_i = \theta t''$. In particular, (1) implies that $\theta t'$ is in normal form and hence (2) imposes $\theta t' = \theta t''$, which is impossible if $t'$ and $t''$ are not unifiable.

**Case 3:** $t_i = t'$ where $\text{top}(t)$ is a constructor, and $\text{top}(t) \neq \text{top}(t')$. Indeed, if the top symbol of $t$ is a constructor $c$, then any normal form of any ground instance of $t$ is of the form $c(u)$, where $u$ is a ground term in normal form. The above constraint is therefore unsatisfiable if the top symbol of $t'$ is $g$, for some $g \neq c$.

**Case 4:** $t_i = t'$ with $t, t' \in T(\mathcal{F}, \mathcal{X}_A)$ not unifiable and $\wedge_{t \rightarrow v} v_i = t'$ unsatisfiable. This criterion is of interest if the unsatisfiability of each conjunct $v_i = t'$ can be shown with one of the four criteria we present here.

As these four conditions only work on the equality part of $A$, dealing with the unsatisfiability of $A$ instead of the satisfiability is of particular interest when the abstraction formula $A$ involves many negations of substitutions. The satisfiability test instead requires to verify that the solutions of the equational part verify the disequality part of $A$.

The unsatisfiability test is precisely advantageous for a succession of priority rules involving more than two or three rules, since narrowing with the $n$th rule requires to accumulate the negation of the narrowing substitutions of the $n - 1$ previous ones.

Moreover, since the unsatisfiability test is an alternative condition of Stop, dealing with the unsatisfiability of $A$ instead of the satisfiability is obviously interesting when Stop applies with the first condition ($\langle C \land H_C(t) \rangle$ is satisfiable). Analyzing $A$ can then be completely avoided. This case is illustrated on the example we give now.

As said in the introduction, rewriting-based specifications with priorities on rules have recently been used to specify security policies, with a concern of verification of consistency, termination and completeness. The example we give below has been proposed in [7], for a conference management system described in [10]. Its termination, due to priority arguments, could not be formally proved until now.

**Example:** If we do not consider priorities, the following rewrite system is divergent, because of the eighth rule. Let us prove that it is IP-terminating.

\[
\begin{align*}
\text{aut}(q(\text{author}(x), SP, \text{pap}(x, z)), \text{SUBMIS}, u) & \rightarrow \text{PERMIT} \\
\text{aut}(q(\text{author}(x), SP, \text{pap}(x, z)), v, u) & \rightarrow \text{DENY} \\
\text{aut}(q(\text{revr}(x), \text{RSC}, \text{pap}(x, z)), v, u) & \rightarrow \text{DENY} \\
\text{aut}(q(\text{revr}(x), \text{RSC}, \text{pap}(y, z)), \text{REV}, \text{ass}(x, \text{pap}(y, z))) & \rightarrow \text{PERMIT} \\
\text{aut}(q(\text{revr}(x), \text{RSC}, \text{pap}(y, z)), v, \text{ass}(x, \text{pa(y, z)})) & \rightarrow \text{DENY} \\
\text{aut}(q(\text{revr}(x), \text{RSC}, \text{pap}(y, z)), \text{MEE}, \text{ass}(x, \text{pap}(y, z))) & \rightarrow \text{PERMIT} \\
\text{aut}(q(\text{revr}(x), w, \text{pap}(x, z)), v, u) & \rightarrow \text{aut}(q(\text{revr}(x), w, \text{pap}(x, z)), v, \text{con}(x, \text{pap}(x, z))) \\
\text{aut}(x, y, z) & \rightarrow \text{NAPPLIC}.
\end{align*}
\]
Let us apply the strategy $S$ on the initial pattern $t_{ref} = aut(x, y, z)$. The proof tree is given below.

We first have an Abstract step. Then, a Narrow step gives 9 branches, following the 9 rewrite rules. With the constrained narrowing substitutions $σ_1 = (σ_2 ∧ σ_7) ∧ ...$, the first seven ones give respectively the states PERMIT, DENY, DENY, DENY, PERMIT, DENY, PERMIT, on which Stop then applies. Indeed, we have $\text{IPT} (\text{PERMIT})$ and $\text{IPT} (\text{DENY})$ because PERMIT and DENY are irreducible constants. The ninth branch gives the state NAPPLIC, on which Stop applies too.

The interesting branch is the eighth one, giving the state $\text{aut}(q(\text{revr}(X'), w, \text{pop}(X', Z'))), Y, \text{conf}(X', \text{pop}(X', Z'))(X = q(\text{revr}(X'), w, \text{pop}(X', Z'))) \text{ constrained by } σ_7 ∧ ...$. To lighten the figure, we only specify this branch in the proof tree.

$$t_{ref} = aut(x, y, z)$$
$$A = \top, C = \top$$

Abstract
$$\text{aut}(X, Y, Z)$$
$$A = (x_1 = X, y_1 = Y, z_1 = Z)$$
$$C = (\text{aut}(x, y, z) > x, y, z)$$

Narrow
$$\text{revr} \circ \sigma$$
$$\text{aut}(q(\text{revr}(X'), w, \text{pop}(X', Z'))), Y, \text{conf}(X', \text{pop}(X', Z'))(X = q(\text{revr}(X'), w, \text{pop}(X', Z'))) \text{ constrained by } σ_7 ∧ ...$$

From this last state, we still apply Narrow, with two narrowing possibilities: one, with the fourth rule and the narrowing substitution $σ_{10} = \text{id}$, gives the state DENY, on which Stop then applies, because we have $\text{IPT} (\text{DENY})$. The other one, using the ninth rule, has also $\text{id}$ as narrowing substitution, but once constrained by $σ_{10} = \text{id}$, the substitution becomes empty, so this second narrowing possibility is not valid.

Applying the inference rules dealing with the satisfiability of $A$ would have required to perform the satisfiability test for the nine branches of the first Narrow step, and on the branch of the second Narrow step of the eighth branch, which is avoided here.

As one can see, the rule Stop applies on all branches of the proof tree thanks to the predicate IPT. So, on this example, we do not even need to consider $A$.

As on the examples of Section 6, to satisfy the ordering constraints, any simplification ordering holds. So this example can also be treated in a completely automatic way.

7. CONCLUSION

In this paper, we have proposed an inductive method for proving termination of the decidable innermost priority rewriting relation of C.K. Mohan [16]. This work is an extension to priority rewriting of an inductive approach given in [12] for proving innermost termination of rewriting.

The priority mechanism localizes in the narrowing relation used to model the rewriting relation. We then have generalized the innermost narrowing relation introduced in [12], to model the IP-rewriting relation on ground terms, and showed, through Theorem 1, that the approach of [12] still holds with the generalized narrowing relation. A lifting lemma involving priorities on the rules establishes correctness of this modelization, and then of Theorem 1. For details, see the appendix.

In fact, our innermost termination technique lends itself to this extension: as explained in Section 4.2, the priority mechanism can be expressed through negations of substitutions, then introducing constraints similar to those already required to model ground innermost rewriting.

Constraints are crucial in our approach: ordering constraints guarantee the applicability of the induction principle, abstraction constraints define the ground terms considered at each step of the proof, and help to contain the narrowing mechanism. The first ones are often satisfiable by a Path Ordering. Otherwise, any automatic ordering constraint solver can be used. For the second ones, if the satisfiability is considered, constructor-based solutions can be synthesized in an automatable way, like for the two examples of Section 5. Otherwise, solutions based on the characterization of normal forms of the rewrite system may be considered [11, 6]. If the unsatisfiability of abstraction constraints is considered instead, simple automatable sufficient conditions as those given in Section 6 can be used. Analyzing $A$ can even be completely avoided for examples exploiting the first condition of the Stop rule.

As termination of the original priority rewriting relation of [4] guarantees a semantics for this relation, one can think that IP-termination guarantees a semantics for the IP-rewriting relation. This has to be investigated. We also plan to generalize our technique to the termination proof of other priority rewriting relations.

APPENDIX

A. THE LIFTING LEMMA

For the proof of Theorem 1, we need the following lifting lemma.

**Lemma 1 (Priority Inner. Lifting Lemma).** Let \( R \) be a term rewrite system. Let \( s \in T(F,X) \), \( \alpha \) a ground substitution such that \( \alpha s \) is \( I^P \)-reducible at a non variable position \( p \) of \( s \), and \( Y \subseteq X \) a set of variables such that \( \text{Var}(s) \cup \text{Dom}(\alpha) \subseteq Y \). If \( \alpha s \xrightarrow{I^P} s' \), then there exist a term \( s'' \in T(F,X) \) and substitutions \( \beta, \sigma = \sigma_0 \land \bigwedge_{j \in [1..n]} \sigma_j \), such that:

1. \( s \xrightarrow{\alpha} \beta \beta' \)
2. \( \beta \beta' = s'' \)
3. \( \beta \sigma \alpha = \sigma \left( \text{Var}(s) \cup \text{Var}(l) \right) \)
4. \( \beta \) satisfies \( \bigwedge_{j \in [1..n]} \sigma_j \land \bigwedge_{i \in [1..n]} \sigma_i \).

where \( \sigma_0 \) is the most general unifier of \( s \), \( \sigma \), \( \sigma_j \) is \( \sigma \) for \( \sigma_j \) a left-hand side of \( \sigma \), and \( \alpha \) a substitution such that \( \alpha s \) is \( I^P \)-reducible at a non variable position \( p \) of \( s \), and \( \sigma_0 \) is the most general unifier of \( \sigma \), and \( \alpha \) a substitution such that \( \alpha s \) is \( I^P \)-reducible at a non variable position \( p \) of \( s \), and \( \sigma \) is \( \sigma \) for \( \sigma \) a left-hand side of \( \sigma \).

For the proof of the lemma, we need the two following propositions.

**Proposition 1.** Let \( t \in T(F,X) \) and \( \sigma \) be a substitution of \( T(F,X) \). Then \( \text{Var}(\sigma t) = (\text{Var}(t) - \text{Dom}(\sigma)) \cup \text{Ran}(\sigma \text{Var}(t)) \).

**Proposition 2.** Suppose we have substitutions \( \sigma, \mu, \nu \) and sets \( A, B \) of variables such that \( (B - \text{Dom}(\sigma)) \cup \text{Ran}(\sigma \text{Var}(t)) \subseteq A \). If \( \nu = \nu[A] \) then \( \nu\sigma = \nu\sigma[B] \).

**Proof.** Let us consider \( \nu\sigma[B] \), which can be divided as follows:

<table>
<thead>
<tr>
<th>( \mu\nu[B] )</th>
<th>( \mu\nu[B - \text{Dom}(\sigma)] \cup \mu\nu[B - \text{Dom}(\sigma)]. )</th>
</tr>
</thead>
</table>
| \( \nu\sigma[A] \) | \( \nu\sigma[B] \).

For \( x \in B \cap \text{Dom}(\sigma) \), we have \( \text{Var}(\sigma x) \subseteq \text{Ran}(\sigma) \), and then \( \nu\sigma x = \mu(\nu\sigma x) = \mu(\nu\sigma(\nu x)) = \mu(\nu\sigma(\sigma x)) = \mu(\nu\sigma(\sigma x))x. \) Therefore \( \nu\sigma[B - \text{Dom}(\sigma)] = (\mu\nu[\sigma A])B - \text{Dom}(\sigma)). \)

For \( x \in B \cap \text{Dom}(\sigma) \), we have \( \sigma x = \sigma x \), and then \( \nu\sigma x = \mu(\nu\sigma x) = \mu(\nu\sigma(\nu x)) = \mu(\nu\sigma(\sigma x)) = \mu(\nu\sigma(\sigma x))x. \) Therefore \( \nu\sigma[B - \text{Dom}(\sigma)] = (\mu\nu[\sigma A])B - \text{Dom}(\sigma)). \)

By a similar reasoning, we get \( \nu\sigma[B] = (\mu\nu[\sigma A])B - \text{Dom}(\sigma)]. \)

**Proof of Lemma 1.** In the following, we assume that \( \text{Var}(\sigma t) \subseteq Y \) for every \( l \in R \).

If \( \alpha s \xrightarrow{\alpha} \beta \beta' \), then there is a substitution \( \tau \) such that \( \text{Dom}(\tau) \subseteq \text{Var}(l) \) and \( \alpha(\alpha s) = \tau l \).

Moreover, since \( p \) is a non variable position of \( s \), we have \( \alpha(\alpha s) = \alpha(\alpha s). \) Denoting \( \mu = \alpha \tau \), we have:

\[
\mu(s) = \alpha(\alpha s) \quad \text{for } \text{Dom}(\tau) \subseteq \text{Var}(l) \text{ and } \text{Var}(l) \cap \text{Var}(\alpha s) = \emptyset
\]

and \( \mu = \alpha \) by definition of \( \tau \).

Since \( \sigma_0 \) is more general than \( \mu \), there is a substitution \( \rho \) such that \( \rho\sigma_0 = \mu(\text{Var}(\alpha s) \cup \text{Var}(l)) \).

Let \( Y_1 = \left( Y - \text{Dom}(\sigma_0) \right) \cup \text{Ran}(\sigma_0) \).

We define \( \beta = \rho\sigma_0 \).

Since \( \beta \) is reducible at position \( l \), it is reducible at position \( l \).

This is impossible by definition of \( I^P \)-reducibility of \( \alpha(\alpha s) \) at position \( l \) in \( l \).
p. So the ground substitution $\beta$ also satisfies $\bigwedge_{i \in [1..n]} \sigma_0$ where $\sigma_0, \ldots, \sigma_n$ are the most general unifiers of $s_0$ with the left-hand sides of rules having a greater priority than $l \to r$ (4).

Therefore, denoting $\sigma = \sigma_0 \land \bigwedge_{i \in [1..k]} \sigma_i$ and $\bigwedge_{i \in [1..n]} \sigma_i$, from the beginning of the proof, we get $s \rightarrow^*_{p,l \to r,s} s'$, and then the point (1) of the current lemma holds. $\square$

B. THE IP-TERMINATION THEOREM

Theorem 1. Let $R$ be a priority term rewrite system on $T(F, X)$ having at least one constructor constant. Every term of $T(F)$ is IP-terminating if there is a noetherian ordering $\succ$ such that for each symbol $g \in D$, we have $\text{SUCCESS}(g, \succ)$.

Proof. Let us suppose that every ground term is IP-terminating and show that the construction of the proof trees always terminates. Let $f(x_1, \ldots, x_m), f \in D$ any initial pattern of a proof tree.

The Abstract rule applies to give $f(X_1, \ldots, X_m), X_1, \ldots, X_m \in N$. Indeed, by hypothesis, we have $\text{IP}(x_i)$. Then Stop applies, because we also have $\text{IP}(f(X_1, \ldots, X_m))$. So any proof tree is finite, and $\text{SUCCESS}(f, \succ)$ for every $f \in D$, with any noetherian ordering $\succ$.

For the converse part, we prove by induction on $T(F)$ that any ground instance $\theta(f(x_1, \ldots, x_m))$ IP-terminates for any term $f(x_1, \ldots, x_m) \in T(F, X)$ with $f \in F$. We use an abstraction lemma, a narrowing lemma, and a stopping lemma, which are given after this main proof.

The induction ordering is constrained along the proof. At the beginning, it has at least to be noetherian. Such an ordering always exists on $T(F)$ (for instance the embedding relation). Let us denote it by $\succ$.

If $f$ is a defined symbol, let us denote it by $g$ and prove that $g(\theta_1, \ldots, \theta_m)$ is IP-terminating for any satisfying $A = \top$ if we have $\text{SUCCESS}(h, \succ)$ for every defined symbol $h$. Note that $g$ may be a reducible constant. Let us denote $g(x_1, \ldots, x_m)$ by $t_{ref}$ in the sequel of the proof.

To each state $s$ of the proof tree of $g$, characterized by a current term $t$ and the set of constraints $A$, we associate the set of ground instances $G = \{\alpha \mid \alpha \text{ satisfies } A\}$, that is the set of ground instances represented by $s$. When $t$ is a reducible constant, the set of ground instances is reduced to $t$ itself.

The Abstract inference rule (resp. Narrow) transforms $\{(t), A, C\}$ into $\{(t'), A', C'\}$ to which is associated $G' = \{\beta' \mid \beta \text{ satisfies } A'\}$ (resp. into $\{(t), A\}$, $i \in [1..q]$ to which are associated $G' = \{\beta_i' \mid \beta \text{ satisfies } A\}$).

By abstraction (resp. narrowing) Lemma, when applying Abstract (resp. Narrow), for each reducible $\alpha$ in $G$, there is a $\beta'$ (resp. there are $\beta_i', i \in [1..q]$) in $G'$ such that $G'$-termination of $\beta'$ (resp. of the $\beta_i', i \in [1..q]$) implies $IP$-termination of $\alpha$.

When the Stop inference rule applies on $\{(t), A, C\}$, by stopping lemma, every term of $G = \{\alpha \mid \alpha \text{ satisfies } A\}$ is $IP$-terminating. Therefore, $IP$-termination is ensured for all terms in sets $G$ in the proof tree.

As the process is initialized with $\{t_{ref}\}$ and a set $A$ of abstraction constraints satisfiable by any ground substitution, we get that $g(x_1, \ldots, x_m)$ is $IP$-terminating, for any $t_{ref} = g(x_1, \ldots, x_m)$, and any ground instance $\theta$.

If $f$ is a constructor, either it is a constant, which is irreducible, and then $IP$-terminating, or we consider the pattern $f(x_1, \ldots, x_m)$. The proof then works like in the case of defined symbols, but with just an application of Abstract and Stop. Indeed, $f(x_1, \ldots, x_m)$ always abstracts into $f(X_1, \ldots, X_m)$. Then Stop applies because $f(X_1, \ldots, X_m)$ is not manageable and all its variables are in $N$. $\square$

Lemma 2 (Abstraction lemma). Let $\{(t), A, C\}$ be a state of any proof tree, giving the state $\{(t' = t(X_1)\epsilon [1..k]), \alpha, \epsilon \}$ by application of Abstract.

For any ground substitution $\alpha$ satisfying $A$, if $\alpha$ is irreducible, there is $\beta$ such that $IP$-termination of $\beta'$ implies $IP$-termination of $\alpha$. Moreover, $\beta$ satisfies $A$.

Proof. We prove that $t \rightarrow_{\text{IP}}^* \beta'$, where $\beta = \alpha \cup \bigcup_{i \in [1..p]} X_i = \alpha[t_{ref}]$.

First, the abstraction positions in $t$ are chosen so that the $\alpha[t_{ref}]$ can be supposed IP-terminating. Indeed, each term $t_{ref}$ is such that:

- either $\text{IP}(t_{ref})$ is true, and then by definition of the predicate $\text{IP}(t_{ref})$ is $IP$-terminating;
- or $t_{ref} > t_{ref}'$ is satisifiable by $\succ$, and then, by induction hypothesis, $\alpha[t_{ref}]$ is $IP$-terminating.

So, $\alpha[t_{ref}]$ reduces to an $IP$-normal form $\alpha[t_{ref}]$. Then, whatever the positions $i_1, \ldots, i_q$ in the term $t$, we have $t \rightarrow_{\text{IP}}^* \alpha[t_{ref}]_{i_1} \cdots \alpha[t_{ref}]_{i_q} = \beta'$.

Thus, $t \rightarrow_{\text{IP}} \beta'$ for every derivation that normalizes all subtrees $\alpha[t_{ref}]_j$, for $j \in \{p_1, \ldots, p_q\}$. As every $\beta'$ represents a reduced form of $\alpha[t_{ref}]$ on every possible rewriting branch of $\alpha$, then $IP$-termination of $\alpha[t_{ref}]$ implies $IP$-termination of $\alpha$.

Finally, $\beta$ satisfies $A' = A \land t_{ref}' = X_1 \cdots \land t_{ref}' = X_n$, provided the $X_i$ are neither in $A$, nor in $\text{Dom}(\alpha)$, which is true since the $X_i$ are fresh variables, neither appearing in $A$, nor in $\text{Dom}(\alpha)$. $\square$

Lemma 3 (Narrowing lemma). Let $\{(t), A, C\}$ be a state of any proof tree, giving the states $\{(t), A', C'\}$, $i \in [1..l]$, by application of Narrow. For any ground substitution $\alpha$ satisfying $A$, if $\alpha$ is IP-reducible, then, for each $i \in [1..l]$, there is $\beta_i$ such that $IP$-termination of the $\beta_i$, $i \in [1..l]$, implies $IP$-termination of $\alpha$. Moreover, $\beta_i$ satisfies $A'$ for each $i \in [1..l]$.

Proof. For any rewriting step $t \rightarrow_{\text{IP}}^* t'$, by Lifting Lemma, there is a term $v \in T(F, X)$ and substitutions $\beta, \sigma = \sigma_0 \land \bigwedge_{i \in [1..k]} \sigma_i$ such that:

1. $t \rightarrow_{\text{IP}}^* v$,
2. $\beta v = t'$,
3. $\beta \sigma_0 = \alpha[\mathcal{Y} \cup \mathcal{Var}(l)]$,
4. $\beta$ satisfies $\bigwedge_{i \in [1..k]} \sigma_i \land \bigwedge_{i \in [1..n]} \sigma_i$,

where $\sigma_0$ is the most general unifier of $t_{ref}$ and $l, \sigma_j, j \in [1..k]$ are all the most general unifiers of $\sigma_0[t_{ref}]$ and a left-hand side $l'$ of a rule of $R$, for all suffix positions $p'$ of $p$ in $s, \sigma_0, i \in [1..n]$ are all the most general unifiers of $t_{ref}$ with the left-hand side of the rules having greater priority than $l \to r$. $\square$
The narrowing steps are effectively produced in the proof tree by the Narrow rule, applied in all possible ways on t. Then, the narrowing step \( t \sim_{\text{Narrow}}^\ast v \) is produced. So a term \( \beta v \) is produced for every \( \text{IP}-\text{rewriting branch} \) starting from \( \alpha t \). Then \( \text{IP}-\text{termination of the } \beta v \) implies \( \text{IP}-\text{termination of } \alpha t \).

Let us prove that \( \beta \) satisfies
\[
A' = A \land \sigma_0 \land \bigwedge_{j \in [1..k]} \overline{\sigma_j} \land
\bigwedge_{i \in [1..n]} \overline{\sigma_i}. 
\]
By Lifting Lemma, we have \( \alpha = \beta \sigma_0 \) on \( Y \). As we can take \( Y \supseteq \text{Var}(A) \), we have \( \alpha = \beta \sigma_0 \) on \( \text{Var}(A) \).

More precisely, on \( \text{Ran}(\sigma_0) \), \( \beta \) is such that \( \beta \sigma_0 = \alpha \) and on \( \text{Var}(A) \setminus \text{Ran}(\sigma_0) \), \( \beta = \alpha \). As \( \text{Ran}(\sigma_0) \) only contains fresh variables, we have \( \text{Var}(A) \cap \text{Ran}(\sigma_0) = \emptyset \), so \( \text{Var}(A) \setminus \text{Ran}(\sigma_0) = \text{Var}(A) \). So \( \beta = \alpha \) on \( \text{Var}(A) \) and then, \( \beta \) satisfies \( A \).

Moreover, as \( \beta \sigma_0 = \alpha \) on \( \text{Dom}(\sigma_0) \), \( \beta \) satisfies \( \sigma_0 \).

So \( \beta \) satisfies \( A \land \sigma_0 \). Finally, with the point 4. of the lifting lemma, we conclude that \( \beta \) satisfies
\[
A' = A \land \sigma_0 \land \bigwedge_{j \in [1..k]} \overline{\sigma_j} \land \bigwedge_{i \in [1..n]} \overline{\sigma_i}. 
\]

**Lemma 4 (Stopping lemma).** Let \((\{t\}, A, C)\) be a state of any proof tree, with \( A \) satisfiable, and giving the state \((\emptyset, A', C')\) by application of an inference rule. Then for every ground substitution \( \alpha \) satisfying \( A \), \( \alpha t \) is \( \text{IP}-\text{terminating} \).

**Proof.** The only rule giving the state \((\emptyset, A', C')\) is \( \text{Stop} \). When \( \text{Stop} \) is applied, then

- either \( \text{IPT}(t) \) and then \( \alpha t \) is \( \text{IP}-\text{terminating} \) for every ground substitution \( \alpha \),
- or \( (t_{\text{ref}} > t) \) is satisfiable. Then, for every ground substitution \( \alpha \) satisfying \( A \), \( \alpha t_{\text{ref}} \succ \alpha t \). By induction hypothesis, \( \alpha t \) is \( \text{IP}-\text{terminating} \).

\( \square \)
