<i>BP 53, F-38041 Grenoble Cedex* 9, *France*

We consider a set of equations modeling contact line dy We consider a set of equations modeling contact line dynamics. The model consists of the 9 Navier–Stokes free surface flow with local slip-type boundary conditions and gradient surface tension coupled with a mesoscopic local surface model (nonlinear degenerated equations) describes the 11 surface tension variations. The dynamical contact angle and the local surface tension variations are unknowns of the model. We present some mathematical and numerical results. 13 © 2005 Published by Elsevier Ltd.

 $Keywords: \blacksquare; \blacksquare; \blacksquare$

15 **1. Introduction**

The aim of the paper is the mathematical and numerical modeling of dynamical contact 17 lines (e.g. coating of solids by liquids). Two main features of such flows are the following. First, the liquid front advances following a rolling motion, similar to a caterpillar vehicle,

19 see [3]. Second, the dynamical contact angle deviates from its static value, determined by the classical Young equation, and depends on the fluid velocity in the bulk. In addition,

21 it seems that its value cannot be prescribed explicitly in a general way, see e.g. [1]. The mathematical modeling of the moving contact line is delicate. A no-slip boundary condition

23 at the solid–liquid interface implies a non-physical singularity: the fluid exerts an infinite

- 1 force on the solid surface [3]. Then, most of the theories and most of models have been based on a slippage description, see e.g. [6,2,4,7].
- 3 The mathematical model studied in the present paper is based on the model established in [7,1]. The main idea of this model is to take into account the rolling motion
- 5 induces a local variation of the surface tension [7]. The induced surface tension gradient influences the motion and the force near the contact line; it implies a Marangoni ef-
- 7 fect. In this model, the (dynamical) wetting angle is not imposed but is a response of the model.

9 **2. The mathematical model**

In this section, we consider the configuration of a solid plate plunging vertically into a ¹¹ 2D pool of liquid at speed *^U*S, Fig. 2, and we present a model derived from [7].

We denote by Ω the liquid pool wetting the solid tape *(S)*, by Γ_{SL} the solid–liquid contact the solid–gas contact surface by Γ_{LG} the free surface liquid–gas and by 13 surface, by Γ_{SG} the solid–gas contact surface, by Γ_{LG} the free surface liquid–gas and by $P_{\rm C}$ the contact point liquid–gas–solid.

15 When the liquid is at rest, the (static) contact angle θ_s satisfies the classical Young equation: σ_{LG}^{eq} cos $(\hat{\theta}_s) = \sigma_{SG}^{eq} - \sigma_{SL}^{eq}$, where σ_{LG}^{eq} , σ_{SL}^{eq} and σ_{SG}^{eq} are the equilibrium surface tensions of the liquid–gas solid–liquid and solid–gas interfaces respectively. In this paper, we con 17 of the liquid–gas, solid–liquid and solid–gas interfaces, respectively. In this paper, we consider the dynamic case where the solid plate is moving at speed U_s , see Fig. 2. In that case, 19 the contact angle becomes variable. The basic idea of the model studied in [7] is to consider that the Young equation remains valid:

$$
21 \qquad \sigma_{LG} \cos(\theta_d) = \sigma_{SG} - \sigma_{SL},
$$

where θ_d denotes the dynamic contact angle.

In this section, we consider the configuration of a solid plate plunging vertically in

D pool of liquid at speed U_S , Fig. 2, and we present a model derived from [7]. D pool of liquid at speed U_S , Fig. 2, and we pre 23 Briefly, the full model considered in the present paper is as follows. A macroscopic hydrodynamic free surface model, HFSM, for the fluid motion is coupled to a mesoscopic 25 local surface model, LSM, describing the local surface tension distribution and the contact line motion. The HFSM consists of the Navier–Stokes equations with free surface and 27 slip-type boundary conditions. The coupling with the LSM is done through these boundary conditions imposed on a small vicinity of the triple line. The LSM describes the dependence 29 between the surface tension parameters and the fluid motion.

2.1. The macroscopic hydrodynamic free surface model

31 We denote by \vec{u} the fluid velocity, *p* its pressure, Σ the stress tensor with components $\Sigma_{\text{tot}} = -n\delta_{\text{tot}} + u(\delta u + \delta u)$ 1 < *i* < 2 where *u* is the dynamic viscosity $\Sigma_{ij} = -p\delta_{ij} + \mu(\partial_i u_j + \partial_j u_i)$ 1 $\leq i, j \leq 2$, where μ is the dynamic viscosity.
We denote by $(\vec{\tau}, \vec{n})$ the unit tangential and external normal vectors such that

33 We denote by $(\vec{\tau}, \vec{n})$ the unit tangential and external normal vectors such that it is direct.
We set: $\vec{\Sigma} = \Sigma' \vec{n} \in \mathbb{R}^2$. $\vec{\Sigma} = \Sigma \vec{n} + \Sigma \vec{\tau}$ We set: $\vec{\Sigma_n} = \vec{\Sigma}', \vec{n} \in \mathbb{R}^2$; $\vec{\Sigma_n} = \Sigma_n \vec{n} + \Sigma_\tau \vec{\tau}$.
The fluid motion is governed by the incor-

35 The fluid motion is governed by the incompressible Navier–Stokes equations (into variables (\vec{u}, p)). To describe the boundary conditions, we decompose Γ_{SL} (respectively, Γ_{LG})
in two parts $\Gamma_{\rm M}^{\rm M}$ and $\Gamma_{\rm m}^{\rm m}$ (respectively, $\Gamma_{\rm M}^{\rm M}$ and $\Gamma_{\rm m}^{\rm m}$). The superscripts $^{\rm M}$ 37 in two parts $\Gamma_{\text{SL}}^{\text{M}}$ and $\Gamma_{\text{SL}}^{\text{m}}$ (respectively, $\Gamma_{\text{LG}}^{\text{M}}$ and $\Gamma_{\text{LG}}^{\text{m}}$). The superscripts $^{\text{M}}$ and $^{\text{m}}$ refer to

J. Monnier, P. Witomski / Nonlinear Analysis () – 3

1 the macroscopic and the mesoscopic boundaries, respectively. The boundary conditions on the free surface (liquid–gas) are

$$
\overline{\mathbf{3}}
$$

3 $\begin{cases} \vec{\Sigma}_n = (-p_{\text{ext}} + \sigma_{\text{LG}}\kappa)\vec{n} & \text{in } (0, T) \times \Gamma_{\text{LG}}^{\text{M}},\\ \vec{\Sigma}_n = (-p_{\text{ext}} + \sigma_{\text{LG}}\kappa)\vec{n} + (\vec{\nabla}\sigma_{\text{LG}} \cdot \vec{\tau})\vec{\tau} & \text{in } (0, T) \times \Gamma_{\text{LG}}^{\text{m}}, \end{cases}$ (1) where κ is the mean curvature and p_{ext} is the external pressure.

The liquid–solid contact is described by: $\vec{u} = \vec{U}_{\text{S}}$ in $(0, T) \times \Gamma_{\text{SL}}^{\text{M}}$, where \vec{U}_{S} is the solid velocity and velocity, and

$$
\begin{cases}\n\vec{u} \cdot \vec{n} = 0 & \text{in } (0, T) \times \Gamma_{\text{SL}}^{\text{m}}, \\
\Sigma_{\tau} = -(\beta(\vec{u} - \vec{U}_{\text{S}}) - \frac{1}{2} \vec{\nabla} \sigma_{\text{SL}}) \cdot \vec{\tau} & \text{in } (0, T) \times \Gamma_{\text{SL}}^{\text{m}},\n\end{cases}
$$
\n(2)

where $\beta > 0$ is a sliding-type coefficient.
The boundary condition (2) removes the

9 The boundary condition (2) removes the shear-stress singularity. Surface tension gradients appear in (1) and (2). It is one of the novel features of the model.

11 We define the free surface Γ_{LG} as the graph of a function $\varphi(t, x)$ and the free surface
motion is described by the classical transport equation with the graph value given at the motion is described by the classical transport equation with the graph value given at the 13 inflow boundary.

Remark 2.1. Let us point out an important feature of the model. The dynamic wetting 15 angle θ_d is not imposed. It is a response of the model. It can be computed using the relation: $\cot \left(\theta_d\right) = -\left(\frac{\partial \varphi}{\partial x_1}\right)(t, P_C)$ for *t* in $(0, T)$.

17 *2.2. The mesoscopic local surface model*

there $\beta > 0$ is a siding-type coefficient.
The boundary condition (2) removes the shear-stress singularity. Surface tension gradien
ppear in (1) and (2). It is one of the novel features of the model.
We define the free s Briefly, the so-called mesoscopic LSM (established in [7]) is as follows. The interfaces 19 are described by surface densities ρ^s which are solution of surface continuity equations. A state equation provides the relation between ρ^s and the surface tension coefficients σ . We 21 denote by ρ_i^s , $i = 1, 2$, the surface density on Γ_{LG} $(i = 1)$ and on Γ_{SL} $(i = 2)$. The surface tension is related to the excess density through a linear state equation tension is related to the excess density through a linear state equation

23
$$
\sigma_i = \gamma(\rho_0^s - \rho_i^s), \quad i = 1, 2,
$$
 (3)

where γ and ρ_0^s are given constants. We have the surface continuity equation

25
$$
\frac{\partial \rho_i^s}{\partial t} + \text{div}(\rho_i^s v_i^s) + \frac{1}{\tau^*}(\rho_i^s - \rho_i^{eq}) = 0, \quad i = 1, 2,
$$
 (4)

where τ^* is the relaxation time relative to the rolling motion, v_i^s is a mean velocity inside
the layer and o^{eq} is its density at equilibrium: $\tau_1(o^{eq}) = \sigma^{eq}$ $i = 1, 2$ 27 the layer and ρ_i^{eq} is its density at equilibrium: $\sigma_i(\rho_i^{eq}) = \sigma_i^{eq}$, $i = 1, 2$.
The velocity v_i^s (respectively v_i^s) is related to ρ_i^s (respectively ρ_i^s) and

The velocity v_1^s (respectively, v_2^s) is related to ρ_1^s (respectively, ρ_2^s) and to the fluid velocity
respectively, the solid velocity $I(s)$. We have the following Darcy laws type: 29 u (respectively, the solid velocity U_S). We have the following Darcy laws type:

$$
(1 + 4\alpha_1 \alpha_2) \nabla \sigma_{LG} = 4\alpha_2 (v_1^s - u) \quad \text{and} \quad v_2^s = \alpha_1 \nabla \sigma_{SL} + \frac{1}{2} (u + U_S), \tag{5}
$$

31 where α_i , $i = 1, 2$, are given constants characterizing the viscous properties of the interface. At the triple junction, the surface flux continuity is imposed: $(\rho_1^s v_1^s) e_f = (\rho_2^s v_2^s) e_g$, where

4 *J. Monnier, P. Witomski / Nonlinear Analysis () –*

¹ *^e*^f and *^e*^g are unit vectors normal to the contact line and tangential to the gas–liquid and gas–solid interface, respectively. Let us notice that $cos(\theta_d) = -e_f \cdot e_g$.

3 **3. The 1D local surface model**

We consider the 1D steady-state LSM. We reformulate the equations by eliminating the 5 variable v_i^s . For both cases $i = 1$ and 2, we obtain similar equations. They are nonlinear and degenerated Case $i = 2$ (solid–liquid surface) leads to: degenerated. Case $i = 2$ (solid–liquid surface) leads to:

$$
(\mathrm{P})
$$

(1)
$$
\begin{cases} -(\rho \rho')' + \delta_1 U \rho' + \delta_2 \rho = f \text{ in }]0, 1[, \\ \rho(0) = \rho_0, \\ (-\rho \rho' + \delta_1 U \rho)(1) = \phi, \end{cases}
$$

(**F**) $\int_{\ell-\rho}^{\rho} f^{(0)}(x-\rho) dx$

there $\delta_1 = IU^*/\lambda \rho^*, \delta_2 = I^2/\lambda \rho^* \tau^*$ are dimensionless numbers, $\phi = \delta_1 \rho_1^{sq} (2U(1))$
 $U(0) \le 0$, ϕ is the flux at the contact point and $f = \delta_2 \rho_0$. Let us notice that if we s
 where $\delta_1 = lU^*/\lambda \rho^*$, $\delta_2 = l^2/\lambda \rho^* \tau^*$ are dimensionless numbers, $\phi = \delta_1 \rho_1^{\text{eq}} (2U(1) - I/(0)) < 0$ *k* is the flux at the contact point and $f = \delta_2 \rho_1$. Let us notice that if we set $U(0) \leq 0$, ϕ is the flux at the contact point and $f = \delta_2 \rho_0$. Let us notice that if we set $l = \tau^* U^*$, then $\delta_1 = \delta_2 = \frac{\tau^*(U^*)^2}{\lambda \rho^*}$.

11 *3.1. Mathematical analysis*

Let us assume

13 **Assumption 3.1.**

(i) $\rho_0 > 0$. (ii) $U \in W^{1,\infty}(0, 1)$ and $U \le 0$ in [0,1]; $U' \ge 0$ a.e. and $||U'||_{\infty} \le \delta_2/\delta_1$.

We consider the nonlinear regularized problem:

$$
(P^{\beta}) \quad \begin{cases} -(\beta_{\varepsilon}(\rho)\rho')' + \delta_1 U \rho' + \delta_2 \rho = f & \text{in } [0, 1[, \\ \rho(0) = \rho_0, \\ (-\beta_{\varepsilon}(\rho)\rho' + \delta_1 U \rho)(1) = \phi, \end{cases}
$$

where $\varepsilon > 0$, $\beta_{\varepsilon} \in C^1(\mathbb{R})$ is Lipschitz, increasing and defined by: $\beta_{\varepsilon}(x) = \varepsilon$ if $x \le 0$ and $\beta(x) = x$ if $x > 2\varepsilon$ 19 $\beta_{\varepsilon}(x) = x$ if $x \ge 2\varepsilon$.

List the Leray

Using the Leray–Schauder fixed-point theorem, we prove that under Assumption 3.1, Problem (P^{β}) has at least one weak solution in $H^1(0, 1)$ and this solution belongs to $H^2(0, 1)$ $H^2(0, 1)$.

23 Furthermore, let η be a real number satisfying: $\rho_0 \ge \eta > 0$ and $\eta \delta_1 U(1) \ge \phi$. For example with $U(1) < 0$, we may set $\eta = \min{\{\rho_0, [\phi/\delta_1 U(1)]\}}$. Combining the weak maximum 25 principle, see [5], and the previous existence result, we obtain:

Theorem 3.1. *Under Assumption* 3.1, *Problem* (P) *has at least one weak solution* ρ *in*

27
$$
H^1(0, 1)
$$
. This solution satisfies $\rho(x) \ge \eta > 0$ in [0,1] and belongs to $H^2(0, 1)$.

Actually, we have the following stronger result.

J. Monnier, P. Witomski / Nonlinear Analysis **(1111) (1111) 111–111 6** 5

1 **Theorem 3.2.** *Under Assumption* 3.1, *Problem* (P) *has an unique solution* .

Proof. We denote by ρ_1 and ρ_2 two solutions of (P).

- 3 (a) First, we prove that $\rho'_1(0) = \rho'_2(0)$. Let us suppose that $\rho'_1(0) > \rho'_2(0)$. Let $]0, \xi_0]$ the largest interval such that $\rho'_1(0) > \rho'_2(0)$. $\chi \in]0, \xi_0]$ largest interval such that $\rho_1(x) > \rho_2(x)$, $x \in]0, \xi_0[$.
- 5 Let us suppose $\xi_0 = 1$. We integrate the first equation of (P) on [0, 1] with ρ_1 and ρ_2 . By differentiating we obtain:

$$
-\rho_1 \rho'_1(1) + \rho_2 \rho'_2(1) + \rho_0(\rho'_1(0) - \rho'_2(0)) + \delta_1 [U(\rho_1 - \rho_2)]_0^1
$$

+
$$
\int_0^1 (\delta_2 - \delta_1 U')(\rho_1 - \rho_2) dx = 0.
$$

Using the boundary conditions of (P), we obtain $\int_0^1 (\delta_2 - \delta_1 U') (\rho_1 - \rho_2) dx < 0$, which is 9 impossible.

Therefore $\xi_0 \in]0, 1[$ and $\rho_1(\xi_0) = \rho_2(\xi_0)$. We integrate again on [0, ξ_0] and we obtain:

Using the boundary conditions of (P), we obtain
$$
\int_0^1 (\delta_2 - \delta_1 U') (\rho_1 - \rho_2) dx < 0
$$
, which
\nimpossible.
\nTherefore $\xi_0 \in]0, 1[$ and $\rho_1(\xi_0) = \rho_2(\xi_0)$. We integrate again on $[0, \xi_0]$ and we obtain
\n $-\rho_1(\xi_0)(\rho'_1(\xi_0) - \rho'_2(\xi_0)) + \rho_0(\rho'_1(0) - \rho'_2(0))$
\n $+ \int_0^1 (\delta_2 - \delta_1 U') \cdot (\rho_1 - \rho_2) dx = 0$
\nhence $(\rho_1 - \rho_2)'(\xi_0) > 0$. It is impossible, and therefore $\rho'_1(0) = \rho'_2(0)$.
\n(b) Second, we write the first equation of (P) as a first order differential equation of the
\nform: $W'(x) = G(W)(x)$, $x \in]0, 1[$ with $W = (u, v)^T$ and
\n $G(W)(s) = \left(v(s), \frac{-1}{u(s)}[-v^2(s) + \delta_1 U(s)v(s) + \delta_2 u(s) - f(s)]\right)^T$.
\nWe consider $G : C^1([0, 1]; \mathbb{R}) \cap \mathcal{F}^+ \times C^0([0, 1]; \mathbb{R}) \to C^0([0, 1]; \mathbb{R}) \times C^0([0, 1]; \mathbb{R})$
\nwith $\mathcal{F}^+ = \{u, u \in C^0([0, 1]; \mathbb{R}), u > 0$ in [0, 1].
\nThen, we set $W_i = (\rho_i, \rho'_i)^T$, $i = 1, 2$. We have $W'_i(x) = G(W_i)(x)$, $x \in]0, 1[$, a
\n $W_1(0) = W_2(0)$. Hence, $(W_1 - W_2)(x) = \int_0^x (G(W_1) - G(W_2))(s) ds$.
\nSince $\rho_i \in C^1([0, 1]; \mathbb{R}) \cap \mathcal{F}^+$ and $G(W_i)$ is of class C^1 , there exists a constant k such
\nthat: $||(G(W_1) - G(W_2))(s)||$

hence $(\rho_1 - \rho_2)'(\zeta_0) > 0$. It is impossible, and therefore $\rho'_1(0) = \rho'_2(0)$.

(b) Second we write the first equation of (P) as a first order different

13 (b) Second, we write the first equation of (P) as a first order differential equation of the form: $W'(x) = G(W)(x)$, $x \in]0, 1[$ with $W = (u, v)^T$ and

15
$$
G(W)(s) = \left(v(s), \frac{-1}{u(s)}[-v^2(s) + \delta_1 U(s)v(s) + \delta_2 u(s) - f(s)]\right)^T.
$$

We consider *G* : $C^1([0, 1]; \mathbb{R}) \cap \mathcal{F}^+ \times C^0([0, 1]; \mathbb{R}) \rightarrow C^0([0, 1]; \mathbb{R}) \times C^0([0, 1]; \mathbb{R})$ 17 with $\mathcal{F}^+ = \{u, u \in C^0([0, 1]; \mathbb{R}), u > 0 \text{ in } [0, 1]\}.$

Then, we set $W_i = (\rho_i, \rho'_i)^T$, $i = 1, 2$. We have $W'_i(x) = G(W_i)(x)$, $x \in]0, 1[$, and $w_i(0) = W_2(0)$. Hence $(W_1 - W_2)(x) = \int_0^x (G(W_1) - G(W_2))(s) ds$ **i**)
 i) $W_1(0) = W_2(0)$. Hence, $(W_1 - W_2)(x) = \int_0^x (G(W_1) - G(W_2))(s) ds$.

Since $0 \in C^1([0, 1]: \mathbb{R}) \cap \mathbb{Z}^+$ and $G(W_1)$ is of class C^1 there exist

Since $\rho_i \in C^1([0, 1]; \mathbb{R}) \cap \mathcal{F}^+$ and $G(W_i)$ is of class C^1 , there exists a constant *k* such at: $\|(G(W_i) - G(W_2))(s)\| \le k\|(W_i - W_2)(s)\|$ 21 that: $||(G(W_1) - G(W_2))(s)|| \le k||(W_1 - W_2)(s)||$.
Then it follows from the previous equality that

Then, it follows from the previous equality that: $\|(W_1 - W_2)(x)\| \le k \int_0^x \|(W_1 - W_2)\| ds$. 23 *(s)* ds. And it follows from Gronwall inequality that $W_1 = W_2$ in [0, 1].

Proposition 3.1. *Let Assumption* 3.1 *be satisfied and U be such that* $U(0) > 2U(1)$ *.*

- 25 (i) If $\phi = \delta_1 U(1) \rho_0$ then $\rho \equiv \rho_0$, ρ being the unique solution of (P).
- (ii) If $\phi < \delta_1 U(1)\rho_0$ then $\rho(x) \ge \rho_0$ and $\rho'(x) \ge 0$ in [0,1].
 iii) If $\phi < \delta_1 U(1)\rho_0$ then $\rho(x) \le \rho_0$ and $\rho'(x) \le 0$ in [0,1].
- 27 (iii) If $\phi > \delta_1 U(1) \rho_0$ then $\rho(x) \le \rho_0$ and $\rho'(x) \le 0$ in [0,1].

Proof. (i) It is straightforward to verify that $\rho \equiv \rho_0$ is a solution and the solution is unique. 29 (ii) We have $\phi < \delta_1 U(1)\rho_0$. Since the weak maximum principle holds, we have $\rho \ge \rho_0$ in [0,1].

6 *J. Monnier, P. Witomski / Nonlinear Analysis () –*

Let us prove that $\rho'(x) \ge 0$. If there exists $\xi_0 \in]0, 1[$ such that $\rho'(\xi_0) < 0$, then

$$
-(\rho \rho')'(\xi_0) + \delta_1 U(\xi_0) \rho'(\xi_0) = \delta_2(\rho_0 - \rho(\xi_0)) \le 0
$$

3 hence $-(\rho \rho')'(\xi_0) = -\frac{1}{2}(\rho^2)'(\xi_0) < 0$. We deduce that $(\rho^2)'(\xi) > 0$ in a neighborhood $\mathcal{L}(\xi_0)$. Therefore *o* is increasing in $\mathcal{L}(\xi_0)$ and $\rho'(\xi) > 0$ in $\mathcal{L}(\xi_0)$, which is a contradiction $\mathcal{V}(\xi_0)$. Therefore ρ is increasing in $\mathcal{V}(\xi_0)$ and $\rho'(\xi) \ge 0$ in $\mathcal{V}(\xi_0)$, which is a contradiction with $\rho'(\xi_0) < 0$. Then, we deduce that $\rho'(x) > 0$ in 10.11 hence in [0.11 since it is continue.

5 with $\rho'(\xi_0) < 0$. Then, we deduce that $\rho'(x) \ge 0$ in]0,1[hence in [0,1] since it is continue.
(iii) We prove the result following the same idea as (ii) (iii) We prove the result following the same idea as (ii). \Box

7 *3.2. Numerical results*

We compute numerically the solution of the LSM using a finite difference method. We 9 assume that $\sigma_{LG} = \sigma_{LG}^{eq}$. It follows from (5) that $v_1^s = u$ on Γ_{LG} . Then, the LSM is reduced to a 1D differential equation in an interval of the *y*-axis (on Γ_m^m) to a 1D differential equation in an interval of the *y*-axis (on $\Gamma_{\text{SL}}^{\text{m}}$).
The computation of the 1D mesoscopic I SM provides a profile of

11 The computation of the 1D mesoscopic LSM provides a profile of $\nabla \sigma_2$. In next section this term will be considered as the local Marangoni source term in the Navier–Stokes boundary 13 conditions HFSM.

We consider an air-water-glass system: $\sigma_{\text{LG}}^{\text{eq}} = 70$, $\sigma_{\text{LG}}^{\text{eq}} = 20$ and $\sigma_{\text{SG}}^{\text{eq}} = 50 \text{ mN/m}$.
In the static case, we have: $\cos(\theta) = (\sigma_{\text{CG}}^{\text{eq}} - \sigma_{\text{eq}}^{\text{eq}})/\sigma_{\text{CG}}^{\text{eq}} \approx 0.429$ hence $\theta \approx 64.6$

We compute numerically the solution of the LSM using a finite difference method. V
sume that $\sigma_L_G = \sigma_{11}^{\text{eq}}$. It follows from (5) that $v_1^k = u$ on Γ_L_G . Then, the LSM is reduce
or a 1D differential equation in an i In the static case, we have: $cos(\theta_s) = (\sigma_{SG}^{ed} - \sigma_{SG}^{eq})/\sigma_{LG}^{gd} \approx 0.429$ hence $\theta_s \approx 64.6°$. In the dynamic case, the Young equation is supposed to remain valid and the case $\theta_s \approx 0.590°$ the dynamic case, the Young equation is supposed to remain valid and the case $\theta_d > 90^\circ$ corresponds to: $\sigma_{SG}^{eq} = 50 < \sigma_{SL} < \sigma_{LG}^{eq} = 70$. We set $\tau^* = 10^{-3}$ s, see [1], and $U^* = 5 \times 10^{-2}$ ms⁻¹ Hange $l \approx \tau^* U^* =$ 10^{-2} ms^{-1} . Hence, $l \approx \tau^* U^* = 5 \times 10^{-5} \text{ m}$.

19 We set $U_S = -1 = U_{\text{stokes}}(0)$ (the no-slip boundary condition for the bulk flow) and $U(x) = \frac{1}{2}(U_S + U_{\text{stokes}}(x)) = (\frac{1}{4}x - 1).$
It generice to set the following two per

21 It remains to set the following two parameters: the product $\lambda \rho^*$ and ρ_1^{eq} . For the present computation we set $\lambda e^* = 10^{-6}$ and $e^{eq} = \frac{1}{2}$. We obtain $\phi = 2.5$ For computational computation we set: $\lambda \rho^* = 10^{-6}$ and $\rho_1^{\text{eq}} = \frac{1}{5}$. We obtain $\phi = -2.5$. For computational reasons we set $l = 10\tau^* l l^*$ and we obtain $\delta_1 = 25$ and $\delta_2 = 250$ reasons we set $l = 10\tau^* U^*$ and we obtain $\delta_1 = 25$ and $\delta_2 = 250$.

Let us notice that the state equation $\sigma_i = \gamma(\rho_0^s - \rho_i)$, $i = 1, 2$, implies that $\rho_1^{eq} < \rho_2^{eq} = 1$.
equally the index a refers to the solid-liquid interface $\sigma_2 = \sigma_{31}$. All the assumptions on 25 (Recall: the index 2 refers to the solid–liquid interface, $\sigma_2 = \sigma_{SL}$). All the assumptions on data presented in the mathematical analysis section are satisfied.

27 The functions ρ , ρ' , σ_{SL} and σ'_{SL} obtained are presented below and in Fig. 1. We obtained:
 σ_{SL} (P_{C1}) = 66.8 σ' (P_{C2}) = 1.01 × 10⁶ θ_1 = 103.9° $\rho(P_{C1})$ = 2.51 × 10⁻⁴ $\| \rho' \|$ = 175. $\sigma_{SL}(P_C) = 66.8$, $\sigma'_{SL}(P_C) = 1.01 \times 10^6$, $\theta_d = 103.9^\circ$, $\rho(P_C) = 2.51 \times 10^{-4}$, $\|\rho'\|$
We note that the surface tension σ_{SL} and its gradient σ' are found from t

 $\sigma_{SL}(P_C) = 66.8$, $\sigma'_{SL}(P_C) = 1.01 \times 10^6$, $\theta_d = 103.9^\circ$, $\rho(P_C) = 2.51 \times 10^{-4}$, $\|\rho'\|_{\infty} = 175.6$.
29 We note that the surface tension σ_{SL} and its gradient σ'_{SL} are found from the values of ρ , ρ' and using the state equation $\sigma_i = \gamma(\rho_0^s - \rho_i)$, $i = 1, 2$. As a matter of fact, since
31 $\sigma_{LG}^{eq} = \gamma(\rho_0^s - \rho_1^{eq})$ and $\sigma_{SL}^{eq} = \gamma(\rho_0^s - \rho^*)$, one can deduce the values of the constants γ and ρ_0^s

33 surface tension coefficient σ_{SL} . Finally, we have

$$
\theta_{\rm d} = \cos^{-1}\left(\frac{\sigma_{\rm SG}^{\rm eq} - \sigma_{\rm SL}(P_{\rm C})}{\sigma_{\rm LG}^{\rm eq}}\right),\,
$$

35 where P_C denotes the triple point liquid–solid–gas.

The choice of the two parameters values of $(\lambda \rho^*)$ and ρ_1^{eq} is the main uncertainty of the odel. The present choice leads to admissible surface tension coefficient σ_{ex} and dynamical 37 model. The present choice leads to admissible surface tension coefficient $\sigma_{\rm SL}$ and dynamical wetting angle θ_d .

1 **4. Influence of the local Marangoni term on the 2D bulk flow**

Let θ_d , σ_{SL} , σ'_{SL} and Γ_{LG} be given, we compute the solution of a simplified HFSM: 3 the Stokes model without curvature term ($\kappa = 0$). The goal is to observe numerically the influence of the local Marangoni source term σ'_{SL} on the bulk fluid motion.

The simplified HFSM considered is the following. Given θ_d , σ'_{SL} and Γ_{LG} , find (u, p) satisfying: $\frac{\partial \Gamma}{\partial u} + \frac{\partial \Gamma}{\partial u} = 0$, $i = 1, 2$ and $\frac{d\psi(u)}{du} = 0$ in $\frac{\partial \Gamma}{\partial u} = \frac{\nabla \Gamma}{\nabla u} = 0$ on $\Gamma_{LG} + \Gamma_{GC}$ satisfying: $\partial_1 \Sigma_{i1} + \partial_2 \Sigma_{i2} = 0$, $i = 1, 2$, and div $(u) = 0$ in Ω ; $\Sigma_n = \Sigma_\tau = 0$ on $\Gamma_{LG} \cup \Gamma_{out}$;
 $u = U_0$ on Γ^M . 7 $u = U_{\rm S}$ on $\overline{\Gamma}_{\rm SL}^{\rm M}$;

$$
u \cdot n = 0
$$
 and $\Sigma_{\tau} = -\beta (u - U_{S}) + \frac{1}{2} \sigma'_{SL}$ on Γ_{SL}^{m} .

The slip coefficient $\beta \approx \mu/h_1 \approx 10^{-3}/10^{-8} = 10^5$ (*h*₁ is the layer thickness) [7]. The only source terms of the model are *U₂* and σ' and for $\sigma' = 0$ the unique solution is only source terms of the model are U_S and σ'_{SL} . And, for $\sigma'_{SL} \equiv 0$, the unique solution is $(u, n) = (U_S, 0)$ (the pressure being defined up to a constant) 11 $(u, p) = (U_S, 0)$ (the pressure being defined up to a constant).

We solve (P_{ST}) using the Hood–Taylor finite element method. The pressure equation is 13 solved using the augmented Lagrangian method and the Uzawa's algorithm.

Fig. 2. Left. Plunging plate configuration. Middle. The Stokes case test. Right. Zoom on \vec{u} near the contact point.

We set $U_S = (0, -10^{-2})^T$ and $L = 10^{-3}$ (in IS units). We set $\tau^* = 10^{-3}$ hence $l \approx \tau^* I^* = 10^{-5}$ and $s \approx l/I \approx 10^{-2}$ We have the Capillary number $Ca = uI^* / \sqrt{2}$, $\approx 10^{-6}$ $\tau^* U^* = 10^{-5}$ and $\varepsilon \approx l/L \approx 10^{-2}$. We have the Capillary number $Ca = \mu U^*/\sigma_{SL} \approx 10^{-6}$
and the Reynolds number $Re = \partial U^* I^* U \approx 50$ 3 and the Reynolds number $Re = \hat{\rho}U^*L^*/\mu \approx 50$.

It remains to set the two following parameters: the slip coefficient β and the given surface 5 tension gradient σ'_{SL} .

ig. 2. Left. Plunging plate configuration. Middle. The Stokes case test. Right. Zoom on \ddot{u} are the contact poi

We set $U_S = (0, -10^{-2})^T$ and $L = 10^{-3}$ (in IS units). We set $\tau^* = 10^{-3}$ hence $l^*l^* = 10^{-5}$ and \v For all tests, we set $\beta = 10^5$, and $\sigma'_{SL}(y) = \sigma'_{max} \times \exp(\frac{y - y_m}{y_{cp} - y_m} - 1) \times (\frac{y - y_m}{y_{cp} - y_m})$ if $y_m \le y \le y_{cp}$ and $\sigma'_{SL}(y) = 0$ if not; where $y_m = 0.00075$ is the middle point of the boundary
part Γ^m and $y_c = 0.0008$ is the contact point *y*-coordinate. Fig. 2 part $\Gamma_{\text{SL}}^{\text{m}}$ and $y_{\text{cp}} = 0.0008$ is the contact point *y*-coordinate, Fig. 2.
Therefore, the present given function σ' (y) behaves qualitative

- Therefore, the present given function $\sigma'_{SL}(y)$ behaves qualitatively similar to the computed one in previous section, Fig. 1.
- 11 First, we consider $\sigma'_{\text{max}} = 10^3$. We observe a simple flow. Second, we consider $\sigma'_{\text{max}} = 5 \times 10^3$. We observe a more complex flow. The given source
- term g_{slip} changes of sign in the vicinity of 7.8×10^{-4} . The computed *y*-coordinate velocity u_2 changes sign too, in the same area. Thus, we observe a local recirculation: the Marangoni
- 15 term induces a recirculation in the vicinity of the contact line, see Fig. 2. In conclusion, we would like to point that the model is too simplified to interpret these
- 17 numerical results from the mechanical point of view. To this end, one must take into account the free surface dynamic, the capillary forces and eventually consider the local slip boundary
- 19 conditions in the upper part of the vicinity of the triple line, i.e. on Γ_{LG} . Nevertheless, these numerical results show clearly the effects of the local slip boundary condition on the fluid
- 21 motion in the bulk. These numerical results are a first step for the simulation of the rolling motion and the dynamic of the contact angle using the model presented in [7,1].
