

## 1 A. Aggregation of identical jobs

2 In the available real life test instances, usually, there are identical jobs.  
 3 We call two jobs  $a$  and  $b$  identical if  $p_a = p_b$ ,  $l_a = l_b$ ,  $\alpha_a = \alpha_b$ ,  $\beta_a = \beta_b$ ,  
 4 and  $n(a) = n(b)$ . In order to decrease the size of the formulation (TIA) we  
 5 will aggregate jobs into groups. We partition the set  $N$  of jobs into the set  
 6  $Q = \{1, \dots, q\}$  of groups  $\{G_k\}_{k \in Q}$  of identical jobs. In the following theorem,  
 7 we show that there exists an optimal schedule, in which the operations of jobs  
 8 in the same group alternate.

9 **Theorem 1.** *There exists an optimal schedule, in which the  $j^{\text{th}}$  operations*  
 10 *of the jobs in the same group are processed in the same order for all  $j$ .*

11 **Proof.** Consider an optimal schedule  $S$ . If it satisfies the condition of the  
 12 theorem, we are done.

13 Otherwise, there should exist a triple  $\langle i, k; j \rangle$  such that  $S_{i,j-1} < S_{k,j-1} <$   
 14  $S_{k,j} < S_{ij}$  (we will call such triples *non-alternating*). Consider such a triple  
 15  $\langle i, k; j \rangle$  with the maximum possible  $j$ .

16 We now transform schedule  $S$  into  $S'$  by setting

$$S'_{ij'} = S_{kj'} \quad \text{and} \quad S'_{jk'} = S_{ij'} \quad \forall j' : j \leq j' \leq n(i) = n(k).$$

17 Obviously,  $S'$  is a feasible schedule (as  $p_i = p_k$ ).

18 First, we show that the cost  $F(S')$  of schedule  $S'$  is not bigger than the  
 19 cost  $F(S)$  of schedule  $S$ . Taking into account that  $\delta_i(x) = \delta_k(x)$ , and setting  
 20  $\epsilon = S_{ij} - S_{kj} > 0$ , we have

$$\begin{aligned} F(S) - F(S') &= \underbrace{\delta(S_{ij} - S_{i,j-1})}_{=\Delta i} + \underbrace{\delta(S_{kj} - S_{k,j-1})}_{=\Delta k} \\ &\quad - \underbrace{\delta(S_{kj} - S_{i,j-1})}_{=\Delta i - \epsilon} - \underbrace{\delta(S_{ij} - S_{k,j-1})}_{=\Delta k + \epsilon}. \end{aligned}$$

21 As the function  $\delta_i(x)$  is convex,  $\Delta k < \Delta i - \epsilon$ , and  $\Delta k + \epsilon < \Delta i$ , we have  
 22  $\delta_i(\Delta k) + \delta_i(\Delta i) \geq \delta_i(\Delta i - \epsilon) + \delta_i(\Delta k + \epsilon)$ , and  $F(S) \geq F(S')$ .

23 Secondly, we show that number of alternating triples has been increased.  
 24 Triple  $\langle i, k; j \rangle$  which was non-alternating in  $S$  became alternating in  $S'$ . It  
 25 is easy to see that, if an alternating triple  $\langle i, k'; j \rangle$ ,  $k' \neq k$ , (or  $\langle i', k; j \rangle$ ,  
 26  $i' \neq i$ ) in  $S$  became non-alternating in  $S'$ , then triple  $\langle k, k'; j \rangle$  (respectively,

27 triple  $\langle i, i'; j \rangle$  was non-alternating in  $S$  and become alternating in  $S'$ . The  
 28 alternating status of other triples in  $S'$  stayed the same as in  $S$ . So, the  
 29 number of alternating triples has been strictly increased in  $S'$ . Therefore,  
 30 repeating the same transformation a finite number of times, we can obtain a  
 31 desired schedule without increasing the cost of schedule  $S$ .  $\square$

32 Using the fact just proved, in the next theorem, we show that the penalty  
 33 functions  $\gamma_i$  for the jobs  $i$  in group  $G_k$ ,  $k \in Q$ , can be “aggregated” into a  
 34 single penalty function  $\theta_k$  for the group. Let  $G_{kt} = \{i \in G_k : t \in \Delta_i\}$ .  
 35 We renumber the jobs such that, for each  $k \in Q$ ,  $G_k = \{i'_k, i'_k + 1, \dots, i''_k\}$ ,  
 36  $S_{i'_k,0} < S_{i'_k+1,0} < \dots < S_{i''_k}$ . We set  $\bar{H}_k = H_{i'_k}$ , and

$$\theta_k(t) = \max \left\{ \alpha_i \left( \sum_{i \in G_k} n_i(t) - |G_{kt}| \right), \beta_i \left( |G_{kt}| - \sum_{i \in G_k} n_i(t) \right) \right\}.$$

37 **Theorem 2.** Consider a group  $G_k$ ,  $k \in Q$ , of jobs and a schedule  
 38  $\{S_{i,0}, S_{i,1}, \dots, S_{i,n(i)}\}_{i \in G_k}$ , in which the operations of jobs in  $G_k$  alternate.  
 39 Then, for all  $t \in \bar{H}_k$ ,

$$\sum_{i \in G_{kt}} \gamma_i(t) = \theta_k(t).$$

40 **Proof.** To prove the proposition, we need to show that, given  $t \in \bar{H}_k$ ,

$$\sum_{i \in G_k} n_i(t) \geq |G_{kt}| \Leftrightarrow n_i(t) \geq 1, \forall i \in G_{kt}, \quad (1)$$

$$\sum_{i \in G_k} n_i(t) \leq |G_{kt}| \Leftrightarrow n_i(t) \leq 1, \forall i \in G_{kt}, \quad (2)$$

41 The implication “ $\Leftarrow$ ” of (1) is obvious. We will now prove the implication  
 42 “ $\Rightarrow$ ” (1) by contradiction. Suppose that  $\sum_{i \in G_k} n_i(t) \geq |G_{kt}|$  and there exists  
 43 a job  $i' \in G_{kt}$  such that  $n_{i'}(t) = 0$ . Then, there is a job  $i'' \in G_{kt}$  such that  
 44  $n_{i''}(t) \geq 2$ . This means that, in the schedule, between two operations of job  
 45  $i''$ , there is no operation of job  $i'$  and an operation of job  $i'$  starts later than  
 46 time  $t$  (as  $i' \in G_{kt}$  and  $n_{i'}(t) = 0$ ). This contradicts the condition of the  
 47 proposition which states that the operations of jobs  $i'$  and  $i''$  alternate.

48 The implications in (2) can be proved in the same way.  $\square$

49 Finally, to find an optimal solution of the problem, we can limit the  
 50 search to the set of “alternating” schedules and use the penalty function

51  $\sum_{k \in Q} \sum_{t \in \bar{H}_k} \theta_k(t)$  instead of  $\sum_{i \in N} \sum_{t \in H_i} \gamma_i(t)$ . We will now modify the for-  
52 mulation (TIA). Integer variables  $X_{kt}$ ,  $k \in Q$ ,  $t \in H$ , are now equal to the  
53 number of operations of jobs in  $G_k$  started before or at time  $t$ . Continuous  
54 variable  $W_{kt}$ ,  $k \in Q$ ,  $t \in \bar{H}_k$ , now represents the value  $\theta_k(t)$ . Here we again  
55 need to introduce additional variables  $E$  in order to compute  $|G_{kt}|$ ,  $k \in Q$ ,  
56  $t \in H$ . Binary variable  $E_{kst}$ ,  $k \in Q$ ,  $s \in \{1, \dots, |Q_k|\}$ ,  $t \in H_k$ , takes value 1  
57 if and only if  $|G_{kt}| \geq s$ . Again, we do not need to impose the integrality on  
58 these variables. We now present the aggregated alternative time indexed ILP  
59 formulation. For each  $k \in Q$ , we set  $\bar{p}_k = p_{i'_k}$ ,  $\bar{l}_k = l_{i'_k}$ ,  $\bar{\alpha}_k = \alpha_{i'_k}$ ,  $\bar{\beta}_k = \beta_{i'_k}$ ,  
60  $\bar{n}(k) = n(i'_k)$ .

$$\min \sum_{k \in Q} \sum_{t \in \bar{H}_k} W_{kt} \quad (3)$$

$$s.t. \quad X_{k,S_{i_0}} = i''_k - i + 1, \quad \forall k \in Q, i \in G_k, \quad (4)$$

$$X_{k,S_{i_0-1}} = i''_k - i, \quad \forall k \in Q, i \in G_k, \quad (5)$$

$$X_{k,t-1} \leq X_{kt}, \quad \forall k \in Q, t \in H \setminus \{0\}, \quad (6)$$

$$X_{k,h-\bar{p}_i} = |Q_k| \cdot (\bar{n}(k) + 1), \quad \forall k \in Q, \quad (7)$$

$$\sum_{k \in Q} X_{kt} - \sum_{\substack{k \in Q, \\ t-\bar{p}_k \geq 0}} X_{k,t-\bar{p}_k} \leq 1, \quad \forall t \in H, \quad (8)$$

$$E_{k1t} \geq X_{k,t-\bar{l}_k+\bar{p}_k} - X_{k,t-\bar{l}_k}, \quad \forall k \in Q, t \in \bar{H}_k, t \geq S_{i''_k,0} + \bar{l}_k, \quad (9)$$

$$E_{kst} \geq X_{k,t-\bar{l}_k+\bar{p}_k} + X_{k,t-\bar{l}_k} + E_{k,s-1,t+\bar{p}_k} - 1, \\ \forall k \in Q, s \in \{2, \dots, |Q_k|\}, t \in \bar{H}_k, t \geq S_{i''_k,0} + \bar{l}_k, \quad (10)$$

$$E_{kst} \leq E_{k,s,t-1} \leq 1, \\ \forall k \in Q, s \in \{1, \dots, |Q_k|\}, t \in \bar{H}_k, t > S_{i''_k,0}, \quad (11)$$

$$W_{kt} \geq \bar{\alpha}_k \left( X_{kt} - X_{k,t-\bar{l}_k} - \sum_{s=1}^{|Q_k|} E_{kst} \right), \quad \forall k \in Q, t \in \bar{H}_k, \quad (12)$$

$$W_{kt} \geq \bar{\beta}_k \left( \sum_{s=1}^{|Q_k|} E_{kst} - X_{kt} + X_{k,t-\bar{l}_k} \right), \quad \forall k \in Q, t \in \bar{H}_k, \quad (13)$$

$$X_{kt} \in \mathbb{Z}_+, \quad \forall k \in Q, t \in H, \quad (14)$$

$$E_{kst} = 0, \quad \forall k \in Q, s \in \{2, \dots, |Q_k|\}, t \in \bar{H}_k, t < S_{i'_k+s-1,0}. \quad (15)$$

<i>Instance</i>	bib2	bib3	bib5

Table 1: Data for small instances

61 The constraints (4)-(5) fix the position of the “zero” operations. The  
62 constraints (6) reflect the nature of the variables  $X$ . The constraints (7)  
63 state that all operations of jobs in  $G_k$  should be processed within the time  
64 horizon. The constraints (8) prevent overlapping. The constraints (9)-(11)  
65 relate the variables  $X$  and  $E$ . The constraints (12)-(13) are used to compute  
66 the values of the variables  $W$ . Here  $\sum_{s=1}^{|Q_k|} E_{kst} = |G_{kt}|, \forall k \in Q, t \in \bar{H}_k$ .

67 The formulation (3)-(15) has roughly  $(2q + n)h$  variables,  $qh$  which are  
68 integer,  $(3q + 2n + 1)h$  constraints and  $(10q + 9n)h$  non-zero coefficients in  
69 the matrix. So, the size of this formulation depends first and foremost on  
70 the length of the time horizon  $h$ , then on the number of groups of identical  
71 jobs  $q$ , and finally on the number of jobs  $n$ .

## 72 B. Testing small instances

73 We have tested the formulations of three small instances whose data is  
74 given in Table 1. These test instances are of the same type as real life  
75 instances but of a reduced size. Results are presented in Table 2.

## 76 C. Testing random instances

77 The random instances were generated using the following procedure. The  
78 time horizon length  $h$ , the density  $d$  (the relation between the total processing  
79 time of operations and the horizon length), the number  $n$  of jobs and the total  
80 number of operations  $o = \sum_{i=1}^n n(i)$  are fixed. Let  $a = \lfloor \frac{o}{n} \rfloor$  and  $b = \lfloor \frac{dh}{o} \rfloor$ .  
81 Then, for each job  $i \leq n$ ,  $n(i)$  and  $p_i$  are uniformly generated over  $[1, 2a]$  and  
82  $[1, 2b]$  accordingly in such a way that  $\sum_{i=1}^n p_i n(i) = dh$ . Next, for each job  $i$ ,

Table 2: Comparison of formulations

83 we set  $l_i = \lfloor \frac{h}{n(i)} \rfloor$ . At last, the “zero” operations are scheduled before time 0  
84 one just after another in the reverse order:

$$S_{i0} = -p_1, \quad S_{i0} = S_{i-1,0} - p_i, \quad i \in [2, \dots, n].$$

85 The instances were generated for the next values of the parameters:  $h \in$   
86  $\{250, 500\}$ ,  $d \in \{0.5, 0.75, 1.0\}$ ,  $o \in \{30, 60, 100, 150\}$ ,  $n \in \{3, 6, 15, 30\}$ . For  
87 each combination of values  $\{h, d, o, n\}$  satisfying the conditions  $3o < dh$  and  
88  $3n < o$ , 2 instances were created. Therefore, in total, 234 instances were  
89 tested.

90 The formulation (TI) was not tested. Firstly, because of its poor results  
91 for the three small instances. Secondly, because of the quality of the lower  
92 bound given by the LP relaxation of the formulation (TI). For the gener-  
93 ated random instances, it was always less than the lower bound of the LP  
94 relaxation of the formulation (TIA), and on the average the relation between  
95 these two bounds was only 25.7%.

96 In the following, we present results for the following statistics:

- 97 •  $P$  — percentage of instances solved within 30 minutes.
- 98 •  $Tm$  — average solution time (if, for some instance, the time limit of  
99 1800 seconds was reached, this time limit is included into statistics).
- 100 •  $Gap$  — average difference between the best upper bound known and the  
101 best lower bound obtained, in percents from the best solution known  
102 (this statistics takes into account only instances for which an upper  
103 bound is known and the LP relaxation can be solved within the time  
104 limit).

Selection	$P_{LP}$	$Tm_{LP}$	$Gap_{LP}$	$P$	$Tm$	$Gap$	$Nd$

$n = 15$	100.0%	403s	50.4%	8.3%	1756s	45.5%	309
$n = 30$	33.3%	1614s	28.0%	0.0%	1800s	27.6%	1

Table 3: Results for random instances — the formulation (TIA)

- $Nd$  — average number of nodes in the branch-and-bound or branch-and-price tree (only instances for which the LP relaxation can be solved within the time limit).

The results for the random instances are presented in Tables 3 and 4. The statistics for the whole set of instances show that the efficiency of both approaches is roughly the same. The strength of the lower bound given by the solution of the LP relaxation of the formulation (TIA) is almost the same in comparison to the lower bound obtained by the column generation procedure (in average, the relation is 94.2%). This advantage of the column generation procedure results in slightly smaller gaps on average for the branch-and-price algorithm. Unfortunately, these gaps remain quite large even after 30 minutes of the solution time. So, the random instances happened to be harder to solve than the real life instances.

It can be also seen that instances with longer time horizon or with bigger operations density  $d$  are harder to solve. The impact of the number of jobs is not so simple. The results show that instances with small number of jobs are simpler for the formulation (TIA) and harder for the branch-and-price algorithm. This can be better seen in Table 5 where detailed results for the statistics  $T_{LP}$ ,  $Gap_{LP}$  and  $Gap$  are presented. From Table 5 it is clear that such a dependence of the approach efficiency from the number of jobs comes from the LP relaxations. The solution of the LP relaxation of the formulation (TIA) takes much more time for instances with a larger number of jobs. The contrary takes place when the column generation procedure is concerned.

Table 4: Results for random instances — the branch-and-price algorithm

128 The main conclusion of the computational tests on random instances is  
129 that the formulation (TIA) should be used when the number of jobs (or the  
130 number of groups of identical jobs) is small (6 or less). When the number  
131 of jobs is big and each job contains a moderate number of operations, the  
132 branch-and-price algorithm should be preferred.
