## ABSTRACT

In this paper, we study the performances of the NEW Unconstrained Optimization Algorithm (NEWUOA) with different numbers of interpolation points. NEWUOA is a trust region method, the number of points used to build the surrogate model is an input parameter of the algorithm. We compare the performances of NEWUOA using three different number of points in search spaces of dimension from two to forty on problems from the BBOB 2009 noiseless function testbed.

In particular we study the performances of an ‘average’ number of interpolation points that scales like the dimension of the search space to the power  $3/2$ . Using this number of interpolation points is expectedly faster than using the maximum number of interpolation points (scaling like the square of the dimension), though it does not grant better performances than using a number of interpolation points scaling like the dimension.

## General Terms

Algorithms

## Keywords

Benchmarking, Black-box optimization

## 1. INTRODUCTION

The NEWUOA, for NEW Unconstrained Optimization Algorithm was introduced in [5] as a method for unconstrained derivative-free optimization. NEWUOA is a trust-region method which uses  $m$  points to build a quadratic approximation of the objective function. The approximation

is considered reliable within the radius of the current trust region. In this paper, we study the effect of the number of interpolation points  $m$  on the performances of NEWUOA on a testbed of noiseless functions.

We use three different values for  $m$  which will be denoted **NEWUOA**, **avg-NEWUOA** and **full-NEWUOA**. These variants are sorted by ascending numbers of interpolation points. The number of interpolation points of these variants depends on the dimension of the search space  $n$ . The variant denoted NEWUOA uses  $2n + 1$  interpolation points as recommended in [5]. The avg-NEWUOA uses the rounded value of  $\sqrt{(n + 1/2)(n + 1)(n + 2)}$  interpolation points which is intermediate. The full-NEWUOA uses the maximum number  $\frac{(n+1)(n+2)}{2}$ . These three settings were already compared on a few test problems in [5].

The performances of the avg-NEWUOA are obtained on the BBOB 2009 testbed of noiseless functions. The avg-NEWUOA is successively compared to NEWUOA and full-NEWUOA. The performances of both NEWUOA and full-NEWUOA on the BBOB 2009 noiseless functions were presented in [7].

## 2. EXPERIMENTAL PROCEDURE

To benchmark the avg-NEWUOA, we use the exact same experimental procedure that was presented in [7]. In particular the algorithm uses an independent multi-start procedure, as do NEWUOA and full-NEWUOA. The crafting effort [3] is equal to  $\text{CrE} = 0$  for all three variants of the NEWUOA.

## 3. CPU TIMING EXPERIMENT

According to [5], the complexity of the NEWUOA variants we consider is at worst  $\Theta(mn)$ , where  $n$  is the dimension of the search space. The algorithms were run on  $f_8$  for at least 30 seconds, according to [3].

Results for the the different variants of NEWUOA are given in Table 1. These figures were obtained on a Intel Core 2 6700 processor (2.66 GHz) with Linux 2.6.24.7.

## 4. RESULTS

Results from experiments according to [3] on the benchmark functions given in [1, 4] are presented in this section. The Figures 1 and 2 and the Table 2 compare the avg-NEWUOA to NEWUOA. The Figures 3 and 4 and the Table 3 compare the avg-NEWUOA to full-NEWUOA. The **expected running time (ERT)**, used in the figures and tables, depends on a given target function value,  $f_t = f_{\text{opt}} +$

**Table 1: CPU-Time per function evaluations of  $f_8$  in microseconds for variants of NEWUOA with different number of interpolation points**

	2-D	3-D	5-D	10-D	20-D	40-D
NEWUOA	8.1	11	21	58	170	620
avg	8.0	13	27	100	580	3900
full	9.0	15	38	240	2400	32000

$\Delta f_t$ , and is computed over all relevant trials as the number of function evaluations executed during each trial while the best function value did not reach  $f_t$ , summed over all trials and divided by the number of trials that actually reached  $f_t$  [3, 6]. **Statistical significance** is tested with the rank-sum test for a given target  $\Delta f_t$  ( $10^{-8}$  in Figure 1) using, for each trial, either the number of needed function evaluations to reach  $\Delta f_t$  (inverted and multiplied by  $-1$ ), or, if the target was not reached, the best  $\Delta f$ -value achieved, measured only up to the smallest number of overall function evaluations for any unsuccessful trial under consideration.

The performances of all variants of NEWUOA are rather similar over all test functions of the BBOB 2009 noiseless testbed as shown in the top sub-figures of Figures 2 and 4. Some differences can be spotted. Figure 1 shows NEWUOA is faster than avg-NEWUOA on functions  $f_1$  and  $f_5$  by a factor growing as the dimension of the search space increases. There is a factor of two in 20-D, a factor of three in 40-D. Also, on the Bent Cigar function  $f_{12}$ , NEWUOA is faster than avg-NEWUOA by a factor of up to a hundred.

In a rather similar way, avg-NEWUOA is faster than full-NEWUOA on functions  $f_1$  and  $f_5$  by a factor growing as the dimension of the search space increases. The avg-NEWUOA is faster than full-NEWUOA in 20-D on functions  $f_2$ ,  $f_6$ ,  $f_8$ ,  $f_9$ ,  $f_{10}$ ,  $f_{11}$ ,  $f_{12}$ .

The performances of all three NEWUOA variants on  $f_{14}$  show strange behaviour since the precision of  $10^{-7}$  is reached consistently but  $10^{-8}$  is not. None of the three variants reached the target precision  $10^{-8}$  on functions  $f_{15}$  to  $f_{19}$  except in 2-D and 3-D.

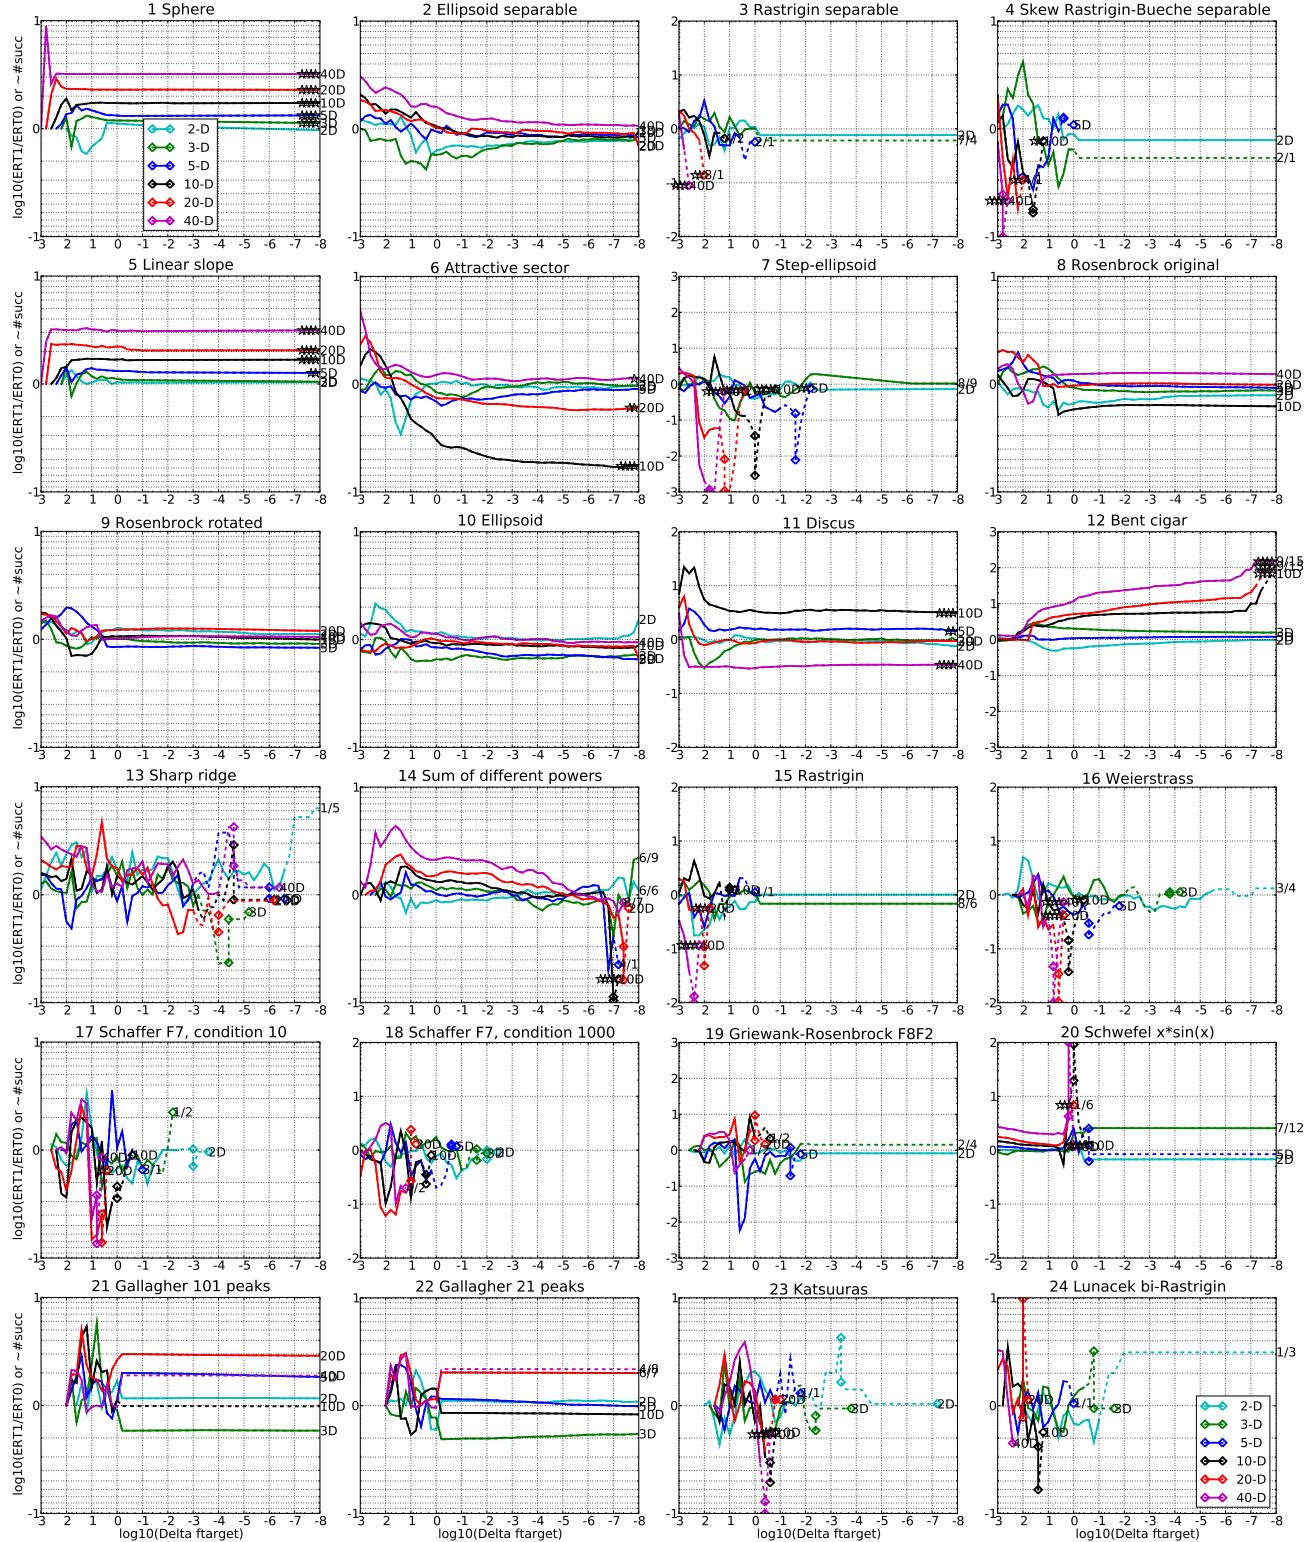

## Acknowledgment

The author would like to acknowledge Dr Mohamed Jebalia for his insights on this paper.

**Figure 1:** ERT ratio of avg-NEWUOA divided by NEWUOA versus  $\log_{10}(\Delta f)$  for  $f_1-f_{24}$  in **2, 3, 5, 10, 20, 40**-D. Ratios  $< 10^0$  indicate an advantage of avg-NEWUOA, smaller values are always better. The line gets dashed when for any algorithm the ERT exceeds thrice the median of the trial-wise overall number of  $f$ -evaluations for the same algorithm on this function. Symbols indicate the best achieved  $\Delta f$ -value of one algorithm (ERT gets undefined to the right). The dashed line continues as the fraction of successful trials of the other algorithm, where 0 means 0% and the y-axis limits mean 100%, values below zero for avg-NEWUOA. The line ends when no algorithm reaches  $\Delta f$  anymore. The number of successful trials is given, only if it was in  $\{1 \dots 9\}$  for avg-NEWUOA (1st number) and non-zero for NEWUOA (2nd number). Results are significant with  $p = 0.05$  for one star and  $p = 10^{-\#^*}$  otherwise, with Bonferroni correction within each figure.

**Figure 2: Empirical cumulative distributions (ECDF) of run lengths and speed-up ratios in 5-D (left) and 20-D (right).** Left sub-columns: ECDF of the number of function evaluations divided by dimension  $D$  ( $\text{FEvals}/D$ ) to reach a target value  $f_{\text{opt}} + \Delta f$  with  $\Delta f = 10^k$ , where  $k \in \{1, -1, -4, -8\}$  is given by the first value in the legend, for avg-NEWUOA (solid) and NEWUOA (dashed). Light beige lines show the ECDF of  $\text{FEvals}$  for target value  $\Delta f = 10^{-8}$  of algorithms benchmarked during BBOB-2009. Right sub-columns: ECDF of  $\text{FEval}$  ratios of avg-NEWUOA divided by NEWUOA, all trial pairs for each function. Pairs where both trials failed are disregarded, pairs where one trial failed are visible in the limits being  $> 0$  or  $< 1$ . The legends indicate the number of functions that were solved in at least one trial (avg-NEWUOA first).

**Table 2:** Expected running time (ERT in number of function evaluations) divided by the best ERT measured during BBOB-2009 (given in the respective first row) for different  $\Delta f$  values for functions  $f_1-f_{24}$ . The median number of conducted function evaluations is additionally given in *italics*, if  $\text{ERT}(10^{-7}) = \infty$ . #succ is the number of trials that reached the final target  $f_{\text{opt}} + 10^{-8}$ . 0: NEW is NEWUOA and 1: AVG is avg-NEWUOA. Bold entries are statistically significantly better compared to the other algorithm, with  $p = 0.05$  or  $p = 10^{-k}$  where  $k > 1$  is the number following the  $*$  symbol, with Bonferroni correction of 48.

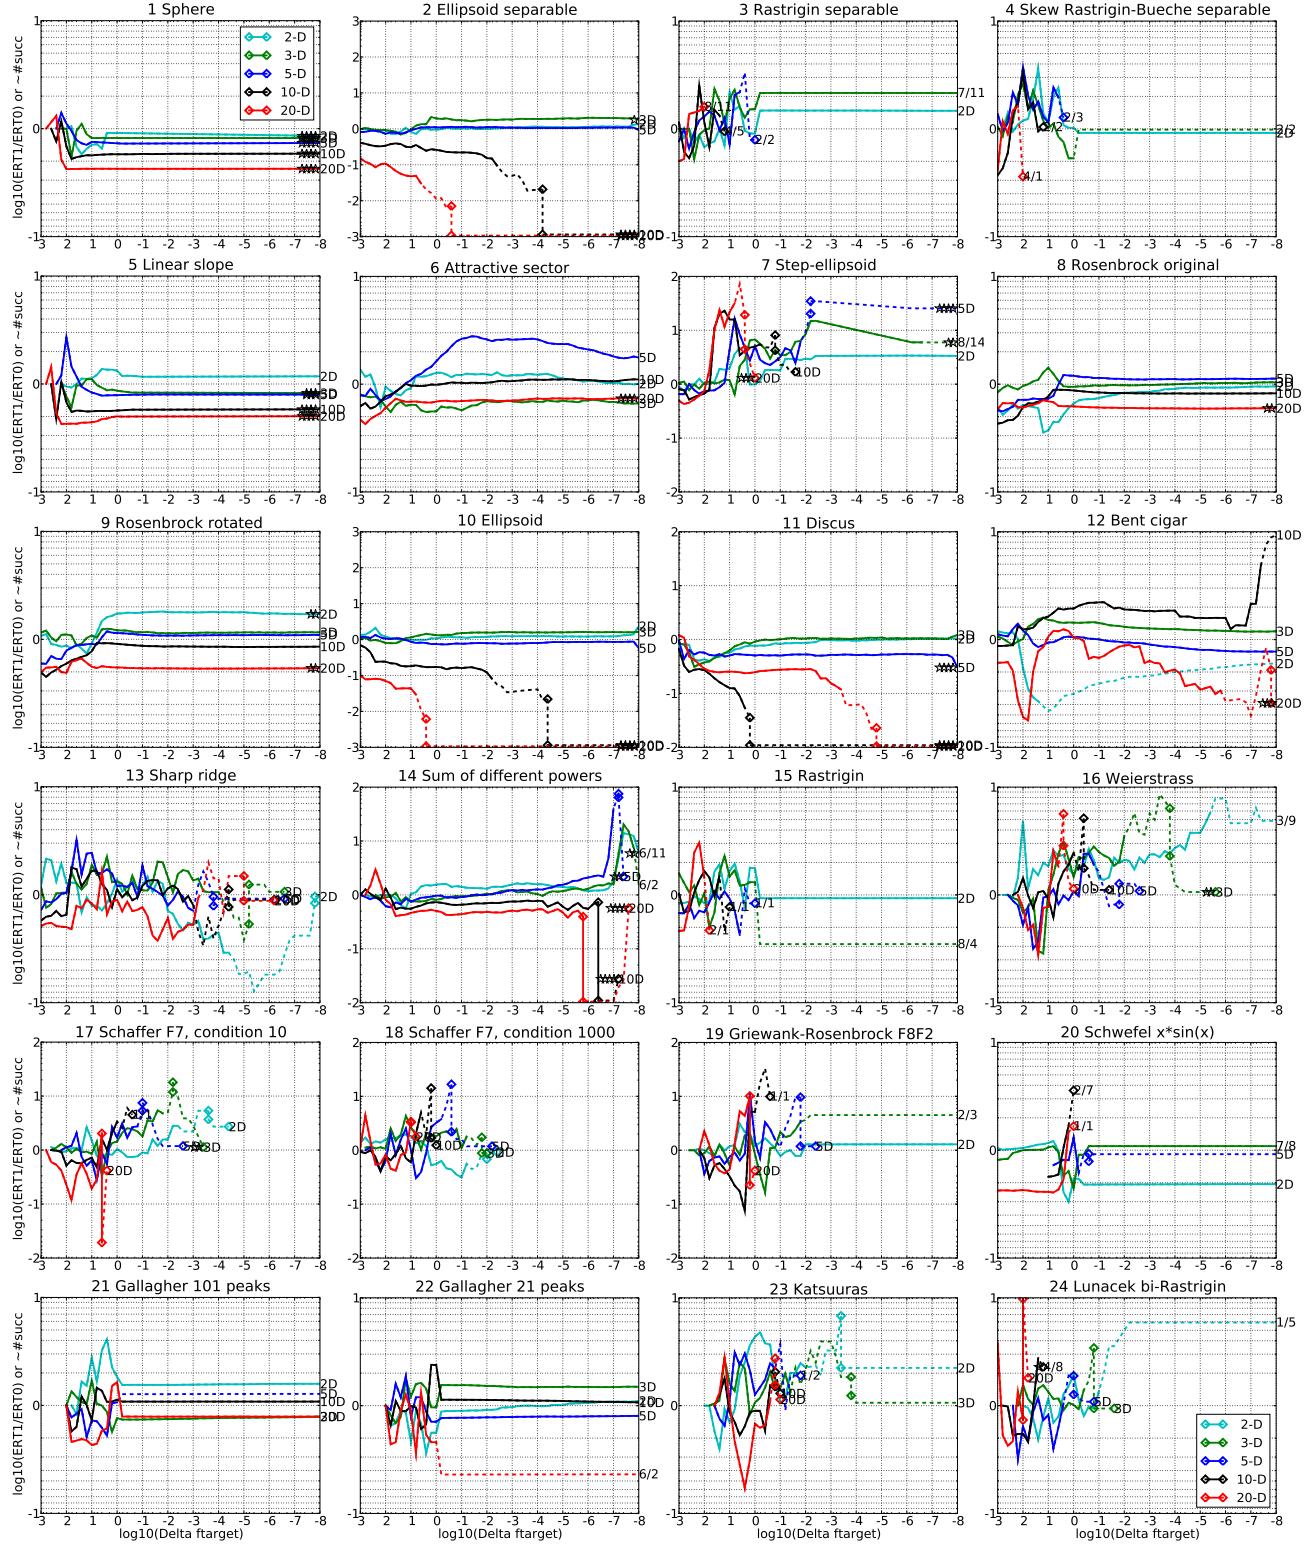

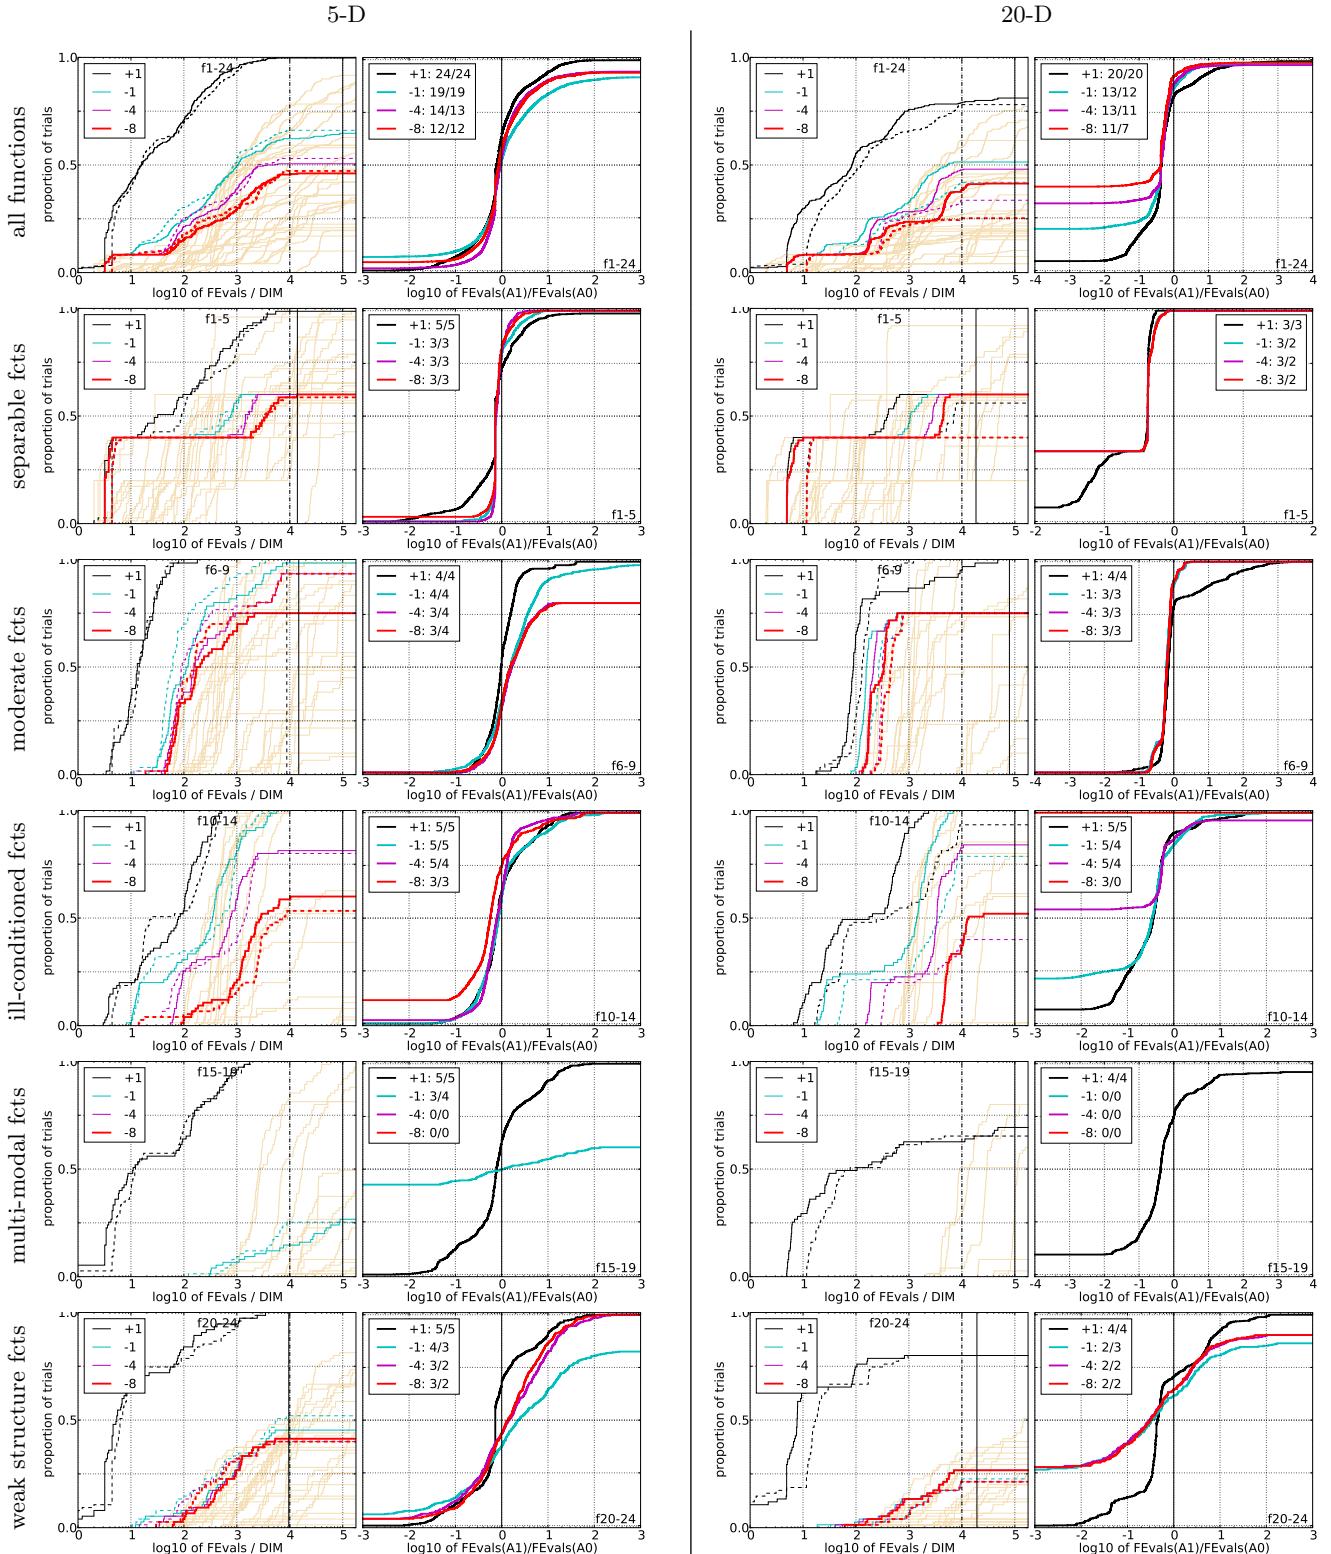

Figure 3: ERT ratio of avg-NEWUOA divided by full-NEWUOA versus  $\log_{10}(\Delta f)$  for  $f_1-f_{24}$  in 2, 3, 5, 10, 20, 40-D. Ratios  $< 10^0$  indicate an advantage of avg-NEWUOA, smaller values are always better. The line gets dashed when for any algorithm the ERT exceeds thrice the median of the trial-wise overall number of  $f$ -evaluations for the same algorithm on this function. Symbols indicate the best achieved  $\Delta f$ -value of one algorithm (ERT gets undefined to the right). The dashed line continues as the fraction of successful trials of the other algorithm, where 0 means 0% and the y-axis limits mean 100%, values below zero for avg-NEWUOA. The line ends when no algorithm reaches  $\Delta f$  anymore. The number of successful trials is given, only if it was in {1...9} for avg-NEWUOA (1st number) and non-zero for full-NEWUOA (2nd number). Results are significant with  $p = 0.05$  for one star and  $p = 10^{-\#^*}$  otherwise, with Bonferroni correction within each figure.

**Figure 4: Empirical cumulative distributions (ECDF) of run lengths and speed-up ratios in 5-D (left) and 20-D (right).** Left sub-columns: ECDF of the number of function evaluations divided by dimension  $D$  ( $\text{FEvals}/D$ ) to reach a target value  $f_{\text{opt}} + \Delta f$  with  $\Delta f = 10^k$ , where  $k \in \{1, -1, -4, -8\}$  is given by the first value in the legend, for avg-NEWUOA (solid) and full-NEWUOA (dashed). Light beige lines show the ECDF of  $\text{FEvals}$  for target value  $\Delta f = 10^{-8}$  of algorithms benchmarked during BBOB-2009. Right sub-columns: ECDF of  $\text{FEval}$  ratios of avg-NEWUOA divided by full-NEWUOA, all trial pairs for each function. Pairs where both trials failed are disregarded, pairs where one trial failed are visible in the limits being  $> 0$  or  $< 1$ . The legends indicate the number of functions that were solved in at least one trial (avg-NEWUOA first).

5-D 20-D

Table 3: Expected running time (ERT in number of function evaluations) divided by the best ERT measured during BBOB-2009 (given in the respective first row) for different  $\Delta f$  values for functions  $f_1-f_{24}$ . The median number of conducted function evaluations is additionally given in *italics*, if  $\text{ERT}(10^{-7}) = \infty$ . #succ is the number of trials that reached the final target  $f_{\text{opt}} + 10^{-8}$ . 0: FUL is full-NEWUOA and 1: AVG is avg-NEWUOA. Bold entries are statistically significantly better compared to the other algorithm, with  $p = 0.05$  or  $p = 10^{-k}$  where  $k > 1$  is the number following the  $*$  symbol, with Bonferroni correction of 48.
