## 1 In Brief

Goal

- Recover 3D human body pose from monocular image silhouettes -3 D pose $=$ joint angles
- use either individual images or video sequences

## Applications

$$
\begin{array}{ll}
\text { Human computer interaction } & \text { - Gesture recognition } \\
\text { Markerless motion capture } & \text { - Visual surveillance }
\end{array}
$$

## Contributions

- "Model-free" learning based approach - no explicit 3D model - Mixture of kernel regressors trained using human motion capture data - Multimodal probabilistic solutions in 3D pose space
- Temporal fusion using a particle filter style tracker

## 2 Silhouette Descriptors

## Why Silhouettes

+ • Relatively simple and low-level
- Capture most of the available pose information - Insensitive to surface attributes (clothing colour, texture.)
- Distortions caused by background subtraction, shadows - Ambiguity: hides internal details and depth ordering

Robust encoding of local shape Shape Context Histograms

## 3 Training and Test Data

- Capture typical human movements, not just kinematically possible ones, using real human motion capture data
- Use both real silhouettes from motion capture and synthetic silhou ettes from several human body models (POSER from Curious Labs)

## 4 Multimodal Pose Estimation

- The silhouette $(\mathrm{z})$ to pose $(\mathrm{x})$ problem is inherently multi-valued
- Treating it as a function can lead to averaging or zig-zagging between different solutions.

Introduce a discrete latent variable $k \in\{1,2 \ldots K\}$ to encode the information missing in the silhouette.
Assume a mixture of experts model based on $K$ underlying func tional regression rules $\mathbf{x} \sim \mathbf{r}_{k}(\mathbf{z})$ :

$$
p(\mathbf{x} \mid \mathbf{z})=\sum_{k=1}^{K} p(\mathbf{x} \mid \mathbf{z}, k) p(k \mid \mathbf{z}), \quad p(\mathbf{x} \mid \mathbf{z}, k)=\mathcal{N}\left(\mathbf{r}_{k}(\mathbf{z}), \boldsymbol{\Lambda}_{k}\right)
$$

5 Mixture of Regressors by E-M

- Reduce dimensionality of silhouette data using kernel PCA: $\mathrm{z} \rightarrow \phi(\mathrm{z}$ - Initialize clustering with local connected components analysis Fit a mixture of regressive Gaussians to the joint density $(\phi(\mathbf{z}), \mathbf{x})$ :

$$
\binom{\phi(\mathbf{z})}{\mathbf{x}} \simeq \sum_{k=1}^{K} \pi_{k} \mathcal{N}\left(\boldsymbol{\mu}_{k}, \boldsymbol{\Gamma}_{k}\right)
$$

Linear regressor within each component $k$

$$
p(\mathbf{x} \mid \mathbf{z})=\mathcal{N}\left(\mathbf{r}_{k}(\mathbf{z}), \boldsymbol{\Lambda}_{k}\right) \quad \mathbf{r}_{k}(\mathbf{z}) \equiv \mathbf{A}_{k} \phi(\mathbf{z})+\mathbf{b}_{k}
$$

- Special covariance structure enforces "regressive" noise model

$$
\boldsymbol{\mu}_{k}=\binom{\phi\left(\overline{\mathbf{z}}_{k}\right)}{\mathbf{r}_{k}\left(\overline{\mathbf{z}_{k}}\right)}, \boldsymbol{\Gamma}_{k}=\left(\begin{array}{cc}
\boldsymbol{\Sigma}_{k} & \boldsymbol{\Sigma}_{k} \mathbf{A}_{k}^{\top} \\
\mathbf{A}_{k} \boldsymbol{\Sigma}_{k} & \mathbf{A}_{k} \boldsymbol{\Sigma}_{k} \mathbf{A}_{k}^{\top}+\boldsymbol{\Lambda}_{k}
\end{array}\right)
$$

- M-step: Estimate $\mathbf{A}_{k}, \mathbf{b}_{k}$ by weighted least squares regression, $\Lambda_{k}$ from residual errors. Compute $\mu_{k}, \Sigma_{k}, \pi_{k}$ for each class.
- E-step: Reestimate class membership weights for each point.

## 6 Pose from Static Images

- Provides multiple solutions for pose, with corresponding probabilities - Most cases of ambiguity are identified

## 7 Self-Initializing 3D Tracking

- Particle filter tracker, samples from dynamics $p\left(\mathbf{x}_{t} \mid \mathbf{x}_{t-1}\right)$ as usual
- Uses regressive mixture $p\left(\mathbf{x}_{t} \mid \mathbf{z}_{t}\right)$ to assign posterior particle weights
- (Re)initializes by sampling from full mixture

$$
p\left(\mathbf{x}_{0} \mid \mathbf{z}_{0}\right)=\sum_{k=1}^{K} p\left(k \mid \mathbf{z}_{0}\right) \cdot \mathcal{N}\left(\mathbf{r}_{k}\left(\mathbf{z}_{0}\right), \boldsymbol{\Lambda}_{k}\right)
$$

- Potentially real time owing to closed form solution for posterior.

### 7.1 Automatic (re)initization

- Errors stabilize rapidly on (re)initialization

RMS tracking error of individual joint angles on a 500 frame sequence - 1 when no person is detected).

名

8

Detects the presence of a person and decides whether to wait, initialize or track using observed silhouette shape.

### 7.2 Upper Body Gesture Recognition

- Associate (by hand) different mixture components with gestures - Use posterior class probabilities to identify action

## Training gestures (Basketball signals)

Test sequence labelling

## 8 Conclusion

[^0]
[^0]:    - "Model free" methods for recovering 3D human pose from monocular
    silhouettes
    - Multiple hypothesis pose estimates with associated probabilities - Stable pose recovery from static images and image sequences - Action recognition using mixture components
