Problem formulation

Modeling improvement Stochastic Arrow-Hurwicz algorithm Numerical results Satellite model and deterministic optimization problem Engine failure Stochastic formulation

Satellite model

$$
\frac{dr}{dt} = v , \quad \frac{dv}{dt} = -\mu \frac{r}{\|r\|^3} + \frac{F}{m}\kappa ,
$$
\n(1a)\n
$$
\frac{dm}{dt} = -\frac{T}{g_0 I_{sp}} \delta .
$$
\n(1b)

 $(1a)$: 6-dimensional state vector (position r and velocity v).

 $(1b)$: 1-dimensional state vector (mass m including fuel).

 κ involves the direction cosines of the thrust and the on-off switch δ of the engine (3 controls), and μ , F, T, g_0 , $l_{\rm sn}$ are constants.

The deterministic control problem is to drive the satellite from the initial condition at t_i to a known final position r_f and velocity v_f at t_f (given) while **minimizing fuel consumption** $m(t_i) - m(t_f)$.

Satellite model and deterministic optimization problem Engine failure Stochastic formulation

Deterministic optimization problem

Using **equinoctial coordinates** for the position and velocity \rightsquigarrow state vector $x \in \mathbb{R}^7$,

and **cartesian coordinates** for the thrust of the engine \rightsquigarrow control vector $u\in\mathbb{R}^3,$

the deterministic optimization problem is written as follows:

$$
\min_{u(\cdot)} K\big(x(t_{\mathrm{f}})\big) \tag{2a}
$$

subject to:

$$
x(t_i) = x_i, \quad \stackrel{\bullet}{x}(t) = f(x(t), u(t)), \qquad (2b)
$$

$$
||u(t)|| \le 1 \quad \forall t \in [t_i, t_f], \qquad (2c)
$$

$$
C(x(t_{f})) = 0.
$$
 (2d)

Satellite model and deterministic optimization problem Engine failure Stochastic formulation

Engine failure

- **•** Sometimes, the engine may fail to work when needed: the satellite **drift away** from the deterministic optimal trajectory. After the engine control is recovered, it is not always possible to **drive the satellite to the final target** at t_{f} .
- By anticipating such possible failures and by modifying the trajectory followed **before** any such failure occurs, one may increase the possibility of eventually reaching the target. But such a deviation from the deterministic optimal trajectory results in a deterioration of the economic performance.
- The problem is thus to **balance** the **increased probability** of eventually reaching the target despite possible failures against the expected economic performance, that is, to quantify the price of safety one is ready to pay for.

Problem formulation

Modeling improvement Stochastic Arrow-Hurwicz algorithm Numerical results Satellite model and deterministic optimization problem Engine failure Stochastic formulation

Stochastic formulation (1)

- A failure is modeled using two random variables:
	- \bullet t_p : random initial time of the failure,
	- \bullet t_d : random duration of the failure.

For every realization $(t_{\rm p}^{\xi},t_{\rm d}^{\xi})$ $\binom{5}{d}$:

- \bullet $u(\cdot)$ denotes the control used prior to any failure
	- \rightsquigarrow u is defined over $[t_{\rm i},t_{\rm f}]$ but implemented over $[t_{\rm i},t_{\rm p}^{\xi}]$ and corresponds to an open-loop control,
- \bullet the control is 0 in $[t_\mathrm{p}^\xi,t_\mathrm{p}^\xi+t_\mathrm{d}^\xi]$ $\frac{1}{d}$,
- $\bullet\;\; \mathsf{v}^\xi(\cdot)$ denotes the control used after the end of the failure \sim v^ξ is defined over $[t_\mathrm{p}^\xi + t_\mathrm{d}^\xi]$ $\mathcal{L}_d^{\mathcal{S}}, t_f$] (if nonempty) and corresponds to a closed-loop strategy v.

The satellite dynamics in the stochastic formulation writes:

$$
x^{\xi}(t_i) = x_i, \quad x^{\xi}(t) = f^{\xi}(x^{\xi}(t), u(t), v^{\xi}(t)) .
$$

Satellite model and deterministic optimization problem Engine failure Stochastic formulation

Stochastic formulation (2)

The problem is to minimize the **expected cost** (fuel consumption)

- \bullet w.r.t. the open-loop control u and the closed-loop strategy \mathbf{v} ,
- the probability to hit the target at time t_f being at least p.

$$
\min_{u(\cdot)} \mathbb{E}\Big(\min_{v^{\xi}(\cdot)} \mathcal{K}\big(x^{\xi}(t_{\mathrm{f}})\big)\Big) \tag{3a}
$$

subject to:

$$
x^{\xi}(t_i) = x_i, \quad x^{\xi}(t) = f^{\xi}(x^{\xi}(t), u(t), v^{\xi}(t)), \qquad (3b)
$$

$$
||u(t)|| \le 1 \quad \forall t \in [t_i, t_f], \quad ||v^{\xi}(t)|| \le 1 \quad \forall t \in [t_p^{\xi} + t_a^{\xi}, t_f], \quad (3c)
$$

$$
\mathbb{P}\Big(C(x^{\xi}(t_f)) = 0\Big) \ge p.
$$
 (3d)

Probability as an expectation Cost refinement Final formulation

Problem formulation

Stochastic Arrow-Hurwicz algorithm

Numerical results

Probability as an expectation Cost refinement Final formulation

Probability as an expectation

Let
$$
I(y) = \begin{cases} 1 & \text{if } y = 0, \\ 0 & \text{otherwise.} \end{cases}
$$

Then
$$
\mathbb{P}\Big(C\big(x^{\xi}(t_{f})\big) = 0\Big) = \mathbb{E}\Big(I\big(\big\|C\big(x^{\xi}(t_{f})\big)\big\|\big)\Big).
$$

Thus, Problem (3) can (shortly) be written:

$$
\min_{u(\cdot)} \mathbb{E}\Big(\min_{v^{\xi}(\cdot)} \mathcal{K}\big(x^{\xi}(t_{\mathrm{f}})\big)\Big) \tag{4a}
$$

$$
\text{s.t.} \quad \mathbb{E}\Big(\mathrm{I}\big(\big\|\mathcal{C}\big(x^{\xi}(t_{\mathrm{f}})\big)\big\|\big)\Big)\geq p\ . \tag{4b}
$$

Formulation (4) opens the possibility to make use of a **stochastic** Arrow-Hurwicz algorithm in order to obtain the solution $u^{\sharp}(\cdot).$

Probability as an expectation Cost refinement Final formulation

Missing the target should not contribute to the cost

Whenever a failure occurred, setting $\mathsf{v}^\xi \equiv 0$ over $[\mathsf{t}^\xi_\text{p} + \mathsf{t}^\xi_\text{d}]$ $\frac{\varsigma}{d}, t_f$

- **•** generally makes the satellite misses the target and **does not** contribute to the probability constraint,
- but it forces fuel consumption to its minimum and contributes to minimize the cost function.

This yields an artificially good expected cost; however, one is not interested in what happens whenever the whole mission has failed.

Therefore, a better formulation is to register only **scenarios** when the target is **effectively hit**; instead of the original expected cost in (4) , we thus prefer to deal with a **conditional expected cost**:

$$
\mathbb{E}\Big(K\big(x^{\xi}(t_{\mathrm{f}})\big)\ \Big|\ C\big(x^{\xi}(t_{\mathrm{f}})\big)=0\Big)=\frac{\mathbb{E}\Big(K\big(x^{\xi}(t_{\mathrm{f}})\big)\times\mathrm{I}\big(\big\|\,C\big(x^{\xi}(t_{\mathrm{f}})\big)\big\|\big)\Big)}{\mathbb{E}\Big(\mathrm{I}\big(\big\|\,C\big(x^{\xi}(t_{\mathrm{f}})\big)\big\|\big)\Big)}~.
$$

Probability as an expectation Cost refinement Final formulation

Conditional expected cost

The problem is reformulated as

$$
\min_{u(\cdot),\mathbf{v}(\cdot)} \frac{\mathbb{E}\left(K(x^{\xi}(t_{f})) \times I(\left\|C(x^{\xi}(t_{f}))\right\|\right))}{\mathbb{E}\left(I(\left\|C(x^{\xi}(t_{f}))\right\|\right))}
$$
\ns.t.
$$
\mathbb{E}\left(I(\left\|C(x^{\xi}(t_{f}))\right\|\right) \geq p.
$$
\n(5a)

Such a formulation is however not well-suited for the stochastic Arrow-Hurwicz algorithm:

a ratio of expectations is not an expectation!

Probability as an expectation Cost refinement Final formulation

An useful lemma

Using compact notation, Problem (5) is:

$$
\min_{\mathbf{u}} \frac{J(\mathbf{u})}{\Theta(\mathbf{u})} \quad \text{s.t.} \quad \Theta(\mathbf{u}) \ge p \,, \tag{6}
$$

in which J and Θ assume positive values.

) If \mathbf{u}^{\sharp} is a solution of (6) and if $\Theta(\mathbf{u}^{\sharp}) = p$, then \mathbf{u}^{\sharp} is also a solution of min $J(\mathbf{u})$ s.t. $\Theta(\mathbf{u}) \ge p$. (7) u

 $\,$ Conversely, if u^\sharp is a solution of (7), and if an optimal Kuhn-Tucker multiplier β^\sharp satisfies the condition

$$
\beta^{\sharp} \geq \frac{J(u^{\sharp})}{\Theta(u^{\sharp})} ,
$$

then \mathbf{u}^{\sharp} is also a solution of (6).

Probability as an expectation Cost refinement Final formulation

Back to a cost in expectation

Finally, instead of (5) we aim at solving

$$
\min_{u(\cdot),\mathbf{v}(\cdot)} \mathbb{E}\Big(K\big(x^{\xi}(t_{\mathrm{f}})\big)\times I\big(\big\|\mathcal{C}\big(x^{\xi}(t_{\mathrm{f}})\big)\big\|\big)\Big) \qquad \text{(8a)}
$$
s.t.
$$
\mathbb{E}\Big(I\big(\big\|\mathcal{C}\big(x^{\xi}(t_{\mathrm{f}})\big)\big\|\big)\Big) \geq p . \qquad \text{(8b)}
$$

The cost function again corresponds to a standard expectation!

Probability as an expectation Cost refinement Final formulation

Final formulation and associated Lagrangian

$$
\min_{\omega(\cdot)}\left(\mathbb{E}\Big(\min_{\mathbf{v}^{\xi}(\cdot)}\mathcal{K}\big(\mathbf{x}^{\xi}(t_{\mathrm{f}})\big)\times\mathrm{I}\big(\big\|\mathcal{C}\big(\mathbf{x}^{\xi}(t_{\mathrm{f}})\big)\big\|\big)\Big)\right)\\ \text{s.t.}\quad \mu\leadsto p-\mathbb{E}\Big(\mathrm{I}\big(\big\|\mathcal{C}\big(\mathbf{x}^{\xi}(t_{\mathrm{f}})\big)\big\|\big)\Big)\leq 0\ .
$$

Assuming there exists a saddle point for the associated Lagrangian, we have finally to solve

$$
\max_{\mu \geq 0} \ \min_{u(\cdot)} \left\{ \mu \, p + \mathbb{E} \Big(\min_{v^{\xi}(\cdot)} \left(K\big(x^{\xi}(t_{f})\big) - \mu\big) \times I\big(\big\| C\big(x^{\xi}(t_{f})\big) \big\| \big) \Big) \right\} \right\}.
$$

Remark: it is convenient to put apart the **no-failure event**, namely $\{ \mathbf{t}_{{\rm p}} \ge t_{\rm f} \}$ in the problem formulation. For the sake of simplicity, we do not present this last problem improvement. We will denote by π_f the probability of this event.

Algorithm overview Downstream closed-loop problem Smoothing function I Solving the resulting approximated problem

Algorithm overview (1)

In order to solve

$$
\max_{\mu \geq 0} \min_{u(\cdot)} \left\{ \mu \, p + \mathbb{E} \Big(\underbrace{\min_{v^{\xi}(\cdot)} \left(K\big(x^{\xi}(t_f)\big) - \mu \right) \times I\big(\big\| C\big(x^{\xi}(t_f)\big) \big\| \big)}_{W(u, \mu, \xi)} \Big) \right\}
$$

that is, max min
 $\mu \geq 0$ $u(\cdot)$ $\{\mu p + \mathbb{E}(W(u,\mu,\xi))\},\}$

we use a stochastic Arrow-Hurwicz algorithm (see $[2]$ and $[3]$).

.

Algorithm overview Downstream closed-loop problem Smoothing function I Solving the resulting approximated problem

Algorithm overview (2)

Arrow-Hurwicz algorithm

At iteration k ,

 $\textbf{1}$ draw a failure $\xi^k = (t^{\xi^k}_{\text{p}},t^{\xi^k}_{\text{d}})$ $\binom{\xi}{d}$ according to its probability law, **2** update $u(\cdot)$:

$$
u^{k+1} = \Pi_{\mathcal{B}}\left(u^k - \varepsilon^k \nabla_u W(u^k, \mu^k, \xi^k)\right),
$$

 \bullet update μ :

$$
\mu^{k+1} = \max\left(0, \mu^k + \rho^k\big(p + \nabla_\mu W(u^{k+1}, \mu^k, \xi^k)\big)\right).
$$

Algorithm overview Downstream closed-loop problem Smoothing function I Solving the resulting approximated problem

Downstream closed-loop problem

Consider the inner optimization problem:

$$
W(u,\xi,\mu)=\min_{v^{\xi}(\cdot)}\left\{\left(K\big(x^{\xi}(t_{\mathrm{f}})\big)-\mu\big)\times\mathrm{I}\big(\big\|\mathcal{C}\big(x^{\xi}(t_{\mathrm{f}})\big)\big\|\big)\right\}\,,
$$

- If reaching the target is $\mathsf{impossible}\;(\mathsf{C}\bigl(\mathsf{x}^{\xi}(t_{\mathrm{f}})\bigr) \neq 0 \;\;\forall \mathsf{v}^{\xi}),$ the best thing to do is to **stop immediately**: $W \equiv 0$.
- **If reaching the target is possible but too expensive (that** is $\mathcal{K}\big(\mathsf{x}^{\xi}(t_{\mathrm{f}})\big) \geq \mu),$ the best thing to do is again to stop **immediately**: $W \equiv 0$.
- Therefore, it must be checked that one can reach the target while maintaining fuel consumption below a threshold, and the corresponding optimal control $v_{*}^{\xi}(\cdot)$ must be computed.

At every iteration k , we must **evaluate** function W as well as its derivatives w.r.t. $u(.)$ and μ . But W is not differentiable!

Algorithm overview Downstream closed-loop problem Smoothing function I Solving the resulting approximated problem

First difficulty: I is not a smooth function

$$
I(y) = \begin{cases} 1 & \text{if } y = 0, \\ 0 & \text{otherwise,} \end{cases} \qquad \rightarrow \qquad I_r(y) = \begin{cases} \left(1 - \frac{y^2}{r^2}\right)^2 & \text{if } y \in [-r, r], \\ 0 & \text{otherwise.} \end{cases}
$$

There are specific rules to drive r^k to 0 as the iteration number k goes to infinity in order to obtain the best asymptotic **Mean Quadratic Error** of the gradient estimates (see [1]).

Downstream closed-loop problem Smoothing function I Solving the resulting approximated problem

Second difficulty: solving the approximated problem

The approximated closed-loop problem to solve at each iteration is:

$$
W_r(u^k,\xi^k,\mu^k)=\min_{v^\xi(\cdot)}\left\{\left(K\big(x^\xi(t_f)\big)-\mu^k\right)\times I_r\big(\big\|\,C\big(x^\xi(t_f)\big)\big\|\big)\right\}\,.
$$

In this setting, we have to check if the target is reached up to r .

In practice, the solution of the approximated problem is derived from the resolution of two standard optimal control problems.

Mission description

Interplanetary mission (Earth-Mars trajectory):

- **o** duration of the mission: 450 days,
- $\mathbf{t}_{\rm p}$: exponential distribution s.t. $\mathbb{P}\big(\mathbf{t}_{\rm p} \geq t_{\rm f}\big) = \pi_{\rm f} \approx 0.58,$
- \mathbf{t}_{d} : exponential distribution s.t. $\mathbb{P}\big(2 \leq \mathbf{t}_{\mathrm{d}} \leq 7\big) \approx 0.80.$

Using normalized units:

• $t_i = 0.69$ and $t_f = 8.73$.

The deterministic optimal control has a "bang–off–bang" shape. Along the deterministic optimal path, the probability to recover a failure is: $\rho^{\rm det}\approx 0.94.$

Brief description Results for different values of p The price of safety

Parameters tuning

Gradient step length:

$$
\varepsilon^k = \frac{a}{b+k} \qquad , \qquad \rho^k = \frac{c}{d+k} \ ,
$$

 \rightarrow usual for a stochastic gradient algorithm.

Smoothing parameter:

$$
r^k = \frac{\alpha}{\beta + k^{\frac{1}{3}}},
$$

 \rightarrow MQE reduced by a factor 2000 in about 100.000 iterations.

Conclusion

Main conclusion

We are able to deal with probability constraints in the optimal control framework.

Future works

- From the theoretical point of view:
	- existence of a saddle point for the constrained problem,
	- smoothing process (results available only for inequality constraints).
- From the numerical point of view:
	- **•** efficient solver for the downstream problem,
	- **•** computer parallelization.
